ABSTRACT

This chapter develops a descriptive-conceptual overview of the main models and standards of processes formulated in the systems engineering (SE), software engineering (SwE) and information systems (IS) disciplines. Given the myriad of models and standards reported, the convergence suggested for the SE and SwE models and standards and the increasing complexity of the modern information systems, we argue that these ones become relevant in the information systems discipline. Firstly, we report the rationale for having models and standards of processes in SE, SwE and IS. Secondly, we review their main
Introduction

The manufacturing of products and the provision of services in the modern world has increased process engineering (including manufacturing or provision) and process managerial complexity (Boehm & Lane, 2006). The engineering complexity has been raised because of the variety of design, manufacturing or provision process, machines and tools, materials and system-component designs, as well as for the high-quality, cost-efficiency relationships, and value expectations demanded from the competitive worldwide markets. The process managerial complexity has increased because of disparate business internal and external process must be coordinated. To meet the time to market, competitive prices, market sharing, distribution scope and environmental and ethical organizational objectives, among others financial and strategic organizational objectives contribute to increased organizational pressures and organizational complexity (Farr & Buede, 2003).

Such process engineering and/or managerial complexity is manifested in: (1) the critical failures of enterprises information systems implementations (CIO UK, 2007; Ewusi, 1997; Standish Group, 2003), (2) the unexpected appearance of large batches of defective products that have had a proved high-quality image for decades, and (3) the increasing of system downtimes and/or low efficiency and effectiveness in critical services such: electricity, nuclear plants, health services and governmental services (Bar-Yam, 2003).

Organizations with global and large-scale operations have fostered the exchange of the best organizational practices (Arnold & Lawson, 2004). The purpose is to improve business processes and avoid critical failures in the manufacturing of products and provision of services. Best practices have been documented (via a deep redesign, analysis, discussion, evaluation, authorization, and updating of organizational activities) through models and/or standards of process by international organizations for the disciplines of systems engineering (SE), software engineering (SwE) and information systems (IS). Some models and standards come from organizations with a global scope, like the International Organization for Standardization (ISO) but others limit their influences in some countries or regions, like the US-based Software Engineering Institute (SEI). Whilst both types of organizations can differ in their geographic scopes, both keep a similar efficacy purpose: to make available a set of generic process (technical, managerial, support and enterprise) that come from the best international practices to correct and improve their organizational process, with the expected outcome being improved quality, value and cost-efficiency issues with respect to the software products and services generated.
However, because of the myriad of models and standards reported in the three disciplines, the convergence suggested for SE and SwE engineering process, models and/or standards (Boehm 2000; Hecht, 1999; ISO, 2006c; ISO, in press; Sommerville, 1998; Thayer, 1997) and the increasing complexity of the modern information systems (Mora et al, 2008), we argue that these models and standards of processes become relevant in the Information Systems discipline. Then, in this chapter we develop a conceptual description (Glass, Armes & Vessey, 2004; Mora, 2004) of the main models and standards of processes formulated in the SE, SwE and IS disciplines with the general purpose to identify aims, purposes, characteristics, and core building-block concepts. Firstly, we report the rationale for having models and standards of processes in such disciplines. Secondly, we review their main characteristics. Thirdly, based in the identified aims and principles, we report and posit the concepts of process, system and service as the conceptual building-blocks for describing such models and standards. Finally, initial theoretical and practical implications for the Information Systems discipline of such models and standards are discussed, as well as recommendations for further research are suggested.

**REVIEW ON MODELS AND STANDARDS OF PROCESSES**

**The Rationale of Models and Standards of Processes**

Currently the global and large-scale organizations are faced with the challenge to meet the highest customer’s expectations for their products and services, as well as to satisfy their own organizational financial and strategic objectives. To cope with such external and internal complexities, organizations have fostered the utilization (deployment and exchange) of best organizational practices. These global best practices have been documented via models and standards of processes. According to Succi, Valerio, Vernazza, and Succi (1998, p. 140) “standardization means that there is an explicit or implicit agreement to do certain things in a defined and uniform way”.

Whilst the models are considered as de facto standards (not a legal mandatory use) and the standards as de jure (legal mandatory use when a country or business sector agrees use it), both help the organizations to improve the quality of their internal processes and to align them with international practices. In this way, the organizations foster an efficient and effective international exchange of goods and services. We consider that an insightful understanding of the models and standards concepts is required for their further analysis. The Table 1 (from several sources: Mora, Gelman, O’Connor, Alvarez & Macías, 2007a; Sheard & Lake, 1998; Tantara, 2001; Wright, 1998) shows the main conceptual attributes of the models and standards of process.

The main similarities between models and standards are the following: (1) both provide a map of generic processes from the best international practices; (2) both establish what-alike and must-be instructions rather than how-alike specific procedures, and (3) both do not impose a mandatory life-cycle but suggest a demonstrative one that is usually taken as a starting point. The implementers must complement such recommendations with detailed procedures and profiles of the deliverables. Regarding to the differences: (1) the models (at least the early reported) have been focused on process improvement efforts (and consequently include a capability maturity level assessment such CMMI) while that the standards, on an overall complaint and not complaint general assessment (e.g., ISO, 1995), (2) models are used under an agreement between companies to legitimate their industrial acceptance (e.g., CMMI in the Americas) while that standards are used under a usually obligatory country-based agreement (e.g., ISO, 2003 in Europe and Australia), and (3) the models can be originated from any
organization while that the standards are strongly endorsed by nations.

It is worth noting that the first standards were product-oriented (Tripp, 1996) (design and final product attributes, tolerances, specifications) and could be objectively assessed through testing and evaluation of the devices using physical instruments. However, the standards for process convey additional difficulties for automatic assessment. Observations, records, interviews, analysis and questionnaires applied to core people in site are required. Furthermore, for the case of the software as a product/artifact, additional complications emerge. While that the standard ISO 9126:1991 offers an initial solution, their set of attributes still requires a final interpretation on how to measure them. Other sources of complexity are the time and the human resource performance variability in the certification of standards of processes.

It has been reported also the critical roles that are played by the information and communications technologies (ICT) and the systems of information systems (SoIS) for supporting practically all business process in worldwide organizations (Mora, Gelman, Frank, Paradice, Cervantes & Forgionne, 2008). This assertion implies that for such organizations, the ICT infrastructure and the SoIS (and IS function), have become an essential resource and macroprocess (e.g., a system of systems of processes) for that the organization operates efficient and effectively. Relevant economic losses from ICT infrastructure downtimes or SoIS failures are present evidences of the high-dependability that worldwide organizations have on the correct availability, capacity, and reliability of such ICT resources and process.

Models and/or standards of processes for engineering and management of ICT and SoIS resources have been also developed. However, such development and deployment have increased the engineering and management complexity per se. To cope holistically with the technical and socio-organizational problems for their efficient and effective engineering and management, this chap-

</table>
ter supports the premise that an integrative and holistic approach based in an extended Systems Engineering philosophy and methods (Forsberg & Mooz, 1997; INCOSE, 2004; Sage, 1992, 2000; Sage & Armstrong, 2000) can provide the suitable conceptual lenses and methodological tools to study and cope with the increasing managerial, technical and organizational complexity of the engineering and management (E&M) of ICT and SoIS resources and processes. Overall expected contribution is to increase our understanding and control of such E&M processes.

This chapter then, is motivated by the reasons identified previously by authors (Mora et al., 2007a):

(i) the SE models and standards of processes have been ignored in IT&S or scarcely analyzed in SwE; (ii) the SwE literature has wrongly equaled the concept of software system with the concept of information systems when both constructs are ontologically different (Mora et al., 2003) and consequently relevant organizational issues have been ignored in SwE models and standards of processes; and (iii) the Systems Engineering field and the Systems Approach philosophy has proved to be very successful in large scale projects when it is correctly applied (Barker & Verma, 2003; Honour, 2002).

Furthermore, we have identified also (idem) core facts that become relevant the interaction of SE, SwE, and IT standards and models of processes for the IS discipline:

(i) the recognition that the scope and effects of software systems do not end with its completion but with its successful deployment of the whole (information) system (Boehm, 2000; Sommerville, 1998); (ii) the acceptance of the software engineering process involves also managerial, organizational, economic, sociopolitical, legal and behavioral issues (Fuggetta, 2000; Kellner, Curtis, deMarco, Kishida, Schulemberg & Tully, 1991); (iii) the proposal of the integration of Systems Engineering (SE) with Software Engineering to enhance mutually their engineering and managerial process (Andriole & Freeman, 1993; Bate, 1998; Boehm, 2000, 2006; Deno & Feeney, 2002; Hecht, 1997; Hole, Verma, Jain, Vitale & Popick, 2005; Johnson, 1996; Johnson & Dindo, 1998; Nichols & Connaughton, 2005; Sommerville, 1998; Thayer, 1997, 2002); (iv) the identification that the Information Technology and Systems (IT&S) field, which traditionally has its focus in the management and evaluation of IT-intensive systems, is highly dependent of the engineering activities (Hevner, March, Park & Ram, 2004; Nunamaker, Chen & Purdin, 1991) conducted in SwE and SE, and despite this has generated its own set of models and standards of processes, their conceptual relation with SwE and SE models and standards has been few explored, and (v) the proposal to widen the scope of SE standards of processes to define business process architectures in organizations (Arnold & Lawson, 2004; Farr & Buede, 2003).

History and Aims of the Main SE, SwE and IS Models of Standards of Processes

A generic aim of the SE, IS and SwE is the definition, development and deployment of large-scale cost-effective and trustworthy integrated systems, system of information systems or software-intensive systems respectively (Sage, 1992, 2000; Sage & Armstrong, 2000; Thayer, 1997). In pursuit of this aim, these disciplines have generated models and standards of processes to guide and control the engineering and managerial activities involved in the creation of such systems. The models and standards provide a set of processes for good (or best) SE, SwE and IS practices, but differs in some items exhibited in Table 1. The Table 2 (derived from Collin, 2004; Garcia, 1998; ISO, 2005; ITGI, 2000; Sheard & Lake, 1998; SEI, 2006; Tantara, 2001; Wright, 1998) shows the history of the main models and standards in SE, SwE, and IS.
Overview of Models and Standards of Processes in the SE, SwE, and IS Disciplines

The main finding from Table 2 is the lack of models and standards of processes for IS area. Except for the ISO 20000 standard (published in 2006 but based in ITIL v.2.0 model from 1995) and the model CobIT, no significant model or standard of process has been posed. SE and SwE disciplines have developed more standards in the last two decades but both face the challenge of integration toward single standards (e.g., ISO 15289, CMMI for SE and SwE). From the descriptions of the aims of the standards and models of processes in Table 3, we identify two core purposes: (1) the improvement/assessment of processes and (2) the definition/provision of processes.

Mora et al (2007a) report that such standards and models also exhibit a(n):

1. "rationality to organize the managerial and engineering functions to define, develop and deploy products and services in a generic organization through a process approach;"

2. "acknowledgement of the increasing inter-relationship between software, hardware and general IT-based products, services and/or systems, [that] has fostered the integration of SwE and SE standards and models to address the needs of a whole product, service or system to be engineered;"

3. "emergence of the service-oriented approach in the future (as the forthcoming CMMI-SVC, and the current ISO20000 standard;"

4. "implicit need for an interdisciplinary body of knowledge and research related to the management and engineering of process from SE, SwE and IT&S disciplines including BPM;"

5. "implicit utilization of the Systems Approach to establish the initial foundations such as concepts, principles and philosophy, for the design of standards."

continued on following page
Overview of Models and Standards of Processes in the SE, SwE, and IS Disciplines

The aforementioned characteristics are based on the fact of the ISO 9000 family of standards (which deal with a generic industry-independent quality management system and an organizational encouragement toward a continuous process improvement) is identified as the main source for the SE, SwE, and IT standards and models of process. Table 3 shows the official self-description and status of these models and standards.

The Core Building-Block Concepts for Understanding Models and Standards of Processes: Process, Service and System

The ISO 9000 standard in its 2000-year version has established eight management principles where two of them (Principle 4 and 5) endorse the process approach and the systems approach as critical management paradigms respectively. Principle 4 establishes that an organization will be more likely to achieve the results expected efficiently, if the resources and activities are managed as processes. In turn, the Principle 5 sets forth that an organization can identify, understand and manage more efficiently and effectively the processes if they conceptualized them as a system. Furthermore, the ISO 9001:2000 standard remarks that “… concerns the way an organization goes about its work ... concern processes not products—at least not directly” (ISO, 2006b). However, this standard admits also that, “ … the way in which the organization manage its processes is obviously to affect its final (quality of) product” (ibid).

This process management premise (e.g., “the quality of a system is largely governed by the quality of the process used to develop and maintain it”) has been largely used in quality management systems (Paulk, Chrissis, Weber & Perdue, 1987). With these insights, we posit that the concepts of process, system and service and their conceptual systemic interrelationships become critical to understanding the different standards and models under study. The relevance of the notion of process is self-evident. The notion of service, for SwE is becoming of critical relevance for the shifting...
Overview of Models and Standards of Processes in the SE, SwE, and IS Disciplines

from the object and component-based paradigm toward the Web service-computing paradigm. In SE and IS, the broad initiative on Service Science, Management and Engineering (SSME) (Chesbrough & Spohrer, 2006; Demirkan & Goul, 2006) justifies its relevance. The notion of system is justified by the ISO 9000:2000 principles.

In order to describe the relationships between process, service and system in the context of standards and models of process, we develop the Tables 4, 5 and 6 (updated from Mora et al., 2007a) to report the main definitions from such concepts.

Definitions in the Table 4 show that the concept of process is not unique. However several attributes are shared in the definitions: (1) an overall purpose (transform inputs in outputs), (2) activities interrelated, and (3) utilization of human and material resources, procedures and methods. Then, a process-based in all definitions-, can be defined as “an ordered set of processes (called sub-process) and/or activities that are performed by agents (either people and/or mechanisms) exercising roles and using procedures, tools and machines for its realization, to transform a set of inputs in a set of expected outputs” (extended from Mora et al., 2007a).

In the Table 5, the concept of service is implicitly used for most standards except by those focused on such an issue. Because the most important standards and models of processes for IS (ITIL, CobiT, ISO 20000) and for SwE/SE (CMMI-SVC) are now oriented toward services, a plausible generic definition of what is a service is fundamental. Similar to the notion of process, there is not unique definition but several attributes are also shared by the definitions: (1) intangible, (2) non-storable, (3) ongoing realization, and (4) people involved for the value appreciation attribute. Whilst the human beings can assess the value scale of nonliving artifacts, the automated processes (by using tools) can assess quality attributes (e.g., agreed physical specifications). Therefore, a service can be defined as “the intangible, non-storable and user value-appreciated ongoing outcome (but with a start and end time point) from a system of processes” and consequently a product can be defined as “the tangible, storable and quality-measured for instruments or users from a system of processes” (extensions from Mora et al., 2007a).

Overview of Models and Standards of Processes in the SE, SwE, and IS Disciplines

Hence, the main visible distinctions between product and service are: (1) its tangibility property that leads to the quality (e.g., the attributes expected in the product) vs. the value (e.g., the benefits to quality-prices rate perceived from a customers’ perspective (e.g., human beings), and (2) the ongoing service experience (Teboul, 2007) vs. the time-discrete (includes also periods) utilization of products. An additional difficult to define the building blocks is the omission of the responsible entity that generates a service. The definitions proposed (because these appear in the standards) are the notions of system and process. Still, the difference between both concepts has not been still well reported.

For the aforementioned arguments and definitions showed in the Table 6, the construct system becomes a critical concept to link logically the process and service/product constructs. Hence, the utilization of a Systems Approach (Ackoff, 1971, 1973; Bertalanffy, 1972; Checkland, 2000) as well as the relevance of the correct conceptualization of what is a system can be considered fundamental notions to be untapped. Despite, it could be considered that the concept system is a well defined and understood construct, Gelman and Garcia (1989), Gelman et al. (2005), Mora, Gelman, Cervantes, Mejia, and Weitzenfeld (2003) and Mora, Gelman, Cano, Cervantes, and Forgionne (2006) studies on the formalization of the construct system, have proved the ambiguity, incompleteness and informality of main definitions reported in the context of SE and IS. Then, the concept of system used in these standards, despite can be considered practically illustrative and useful is theoretically incomplete from a systems science discipline. In Mora et al. (2007a) it is argued that “it has diminished the clarity on the critical role of the Systems Approach as the philosophical and practical source to establish the principles and methods of such standards and has increased consequently the complexity for a mutual understanding and integration. Whilst Process Approaches have been the corner stone for the development and utilization of standards and models of processes, we claim that the Systems Approach is in turn the corner stone that holds to the Process Approach.”

</table>

However, from a practical worldview and with the purpose to propose a plausible relationship between the three concepts, a system as an abstract entity, can be defined as “a whole into a wider system, with unique attributes co-generated by their parts, where the main attribute is its purpose, function or mission”. Given that such a definition is open, a specific definition of a system abstraction in the context of organizations is required. In particular, the notion of organizational system is relevant for the context of standards and models of processes. In concordance with system foundations (Gelman & Garcia, 1989; Mora et al., 2006), this concept can be defined as: “a whole (the real physical system) into a wider system (the wider real physical system), with unique attributes co-generated by their parts (subsystems and process (that include the parts of every process has)), which the main attribute is its purpose, function or mission (to manufacturing a product or provision a service)”. Such a notion is also congruent with the SSME’s notion of service system (Spohrer et al., 2007).

As illustration, from a high practical worldview perspective, the following eleven conceptual relationships between the core building-block concepts can be posed:

1. R1: a <S: system> is whole into a wider <SS: system>, with unique <A: attributes: a1,a2,..> co-produced by their (at least two) parts called <sB: subsystems>, where the main attribute is its purpose, function or mission <attribute: a*>.
2. R2: a <sB: subsystem> is just a <S: system> that is part of a wider <SS: system>.
3. R3: a <C: component> is a constituent of a <sB: subsystem> that is not decomposable in parts (from a modeling viewpoint) but with attributes.
4. R4: an <O: organization> is a <S: system> composed of <OsS: organizational sub-systems>.
5. R5: an <OsB: organizational sub-system> is a <S: system> composed of <OsB: organizational sub-systems> and/or <BP: business processes>.
Overview of Models and Standards of Processes in the SE, SwE, and IS Disciplines

• R6: a <BP: business process> is a <S: system> composed of <BsP: business sub-process> and/or <BA: business activities>.
• R7: a <BA: business activity> is a <C: component> with the <A: attributes: a-tasks, a-personnel, a-tools-infrastructure, a-methods-procedures and a-socio-political-mechanisms-structures>
• R8: a <Sv: service> is an intangible ongoing <BO: business outcome> of a <BP: business process> into an <OsB: organizational sub-system>.
• R9: a <Pr: product> is a tangible and discrete <BO: business outcome> of a <BP: business process> into an <OsB: organizational sub-system>.
• R10: a <BsP: business sub-process> is just a <BP: business process> that is into a <process>.
• R11: a <BO: business outcome> is a perceived output of a <BP: business process> with either <VoP: value-oriented people attributes: v1,v2, …> or <QoM: quality-oriented machines attributes: q1,q2, …>.

Hence, the manufacturing of products and the provision of services needs a business process approach where the business process can be conceptualized as a system (composed of business subprocesses and/or business activities) contained in an organizational system that affects to and it is affected by a wider system called the suprasystem. Initial but substantial theoretical and practical implications of such relationships are discussed in the final section.

INITIAL THEORETICAL AND PRACTICAL IMPLICATIONS FOR THE IS DISCIPLINE

This chapter is part of a research in progress and an extensive discussion of their contributions is out of the planned scope. However, initial results on the how to apply such a set of conceptual relationships have been reported in Mora et al. (2007a, 2007b).

From a theoretical viewpoint, however, we can argue that these conceptual findings contribute: (1) to identify the building-block concepts of the highest abstraction level to define and understand the rationale of standards and models of processes; (2) to establish a conceptual hierarchical set of initial relationships between such conceptual building-blocks that permits the development of a further formalization via an ontology; (3) to keep a theoretical congruence with the formal notions of what is a system, subsystem and suprasystem; and (4) to provide a parsimonious theoretical model of what is a business organization, business process, business activity, service and product.

From a practical viewpoint, this study contributes: (1) to help to practitioners to understand the conceptual relationships between process, system and the final outcomes of services and products using a domain vocabulary linked to formal systemic foundations; (2) to provide the foundation for the development of a computerized ontology for standards and models of processes that would permit automated knowledge-based inquire; and (3) to provide the foundations for the development of a framework/model to describe and compare the standards and models of processes from a top-bottom perspective according to the level of detail required by the modeler (Mora et al., 2007b).

CONCLUSION

In this chapter, we have developed a conceptual description of the main models and standards of processes formulated in the disciplines of SE, SwE and IS. Based in such descriptions, we have developed a conceptual analysis of the concepts of process, system and service. Such concepts have been identified as the core building blocks for describing models and standards of processes. Eleven semi-formal conceptual relationships between the building-blocks concepts have been
also posed. The main theoretical contribution is the generation of a parsimonious model theoretically congruent with the Theory of Systems. The main practical contribution is the provision of a conceptual tool to describe and compare standards and models of processes. Two recommendations that emerge for further research are: (1) the refinement of the relationships to describe and compare standards and models of processes and (2) the development of a computerized ontology based in this theoretical model for permitting knowledge-based inquires on the digital description of standards and models of processes in SE, SwE and IT. These two research recommendations are part of the research goals of this study under progress.

ACKNOWLEDGMENT

This research is being developed with the financial support of the Autonomous University of Aguascalientes (www.uaa.mx) (Project PIINF-06-8) as well as from the Mexican National Council of Science and Technology (CONACYT, www.conacyt.mx) (Project P49135-Y).

Overview of Models and Standards of Processes in the SE, SwE, and IS Disciplines

## ENDNOTES

1. A standard is a “... document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context.” (ISO, 2004b)

2. Most recent standards have incorporated such improvement purpose (e.g., ISO 15504).

3. The initial results from such a premise have been reported in Mora et al (2007a) and final findings will be reported in a further study.

4. In particular, Fuggetta (2000, p. 28) points out that “... rather, we (e.g., the software process community) must pay attention to the complex interrelation of a number of
Overview of Models and Standards of Processes in the SE, SwE, and IS Disciplines

organizational, cultural, technological and economic factors.”

SE is an older discipline than SwE that copes with the definition, development/acquisition and deployment of large scale systems comprised of multiples components of people, facilities, hardware, software, mechanical, and so forth.

SwE is defined as the discipline to generate software components or systems on time, on budget and with the expected technical requirements achieved.

CMMI-SVC will be the constellation focused on the management and engineering of process for delivering services. It is planned to be released in 2007. Other CMMI-ACQ constellation for acquisition process is also being developed for 2007.

In this chapter is analyzed the version 3.0 released in 2000. The new version 4.0 has been recently released ending 2006.

This standard is derived from the BS15000 standard. In turn, the later evolved from the ITIL V.2.0 (1995) Model. Because the ITIL V.3.0 was liberated during the ending of this study, this is not considered. Major change realized is a lifecycle approach to arrange the previous main six categories of processes.

Other IS standards (e.g., Computer standards) are oriented to computer sciences and these are not considered in this chapter. ICT security standards can be considered hybrid but are out of the scope of this research.

These definitions are based in Gelman & Garcia (1989), Mora et al. (2003), Gelman et al. (2005) and Mora et al. (2006, 2007b).
