

**Transcriptional Regulation of  
Chemically Induced Epithelial Lung Cell  
Differentiation, *in vitro***

A thesis submitted for the degree of Ph D

Dublin City University

By

Jason McMorow B Sc (Biotechnology)

The research work described in this thesis was performed  
under the supervision of

Prof Martin Clynes

National Institute for Cellular Biotechnology  
Dublin City University

I hereby certify that this material, which I now submit for assessment on the programme of study leading to the award of Ph D is entirely of my own work and has not been taken from the work of others save and to the extent that such work has been cited and acknowledged within the text of my own work

Date

26 Jan. 2004

*This thesis is dedicated to my parents  
and my brother who have been so  
supportive throughout my life*

## Acknowledgements

First and foremost, I would like to thank my supervisor, Prof. Martin Clynes for his patience, guidance and encouragement during this research thesis, especially during the final stages of the project. Without his constant support none of this work would have been possible.

I would also like to thank Dr. Paula Meleady for all her help and training in the earlier stages of the project and for showing me the ropes! Also I wish to sincerely thank Dr. Niall Barron for all his help in the final years of the project. No matter what time, how busy or how stupid my question was, Niall has always been there to offer help, guidance and most of all encouragement. He has done his best to try and teach me some molecular biology...but I still have so much more to learn! A huge thank you to Eoin Ryan for all his help with the Bioinformatic and Microarray side of the project. Without Eoin's help with GeneSpring I would still be stuck in the lab trying to make sense of the Microarray datasets! I do appreciate all the time Eoin has spent trying to teach me some Bioinformatics, it hasn't been easy!

To all the girls in Diabetes, Lorraine, Elaine (yes Elaine I'm finally finished!), Eadaoin, Maider, Bella and to my laminar partner Irene; a huge thank you for letting me take over your lab and become an adopted Diabetes member over the last four years. I don't think that the laminar suites in the lab, not to mention Irene's ears, will ever recover from my singing and continual moaning! To the members of my own lab Finbarr, Brendan and William; thanks for putting up with my ever-changing moods...I know it hasn't been that easy!!! But thanks for all your support and letting me use certain pieces of equipment towards the end when time was scarce.

A special thanks to my proof reader, Dr. Anne-Maire Larkin, for the time she spent giving me advice and encouragement in the last couple of weeks of write-up and all the late evenings she spent in the lab spotting all my typos!! Also to Mairead, Yvonne and Carol for all their help and support as well as for letting me take over the printer for the last few months!

To my coffee ladies...Anne-Maire, Aine, Helena and in the earlier days Catherine, thanks for listening to my daily moaning and complaining about never seeing the end! I don't think there's a single conversation topic that we haven't touched on over the last four years. I think I brightened many a dull day with my little stories and more than likely shocked you in the process. To Elisa and Lisa - thank you for putting up with me at home over the last year! A big thank you to Eadaoin, Bernie and Catherine for always being there and for being such good mates. I owe you all so many dinners and drinks!! I promise to pay you back...as soon as I get a job!! But thanks for all your support, it really means a lot. But I truly am grateful for your friendship

Finally, I would like to thank my parents, Kevin and Mary, and my brother Kevin, for always being there no matter what. For always encouraging and supporting me in whatever choices I made. Without them I would never have gotten this far and this achievement is as much their moment as it is mine. I truly can never repay you for all the love you have given me, but can only hope to make you proud.

## Abstract

Bromodeoxyuridine (BrdU) is a thymidine analogue capable of inducing epitheloid morphology and altering the expression of neuroendocrine markers in SCLC cell lines. The ability of BrdU to alter differentiation in neuronal, muscle and haematopoietic lineages has been well documented in the literature. Evidence suggests that this incorporation into the DNA alters the DNA's conformation, which in turn may affect interactions with specific transcription factors, leading to either inhibition or induction of differentiation. Following on from work previously performed in our laboratory, several pyrimidine analogues were studied to investigate if they possessed similar differentiating properties to BrdU.

The DLKP cell line was established at the NICB from a tumour histologically diagnosed as a poorly differentiated lung carcinoma. DLKP cells have properties which suggest they could be classified as either SLCL-V or non-small-cell-lung carcinoma with neuroendocrine differentiation (NSCLC-NE). In this study it is demonstrated that the DLKP cell line, and the more differentiated adenocarcinoma line, A549, upon treatment with the BrdU and a panel of other pyrimidine analogues, showed increased expression of cytokeratins 8, 18 and 19 proteins. Increased protein expression levels of integrin subunits  $\alpha_2$  and  $\beta_1$ , as well as the cellular adhesion molecule Ep-CAM, was demonstrated in both cell lines following exposure to drug.

DNA microarray experiments were also performed on DLKP cells exposed to BrdU, IdU and 5,2 -FdU. Following gene expression analysis on these microarray experiments, lists of differentially expressed genes were generated. From earlier work performed in this thesis, we demonstrate that all three pyrimidine analogues induce a similar pattern of differentiation in DLKP cells. Therefore, the three microarray experiments were compared to each other in order to identify a common differentiation pathway. We reveal that a total of 93 up-regulated genes were common to all three microarray experiments. EASE analysis was performed on these 93 genes and identified 20 genes from this list of 93, which are thought to be involved in cellular development. From this list of 20 development genes, we identify in particular, two families of transcription factors that potentially are involved in the regulation of differentiation in our system. These transcription factor families are the Id and KLF proteins. We propose that the Id family of proteins play an important part in the regulation of differentiation in pyrimidine-treated DLKP cells. We also suggest a role for KLF4 in the regulation of cytokeratin expression, mediated through IFN $\gamma$  and STAT-1 proteins.

The transcription factor YY1 is a 65kDa protein that is ubiquitously expressed and is highly conserved among human, mouse and *Xenopus*. YY1 possesses the unusual property of regulating transcription in three ways, depending on the cellular context. YY1 has been shown to activate, repress or initiate transcription.

of a number of cellular genes and has previously been shown to associate with *c-myc*, resulting in its activation and up-regulation

We have also shown that BrdU-treated cells show increased levels of c-Myc and eIF-4E protein. In order to investigate the role c-Myc and eIF-4E play in the differentiation of the DLKP lung cell line, a clonal variant of DLKP, DLKP-SQ, was transiently and stably transfected with a human YY1 cDNA expression vector. It was observed that in stable clones over-expression of YY1 up-regulated c-Myc protein levels. The over-expression of YY1 appears to have further effects on other cellular genes such as increased levels of eIF-4E, eIF-2 $\alpha$  and Ornithine Decarboxylase proteins. We also demonstrate that the transient over-expression of YY1 is capable of inducing genes identified as differentially expressed, namely Id2, Id3, HMOX1 and FHL1, in the DLKP, IdU and 5,2 -FdU microarray experiments.

***Section 1.0***      **Introduction**

## 1.1 Cellular differentiation

Cellular differentiation can be defined as the process leading to the expression of phenotype characteristic of the functionally mature cell *in vivo*. As the differentiation process progresses there is an associated reduction in cell division and cell proliferation activities are eventually lost (Davila, *et al*, 1990). The principal cells that differentiate are referred to as stem cells, which are capable of rapid cell growth and division. These cells are multipotent and have the potential to differentiate into several different cell types. In general, stem cells possess unlimited proliferative potential but they can remain quiescent under certain microenvironment conditions (Davila, *et al*, 1990). Differentiated cells are thought to be produced, not directly from stem cells, but rather via a committed progenitor or transit amplifying population (Watt, 1991).

The density of a cell during embryogenesis and development is regulated by gene expression which restricts the number of lineages that stem cells have the potential to form. Previous studies (Ham and Veomott, 1980) have proposed that 'determination' is a process whereby a cell becomes committed to differentiate into a specific lineage. A determined or committed cell initially may not appear phenotypically different, this only occurs after the genetic blueprint has been implemented (Maclean and Hall, 1987). A cell can differentiate in a manner which results in either the irreversible loss of its proliferative properties, terminally differentiated, or in the retention of some of its proliferative capacity while the cell itself is fully differentiated, non-terminally differentiated. A number of differentiation states are also well documented. Dedifferentiation is the process by which a cell loses its differentiated phenotype and transdifferentiation occurs when a cell dedifferentiates and redifferentiates into a new and distinct phenotype (Davila, *et al*, 1990). It is apparent from this that as a cell undergoes differentiation, its gene expression profile will likewise change.

The process of cellular differentiation is often mediated by the tissue type the cell is present in. A progenitor stem cell represents the progeny of stem cells which possess more limited proliferation and differentiation potential. This cell is usually involved in a single lineage. Although stem cells in adult organs are pluripotent, the differentiated daughter cells are not usually expressed beyond the relevant organ in

which the stem cell originates from, i.e., the cells are tissue determined stem cells (TDS) and are thus considered separate from embryonic stem cells (ES cells) (Sell, 1994)

Tissue determined stem cells are believed to undergo a slow cell cycle in order to reduce the risk of errors during DNA replication. As TDS cells are present throughout the life of an organism, such errors could become amplified in the organism (Lajtha, 1982) and had been proposed that many tumours contain TDS cell populations (Khan, *et al*, 1991) and that the overlapping expression of differentiation markers (Gazdar, *et al*, 1988) within cancer cells is indicative of a stem cell origin for most lung epithelial carcinomas. During the differentiation process of TDS cells it is necessary that they maintain a constant cell number. One popular model for this is asymmetrical cell division. According to this model, when the stem cell divides one daughter cell remains as a stem cell while the other becomes a transit cell and enters the differentiation process.

Although proliferation and differentiation appear to be interlinked processes during stem cell maturation, they are quite often separate events that occur concomitantly. This suggests the whole differentiation process may be understood in terms of spiral model (Potten and Loffler, 1990). Some TDS cells appear to be highly pluripotent giving rise to several different cell lineages, e.g. the haematopoietic system. Given its pluripotency, it can be envisaged that depending on the signal, a stem cell will adopt one direction of maturation over another.

## **1.2 Lung Development**

The development of the lung requires cell proliferation, branching morphogenesis, alveolar sac formation and cell differentiation. These processes require well coordinated events, which are achieved by epithelial-mesenchymal interactions, activation and repression of transcriptional factors and signalling.

The existence of principle of stem cells and the *in vitro* cultivation and manipulation has now been well established and demonstrated for tissues such as mammary glands (Rudland and Barraclough, 1998), Liver (Sell, 1994), haematopoietic tissue (Fraser, *et*

*al* , 1995) and skin (Jones, *et al* , 1995) However, the existence of a similar stem cell model has not yet been identified in lung tissue, though it is strongly suspected given the ability of the lung to regenerate when exposed to local damage by atmospheric components Identification of such lung stem cells is hampered by the complexity of the respiratory system and the variety of cell types present (Plopper and Hyde, 1992, Paine and Simon, 1996)

The most predominant hypothesis for stem cells *in vivo* is that different sets of progenitor cells exist each destined to give rise to a discrete differentiated cell type (Plopper *et al* 1992) In the case of type II lung cells, these cells proliferate and then differentiate into type I cells (Adamson and Bowden, 1979) and Clara cells can differentiate into ciliated cells (Juttner, 1991) However, other thinking on the existence of lung stem cells suggests the existence of a monotypic stem cell, which gives rise to a transit cell described as a small mucous granule cell (SMGC) This cell is defined as being of a secretory yet premature type containing a few small granules which are periodic acid Schiff reaction positive, and also possess a well developed endoplasmic reticulum, prominent Golgi complex and tonofilament bundles It is believed that SMGCs are able to give rise through dedifferentiation to any differentiated secretory cell type

To date, very little scientific evidence exists relating to stem cells of the lung, the pathways they follow, their distribution and mechanism of action No markers yet exist for lung stem cells and the idea of dedifferentiation is in contrast to the stem cell models developed in other tissues such as the skin, liver and intestine, where stem cells pre-exist in the epithelium (Emura, 1997) The lung is susceptible to local damage from a number of different sources including ozone, carbon black particles, lipophilic chemicals absorbed into the blood stream from the gut, or damage induced from bacterial or viral infection Therefore, the lung must possess some form of self regeneration, even if limited to overcome such damage In attempting to identify if a cell is a stem cell, its native state is often altered during the investigation This may result in loss of the stem cell or only a limited spectrum of responses being observed Thus, due to the variety of cell types present and the complexity of the respiratory system, identification of a lung stem cell may prove to be a difficult task

### **1 3 Identification of a stem-like lung cell line, DLKP**

All of this has interesting implications with the isolation of a poorly-differentiated lung cell line, DLKP, at the NICB (Law, *et al* , 1992) Clones derived from this cell line exhibit the amazing capacity to regenerate the mixed parental population over time The DLKP novel cell line has been categorised as extremely poorly differentiated and consists of at least three subpopulations, termed SQ (Squamous), I (Intermediate) and M (Mesenchymal) (McBride, *et al* , 1998) These populations have demonstrated the ability to interconvert and eventually, when cultured alone, replenish the parental phenotype This, combined with the lack of expression of a number of differentiation-specific markers, has led to the speculation that DLKP may represent a stem cell-like population This has afforded a unique opportunity to study the process of lung cancer differentiation *in vitro*, particularly the early stages of this process Such studies will provide insights in the mechanisms of early lung development

### **1 4 Synthetic agents capable of inducing epithelial lung cell differentiation**

#### **1 4 1 Halogenated thymidine analogues - BrdU, IdU and CldU**

Bromodeoxyuridine (BrdU) is a halogenated thymidine analogue that is known to influence the differentiation of cells It is best referred to as a differentiation modulating agent since it has been shown to be a potent inducer of differentiation in some cell lines (Yen *et al* , 1987, Sugimoto *et al* , 1988, Valyi-Nagy *et al* , 1993), while it can inhibit the differentiation of others (Seecoff and Dewhurst, 1976, Tapscott *et al* , 1989, Lee *et al* , 1992) BrdU competes with naturally occurring Thymidine for incorporation into DNA during replication and as such it, and other similar compounds, should be ideal candidates for anti-tumour agents, since they require cell division and DNA synthesis to exert their effects (Bick and Devine, 1977) While few clinical trials are based on the differentiation-modulating properties of this drug (Freeman, 1969, Ameye *et al* , 1989), BrdU has been used widely as a radiosensitiser in an attempt to improve radiological treatments (Lawrence *et al* , 1992, McGinn and Kinsella, 1993) Radiosensitisation trials to date include the treatment of malignant glioma (Vander *et al* , 1990), ulcerative herpetic keratitis (van

Bijsterveld *et al.*, 1989), malignant astrocytomas (Greenberg *et al.*, 1988) and malignant brain tumours (Matsutani *et al.*, 1988). More recently, BrdU has entered clinical trials as a radiosensitiser in the treatment of pancreatic cancer (Robertson *et al.*, 1997), colorectal liver metastases (Robertson *et al.*, 1997) and cervical cancer (Eisbruch *et al.*, 1999), while studies in relation to malignant gliomas continue (Prados *et al.*, 1998). Administration of BrdU is normally by controlled perfusion (Doirion *et al.*, 1999), and has been used in combination with radiolabelled monoclonal antibodies (Buchsbaum *et al.*, 1994). While radiolabelled antibody approaches offer the potential of targeted chemotherapy, they are limited by low dose-relate deliverable. As such, the trials of Buchsbaum *et al* (1994) may offer a means of enhancing the efficacy of low dose radiolabelled monoclonal antibody approaches.

BrdU incorporates into DNA in a non-random fashion at sequences termed "fragile sites" (Hecht *et al.*, 1988; Sutherland, 1988; Sutherland, 1991). This explains the reproducibility of the effects observed with BrdU-induced differentiation. O'Neill and Stockdale (1973) developed a model for BrdU-induced modulation of differentiation that assumes that BrdU "sensitivity" resides on a single pair of chromosomes, suggesting the presence of a "master gene" or target through which BrdU exerts its effects. In this model, inhibition of differentiation occurs in a dominant fashion if approximately 30% or more of naturally occurring thymidine is replaced by BrdU in the readout strand of either chromosome. This sort of model agrees with the predicted mechanisms of action of a number of DNA-intercalating agents. BrdU substitution into DNA and intercalation of such agents may have similar effects, thought to be through direct DNA bending at either major or minor grooves, thereby altering promoter structure and availability to transcription factors. Intercalation of the antibiotics, elsamycin A or actinomycin D in the promoter of the *c-myc* gene induced a decrease in the level of transcription from this promoter (Vaquero and Portugal, 1998). However, relatively low levels of elsamycin incorporation actually induced an increase in *c-myc* transcription through the P1 promoter. Bromodeoxyuridine (BrdU) has been demonstrated to decrease *c-myc* expression at the transcriptional level in the leukaemic cell line, HL60 (Yen and Forbes, 1990) and in human melanoma lines (Valyi-Nagyi *et al.*, 1993). These results would appear to suggest that the *c-myc* promoter regions are particularly susceptible to modulation by agents that disrupt

promoter structure either through Thymidine substitution (BrdU) or intercalation (Elsamycin). Alternatively, BrdU may directly influence the ability of proteins to associate with DNA. In the *lac* operon, BrdU-substitution has been shown to result in increased binding of the *lac* repressor protein (Lin and Riggs, 1972), suggesting that BrdU may be capable of altering the binding of regulatory factors.

The mechanism by which BrdU exerts its differentiation-modulating effects remains unclear, but it appears that incorporation into DNA is essential. This involves BrdU being converted to Bromodeoxyuridine monophosphate, which competes with thymidine for incorporation into DNA (O'Neill and Stockdale, 1974). Experimental evidence for this hypothesis comes from a study by Keoffler *et al.* (1983) which showed that a thymidine kinase-deficient human myeloid cell line, HL60, was unable to incorporate BrdU into its DNA and subsequently failed to respond to the ability of BrdU to modulate its differentiation status.

A number of models exist to explain the ability of BrdU to modulate differentiation:

**Model 1:**

This model envisages that BrdU induces chromosomal breakages. These breakages and the associated chromosomal aberrations can be associated with stepwise changes in the differentiation status of a cell. These breakages are specific points called 'fragile' sites, 32 of which have been identified in murine chromosomes. It is proposed that BrdU associates with these fragile sites which are known to be recombinogenic (Alexander, *et al.*, 1992).

**Model 2:**

BrdU alters the affinity of DNA sequences for regulatory proteins. Studies on the *lac* operon with BrdU incorporation demonstrate that the *lac* suppressor was bound with greater affinity (Lin and Riggs, 1972).

**Model 3:**

In this model BrdU has been found to exert its effects on differentiation by alteration of a key regulatory gene(s) that alters transcription of genes involved in differentiation (Arnold, *et al.*, 1988; Rauth and Davidson, 1993). In BrdU inhibition

of myoblast differentiation, such alterations occurs with the down-regulation or complete inhibition of the key regulatory gene, MyoD1 (Topscott, *et al* , 1989, Nanthakumar and Henning, 1993)

#### ***Model 4.***

This model envisages that BrdU incorporation causes an alteration in the reading frame of the DNA template resulting in the formation of abnormal mRNA, which is incapable of synthesising the correct differentiation products (Hill, *et al* , 1974)

BrdU is considered by some scientists to be an inducer of pre-commitment to differentiation rather than an actual differentiation inducing agent This was highlighted by the findings that BrdU treatment of HL60s for 24 hours, followed by treatment with Retmoic Acid resulted in a faster response to Retinoic Acid (RA) than the single addition of RA alone (Yen *et al* , 1990) It would appear that BrdU can initiate some of the early changes induced by RA in HL60 differentiation, including early c-myc down-regulation However, the same author reported previously (Yen *et al* , 1987) that pre-commitment to differentiation involves an early increase in c-myc levels in the same Leukaemic line, as induced by RA This suggests that pre-commitment to differentiation in these cells involves increased expression of c-myc It therefore appears that the true mechanisms of induction and commitment to differentiation remain unclear, even in individual cell types

### **1 4 2 Mode of Action of Thymidine Analogues**

The exact mechanism(s), by which BrdU and the various thymidine analogues investigated in these this study, exert their differentiation-modulating effects remains poorly understood In the case of BrdU, it is thought that incorporation into DNA is critical in the process (O'Neill and Stockdale, 1974) Low levels of BrdU have been shown to alter the differentiation status of many different cell types in both inhibitory e g myoblast cells (O'Neill and Stockdale, 1974) and stimulatory e g neuroblastoma cells (Ross A H , *et al* , 1995) Incorporation into DNA involves the conversion of BrdU to Bromodeoxyuridine monophosphate, which competes with thymidine for incorporation into DNA (O'Neill and Stockdale, 1974) A study by Keoffler *et al* (1983) showed that a thymidine kinase-deficient human myeloid cell line, HL-60, was

unable to incorporate BrdU into its DNA and subsequently failed to respond to the ability of BrdU to modulate the differentiation status of HL-60 cells.

Incorporation of BrdU into DNA occurs in a non-random fashion, with incorporation occurring into repeated nucleotide sequences; known as 'fragile sites' (Schwartz and Snead, 1982; Hecht *et al.*, 1988). It is as a result of this consistency of incorporation that may explain the reproducibility of BrdU-induced differentiation. It is thought that breakages in DNA may occur at these fragile sites and these breakages and chromosomal aberrations may be associated with changes in the differentiation status of the cell. It has been also reported that BrdU associates with these fragile sites. (Alexander *et al.*, 1992).

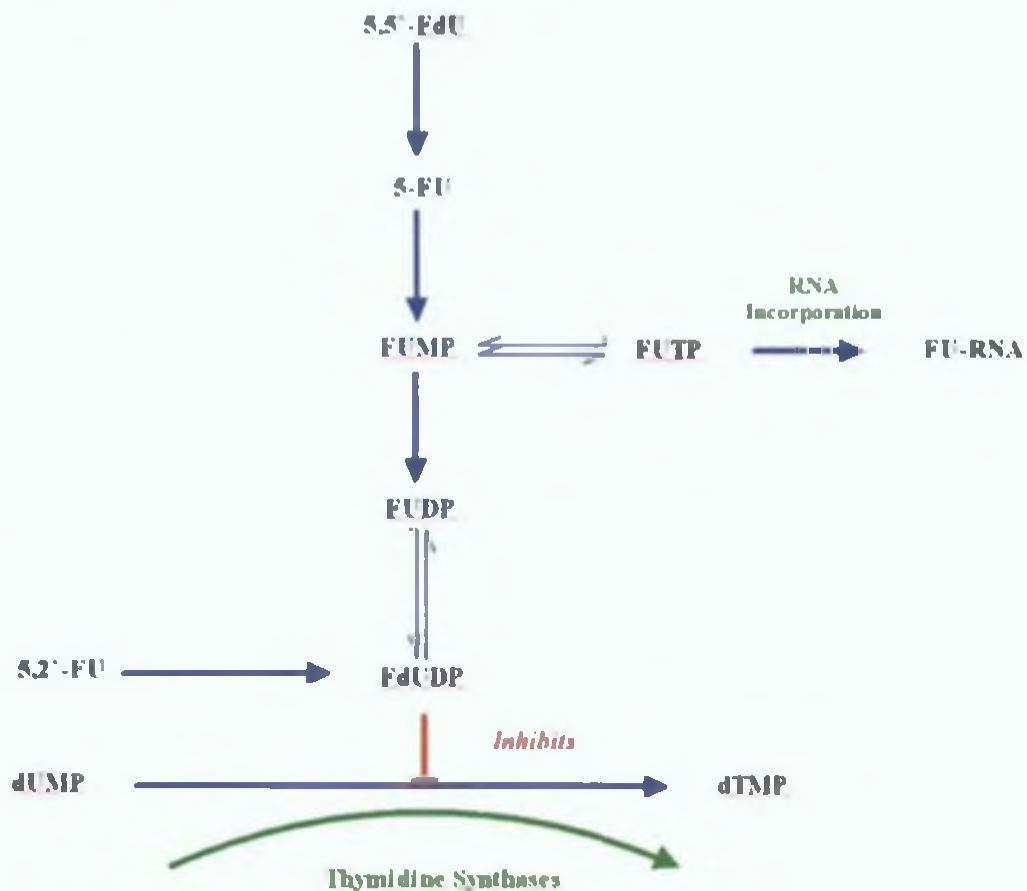

It is also thought BrdU substitution into DNA may also induce effects similar to DNA-intercalating agents, by altering DNA bending at either the major or minor grooves, and thus alter the structure of promoter regions and the affinity of DNA binding proteins (Lin and Riggs, 1972). Thus, BrdU is likely to exert its effects at least in part, on differentiation by altering expression of set of regulatory genes that are involved in the control of another set of differentiation-related genes (Arnold *et al.*, Rauth and Davidson, 1993).

The biological action of CdU and IdU is also thought to be similar to that of BrdU. CdU is converted to chlorodeoxyuridine monophosphate by thymidine kinase, and has been shown to compete with thymidine for incorporation into DNA (Cortès *et al.*, 1987).

#### **1.4.3 Mode of Action of Fluoro-pyrimidines**

In contrast to BrdU, IdU and CdU, the 5,5'-Fdu, 5-FU and 5,2'-FdU analogues modes of action are slightly different. 5,5'-FdU is cleaved by nucleoside phosphorylase enzyme to yield 5-fluorouracil (5-FU) (Armstrong and Diasio, 1980). The 5-FU generated is subsequently metabolised via several steps to yield flurodeoxyuridine monophosphate (FdUMP) (Pratt *et al.*, 1994). FdUMP binds to thymidylate synthase, forming an irreversible covalent ternary complex in which enzyme, folate cofactor, and FdUMP are bound, thus inhibiting thymidine monophosphate production and

hence DNA synthesis (Pratt *et al.*, 1994). The inhibition of DNA synthesis causes cells to delay in the S-phase of cell cycle and this stall has previously been shown to induce differentiation of embryonal carcinoma cells, PC13, to endoderm-like cells, following exposure of the cells to Retinoic Acid (Nishimure *et al.* 1983; Mummery *et al.*, 1984).

**Figure 1.?** Pathway of 5,5'-FdU Metabolism

A large proportion of the cytoplasm of vertebrate cells, normal and transformed, is occupied by components of the cytoskeleton, including actin, tubulin and the intermediate filaments (Moll *et al* , 1982) They are formed in different cell types from different proteins of a multigene family or from different subunit polypeptides of a class of related proteins By far the most striking differentiation specificity of composition has been observed in the intermediate-sized filaments This class of filaments includes the desmin filaments typical of myogenic cells, the neurofilaments typical of neuronal cells, vimentins occur in mesenchymally derived cells and vascular smooth muscle cells, and the keratins occur in epithelial cells (Moll *et al* , 1982, Hatzfeld and Franke, 1985, Daly *et al* , 1998) Keratin Intermediate Filament (IF) proteins have three domains a central alpha-helical rod domain of constant size that derives from common ancestors, and two end-domains of variable structure thought to be involved in tissue-specific functions (Blumenberg, 1988) The specificity of keratin expression patterns in epithelial cells has been used in prognostic and diagnostic situations as markers of both epithelial origin and state of differentiation in patients with small cell lung cancer (Bepler *et al* , 1987, Broers *et al* , 1988), and other tumour pathologies (Virtanen *et al* , 1984, Trask *et al* , 1990) to distinguish normal and tumour-derived epithelial cells Keratins are thought to serve a structural function to protect the cell against environmental stresses and strains as for other filaments (Daly *et al* , 1998), but their expression in human ovarian adenocarcinoma lines has been associated with altered sensitivity to various chemotherapeutic drugs (Parekh and Simpkins, 1995) Interestingly, in studies using a number of chemical differentiating agents the levels of mdr-1/Pgp (p-glycoprotein) increased and expression appears to correlate with the degree of differentiation (Mickley *et al* , 1989) However, induction of these pumps is not always accompanied by expression of the multidrug-resistance phenotype, which may possibly be explained by changes in keratin expression during the differentiation of these cells The human K8 mRNA encodes a nucleic acid-binding domain, suggesting that keratin filaments may bind to nucleic acid sequences and play a role in regulating DNA replication and gene transcription (Yamamoto *et al* , 1990) It is also possible that they play a role in the regulation of translation of particular mRNAs through their localisation to regions within the cell, in a similar manner to the way in which polar

expression of developmental proteins *nos* and *hicoid* are regulated (Gavis *et al.*, 1992). Genetic disease states associated with loss of keratin regulation include the blistering phenotype of Epidermolysis Bullosa Simplex (EBS) (Oshima, 1992; Fuchs and Byrne, 1994) and development of dwarf phenotypes and diabetes in transgenic mice expressing the K8 gene (Casanova *et al.*, 1995).

The keratins (K) are divided into two categories; the acidic type I keratins are K9-20, while the more basic type II keratins are K1-8. Keratin filament formation is dependent on the pairing of partners from both groups to produce a proteolytically stable hetero-polymer filament (Kulesch *et al.*, 1989). Despite the fact that their function is relatively unknown, the pattern of expression of keratin filaments is specific to both epithelial origin and degree of differentiation (Tseng *et al.*, 1982). As described in "The Catalogue of Human Cytokeratins" (Moll *et al.*, 1982), while K9-K11 is predominant in the epidermis, K12 has only been observed in the cornea. Cytokeratin 8 represents simple epithelia, and its normal partner, K18, shows the same tissue distribution (Trask *et al.*, 1990). K8 and K18 are the first keratins to appear during mouse development (Casanova *et al.*, 1995) and are thought to be the evolutionary ancestors of many of the present keratin forms (Blumenberg, 1988). Cytokeratin 19 is found in a broad range of epithelial tissues and is a major component of simple epithelia. K14 and K19 are known to be "promiscuous" in that they can partner Type II Keratins in the absence of their "usual" Type I partner to form stable filaments (Hatzfeld and Franke, 1985; Darmon, 1985; Lersch *et al.*, 1989). K19 lacks a variable terminal domain. This, combined with its promiscuity, means that K19 is thought to play a critical regulatory role by pairing with any one of the basic keratins without contributing a potentially harmful variable terminal domain, the region in which tissue-specific function of keratins resides (Blumenberg, 1988). It therefore acts to redress keratin imbalances. Keratins 7/8/18/19/20 have been associated with simple epithelia, while K4/5/17 are associated with stratified epithelia (Mobus *et al.*, 1994). Both classic and variant small cell lung cancers express K8 and K18/19, detectable by western blotting when immunocytochemical staining is weak (Elias *et al.*, 1988). Stem cell populations of the lung have been speculated to exist as pluripotent populations residing in tumours and cell lines (Trask *et al.*, 1990; Pfeifer *et al.*, 1991). The almost complete absence of keratin expression in DLKP, a novel

poorly differentiated NSCLC-NE/SCLC-variant cell line isolated at the NCTCC, has led to speculation that this cell line may represent a stem cell-like population

## **1 5 1 Regulation of Keratin Expression**

The regulation of keratin filament formation is complex and is controlled at multiple levels. Regulation of keratin expression has been reported at the transcriptional level (Roop *et al* , 1988), involving AP-1 activation of transcription (Neznanov and Oshima, 1993) which is mediated by the ras signalling pathway (Pankov *et al* , 1994). Relatively short sequences in the 5' upstream region of keratin genes can confer tissue-specific transcription (Blessing *et al* , 1989, Neznanov and Oshima, 1993). In addition, histone and chromosomal insulation of keratin genes (Casanova *et al* , 1995), labile inhibitors of transcription (Cremisi and Duprey, 1987), and post-transcriptional proteolysis (Kulesh *et al* , 1989) have all been implicated in the cell-specific and developmental regulation of keratin filament formation. An important aspect to the proteolytic regulation of keratin filament formation, in which both partners of the pair are required for proteolytic stability and filament expression, is that it would appear that the expression of a type II keratin is sufficient to induce the expression of a type I partner (Giudice and Fuchs, 1987, Knapp and Franke, 1989, Lersch *et al* , 1989, Rothnagel *et al* , 1993). Type I keratin expression has been suggested to be dependent on accumulation of unpolymerised Type II keratin (Giudice and Fuchs, 1987) for proteolytic stability for overall filament formation. Type I proteolysis may form a universal regulatory element while specificity in Type II expression will therefore result in Type I induction and tissue-specific Intermediate Filament formation (Rothnagel *et al* , 1993). Synthesis of both keratin types can be uncoupled and control of cytokeratin Intermediate Filament formation can occur at different levels (Knapp and Franke, 1989), strengthening this suggestion. There is substantial evidence for additional post-transcriptional regulatory mechanisms (Blouin *et al* , 1991, Crowe *et al* , 1993), including mRNA degradation (Paine *et al* , 1992) and the suggestion that there is a possible block on the translation of certain keratin mRNAs, such as K8 (Tyner and Fuchs, 1984). This speculatively involves translational repression (Su *et al* , 1994) and even masking of keratin mRNAs in epithelial squamous cell carcinomas (Winter and Schweizer, 1983).

## 1.6 Integrins

The integrin receptors consist of two heterodimer chains,  $\alpha$  and  $\beta$ , both of which form a non-covalently associated complex (Hynes, 1987). The  $\alpha$  subunit family of integrins possesses 15 variants, while the  $\beta$  subunit family contains 8 variants. In theory these two families could associate to give rise to over 100 integrins. However, the actual diversity is much more restricted and in reality the subunits combine into 22 different integrins (Buck and Horwitz, 1987). The integrin family is subdivided on the basis of its  $\beta$  subunit (Newham and Humphries, 1996). For example, the  $\beta_1$  integrins are involved principally in the adhesion between the ECM and the cellular cytoskeleton (Buck *et al.*, 1987), while the  $\beta_2$  integrins participate in cell-cell interactions (Ruoslahti, 1991). The specificity of binding is not determined solely by integrin pairing, but also by the cell type it is expressed in.

Integrins have been implicated in such diverse processes as inflammation, cellular growth and differentiation (Albelda and Buck, 1990). For example, the interaction in developing lung between the ECM and the epithelium is mediated by integrin receptors, and allows normal lung branching to occur (Gumbiner, 1996). As well as functioning as cell adhesion molecules, the integrins have signalling functions that regulate various aspects of cell behaviour and differentiation. This signalling is accomplished through focal adhesion proteins. In this study we have chosen the increased expression of both  $\alpha_2$  and  $\beta_1$  integrins as markers of differentiated epithelial lung cell differentiation.

Transcriptional control of gene expression during both proliferation and differentiation has been widely studied. Transcription factors such as MyoD and Myogenin have been shown to play critical roles in the regulation of muscle-specific differentiation (Weintraub, 1993, Buckingham, 1994). On the other hand, factors such as *c-fos*, *c-jun*, and *c-myc* have long been established as playing roles in the regulation of cellular proliferation, differentiation and transformation of a wide variety of cell types. Selective transcription of genes such as alcohol dehydrogenase (*Adh*) during development is known to occur through specific sequences in the promoter regions of genes that bind regulatory factors known as transcriptional enhancers (Novina and Roy, 1996). Despite this, the process of transcription and the mechanisms by which transcription factors regulate differentiation are still not fully understood.

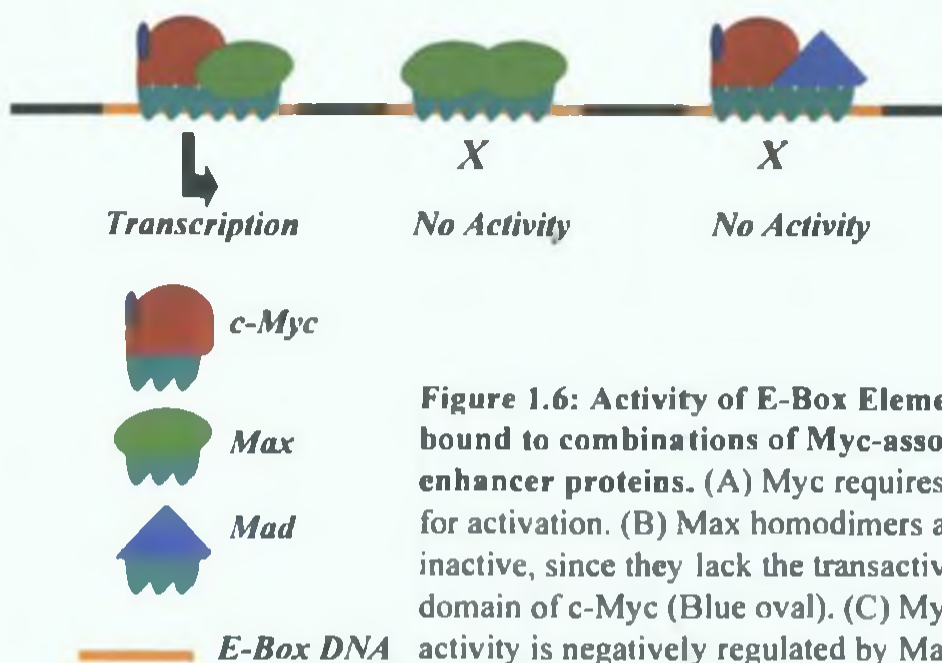

First identified as the transforming gene of the avian myelocytomatosis virus (*v-myc*) (reviewed, Evan, 1990), the *myc* family of oncogenes must rank among the most widely studied of all proto-oncogenes. Despite this, there is a relative paucity of direct *c-myc* targets that have been identified to explain the capacity of this gene to induce transformation and malignancy (Ryan and Birnie, 1996). While no direct role for *c-myc* was found in some malignant conversions (DeBenedetti *et al*, 1994), *c-myc* expression has been shown to be critical to transformation by both *v-abl* and BCR-ABL, as evidenced using dominant negative *c-myc* expression (Sawyers *et al*, 1992). Genetic instability and abnormality is associated with lung cancers (Fong *et al*, 1995) and *c-myc* abnormalities are frequently associated with carcinogenesis. *c-myc* activation has been shown to occur via gene amplification, chromosomal translocation, proviral insertion and retroviral transduction (Ryan and Birnie, 1997).

### 1 7.1 1 c-Myc structure and Function

The *c-myc* gene is highly conserved, apart from its first exon, throughout vertebrate evolution. It first came to notice because of its homology to the viral oncogene, *v-myc*. While deregulated expression of *c-myc* has been associated with a variety of neoplasms, early studies indicated that introduction of the *c-myc* gene into normal fibroblasts was not sufficient to transform cells (reviewed Evan *et al*, 1990). The 5' region of the *c-myc* gene contains four promoters, termed P0-P3. However, the two major promoters, P1 and P2 contribute 75%-90% and 10-25% of the cytoplasmic *c-myc* mRNAs, respectively (Ryan and Birnie, 1996, Nanbru *et al*, 1997). The functional significance of these promoters remains a mystery. They may play roles in processes such as proliferation and differentiation, or may simply represent evolutionary redundancy of the P0 and P3 promoters. The c-Myc protein is a phosphoprotein, phosphorylated by casein kinase II (Hagiwara *et al*, 1992) and DNA-PK (DNA-activated protein kinase) (Iijima *et al*, 1992, Chibazakura *et al*, 1997), and its expression is induced in response to serum and growth factor stimulation. c-Myc possesses a short cluster of basic amino acids that serve as nuclear localisation sequences (NLS) (Saphire *et al*, 1998), in addition to DNA-binding leucine zipper motifs. The N-terminal region contains the transcriptional transactivation domain (Ryan and Birnie, 1996). There are two isoforms of the protein, c-Myc1 and c-Myc2, which differ by 20 amino acids in their N-terminal region (DeBenedetti, personal correspondence).

c-Myc exerts its effects through oligomerisation with other proteins (Figure 1 6), characteristic of other DNA-binding transcription factors (e.g. Jun and Fos). Originally thought to homodimerize, it is now known that this is untrue. Oncogenic activation of c-Myc requires heterodimerization with activating Max proteins (Amati *et al*, 1993), which then bind DNA through basic-helix-loop-helix-leucine zipper motifs. Negative regulation of c-Myc activity occurs through interaction with another factor, termed Mad (Ryan and Birnie, 1996), which has no transactivating function but competes with Max for binding to the same region of the c-Myc protein. It is, therefore, a competitive inhibitor of c-Myc activation by Max. No initial sequence specificity of c-Myc binding was apparent, but it is now understood that c-Myc binds through a basic amino acid  $\alpha$ -helix region (Fisher *et al*, 1993) to what are termed

myc-binding sequences or “E-box elements” (CACGTG). These sites require association of Max in addition to c-myc for activation (Ryan and Birnie, 1997). *In-vivo* activation of E-box containing genes by Myc/Max heterodimers, including an RNA helicase gene belonging to the DEAD-box family, has been demonstrated (Grandori *et al.*, 1996). c-Myc/Max complexes, active in transcription, appear to be dependent on the levels of c-Myc available within the cell (Amati *et al.*, 1993), that is, Myc synthesis is rate-limiting for Myc-Max dimerisation and activity. Myc overexpression activates, while Max overexpression represses transcription through E-box sites. This is because Max/Max homodimers do not activate, and so compete with Myc/Max complexes when Max is over-expressed (Somer *et al.*, 1998). Max overexpressing lines show reduced expression of transiently transfected Myc-responsive genes (Zhang *et al.*, 1997), implying a role for Max expression in the regulation of processes such as differentiation.

**Figure 1.6: Activity of E-Box Elements bound to combinations of Myc-associated enhancer proteins.** (A) Myc requires Max for activation. (B) Max homodimers are inactive, since they lack the transactivation domain of c-Myc (Blue oval). (C) Myc activity is negatively regulated by Mad.

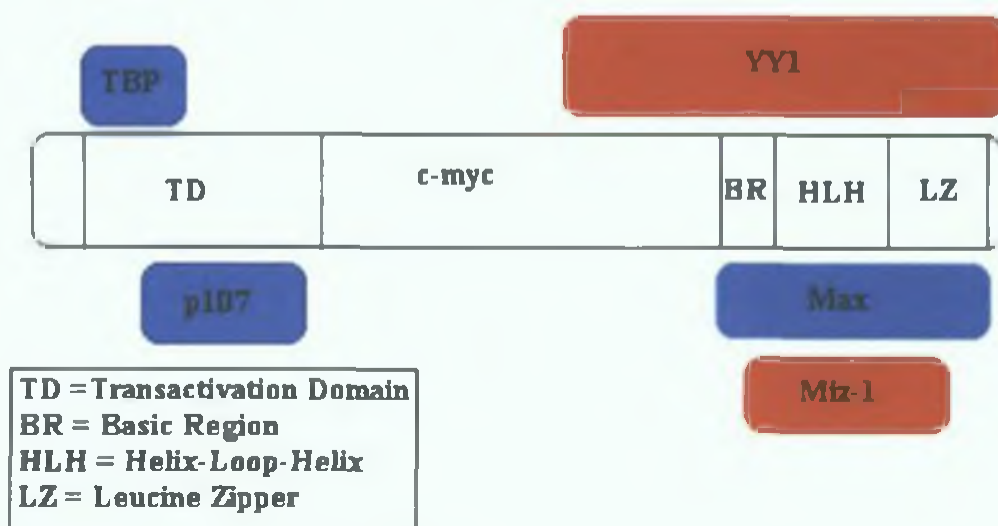

Max appears to be extremely simple and is comprised of only 160 amino acids, 80 of which constitute the DNA-binding/dimerization domain (Cole, 1991), suggesting that

transactivation of basal transcription occurs through the longer N-terminal region of the c-myc portion of the Myc/Max complex. This explains the lack of transactivation by Max homodimers and the findings that myc levels are rate limiting in the transactivation by Myc/Max heterodimeric complexes. Myc/Max, Max/Max and Mad/Myc complexes all bind to the Myc E-box with the same affinity (Somer *et al.*, 1998). Therefore, since the transactivation domain of these complexes lies in the Myc N-terminal, complexes lacking a Myc partner act as competitive inhibitors of Myc/Max transactivation.

However, c-Myc has also been shown to exhibit a degree of "dual functionality" in that it is capable of transcriptional repression, as well as activation (Antonson *et al.*, 1995), depending upon the position of the E-box relative to the transcription start site. As such, the role of c-myc in the regulation of cellular growth and proliferation should not be confined to a narrow view of transcriptional enhancement and stimulation of proliferation. Roles for c-myc in apoptosis and differentiation are evident, but as yet unclear. "It would be naïve to assume that the only transcriptional targets of c-myc are those involved in transformation" (Ryan and Birnie, 1997). Human bronchial epithelial cells transformed by overexpression of c-raf-1 and c-myc proto-oncogenes were capable of inducing multi-differentiated carcinomas in nude mice (Pfeifer *et al.*, 1991). This suggests that the role of c-myc in regulating differentiation may be cell-specific, and that down-regulation of myc expression during differentiation (Yen and Forbes, 1990; Valy-Nagy *et al.*, 1993) may not be a "universal" requirement of all cell types, as observed for AP-1. In addition, c-myc has been shown to play a role in the induction of apoptosis (Harrington *et al.*, 1994; Kohlhuber *et al.*, 1995).

c-Myc has been found to directly interact with a number of additional proteins, many of which are novel transcription factors in themselves (Figure 1.7). These interactions may form another level at which myc exerts its influence over the transcription process. A novel zinc-finger protein, termed Miz-1 (Myc interacting zinc-finger protein-1) has been identified that specifically interacts with Myc, but not with Max (Peukert *et al.*, 1997). Miz-1 is a transcription factor with potent anti-proliferative effects. Binding of Myc to Miz-1 inhibits the promoter activation activity of Miz-1, relieving the anti-proliferative effects of Miz-1 expression. Of note is the interaction between c-myc and the developmental regulator known as Yin-Yang 1 (YY1). YY1

regulates c-Myc levels, while association of c-Myc and YY1 proteins reduces the activity of both proteins. This may form the basis of an auto-regulatory mechanism to control the levels/activity of these two proteins. Such interactions with key transcription factors, regulating their activity, may play a significant role in the activity of c-Myc. This is particularly intriguing in light of the lack of direct transcriptional targets identified for c-Myc to date. A diagram of the known interactions between c-Myc and other enhancer proteins is shown in Figure 1.7

(reproduced from Ryan and Birnie, 1996):

**Figure 1.7:** Regions of c-Myc interacting with other transcription factors. (Note: p107 is a member of the Retinoblastoma family of negative regulators. Its association with c-Myc inhibits the transactivation activity of c-Myc).

## 1 7 2      The Yin-Yang Transcription factor, YY1 (NF-E1, NF- $\delta$ , UCRBP, CF-1)

YY1 (Yin-Yang 1) is a developmentally important transcription factor, so-named because of its ability to act as both a transcriptional activator and repressor. It belongs to the GLI-Kruppel family of negative transcription factors (Licht *et al*, 1990, Shi *et al*, 1991), of which relatively few are known in eukaryotes. The YY1 gene was localised to chromosome 14 in humans (Yao *et al*, 1998), although pseudogenes or additional YY1 genes have been suggested to exist (Zhu *et al*, 1994). The promoter region of YY1 lacks consensus TATA or CCAAT boxes, but contains multiple SP-1 binding sites (Yao *et al*, 1998), including a critical promoter region (Safrany and Perry, 1993). Four laboratories working independently cloned the YY1 gene in 1991, perhaps highlighting the universally important role of YY1 in transcriptional regulation.

- 1 Park and Atchison (1991) isolated a factor they termed NF-E1, which was capable of binding to both the immunoglobulin  $\kappa$  3' enhancer and the immunoglobulin heavy-chain  $\mu$ E1 site, transcriptionally repressing and activating these promoters, respectively. The authors also reported that NF-E1 (Common Factor 1, CF1) was capable of binding the *c-myc* promoter. The binding of CF1 was shown to be capable of activating transcription through a *c-myc* CF1 site (Riggs *et al*, 1991). Overexpression of YY1 was shown to be a strong activator of murine *c-myc* expression, with mRNAs increasing from both the P1 and P2 promoters of the endogenous *c-myc* gene (Riggs *et al*, 1993). These promoters account for the vast majority of *c-myc* transcript present in the cytoplasm.
- 2 NF- $\delta$  was found to bind to and activate critical downstream promoter elements in the mouse ribosomal protein rpL30 and rpL32 genes (Hariharan *et al*, 1991).
- 3 Flanagan *et al* (1991) isolated a negative transcription factor, UCRBP (UCR-Binding Protein) that bound to the upstream conserved region (UCR) of MMLV (Moloney Murine Leukaemia Virus), down-regulating promoter activity. A negative regulatory region in the HPV-18 (Human Papilloma Virus) was shown to bind YY1 with high affinity (Bauknert *et al*, 1992) and mutation of the YY1

binding site leads to enhanced activity of the HPV-18 promoter. Many viruses that cause cancer have been found to have lost YY1 binding sites, which may be a means of escaping this negative regulation (Shrivastava and Calame, 1994)

- 4 Finally, YY1 was isolated and given its more widely used name by Shi *et al* (1991) when it was found to associate with the Adenovirus P5 promoter, activated by the viral E1A protein. In the absence of E1A this promoter is silenced by YY1, and only becomes activated in the presence of E1A. Both E1A and YY1 were found to share overlapping binding sites in the P5 promoter, but YY1 binding is not eliminated upon E1A binding, suggesting that competition for binding is not the means by which regulation occurs. E1A-mediated activation is speculated to involve unmasking regions of the YY1 N-terminal involved in activation but normally masked in the full-length protein (Lee *et al*, 1994) (Figure 1.8)

Consensus activation and repression sequences for YY1 are shown below, although these are known to vary giving rise to changes in binding capacity of these sites for YY1 (Hyde-DeRuyscher *et al*, 1995)

Activation	<b>CGGCCATCTTGNCTG</b>
Repression	<b>CCATNTTNNA</b>

### **1.7.2.1 The Structure and Function of YY1**

There is evidence that YY1 is a phosphoprotein. Eight consensus phosphorylation sites are found in the deduced amino acid sequence and YY1 activity can be abolished through the use of phosphatases (Becker *et al*, 1994). The amino acid sequence of the YY1 protein displays a number of unique properties to date, including acid rich domains similar to transcriptional activators, as well as Ala+Gly-rich and His rich sequences common to transcriptional repressors (Park and Atchison, 1991). The very unusual N-terminal region consists of 11 consecutive negatively charged amino acids and 12 consecutive histidines, thought to form two oppositely charged symmetrical helices separated by a highly flexible glycine-rich loop (Helix-Loop-Helix, HLH) (Hariharan *et al*, 1991). These regions are speculated to be capable of forming an acidic activation domain that could be neutralised or modulated under certain

conditions to allow interaction with polymerase II before and after transcription has commenced. The amino terminal transactivation domain requires amino acids 16-29 and 80-100 for maximal activity (Bushmeyer *et al* , 1995)

The C-terminal contains four zinc fingers, characteristic of DNA-binding transcription factors, while the central region is largely unstructured, consisting of large loop and helix regions. The YY1 repression domain lies near the carboxy terminus and is embedded within the YY1 zinc finger region necessary for DNA-binding (Bushmeyer *et al* , 1995). Particular importance has been placed upon zinc fingers 3 and 4 for repression activity.

The functional diversity of YY1 was conceivably attributed to its structural plasticity (Hariharan *et al* , 1991). It is generally thought that repression of gene transcription is the usual function of YY1, with the activating N-terminal region being masked. Interaction with activating proteins, such as viral E1A, then releases the N-terminal region and converts YY1 to an activator of transcription through the same promoter (Figure 1.8). However, it has also been suggested that repression is not the intrinsic activity of YY1. Rather, YY1 acts to bend DNA (Natesan and Gilman, 1993) in a way that modulates the interaction of proteins bound to the two flanking regions. When the orientation of the YY1 binding site is reversed or the phasing of the sites is changed, YY1 becomes an activator of the same promoter (Natesan and Gilman, 1995). Rather than bending two proteins away from one another, YY1 now bends them towards one another to bring them into closer contact and increase association. Therefore, YY1 will have distinct local effects on protein-DNA and protein-protein interactions depending upon the position and orientation of its binding site within the promoter, supporting a general role for YY1 in the building of highly organised promoter complexes. This is particularly important in the formation of promoter structures at TATA-less promoters, since YY1 has been shown to bend DNA in a manner suitable to provide a site for transcription initiation (Kim and Shapiro, 1996). Both promoter orientation-dependent and co-factor-dependent activity of YY1 was also suggested in the human Interferon- $\gamma$  promoter (Ye *et al* , 1994). In this case, DNA-binding is a required function of YY1, while in other cases DNA-binding is not required for YY1 to exert its effects upon promoter formation and activity.

**Figure 1.8: Diagrammatic Representation of E1A-mediated activation of YY1 Transactivating Potential.** YY1 is a repressor of the P5 promoter (A), but in the presence of E1A, the N-terminal Activating Region (Blue) is unmasked and transcription is activated (B).

#### 1.7.2.2 Transcription Factors interact with YY1 to regulate its activity

A YY1 binding site in the *c-fos* promoter is required for adenovirus E1A activation of *c-fos* transcription (Gedrich and Engel, 1995). Rather unusually and almost paradoxically, repression by YY1 was also found to be independent of the presence of YY1 binding sites in *c-fos* reporter constructs (Zhou *et al.*, 1995). It was shown that YY1 repression was mediated through interaction of YY1 with CREB (cyclic AMP Response Element Binding) Proteins. Thus, within the *c-fos* promoter alone YY1 is known to interact with E1A and CREBPs to either increase or decrease transcription, respectively, and these functions can be both dependent and independent of the ability of YY1 to bind DNA. This has lead to claims that YY1 activity is regulated through interactions with other proteins and that it must contain a C-terminal repression domain that is independent of its ability to bend DNA (Hyde-DeRuyscher *et al.*, 1995).

Numerous YY1-associated complexes appear to be targets for E1A activation (Shi *et al.*, 1991; Gedrich and Engel, 1995; Labrie *et al.*, 1995). In fact, a major role of viral E1A may be the activation of genes normally repressed by YY1, including viral genes (Shrivastava and Calame, 1994). SP1 frequently acts as a regulator of YY1-associated complexes (Bennett *et al.*, 1999), particularly during TATA-less promoter complex formation. "Bi-functionality" is evident in the ability of YY1 to simultaneously up-

regulate some genes while down-regulating their antagonists. For example, transcription of the LDL (Low-Density Lipoprotein) receptor gene is inhibited by YY1 during high cholesterol (Bennett *et al.*, 1999), while that of Cholesterol Esterase is enhanced (Gauthier *et al.*, 1999). This was attributed to interactions of YY1 with SP1 in the cholesterol esterase promoter and with SRE-BP in the LDL promoter, inhibiting their function. The ability of YY1 to repress numerous SRE-BP (Serum Response Element-Binding Proteins) regulated genes has been associated with the displacement of Factor Y, a positive regulator of gene transcription (Ericsson *et al.*, 1999). Similar "bi-functionality" is evident during proliferation, in which YY1 up-regulates *c-myc* gene transcription, correlating with cellular proliferation, and inhibits muscle actin expression, correlating with differentiation (Lee *et al.*, 1994). However, despite being shown to interact both *in-vitro* and *in-vivo* (Lee *et al.*, 1993; Seto *et al.*, 1993), both YY1 and SP-1 appear to function independently at the surf-1 promoter, where the YY1 binding site has been shown to be both necessary and sufficient to confer growth-factor inducibility in transcription of the Surf-1 gene (Cole and Gatson, 1997). Activation of transcription by YY1 independent of DNA-binding has been shown for the  $\alpha$ -1 acid glycoprotein (AGP) promoter through functional interaction with a negative DNA-binding factor, termed Factor B (Lee and Lee, 1994). In the human GM-CSF (Granulocyte Macrophage-Colony Stimulating Factor) promoter co-factors in addition to YY1 were required for activator function and promoter complex formation (Ye *et al.*, 1994), but in this case binding of YY1 to DNA is required (Ye *et al.*, 1996),

Additionally, YY1 has been suggested to participate in the stimulation of autonomously replicating human chromosome fragments through interaction with a replication-enhancing element, REE1 (Obuse *et al.*, 1998) and in the regulation of transposable elements of the genome (Becker *et al.*, 1993; Satyamoorthy *et al.*, 1993; Singer *et al.*, 1993). These elements are thought to be a major source of functional diversity allowing evolution to continue. Overall, YY1 appears to perform a multitude of tasks, many of which are influenced by its ability to bind to DNA and affect promoter structure and formation, as well as interact with numerous transcriptional enhancers to modify its own activity. The complexity of the regulatory effects of YY1 is highlighted by Bushmeyer *et al.* (1995); "YY1 can either activate or repress some

promoters depending on either promoter architecture or intracellular milieu” These unique properties suggest an unusual and complex role for YY1 in the regulation of gene expression

### **1 7.2 3        YY1 and TATA-less Transcription**

YY1 is thought to play a central role in the formation of transcription initiation complexes at TATA-less promoters. Promotion of TATA-less transcription by YY1 was initially suggested by the *in-vitro* transcription experiments of Seto *et al* (1991) and Hahn *et al* (1992). YY1 has been shown to bend DNA and is thought to play a role in the formation of promoter structures for RNA pol II binding (Natesan and Gilman, 1995, Kim and Shapiro, 1996). In an *in-vitro* transcription reaction, supercoiled DNA templates could be transcribed in the presence of only YY1, TFIIB and RNA Pol II (Usheva and Shenk, 1994). Overall, YY1 is thought to be a key regulator of TATA-less promoter initiation, probably in all TATA-less promoters (Azizkhan *et al*, 1993). Its ubiquitous expression is in agreement with the findings that many universally expressed housekeeping genes appear to lack any discernible TATA recognition sequence, including the YY1 gene itself (Yao *et al*, 1998). In light of this, a report challenging the concept that TBP-mediated association of TFIID with the TATA-box is limiting in the rate of transcription initiation is of interest (Antoniou *et al*, 1995). Altered transcription was only observed when TBP binding was drastically decreased in the promoter of the  $\beta$ -globin gene. However, this promoter also contains an active YY1 binding site, the importance of which may have been overlooked by the authors.

The ability of YY1 to interact with TFIIB/D is also thought to be a means by which YY1 regulates TATA-less promoter formation, by-passing the requirement for TBP in these systems. Recently TAF<sub>II</sub>55 (TATA-Binding Protein-Associated Factor), a subunit of TFIID, has been shown to interact directly with the largest subunit, TAF<sub>II</sub>230 through its central region and with multiple activators – including SP1, YY1 and Adenoviral E1A – through a distinct amino-terminal domain (Chiang *et al*, 1995). This subunit may form the “bridge” between transcriptional enhancers and the actual transcriptional components surrounding RNA polymerase II. It is possible that

YY1 is part of, or is actually the “bridging unit”, particularly in TATA-less promoters (since TAF<sub>55</sub> is a basal unit, while YY1 appears to be “in-limbo” between enhancer and basal transcription factor, depending upon the promoter) The effects of SP1 on YY1-mediated transcription initiation, particularly from TATA-less promoters, may reside in its interaction with TAF<sub>II</sub>55/230 to guide the initiation complex towards the Inr-associated YY1 to begin initiation

Further evidence that YY1 plays a role transcription through TATA-less promoters has been provided by Gatson and Fried (1994), Cole and Gaston (1997), Johansson *et al* (1998) and Karantzoulis *et al* (1999) In addition, YY1 is thought to play a role in the downstream regulation of transcription (Last *et al* , 1999) The majority of known transcriptional enhancers are upstream, since they would interfere with the actual transit of the RNA polymerase II if situated downstream, while YY1 appears to interact with many of the basal factors and may form part of the basal RNA holoenzyme in some circumstances

#### **1 7 2 4      YY1 in Differentiation and Development**

The unusual nature of the YY1 protein has led to speculation that it may play a key role in the regulation of differentiation and development Both Chromatin structure and methylation are thought to be key mechanisms by which cells control specific gene transcription during differentiation The Nuclear Matrix Protein-1 (NMP-1), a transcription factor which has been shown to associate with the nuclear matrix to mediate gene-matrix interactions within the nucleus, has been shown to be none other than YY1 (Guo *et al* , 1995) Sequences necessary for nuclear localisation and association with the nuclear matrix have been identified in the C-terminal region of the YY1 peptide (Bushmeyer and Atchison, 1998, McNeil *et al* , 1998) Nuclear-matrix-associated transcription factors may affect gene regulation by mediating transient associations between DNA and the nuclear matrix, locally unravelling chromatin structure to allow the transcriptional machinery to access promoters and begin transcription, implying roles for YY1 in activating repressed genes during development

Binding of YY1 to DNA during globin promoter formation is known to be methylation-sensitive (Satyamoorthy *et al* , 1993, Yost *et al* , 1993), which may imply a role for YY1 in tissue- and developmental-specific transcription of genes. A YY1 binding site is thought to function in the stage-specific expression of the fetal (gamma) globin gene (Zhu *et al* , 1999). The human  $\epsilon$ -globin gene is transcribed in erythroid cells only during the embryonic stages of development. A binding site for YY1, around nucleotide -269, was identified as critical in the formation of the  $\epsilon$ -globin repressor complex (Raich *et al* , 1995), forming part of the local regulatory elements suggested to be involved in the regulation of embryonic stage-specific expression of this gene. Processes such as these, resulting in the stage-specific switches in gene expression, are thought to be associated with methylation of CpG islands, which silence transcription of developmentally important genes and to which YY1 binding is sensitive.

In addition, levels of YY1 have been shown to decrease during differentiation of mouse myoblasts (Lee *et al* , 1992). YY1 contains several peptide regions prone to proteolytic cleavage, raising the possibility that protease-mediated degradation events may contribute to diminished YY1 protein levels during myogenesis (Lee *et al* , 1994). Two proteolytic pathways through which YY1 can be differentially targeted under different cell growth conditions have been identified (Walowitz *et al* , 1998), identifying a role, at least partially, for protease calpain II (m-calpain). However, in serum starvation studies YY1 protein expression was lost only after 24 hours, despite the fact that YY1 transcript expression was lost within hours (Flanagan, 1995), suggesting that the YY1 protein is relatively stable. This does not exclude the possibility that proteolytic regulation of YY1 levels may play a role in different processes.

Treatment of myoblasts with the differentiation modulating agent, BrdU results in inhibition of myogenesis, resulting in/from an increase in expression of YY1 and decreased  $\alpha$ -actin levels (Lee *et al* , 1992). Transfection of SRF (Serum Response Factor), which competes with YY1 for the regulation of  $\alpha$ -actin gene transcription, could directly transactivate the actin promoter in BrdU-treated myoblasts. Both SRF and YY1 are ubiquitously expressed, suggesting that they may have antagonistic

functions in regulating genes such as *c-fos*,  $\alpha$ -actin and cardiac creatine kinase-M (Vincent *et al* , 1993, Liu *et al* , 1995) during development. High levels of YY1 in non-differentiated muscle cells down-regulate the dystrophin promoter, at least in part, by interfering with the spatial organisation of the promoter (Galvagni *et al* , 1998). YY1 and a positive regulator of dystrophin, DPBF (dystrophin promoter bending factor), induce opposite bends in the CArG element of this promoter, suggesting that their binding induces alternative promoter structures to regulate muscle development.

## **1.8 eukaryotic Translation Initiation Factor, eIF-4E**

eIF4E, otherwise known as eIF4 $\alpha$  or the small cap binding protein, binds directly to the 5' 7-Methyl-Gppp cap in an ATP-dependent manner, and is thought to be the first factor to interact with the mRNA to initiate translation. eIF-4E is a 25 kDa phosphoprotein responsible for Cap-binding specificity in eIF-4F complexes during eukaryotic translation initiation events. eIF-4E consists of a single  $\alpha\beta$  domain which contains 8 anti-parallel  $\beta$  strands forming a curved  $\beta$  sheet (Sonenberg and Gingras, 1998). This sheet is backed by three long  $\alpha$ -helices. The mRNA cap-structure binds loosely to an hydrophobic pocket in the concave inner surface of eIF-4E, across which salt-bridges form after phosphorylation to "lock" the cap in place (Marcotrigiano *et al* , 1998, CSHL abstracts), while the convex dorsal surface interacts in a mutually exclusive manner with either eIF-4G or the 4E-BPs. Phosphorylation of eIF-4E occurs as part of the eIF-4F complex (Tazon *et al* , 1990) greatly enhancing and stabilising its association with the cap (Minich *et al* , 1994, Joshi *et al* , 1995).

eIF-4E is widely accepted as the limiting factor in translation initiation, particularly for mRNAs with complex 5' UTRs. It is present in molar levels significantly lower than that of other initiation factors (DeBenedetti and Rhoads, 1990, Sonenberg, 1996). It is the most specifically targeted mRNA-binding eIF and is an essential component of the cytoplasmic cap-binding complex. The cap-binding activity of the eIF-4E

peptide is thought to reside in a highly evolutionarily conserved placement of tryptophan residues in both yeast and mammals (Altmann *et al*, 1988) This factor therefore plays a critical role in the regulation of translation, particularly of specific mRNA species, and the levels and activity of eIF-4E are critical to the control of cellular proliferation and differentiation (Jaramillo *et al*, 1991) A rather novel and as-yet to be proven additional function for eIF-4E has been suggested, namely that it may play some part in the transport of mRNAs from the nucleus The 5' Cap-structure is known to be involved in the process of nucleocytoplasmic transport (Sonenberg and Gingras, 1998), already thought to be the function of the novel eIF-4E homologue protein, eIF-4EHP (Rome *et al*, 1998) In light of the Cap-binding specificity of eIF-4E and recent findings of localisation of a fraction of eIF-4E to the nucleus (Pollard *et al*, 1999), this additional role for eIF-4E is not implausible

Frequently mammalian cells express at least two forms of this factor (Jaramillo *et al*, 1991, Haghighat *et al*, 1995) The gene(s) for eIF-4E is thought to lie on chromosome 4 in humans (Gao *et al*, 1998) Gao *et al* (1998) isolated two genes for eIF-4E from placental genomic libraries, in which case eIF-4E1 contained six introns but the other (eIF-4E2) was intronless Subtle differences between the two genes were identified and both genes were reported to be differentially expressed in four human cell lines A notable difference between the two genes was that the eIF-4E1 promoter contained c-myc-binding elements while that of eIF-4E2 did not, suggesting constitutive expression of the latter and inducible expression of the former In fact, eIF-4E has been identified as one of the few targets for c-Myc induction (Rosenwald *et al*, 1993, Jones *et al*, 1996) The complexity of eIF-4E expression patterns in eukaryotic cells was highlighted by the findings that in *Drosophila* a single eIF-4E gene could code for three alternatively spliced mRNA transcripts, two of which resulted in expression of the same form of eIF-4E, while the other encoded an isoform differing at the amino-terminal sequence of the protein (Lavoie *et al*, 1996) The three eIF-4E transcripts varied greatly in the lengths of their respective 5' UTRs, suggesting that each was subject to varying degrees of translational regulation themselves This may reflect a means of auto-regulating levels of eIF-4E expression during phases of hyper- and hypo-proliferation of cells

Following on from BrdU work that has previously been performed in the laboratory (McBride S , *et al* , 1999, P Meleady, PhD Thesis, 1997, F O'Sullivan, PhD Thesis, 1999, D Walsh, PhD Thesis 1999, P Doolan, PhD Thesis, 2001) it was decided to investigate the ability of other halogenated thymidine analogues to induce differentiation in DLKP and A549 cells. In this study it was decided to utilise the expression of  $\alpha_2$ -,  $\beta_1$ -integrin, EpCAM, cytokeratins 8, 18 and 19 as markers of differentiation in the two cell lines. The thymidine analogues initially chosen for this work were 5-Iodo-2'-deoxyUridine, 5-Chloro-2'-deoxyUridine, 5-FluoroUracil, 5-Fluoro-2'-deoxyUridine, 5-Fluoro-5'-deoxyUridine, 5-BromoUridine and 5-BromoUracil.

Exposure of the both cell lines to BrdU and the other halogenated thymidine analogues investigated also resulted in a morphological change in the treated cells. These changes included a flattening and stretching of the cells, with the cells doubling or quadrupling in size, following treatment. Cells treated with 5,2'-FdU exhibited the greatest alteration in morphology and the greatest increase in cell size.

- ❖ Previous research performed in this laboratory has demonstrated that the halogenated thymidine analogue, Bromodeoxyuridine, induces the *in vitro* differentiation of the lung cell lines DLKP and A549. This differentiation is indicated by the induction of cytokeratins 8, 18 and 19 (McBride, *et al* , 1999, Meleady and Clynes 2001a, Meleady and Clynes, 2001b, O'Sullivan, PhD Thesis, 1999). Also shown to be induced by BrdU are the integrins  $\alpha_2$  and  $\beta_1$  (Meleady, PhD Thesis, 1997) and Ep-CAM (O'Sullivan, PhD Thesis, 1999).
- ❖ The thymidine analogues BrdU has been shown in this laboratory to induce the expression of cytokeratin and integrin proteins. The ability of other halogenated pyrimidine analogues, IdU, CdU, 5,5 -FdU, 5,2 -FdU, 5-FU, BromoUracil and Bromouridine, to alter expression of these proteins was also to be investigated. It was hoped that such investigation would help us gain a better understanding of the mechanisms by which differentiation is regulated in our *in vitro* model system.
- ❖ In order to investigate the mechanisms involved in lung cell differentiation in our model system initial work examined the effect of the pyrimidine analogues had on the cytokeratin and integrin proteins in DLKP and A549 cell lines. This was principally performed by immunocytochemistry.
- ❖ To investigate the global transcriptional changes induced in the DLKP cell line following exposure to the pyrimidine analogues, DNA microarray experiments were employed to help to elucidate genes which may be common to the pathway(s) regulating differentiation in our cell system. The use of such techniques may yield helpful leads to help us understand the overall processes of differentiation involved.
- ❖ Work performed by Walsh (PhD Thesis, 1999) in our laboratory suggested that the transcription factors *c-myc* and Yin Yang 1 may be key proteins

involved in the control of differentiation which is induced by BrdU in DLKP cells cDNAs coding for these two proteins were transfected into DLKP and a clonal subpopulation DLKP-SQ, to assess their ability to induce simple differentiation in this poorly differentiated cell line It was hoped that compiling results from BrdU-treated cells and transfections would allow us to develop a model for the regulation of K8 and K18 synthesis in our lung cell line models, with possible implications for understanding the early stages of lung development as well as aspects of de-differentiation in lung cancer Such models are severely lacking in lung biology

## ***Section 2.0*      **Materials & Methods****

## **2.1 WATER**

Ultrapure water was used in the preparation of all media and solutions. This water was purified by a reverse osmosis system (Millipore Milli-RO 10 Plus, Elgastat UHP) to a standard of 12 - 18 MΩ/cm resistance.

## **2.2 GLASSWARE**

Solutions pertaining to cell culture and maintenance were prepared and stored in sterile glass bottles. Bottles (and lids) and all other glassware used for any cell-related work were prepared as follows:- all glassware and lids were soaked in a 2% (v/v) solution of RBS-25 (AGB Scientific) for at least 1 hour. Following scrubbing and several rinses in tap water, the bottles were then washed by machine using Neodisher detergent, an organic, phosphate-based acid detergent. The bottles were then rinsed twice with distilled water, once with ultrapure water and sterilised by autoclaving.

## **2.3 STERILISATION**

Water, glassware and all thermostable solutions were sterilised by autoclaving at 121°C for 20 minutes (min) under pressure of 1bar. Thermolabile solutions were filtered through a 0.22µm sterile filter (Millipore, millex-gv, SLGV-025BS). Low protein-binding filters were used for all protein-containing solutions.

## **2.4 MEDIA PREPARATION**

Medium was routinely prepared and sterility checked by Joe Carey. The basal media used during routine cell culture were prepared according to the formulations shown in Table 2.4.1. 10x media were added to sterile ultrapure water, buffered with HEPES and NaHCO<sub>3</sub> and adjusted to a pH of 7.45 - 7.55 using sterile 1.5M NaOH and 1.5M HCl. The media were then filtered through sterile 0.22µm bell filters (Gelman, 121-58) and

stored in 500ml sterile bottles at 4<sup>0</sup>C Sterility checks were carried out on each 500ml bottle of medium as described in Section 2 5 6

The basal media were stored at 4<sup>0</sup>C up to their expiry dates as specified on each individual 10x medium container Prior to use, 100ml aliquots of basal media were supplemented with 2mM L-glutamine (Gibco, 25030-024) and 6% foetal calf serum (Sigma, F-7524 Batch) and this was used as routine culture medium This was stored for up to 2 weeks at 4<sup>0</sup>C, after which time, fresh culture medium was prepared

**Table 2 4 1** Preparation of basal media

	<b>DMEM</b> (Gibco, 12501-029)	<b>Hams F12</b> (Gibco, 21700-109)
<b>10X Medium</b>	500ml	Powder
<b>Ultrapure H<sub>2</sub>O</b>	4300ml	4700ml
<b>1M HEPES*</b> Sigma , H-9136	100ml	100ml
<b>7 5% NaHCO<sub>3</sub></b> BDH, 30151	45ml	45ml

\* HEPES = N-(2-Hydroxyethyl)piperazine-N'-(2-ethanesulfonic acid)

For most cell lines, ATCC (Ham’s F12/ DMEM (1 1)) supplemented with 6% FCS, 1% Sodium Pyruvate and 2mM L-glutamine was routinely used

## 2.5 CELL LINES

All cell culture work was carried out in a class II down-flow re-circulating laminar flow cabinet (Nuaire Biological Cabinet) and any work which involved toxic compounds was carried out in a cytoguard (Gelman). Strict aseptic techniques were adhered to at all times. The laminar flow cabinet was swabbed with 70% industrial methylated spirits (IMS) before and after use, as were all items used in the cabinet. Each cell line was assigned specific media and waste bottles. Only one cell line was worked with at a time in the cabinet which was allowed to clear for 15min between different cell lines. The cabinet itself was cleaned each week with industrial detergents (Virkon, Antec International, TEGO, TH Goldschmidt Ltd), as were the incubators. The cell lines used during the course of this study, their sources and their basal media requirements are listed in Table 2.5.1. Lines were maintained in 25cm<sup>2</sup> flasks (Costar, 3050), 75cm<sup>2</sup> (Costar, 3075) or 175cm<sup>2</sup> flasks (Corning, 431079) at 37°C and fed every two to three days.

### 2.5.1 Subculture of Adherent Lines

During routine subculturing or harvesting of adherent lines, cells were removed from their flasks by enzymatic detachment.

Waste medium was removed from the flasks and rinsed with a pre-warmed (37°C) trypsin/EDTA (TV) solution (0.25% trypsin (Gibco, 25090-028), 0.01% EDTA (Sigma, EDS) solution in PBS A (Oxoid, BR14a)). The purpose of this was to remove any naturally occurring trypsin inhibitor which would be present in residual serum. Fresh TV was then placed on the cells (2ml/25cm<sup>2</sup> flask or 4ml/75cm<sup>2</sup> flask) and the flasks incubated at 37°C until the cells were seen to have detached (5-10 min). The trypsin was deactivated by addition of an equal volume of growth medium (*i.e.* containing 6% serum). The entire solution was transferred to a 30ml sterile universal tube (Sterilin, 128a) and centrifuged at 1,000 rpm for 5 min. The resulting cell pellet was resuspended in pre-warmed (37°C) fresh growth medium, counted (Section 2.5.3) and used to re-seed a flask at the required cell density or to set up an assay.

**Table 2 5.1** Cell lines used during the course of this study

Cell line	Basal medium	Cell type	Source
DLKP (and subpopulation SQ)	ATCC <sup>2</sup>	Human poorly-differentiated lung carcinoma	Dr Geraldine Grant, NCTCC
A549	ATCC <sup>2</sup>	Human lung adenocarcinoma	ATCC <sup>2</sup>

\* These cells grow in suspension

<sup>1</sup> ATCC = American Type Culture Collection

### **2 5 3 Cell Counting**

Cell counting and viability determinations were carried out using a trypan blue (Gibco, 15250-012) dye exclusion technique

An aliquot of trypan blue was added to a sample from a single cell suspension in a ratio of 1 : 5. After 3 min incubation at room temperature, a sample of this mixture was applied to the chamber of a haemocytometer over which a glass coverslip had been placed. Cells in the 16 squares of the four outer corner grids of the chamber were counted microscopically, an average per corner grid was calculated with the dilution factor being taken into account, and final cell numbers were multiplied by  $10^4$  to determine the number of cells per ml. The volume occupied by the chamber is  $0.1\text{cm} \times 0.1\text{cm} \times 0.01\text{cm}$  i.e.  $0.0001\text{cm}^3$ . Therefore cell number  $\times 10^4$  is equivalent to cells per ml. Non-viable cells were those that stained blue while viable cells excluded the trypan blue dye and remained unstained.

### **2 5 4 Cell Freezing**

To allow long-term storage of cell stocks, cells were frozen and cryo-preserved in liquid nitrogen at temperatures below  $-180^\circ\text{C}$ . Once frozen properly, such stocks should last indefinitely.

Cells to be frozen were harvested in the log phase of growth (*i.e.* actively growing and approximately 50 - 70% confluent) and counted as described in Sections 2.5.3. Pelleted cells were re-suspended in serum. An equal volume of a DMSO/serum (1:9, v/v) was slowly added dropwise to the cell suspension to give a final concentration of at least  $5 \times 10^6$  cells/ml. This step was very important as DMSO is toxic to cells. When added slowly the cells had a period of time to adapt to the presence of the DMSO, otherwise cells may have lysed. The suspension was then aliquoted into cryovials (Greiner, 122 278) which were then quickly placed in the vapour phase of liquid nitrogen containers (approximately  $-80^{\circ}\text{C}$ ). After 2.5 to 3.5 hours, the cryovials were lowered down into the liquid nitrogen where they were stored until required.

### **2.5.5 Cell Thawing**

Immediately prior to the removal of a cryovial from the liquid nitrogen stores for thawing, a sterile universal tube containing growth medium was prepared for the rapid transfer and dilution of thawed cells to reduce their exposure time to the DMSO freezing solution which is toxic at room temperature. The suspension was centrifuged at 1,000 rpm for 5 min, the DMSO-containing supernatant removed and the pellet re-suspended in fresh growth medium. A viability count was carried out (Section 2.5.3) to determine the efficacy of the freezing/ thawing procedures. Thawed cells were placed into tissue culture flasks with the appropriate volume of medium (5ml/25cm<sup>2</sup> flask and 10ml/75cm<sup>2</sup> flask) and allowed to attach overnight. After 24 hours, the cells were re-fed with fresh medium to remove any residual traces of DMSO.

### **2.5.6 Sterility Checks**

Sterility checks were routinely carried out on all media, supplements and trypsin used for cell culture. Samples of basal media were inoculated into Columbia (Oxoid, CM331) blood agar plates, Sabouraud (Oxoid, CM217) dextrose and Thioglycollate (Oxoid, CM173) broths which detect most contaminants including bacteria, fungus and yeast. Growth media (*i.e.* supplemented with serum and L-glutamine) were sterility checked at least 2 days prior to use by incubating samples at  $37^{\circ}\text{C}$ , which were subsequently examined for turbidity and other indications of contamination.

## 2.6 MYCOPLASMA ANALYSIS

*Mycoplasma* examinations were carried out routinely (at least every 3 months) on all cell lines used in this study. These analyses were performed by Aine Adams and Michael Henry.

### 2.6.1 Indirect Staining Procedure

In this procedure, *Mycoplasma*-negative NRK cells (a normal rat kidney fibroblast line) were used as indicator cells. These cells were incubated with supernatant from test cell lines and then examined for *Mycoplasma* contamination. NRK cells were used for this procedure because cell integrity is well maintained during fixation. A fluorescent Hoechst stain was utilised which binds specifically to DNA and so will stain the nucleus of the cell in addition to any *Mycoplasma* DNA present. A *Mycoplasma* infection would thus be seen as small fluorescent bodies in the cytoplasm of the NRK cells and sometimes outside the cells.

NRK cells were seeded onto sterile coverslips in sterile Petri dishes at a cell density of  $2 \times 10^3$  cells per ml and allowed to attach over night at  $37^{\circ}\text{C}$  in a 5%  $\text{CO}_2$ , humidified incubator. 1ml of cell-free (cleared by centrifugation at 1,000 rpm for 5 min) supernatant from each test cell line was then inoculated onto a NRK Petri dish and incubated as before until the cells reached 20 - 50% confluency (4 - 5 days). After this time, the waste medium was removed from the Petri dishes, the coverslips washed twice with sterile PBS A, once with a cold PBS/Carnoy's (50/50) solution and fixed with 2ml of Carnoy's solution (acetic acid:methanol:1:3) for 10 min. The fixative was then removed and after air drying, the coverslips were washed twice in deionised water and stained with 2ml of Hoechst 33258 stain (BDH)(50ng/ml) for 10 min.

From this point on, work was carried out in the dark to limit quenching of the fluorescent stain.

The coverslips were rinsed three times in PBS. They were then mounted in 50% (v/v) glycerol in 0.05M citric acid and 0.1M disodium phosphate and examined using a

fluorescent microscope with a UV filter

### **2.6.2 Direct Staining**

The direct stain for *Mycoplasma* involved a culture method where test samples were inoculated onto an enriched *Mycoplasma* culture broth (Oxoid, CM403) - supplemented with 16% serum, 0.002% DNA (BDH, 42026), 2mg/ml fungizone (Gibco, 15290-026),  $2 \times 10^3$  units penicillin (Sigma, Pen-3) and 10ml of a 25% (w/v) yeast extract solution - to optimise growth of any contaminants and incubated at 37°C for 48 hours. Samples of this broth were then streaked onto plates of *Mycoplasma* agar base (Oxoid, CM401) which had also been supplemented as above and the plates incubated for 3 weeks at 37°C in a CO<sub>2</sub> environment. The plates were viewed microscopically at least every 7 days, the appearance of small, “fried egg” -shaped colonies is indicative of a *Mycoplasma* infection.

## 2 7 DIFFERENTIATION STUDIES

Differentiation studies were carried out using 5-bromodeoxyuridine (BrdU) (Sigma, B5002), 5-Chloro, 2-deoxyuridine (Sigma, C6891) and 5-Iodo, 2-deoxyuridine (Sigma, I7125), 5,2 -FdU (Sigma, B5002), 5,5 -FdU (Sigma, F8791), 5-FU (Sigma, F8423), 5-bromouracil (Sigma, 852473) and 5-bromouridine (Sigma, B9752) For each of the analogues, the powder was reconstituted in UHP water to a stock concentration of 10mM and the resultant solution was filter sterilised through a sterile 0.22µm filter, aliquoted into sterile Eppendorfs and stored at -20°C for up to 1 year

### 2.7.1 Differentiation Assays

For immunocytochemical analysis (Section 2 8), cells were plated onto 6-well plates (Costar, 3516) at densities of  $1 \times 10^4$  cells per well. 1 ml of medium was sufficient for each well. The cells were allowed to attach and form colonies by incubating at 37°C, 5% CO<sub>2</sub> for 24 hours. The plates were covered with parafilm to prevent contamination. After this time the media was replaced with fresh medium containing 10µM the appropriate thymidine. Plates were wrapped in parafilm and incubated for up to 7 days. Medium was replaced every 3-4 days over the course of the assay. All waste medium was retained for disposal by incineration. At the end of the assay the cells were fixed with methanol as described in Section 2 8 1. Immunocytochemistry/fluorescence was then carried out using a range of antibodies as described in Section 2 8 2.

For additional analytical techniques (Western blotting, immunoprecipitation, iso-electric focusing, PCR and DNA Microarrays), cells were inoculated into 75cm<sup>2</sup> flasks at a density of  $1 \times 10^5$  cells per flask or into 175 cm<sup>2</sup> flasks at a density of  $5 \times 10^5$  cells per flask, and were incubated for two days at 37°C. Analogue containing medium, at a concentration of 10µM, was then added to the cells. The medium was replaced with fresh, drug-containing media every 3-4 days. The cells were then harvested by trypsinisation, washed in sterile PBS A, counted, pelleted and stored at -80°C until required. For RNA extraction (section 2 14), pellets were lysed in tri-reagent and stored at -80°C.

## **2 8 IMMUNOCYTOCHEMISTRY**

### **2 8 1 Fixation of cells**

For fixation, medium was removed from 6-wells plates, cells were rinsed 3 times with PBS A and then incubated at  $-20^{\circ}\text{C}$  for 7 minutes using ice-cold methanol. The methanol was then removed from the cells, which were allowed to dry at  $37^{\circ}\text{C}$  for a few minutes and then stored at  $-20^{\circ}\text{C}$  until required.

### **2 8 2 Immunocytochemical procedure**

The avidin-biotin-peroxidase complex (ABC) immunoperoxidase technique combined with the diaminobenzidine (DAB) visualisation procedure was employed to indicate primary antibody binding. The ABC method involves application of a biotin-labelled secondary antibody, followed by the addition of avidin-biotin-peroxidase complex which results in a high staining intensity due to the formation of an avidin-biotin lattice which contains several peroxidase molecules. The peroxidase enzyme reacts with DAB solution to give an insoluble, brown-colour precipitate. Therefore, observation of a brown precipitate following this procedure is indicative of primary antibody reactivity.

The procedure used is as follows

Cell preparations (6-well tissue culture plates) which had been previously fixed in methanol and frozen at  $-20^{\circ}\text{C}$  were allowed to thaw and equilibrate at room temperature. A grease pen (DAKO, S2002) was used to encircle cells in tissue culture plates to retain the various solutions involved. The cells were equilibrated in Tris-buffered saline (TBS) (0.05M Tris/HCl, 0.15M NaCl, pH 7.6) for 5 minutes. The slides were then incubated for 20 minutes at room temperature (RT) with either normal rabbit (DAKO, X092) or goat (DAKO, X0907) serum diluted 1:5 in TBS to block non-specific binding, depending upon the host source of the primary antibody in question. This was then removed and 25-30 $\mu\text{l}$  of optimally diluted primary antibody (Table 2.8.1) was placed on the cells. The slides and tissue-culture plates were placed on a tray containing moistened tissue paper and incubated at  $37^{\circ}\text{C}$  for 2 hours or  $4^{\circ}\text{C}$

overnight. The primary antibodies used in the study are listed in Table 2.8.1. The slides were then rinsed in TBS/ 0.1% Tween (Sigma, P-1379) for 5 min x3 times, and then incubated for 30 min with a suitable biotinylated secondary antibody (rabbit anti-mouse immunoglobulins (DAKO, E354), goat anti-rabbit (DAKO, E0432) diluted 1:300 in TBS. The slides were rinsed as before and incubated with strepABComplex/Horse Radish Peroxidase (HRP) (DAKO, K377) for 30 min at RT, after which they were rinsed again in TBS/ 0.1% Tween for 5 min x3 times. The cells were then incubated with a DAB solution (DAKO, S3000) for 10-15 min. The plates were then rinsed off with UHP water and counterstained with 2% methyl green solution, and samples mounted using a commercial mounting solution (DAKO, S3023).

### 2.8.3 Immunofluorescence

Immunofluorescence was performed using a similar approach to that described in 2.8 above. Cell preparations (6-well tissue culture plates) which had been previously fixed in methanol and frozen at -20°C were allowed to thaw and equilibrate at room temperature. A grease pen (DAKO, S2002) was used to encircle cells in tissue culture plates to contain the various solutions involved. The cells were equilibrated in Tris-buffered saline (TBS) (0.05M Tris/HCl, 0.15M NaCl, pH 7.6) for 5 minutes. The slides were then incubated for 20 minutes at room temperature (RT) with normal rabbit/goat serum (DAKO, X092/Dako, X0907) (depending upon the primary in question) diluted 1:5 in TBS to block non-specific binding. This was then removed and 25-30 µl of optimally-diluted primary antibody was placed on the cells and incubated on a tray containing moistened tissue paper at 4°C overnight. The following day the slides were then rinsed in TBS/ 0.1% Tween (Sigma, P-1379) for 5 min x3 times. All subsequent manipulations were performed in a darkened room, and incubations were performed in trays covered in tinfoil as a precaution to minimise “quenching” of fluorescence by exposure to light for extended periods. Cells were incubated for 60 min with FITC-labelled goat anti-rabbit immunoglobulin (Sigma, F-6005) diluted 1:160 in TBS/0.1% Tween. The slides were then rinsed in TBS/ 0.1% Tween (Sigma, P-1379), x3 in 15 min, air-dried and mounted in fluorescent mounting medium (DAKO, S3023). Antibody reactivity was determined by examination under a fluorescent microscope.

Antibody	Dilution/ Concentration	Supplier	Catalogue no

## 2 9 WESTERN BLOT ANALYSIS

Proteins for western blot analysis were separated by SDS-polyacrylamide gel electrophoresis (SDS-PAGE)

### 2.9 1 Sample preparation

Cell pellets (Section 2 7 1) were lysed in TG lysis buffer (20mM Tris-HCl pH 8, 10% glycerol, 1% TritonX-100, 1 5mM MgCl<sub>2</sub>, 2mM EDTA, 137mM NaCl, 1mM Na<sub>3</sub>VO<sub>4</sub>, 1mM Pefabloc (Boehringer, 84500920-22), and 1X Protease inhibitor cocktail (Boehringer, 1697498) for 20 min on ice. The extracts were either used immediately for western blot analysis or snap frozen in liquid nitrogen and stored at -80°C. Alternatively, cells were lysed by resuspension in boiling loading buffer (2 5ml

1 25M-Tris/HCl, 1 0g SDS, 5 8ml glycerol and 0 1% bromophenol blue (Sigma, B8026) made up to 25ml with distilled water) and incubated at 100°C for 2-3 min , cooled to room temperature and used immediately for western blot analysis

## 2 9.2 Gel electrophoresis

Resolving and stacking gels were prepared as outlined in Table 2 9 1 and poured into clean 10cm x 8cm gel cassettes which consisted of 1 glass and 1 aluminium plate, separated by 0 75cm plastic spacers The resolving gel was poured first and allowed to set The stacking gel was then poured and a comb was placed into the stacking gel in order to create wells for sample loading Once set, the gels could be used immediately or wrapped in aluminium foil and stored at 4°C for 24 hours

Before samples were loaded onto the stacking gels, equal cell numbers ( $2 \times 10^4$  cells per lane) were lysed in 2x loading buffer (Section 2 9 1) The samples were then loaded alongside molecular weight colour protein markers (Sigma, C-3437) The gels were run at 250V, 45mA for approximately 1 5 hours (until the protein was run at least half way into the gel as judged by the migration of colour markers during the electrophoretic process All gels were made from a stock of Acrylamide (details below) Sample calculations for two different percentage gels are shown in table 2 9 1

Components	Resolving gel (7 5%)	Resolving gel (12%)	Stacking gel
Acrylamide stock *	3 75ml	6ml	0 8ml
Ultrapure water	8 0ml	5 75ml	3 6ml
1 875M-Tris/HCl, pH 8 8	3 0ml	3 0ml	-
1 25M-Tris/HCl, pH 6 8	-	-	0 5ml
10% SDS (Sigma, L-4509)	150µl	150µl	50µl
10% APS (Sigma, A-1433)	60µl	60µl	17µl
TEMED (Sigma, T-8133)	10µl	10µl	6µl

\* Acrylamide stock – Sigma Cat No - 148660

**Table 2 9.1** Preparation of electrophoresis gels

### 2.9.3 Western blotting

Following electrophoresis, the acrylamide gels were equilibrated in transfer buffer (25mM Tris, 192mM glycine (Sigma, G-7126) pH 8.3-8.5 without adjusting) for 20 min. Proteins in gels were transferred onto Hybond ECL nitrocellulose (Amersham, RPN 2020D) or PVDF (Polyvinyl difluoride) (Boehringer, 1722026) membranes by semi-dry electroblotting. Six sheets of Whatman 3mm filter paper (Whatman, 1001824) were soaked in transfer buffer and placed on the cathode plate of a semi-dry blotting apparatus. Excess air was removed from between the filters by moving a glass pipette over the filter paper. Nitrocellulose or PVDF (pre-activated in methanol for 1-2 min. and washed in UHP for 5 min), cut to the same size of the gel, was soaked in transfer buffer and placed over the filter paper, making sure there were no air bubbles. The acrylamide gel was placed over the nitrocellulose and six more sheets of presoaked filter paper were placed on top of the gel. Excess air was again removed by rolling the pipette over the filter paper. The proteins were transferred from the gel to the nitrocellulose/PVDF at a current of 0.34mA at 15V for 20-30 min. depending upon the size of the protein.

**1. Anode buffer 1: (4 sheets of filter paper; squeeze dry)**

33.35g Tris, 200ml Methanol in 1 L.

**2. Anode buffer 2: (2 sheets of filter paper; squeeze dry)**

3.03g Tris, 200ml Methanol in 1 L.

**3. PVDF membrane (pre-activated in methanol as before).**

**4. Polyacrylamide gel.**

**5. Cathode Buffer: (4 sheets of filter paper; squeeze dry)**

3.03g Tris, 5.25g 6-amino-n-hexanoic acid (Sigma, A-2504), 200ml Methanol in 1 L.

All incubation steps from now on, including the blocking step, were carried out on a revolving apparatus to ensure even exposure of the membrane blot to all reagents.

The nitrocellulose/PVDF membranes were blocked for 2 hours at room temperature with fresh filtered 5% non-fat dried milk (Cadburys; Marvel skimmed milk) in TBS/ 0.1% Tween, pH 7.4.

After blocking, the membranes were rinsed with TBS/0.1% Tween and incubated with primary antibody overnight at 4°C. Primary antibodies used are listed in table 2.9.2. The following day the primary antibody was removed and the membranes rinsed 3 times with TBS/0.1% Tween. The membranes were incubated in 1/1000 dilution of a suitable HRP-labelled secondary antibody (Mouse, Sigma, A-6782 or Rabbit, Sigma, A-4914) in TBS/0.1% Tween for 1 hour at room temperature (R.T.). The secondary was then removed and blots were washed for 15 min in TBS/0.1% Tween. Bound antibody was detected using enhanced chemiluminescence (ECL) (Section 2.9.4).

**Table 2.9.2** Antibodies used for western blot analysis

## 2.9.4 Enhanced chemiluminescence detection

Protein bands were developed using the Enhanced Chemiluminescence Kit (ECL) (Amersham, RPN2109) according to the manufacturer's instructions.

After blots were washed in TBS/0.1% Tween x3 times for 5 min, a sheet of parafilm was flattened over a smooth surface, e.g. a glass plate, making sure all air bubbles were removed. The membrane was then placed on the parafilm, and excess fluid removed. 1.5 ml of ECL detection reagent 1 and 1.5 ml of reagent 2 were mixed and covered over

the membrane. Charges on the parafilm ensured the fluid stayed on the membrane. The reagent was removed after one minute and the membrane wrapped in cling film. The membrane was exposed to autoradiographic film (Kodak, X-OMAT S, 500 9907) in an autoradiographic cassette for various times, depending upon the strength of the signal obtained. The autoradiographic film was then developed. The exposed film was developed for 5min in developer (Kodak, LX24), diluted 1:6.5 in water. The film was briefly immersed in water and transferred to a Fixer solution (Kodak, FX-40) diluted 1:5 in water, for 5min. The film was transferred to water for 5 min and then air-dried.

## **2.10 RNA EXTRACTION**

RNA was extracted from cells as follows

Cells were trypsinised, washed once with PBS A and the sample was counted. Approximately  $10^8$  cells were pelleted and lysed using 1ml of TRI REAGENT™ (Sigma, T-9424). The samples were allowed to stand for 5 min at RT to allow complete dissociation of nucleoprotein complexes and then snap-frozen in liq. N<sub>2</sub> and stored at -80°C.

When thawed, samples were allowed to stand for 5 min before 0.2ml of chloroform was added per ml of TRI REAGENT™ used. Samples were then shaken vigorously for 15 sec and allowed to stand for 15 min at RT. Samples were then centrifuged at 13000rpm in a microfuge for 15 min at 4°C. This step separated the mixture into 3 phases, the RNA was contained in the colourless upper aqueous layer. This layer was then transferred to a fresh Eppendorf and 0.5ml of isopropanol was added. The sample was mixed and allowed to stand at RT for 10 min before being centrifuged at 13000rpm in a microfuge for 10 min at 4°C. The RNA formed a precipitate at the bottom of the tube. The supernatant was removed and the pellet was washed with 1ml of 75% ethanol and centrifuged at 4°C for 5-10 min at 8500rpm. The supernatant was removed and the pellet was briefly allowed to air-dry. 20-30µl of DEPC-treated water was then added to the RNA to resuspend the pellet.

Concentrations of RNA in samples were calculated by determining OD at 260nm and 280nm and using the following formula -

$$OD_{260nm} \times \text{Dilution factor} \times 40 = \mu\text{g}/\mu\text{l RNA}$$

The purity of the RNA extraction was calculated by determining its OD at 260nm and 280nm. An  $A_{260nm} / A_{280nm}$  ratio of 2 is indicative of pure RNA. Only those samples with ratios between 1.7 and 2.1 were used.

## 2.10.1 Qiagen Kit RNA Isolation

Alternatively, high quality RNA was isolated from cells using the Rneasy mini kit (Qiagen, 74104). The Rneasy extraction is based on guanidine thiocyanate method of extraction. The procedure was performed according to the manufacturer's instructions.

## 2.11 REVERSE TRANSCRIPTASE REACTION

Reverse transcriptase (RT) reactions were carried out in laminar flow cabinets using micropipettes which were specifically allocated to this work.

cDNA was formed using the following procedure -

- ❖ 1  $\mu\text{l}$  oligo (dT)<sup>12-18</sup> primers (1  $\mu\text{g}/\mu\text{l}$ ) (Promega, C1101)
- ❖ 1  $\mu\text{l}$  total RNA (1  $\mu\text{g}/\mu\text{l}$ ) (section 2.14)
- ❖ 3  $\mu\text{l}$  water

were mixed in a 0.5ml Eppendorf (Eppendorf, 0030 121 023), heated to 70°C for 10 min and then chilled on ice. To this, the following were added -

- ❖ 4  $\mu\text{l}$  of a 5x buffer (250mM-Tris/HCl pH 8.3, 375mM-KCl and 15mM-MgCl<sub>2</sub>)
- ❖ 2  $\mu\text{l}$  DTT (100mM) (Gibco, 510-8025 SA)
- ❖ 1  $\mu\text{l}$  RNasin (40U/ $\mu\text{l}$ ) (Promega, N2511)
- ❖ 1  $\mu\text{l}$  dNTPs (10mM of each dNTP)
- ❖ 6  $\mu\text{l}$  water
- ❖ 1  $\mu\text{l}$  Moloney murine leukaemia virus-reverse transcriptase (MMLV-RT) (40,000U/ $\mu\text{l}$ ) (Gibco, 510-8025 SA)

The solutions were mixed and the RT reaction was carried out by incubating the Eppendorfs at 37°C for 1 hour. The MMLV-RT enzyme was then inactivated by heating to 95°C for 2 min. The cDNA was stored at -20°C until required for use in PCR reactions as outlined in Section 2.16.

## 2 12 1 POLYMERASE CHAIN REACTION

A standardised polymerase chain reaction (PCR) procedure was followed in this study. The Eppendorf tubes used (Eppendorf, 0030 121 023) and the sterile water were DEPC-treated. All reagents had been aliquoted and were stored at  $-20^{\circ}\text{C}$  and all reactions were carried out in a laminar flow cabinet.

Each PCR tube contained the following -

- ❖ 24.5  $\mu\text{l}$  water
- ❖ 5  $\mu\text{l}$  10x buffer\* (100mM-Tris/HCl, pH 9.0, 50mM-KCl, 1% Triton X-100)
- ❖ 3  $\mu\text{l}$  25mM-MgCl<sub>2</sub>\*
- ❖ 8  $\mu\text{l}$  dNTPs (1.25mM each of dATP, dCTP, dGTP and dTTP) (Promega, U1240)
- ❖ 1  $\mu\text{l}$  each of first and second strand target primers (250ng/ $\mu\text{l}$ )
- ❖ 1  $\mu\text{l}$  each of first and second strand endogenous control primer (250ng/ $\mu\text{l}$ ) ( $\beta$ -actin)
- ❖ 0.5  $\mu\text{l}$  of 5U/ $\mu\text{l}$  *Taq* DNA polymerase enzyme\*
- ❖ 5  $\mu\text{l}$  cDNA

\*(Promega, N1862)

DNA was amplified by PCR as follows

95 $^{\circ}\text{C}$  for 5 min - to denature double-stranded DNA

30 cycles      95 $^{\circ}\text{C}$  for 30 sec - denature

                  \* $^{\circ}\text{C}$  for 30 sec - anneal

                  72 $^{\circ}\text{C}$  for 30 sec - extend

                  72 $^{\circ}\text{C}$  for 7 min - extend

\* the annealing temperature varied with the primer set used. See Table 2 appropriate annealing temperatures

The reaction tubes were then stored at 4 $^{\circ}\text{C}$  until analysed by gel electrophoresis as described in Section 2.17

Primers were K8/18 (McBride *et al*, 1999), K19 (Meleady, PhD Thesis 1997) c-myc (NicAomhlímh, R, PhD thesis, 1997) and  $\beta$ -actin (NicAomhlímh, R, PhD thesis, 1997)

**Table 2 12 1** Primer Sequences for PCR amplification

## 2 12 2 Real Time-PCR

RNA was isolated (Section 2 14) cell and cDNA synthesised as per Section 2 15 The Taqman® Real time PCR analysis was preformed using the Applied BioSystems Assays on Demand PCR Kits, and experiments were preformed in triplicate, following per manufacturer's instructions

## **2 13 ELECTROPHORESIS OF PCR PRODUCTS**

A 2% agarose gel (NuSieve, GTG) was prepared in TBE buffer (5.4g Tris, 2.75g boric acid, 2ml 0.5M-EDTA pH 8.0 in 500ml water) and melted in a microwave oven. After allowing to cool, 0.003% (v/v) of a 10mg/ml ethidium bromide solution was added to the gel which was then poured into an electrophoresis apparatus (BioRad). Combs were placed in the gel to form wells and the gel was allowed to set.

10µl loading buffer (50% glycerol, 1mg/ml xylene cyanol, 1mg/ml bromophenol blue, 1mM EDTA) was added to 50µl PCR samples and 20µl was run on the gel at 80-90mV for approximately 2 hours. When the dye front was seen to have migrated the required distance, the gel was removed from the apparatus and examined on a UV-transilluminator and photographed.

## **2 14 OVEREXPRESSION STUDIES**

### **2 14 1 Plasmid Preparation**

Cultures were streaked on LB agar containing 50µg/ml AMP (Sigma, G9516) and 50µg/ml Ampicillin and incubated at 37°C overnight. From these, a single colony was inoculated into 10ml of LB AMP (50µg/ml each) and grown overnight. A 2ml sample of this suspension was then added to 200ml of TB AMP 50µg/ml and left to grow overnight at 37°C for large-scale isolation of plasmid from transformed cells. The following day the cells were pelleted, 15 minutes at 5000 rpm. The plasmid DNA was then isolated from the cells using the Maxi-Mini Qiagen Plasmid DNA Extraction kit (Qiagen, 12143). The DNA concentration was determined by measuring the OD<sub>260nm</sub>.

### **2 14 2 Lipofectin Transfection of attached mammalian cells**

On the day prior to transfections, cells to be transfected were plated from a single cell suspension and seeded into 25cm<sup>2</sup> flasks at 3x10<sup>5</sup> cells per flask. On the day of the transfection, the plasmids to be transfected were prepared along with the lipid

transfection reagents according to the manufacturers protocols (Lipofectin - GibcoBRL , 18292-011) The cells were transfected for four hours in the absence of serum after which the media was supplemented with 10% serum overnight The following morning flasks were washed with serum-containing medium and re-fed Selection began 12-24 hours after re-feeding For all transfections the cells were incubated at 37°C

### **2 14.3 Selection of Transfected cells**

After transfection, cells that had taken up the plasmid were selected by feeding the cells with media containing geneticin (Sigma, G9516) - the plasmids used had a geneticin-resistance marker, therefore, only those cells containing the plasmid will survive treatment with geneticin 2 days after transfection the flask of cells was fed with 200µg/ml geneticin in complete media The concentration of geneticin was increased step-wise every 2 days to a final concentration of 800µg/ml Untransfected control flasks were killed after 4-5 days From surviving cells, frozen stocks were made and cells were prepared for immunocytochemical (Section 2 8) and western blot (Section 2 9) analysis

### **2 14 4 Transient Transfection of DNA using Eugene 6 Reagent**

Cells were seeded into 25cm<sup>2</sup> flasks at a cell density of  $1.5 \times 10^5$  cells/ml (in 4 mL medium) Eugene 6 reagent DNA complex was used at a 3:2 ratio which was found to be an optimal ratio The Eugene DNA complex was made up according to manufacturer's recommendations and with 100µL of the complex mixture was added to the cells in a drop-wise fashion Cells were returned to the 37°C incubator Cells were harvested for RNA and protein at 24, 48 and 72 hours

## 2.15 Affymetrix GeneChips®

The microarray gene expression experiments which were performed in this body of work were performed using Affymetrix® Human Genome U133A GeneChips®. Affymetrix GeneChip probe microarrays are manufactured using technology that combines photolithography and combinatorial chemistry. Tens to hundreds to thousands of different oligonucleotide probes are synthesised and each of these oligonucleotides is located in a specific area on the microarray slide, called a probe cell. Each probe cell contains millions of copies of a given oligonucleotide and each feature size on the Affymetrix U133A GeneChip is 18 microns. Due to advances in microarray design, Affymetrix have since launched a new GeneChip, U133 Plus 2, which has decreased the feature size of the probes from 18 microns to 11 microns. The new U133 Plus 2 GeneChips are now comprised of the old Affymetrix U133A and U133B GeneChips on a single slide. The reduction in feature size to 11 microns has resulted in an increase in feature definition, with improved sharpness and signal uniformity.

The most important aspect in efficient probe design is the quality of the sequence information used. Probe selection and array design are two major factors in reliability, sensitivity, specificity and versatility of expression probe arrays. Probes selected for gene expression arrays by Affymetrix are generated from sequence and annotation data obtained from multiple databases such as GenBank, RefSeq and dbEST. Sequences from these databases are collected and clustered into groups of similar sequences. Using clusters provided by UniGene database as a starting point, sequences are further subdivided into subclusters representing distinct transcripts.

This categorisation process involves alignment to the human genome, which reveals splicing and polyadenylation variants. The alignment also extends the annotation information supplied by the databases pinpointing low quality sequences. These areas are usually trimmed for subsequent generation of high quality consensus sequences or alternatively Affymetrix employ quality ranking to select representative sequences, called exemplars, for probe design.

In general, Affymetrix use 11 to 16 probes which are 25 bases in length for each transcript. The probe selection method used by Affymetrix for their U133 GeneChips

takes into account probe uniqueness and the hybridisation characteristics of the probes which allow probes to be selected based on probe behaviour. Affymetrix use a multiple linear regression (MLR) model in the probe design that was derived from thermodynamic model of nucleic acid duplex formation. This model predicts probe binding affinity and linearity of signal changes in response to varying target concentrations. An advantage of this type of model-based probe selection system is that it provides a physical and mathematical foundation for systematic and large-scale probe selection. Also, an essential criterion of probe selection by Affymetrix for quantitative expression analysis is that hybridisation intensities of the selected probes must be linearly related to target concentrations.

A core element of Affymetrix microarray design is the Perfect/Mismatch probe strategy. For each probe that is designed to be perfectly complementary to a given target sequence, a partner probe is also generated that is identical except for a single base mismatch in its center. These probe pairs, called the Perfect Match probe (PM) and the Mismatch probes (MM), allow the quantitation and subtraction of signals caused by non-specific cross-hybridisation. The differences in hybridisation signals between the partners, as well as their intensity ratios, serve as indicators of specific target abundance.

### **2.15.1 Sample and Array Processing**

After RNA isolation, quantification and purification using the Qiagen RNeasy isolation method (Section 2.14.1), cDNA was synthesised using the GeneChip T7-Oligo (dT) Promoter Primer Kit (Affymetrix, 900375) from 10 µg total RNA. First strand cDNA synthesis was then performed using the SuperScript Choice Kit (BioSciences, 11917-010). First strand cDNA synthesis involved 'primer hybridisation' where the T7-Oligo (dT) primer was incubated with the RNA and DEPC-treated H<sub>2</sub>O at 70°C for 10 mins, followed by a short incubation in ice, 'temperature adjustment' where 5X first strand buffer, DTT and dNTP mix were added to the RNA mix and incubated at 42°C for 2 mins, and 'First Strand synthesis' where SuperScript II RT was added to the mix and incubated at 42°C for 1 hour. Second strand cDNA synthesis was performed and purified using GeneChip Sample Cleanup module (Affymetrix, 900371) as recommended by the manufacturers instructions.

cRNA was then synthesised and biotin-labelled using the Enzo BioArray HighYield RNA Transcript Labelling Kit (Affymetrix, 900182). Biotin-labelled cRNA was purified using the GeneChip Cleanup Module Kit (Affymetrix, 900371) and quantified. The value obtained was adjusted to reflect carryover of unlabelled total RNA. A sample of biotin-labelled cRNA was taken for gel electrophoresis analysis. The labelled cRNA was then fragmented before hybridisation onto the Affymetrix GeneChip probe microarrays. The aliquot of fragmented sample RNA was stored at  $-20^{\circ}\text{C}$  until ready to perform the hybridisation step.

Hybridisation of cRNA onto the Affymetrix GeneChip probe human microarrays (Affymetrix, HU133A and HU133 Plus 2) was performed in the Conway Institute, University College Dublin, where the Affymetrix Hybridisation Oven and Fluidics Station is set up along with the Affymetrix GeneChip Scanner, which exported the data directly into the Affymetrix analysis software, MicroArray Suite 5.1 (MAS 5.1).

### **2.15.2 Microarray Data Normalisation**

The purpose of data normalisation is to minimise the effects of experimental and technical variation between microarray experiments so that meaningful biological comparisons can be drawn from the data sets and that real biological changes can be identified among multiple microarray experiments. Several approaches have been demonstrated to be effective and beneficial. However, most biologists use data scaling as the method of choice despite the presence of other alternatives. In order to compare gene expression results from experiments performed using microarrays, it is necessary to normalise the data obtained following scanning the microarray chips. There are two main ways in which this type of normalisation is performed, the first of which is 'Per-chip' normalisation. This type of normalisation helps to reduce minor differences in probe preparation and hybridisation conditions which may potentially result in high intensity of certain probe sets. These adjustments in probe intensity are made to set the average fluorescence intensity to some standard value, so that all the intensities on a given microarray chip go up or down to a similar degree. However, this type of normalisation should only be performed on microarrays using similar cell or tissue types. One drawback from this type of normalisation is that some aspects of the microarray

data may potentially be obscured, such as whether the RNA samples or the probe preparation steps were equivalent for each sample.

The second way in which most biologist normalise their data sets is by employing 'per gene' normalisation method. The main aim of microarray experiments is to identify genes whose expression changes in different conditions, be that tracking gene changes across a temporal experiment or when comparing gene expression between normal and diseased tissue. Therefore, it is necessary to normalise microarray data sets using 'per gene' normalisation. In 'Per gene' normalisation is necessary to find genes that have similar expression pattern across an experiment. Analysis of raw data from microarray experiments is useful for identifying genes that are expressed at the same level, for example, genes that are highly abundant in the samples.

### **2.15.3 Probe Logarithmic Intensity Error estimation (PLIER)**

The PLIER algorithm (<http://www.affymetrix.com>) is a new tool introduced by Affymetrix for the use in data analysis of their GeneChips and has replaced the need to normalise microarray data by using the 'per chip' and 'per gene' normalisation methods. This algorithm incorporates model-based expression analysis and non-linear normalisation techniques. PLIER accounts for differences in probes by means of a parameter termed "probe affinity". Probe affinity is a measure of how likely a probe is to bind to a complimentary sequence, as all probes have different thermodynamic properties and binding efficiencies. Probe affinities determine the signal intensities produced at a specific target concentration for a given probe, and are calculated using experimental data across multiple arrays. By accounting for these observed differences, all the probes within a set can be easily compared. An example of how the PIER algorithm works is if one probe is consistently twice as bright as other probes with in a set, PLIER appropriately scales the probe intensities. In the case of a probe set, this enables all set numbers to be compared and combined accurately.

PLIER also employs an error model that assumes error is proportional to the probe intensity rather than of the target concentration. At high concentrations, error is approximately proportional to target concentration, since most of the intensity is due to target hybridisation signal. However, at the low end, error is approximately

proportional to background hybridisation intensity, which is the largest component of the observed intensity. Due to this effect, it is inaccurate to treat errors as a proportion of target concentration in all circumstances. The PLIER error model smoothly transitions between the low end, where error is dependent upon background, and the high end, where error is dependent on signal.

The PLIER algorithm supports a multi-array approach that enables replicate sample analysis. PLIER ensures consistent probe behaviour across experiments to improve the quality of results in any one given experiment and helps to discount outliers. Benefits of this algorithm include an improved coefficient of variation of signals from probe sets while retaining accuracy. Also higher differential sensitivity for low expressors may be achieved using PLIER.

## **2.16 Genomatix Software Suite**

One company that is providing software that allows users to explore textual data as well as combine sequence analysis, and genome annotation in order to help researchers to discover new contexts from biological data; is Genomatix ([www.genomatix.de](http://www.genomatix.de)). The analysis offered by Genomatix software is aimed to help researchers gain a better understanding of gene regulation at the molecular level. The Genomatix software suite is comprised of six main tools: ElDorado, Gene2Promoter, BiblioSphere, GEMS Launcher, MatInspector and PromoterInspector. ElDorado is a gene orientated genome search engine which provides the user with information about functional genomic elements within a specific region of the genome. This piece of software compiles and integrates information from several sources and includes functional information, synonyms and information on gene function and regulatory pathway. In addition, information on mRNAs, their exon/intron structure and coding sequences, single nucleotide polymorphisms (SNPs) and potential promoter regions may be retrieved using ElDorado.

Since co-regulation of gene transcription often originates from common promoter elements the identification and characterization of these elements provides a more in-depth analysis for expression of microarray clusters. Gene2Promoter allows users to automatically extract groups of promoters for genes that may of interest. This piece of

Genomatix software provides access to promoter sequences of all genes annotated in available genomes. Results from Gene2Promoter are presented in a graphical format and common transcription factor binding sites are high lighted along the gene input sequence.

One powerful member of the Genomatix Software Suite, which illustrates the emerging emphasis on the visual presentation of complex data, is BiblioSphere. BiblioSphere is a data-mining tool for extracting and studying gene relationships from literature databases and genome-wide promoter analysis. The data-mining strategy allows to find direct gene-gene co-citations and even yet unknown gene relations via interlinks. BiblioSphere data is displayed as 3D interactive view (Figure 1.?) of gene relationships. Results can be classified by tissue, Gene Ontology and MeSH. Statistical rating by z-scores indicates over- and under-representation of genes in the referring biological categories.

**Figure 2.1** Screen shot of BiblioSphere

Although transcription is regulated by a variety of DNA sequences, including enhancer and matrix attachment regions, promoters can be seen as the most important part of the sequence because any activator or repressor has to act on the promoter to influence transcriptional initiation of a particular gene. Promoters are DNA regions of several hundred base pairs that contain the transcription start site of genes. The most important functional elements within promoters are binding sites for specific proteins called transcription factors. The control of gene transcription is a common method used in biological systems to regulate protein expression. Transcription regulation in eukaryotes depends on a series of complex signal transduction networks that control

gene promoter activity. Genomatix have develop a software packages, GEMS Launcher with helps researchers to identify transcription factor binding sites in a given gene promoter. GEMS Launcher is divided up into several parts, the first of which is MatInspector.

**Figure 2.2** Graphical example of Transcription Factor Binding Sites located in a Promoter sequence.

MatInspector is a tool that employs a library of matrix descriptions for transcription factor binding sites and locates these binding sites on a given promoter sequence. Graphical display of transcription factor binding sites common to a set of inputted promoters is obtained following MatInspector analysis. FrameWoker software tool that allows users to extract a common *framework* of elements from a set of DNA sequences. These elements are usually transcription factor binding sites since this tool is designed for the comparative analysis of promoter sequences. FrameWorker generates the most complex models that are common to the input sequences. These are all elements that occur in the same order and in a certain distance range in all (or a subset of) the input sequences.

**Figure 2.3** Screen shot of FrameWorker Results

Once a model of transcription factor binding sites is generated using FrameWorker software, it is possible using Genomatix ModelInspector program to scan sequence databases for regulatory units that match the model which have been generated using MatInspector. ModelInspector provides a library of experimentally verified promoter models against which transcription factor models maybe scanned.

It is with software packages provided by companies such as Genomatix, that scientists will have to rely on in order to help them make sense of the vast quantities of data that is being generated by DNA microarray experiments, not only carried out in their own laboratories, but also the great wealth of information that is available in public access databases. The type information retrieval, visualisation, standardisation and analysis offered by Genomatix, is and will receive a great deal of attention from countless other companies and bioinformatics will undoubtedly remain an extremely important and ever changing area of scientific research in the future.

### **Section 3 1 INVESTIGATION OF THE EFFECT OF PRYIMIDINE ANALOGUE EXPOSURE IN THE HUMAN LUNG CARCINMOA CELL LINES, DLKP AND A549**

Pervious studies in this laboratory have shown that 10 $\mu$ M 5,2 -Bromodeoxyuridine (BrdU) induces cytokeratin 8, 18 and 19 protein expression in the DLKP cell line and enhances their expression in A549 (McBride, *et al* , 1999, O'Sullivan, PhD Thesis, 1999, Meleady and Clynes, 2001) Induced  $\alpha_2$ -,  $\beta_1$ -integrin has been observed in both cell lines (Meleady and Clynes, 2001) as well as the protein expression of Ep-CAM (O'Sullivan, PhD Thesis, 1999)

In this study we expand the range of pyrimidine analogues investigated in our pervious studies in order to determine if all analogues investigated induced a similar pattern of differentiation in both the DLKP and A549 cell lines Immunocytochemistry was the primary analysis carried on treated cells and was used to qualitatively investigate the changes in cytokeratins 8, 18 and 19,  $\alpha_2$ -,  $\beta_1$ -integrin and Ep-CAM protein expression in both cell lines following treatment (Section 2 7) with each analogue investigated Western blot analysis was performed on a subset of treatments

### **Section 3 1 1 Changes in $\alpha_2$ -integrin expression in A549 cells following treatment with the thymidine analogues**

Immunocytochemical analysis of A549 cells treated with 10 $\mu$ M BrdU, IdU, CdU, 5-FU, 5,2 -FdU, and 70 $\mu$ M Bromouracil and Bromouridine showed that expression of  $\alpha_2$ -integrin protein to be increased in treated cells. The intensity of the observed staining in IdU, CdU and 5,2 -FdU treated A549 cells was comparable to that obtained following 10 $\mu$ M BrdU treatment. In contrast immunocytochemistry analysis showed that cells treated with Bromouracil, Bromouridine and 5-FU did not exhibit the same intensity as seen with the other analogues.

### **Section 3 1 2 Changes in $\beta_1$ -integrin expression in A549 cells following treatment with the thymidine analogues**

Immunocytochemical analysis of A549 cells treated with 10 $\mu$ M BrdU, IdU, CdU, 5-FU, 5,2 -FdU, and 70 $\mu$ M Bromouracil and Bromouridine showed that expression of  $\beta_1$ -integrin protein to be increased in treated cells. The intensity of the observed staining in CdU, 5-FU and 5,2 -FdU treated A549 cells was comparable to that obtained following 10 $\mu$ M BrdU treatment. Immunocytochemical analysis showed that IdU-treated cells to have a greater increase in  $\beta_1$ -integrin protein than BrdU-treated cells. In contrast immunocytochemistry revealed that treatment with Bromouracil and Bromouridine did not exhibit the same intensity as seen with the other analogues.

### **Section 3 1 3 Changes in EpCAM expression in A549 cells following treatment with the thymidine analogues**

Immunocytochemical analysis of A549 cells treated with 10 $\mu$ M BrdU, IdU, CdU, 5-FU, 5,2 -FdU, and 70 $\mu$ M Bromouracil and Bromouridine showed that expression of EpCAM protein to be increased in treated cells. The intensity of the observed staining in IdU, 5-FU and 5,2 -FdU treated A549 cells was comparable to that obtained following 10 $\mu$ M BrdU treatment. Immunocytochemical analysis showed that CdU-, Bromouracil- and Bromouridine-treated cells to have an only slightly greater level of increase in EpCAM expression than the control A549 cells.

### **Section 3 1 4 Changes in CK8 expression in A549 cells following treatment with the thymidine analogues**

Immunocytochemical and immunofluorescence analysis of A549 cells treated with 10 $\mu$ M BrdU, IdU, CdU, 5-FU, 5,2 -FdU, and 70 $\mu$ M Bromouracil and Bromouridine showed that expression of cytokeratins 8 protein to be increased in treated cells. The intensity of the observed staining in all the analogue treatments was increase in comparison to the A549 control cells. CdU and 5,2 -FdU treated A549 cells exhibited a greater increase cell size in comparison to the other treatments. The morphology of 5,2 -FdU treated A549 cells were greatly altered in comparison to control cells and the other analogue treatments.

### **Section 3 1 5 Changes in CK18 expression in A549 cells following treatment with the thymidine analogues**

Immunocytochemical analysis of A549 cells treated with 10 $\mu$ M BrdU, IdU, CdU, 5-FU, 5,2 -FdU, and 70 $\mu$ M Bromouracil and Bromouridine showed that expression of cytokeratin 18 protein to be increased in treated cells. The intensity of the observed staining in all the analogue treatments was increase in comparison to the A549 control cells. All treatments displayed a similar increase in CK18 comparable to that observed in 10 $\mu$ M BrdU treated cells. CdU and 5,2 -FdU treated A549 cells exhibited a greater increase in size of the cells in comparison to the other treatments. The morphology of 5,2 -FdU treated A549 cells were greatly altered in comparison to control cells and the other analogue treatments.

### **Section 3 1 7 Changes in $\alpha_2$ -integrin expression in DLKP cells following treatment with the thymidine analogues**

Immunocytochemical analysis of DLKP cells treated with 10 $\mu$ M BrdU, IdU, CdU, 5,2 -FdU and 5,5 -FdU (results not shown) showed that expression of  $\alpha_2$ -integrin protein to be increased in treated cells. The intensity of the observed staining in these analogue treatments was increase comparable to that seen in BrdU treated cells. In contrast, immunocytochemical analysis of DLKP cells treated with 70 $\mu$ M Bromouridine and Bromouracil revealed that the cells did not exhibit the same increase in  $\alpha_2$ -integrin as seen with the other analogues.

### **Section 3.1.13    INVESTIGATION OF CHANGES IN CYTOKERATIN 8 AND EIF4E EXPRESSION LEVELS IN TREATED A549 CELLS**

To quantify the changes in expression of cytokeratin 8 protein observed in the immunochemical analysis of treated A549 cells, Western blot analysis was performed on cells which had been treated for up to 14 days with a selection of analogues

An increase in cytokeratin 8 protein levels was demonstrated in A549 cells treated with BrdU, IdU, CdU, 5,2 -FdU, 5,5 -FdU and 5-FU. An increase in cytokeratin expression was observed at day 7 with a great increase noted in cells exposed to drug for 14 days

The expression level of eIF4E in treated A549 cells was also investigated and we demonstrate an increase of this protein in A549-treated cells. Western blot analysis also revealed that only phosphorylated eIF4E was present in treated cells

**Figure 3.2.1** Western Blot analysis of Keratin 8 protein in A549 cells following treatment with 10µM IdU for 7- and 14-days.

**Figure 3.2.2** Western Blot analysis of Keratin 8 protein in A549 cells following treatment with 10µM CdU for 7- and 14-days.

**Figure 3.2.3** Western Blot analysis of Keratin 8 protein in A549 cells following treatment with 10µM 5-FU for 7- and 14-days.

**Figure 3.2.4** Western Blot analysis of Keratin 8 protein in A549 cells following treatment with 10µM 5,2'-FdU for 7- and 14-days.

**Figure 3.2.5** Western Blot analysis of Keratin 8 protein in A549 cells following treatment with 10µM 5,5'-FdU for 7- and 14-days.

**Figure 3.2.6** Western blot analysis for K8 expression in A549 cells treated with 10µM BrdU, 5-FU and 5,2'-FdU for 7-days.

A549 cells were treated with IdU, CdU and Bromouracil (Section 2.7) in order to investigate the effect these treatments had on the protein expression levels of eIF4E in the A549 cell line. Western blot analysis revealed an increase in the expression of phosphorylated eIF4E in the three drug treatments.

**Figure 3.2.8** Western Blot analysis of eIF4E protein in A549 cells following treatment with 10µM CdU for 7 days.

**Figure 3.2.9** Western Blot analysis of eIF4E protein in A549 cells following treatment with 70µM BromoUracil for 7 days.

**Section 3.1 15                      Summary of the effects of 5-Bromo-2'-deoxyUridine (BrdU)  
on differentiation status of DLKP and A549 cell lines**

The change of morphology in both cell lines following 7-days of treatment with 10 $\mu$ M BrdU was investigated. Both cell lines an approximate 5- to 10-fold increase in cell surface area occurred, with most of the cells acquiring a stretched, flattened appearance.

Immunocytochemical analysis for was conducted on treated DLKP and A549 cells to investigate if the observed changes in morphology were accompanied by changes in marker protein expression. CK8, CK18 or CK19 were not detected by immunocytochemistry or western blot analysis in DLKP prior to treatment with BrdU, but following treatment all three cytokeratins were present in approximately 10% of the treated-DLKP cells. Increased number of keratin-positive cells and increased intensity of staining was evident in DLKP cells treated for 7 days.

CK8, CK18 and CK19 filaments were present in A549 cells prior to BrdU treatment. Increased keratin synthesis was detected immunocytochemically following BrdU-treatment and this was further confirmed for CK8 by western blotting where an increase in the cytokeratin proteins were observed after 7-day and 14-day exposure.

DLKP and A549 BrdU-treated cells were also examined immunocytochemically to determine any alterations in integrin expression. Analysis revealed that appeared to be marked increases both  $\alpha_2$ - and  $\beta_1$ -integrin subunits. EpCAM expression levels were also up-regulated in both cell lines following BrdU-treatment.

### **Section 3.1 16            Summary of the effects of 5-Iodo-2'-deoxyUridine (IdU) on the differentiation status of DLKP and A549**

The ability of 5-Iodo-2'-deoxyUridine (IdU) to induce differentiation was also investigated. DLKP and A549 cells treated with 10 $\mu$ M IdU for 7-days and investigated for morphological changes. Both DLKP and A549 treated cells became very flattened and stretched. The observed alteration in morphology after IdU treatment was comparable to the observed in BrdU treatments.

Analysis of the selected marker proteins by immunocytochemistry revealed that cytokeratins 8, 18 and 19 were all increased in A549-treated cells and that they were induced in the DLKP cell line, when compared to the control untreated DLKP and A549 cells. Western blot analysis was performed for CK8 in IdU-treated A549 cells exposed for 7- and 14-days. All three cytokeratins were found to be increased after 7-days with a greater increase observed after 14-days by immunocytochemistry.

Immunocytochemical analysis for  $\alpha_2$ -,  $\beta_1$ -intergrin and EpCAM revealed that expression levels of these markers were increased following exposure to IdU for 7-days in both DLKP and A549 cell lines.  $\beta_1$ -intergrin showed a greater increase than the other two markers.

DLKP and A549 cells exposed to CdU for 7-days were investigated for morphological changes. Treated DLKP and A549 cells became very flattened and stretched and an approximately 5- to 10-fold increase in cell surface area occurred. The morphological changes seen were comparable to those noted in BrdU treatment of these cell lines.

Analysis of the selected differentiation protein markers by immunocytochemistry revealed that cytokeratins 8, 18 and 19 were induced in DLKP and increased in A549 following CdU treatment. Increases in the cytokeratin filaments were also observed in A549 treated cells. Western blot analysis confirmed that A549 cells treated with CdU for 7- and 14-days that cytokeratin 8 was increased.

DLKP and A549 BrdU-treated cells were also examined immunocytochemically to determine any alterations in integrin expression. Analysis revealed that there appeared to be marked increases both  $\alpha_2$ - and  $\beta_1$ -integrin subunits. EpCAM expression levels were also up-regulated in both cell lines following CdU treatment.

Note the affect of 5-FU was not investigated in the differentiation status of DLKP

A549 cells exposed to 5-FU for 7-days were investigated for morphological changes. Treated A549 cells became flattened and stretched. The increase in cell surface area observed in BrdU treated cells did not occur to the same extent in 5-FU treated cells.

Analysis of the selected differentiation protein markers by immunocytochemistry revealed that cytokeratins 8, 18 and 19 were noted A549 cells following treatment with 5-FU. Western blot analysis confirmed that A549 cells treated with 5-FU for 7- and 14-days that cytokeratins 8 was increased.

A549 5-FU-treated cells were also examined immunocytochemically to determine any alterations in integrin expression. Analysis revealed that appeared to be marked increases both  $\alpha_2$ - and  $\beta_1$ -intergrin subunits. EpCAM expression levels were also up-regulated in both cell lines following 5-FU treatment.

DLKP and A549 cells exposed to 5,2 -FdU for 7-days were investigated for morphological changes. Treated DLKP and A549 cells became very flattened and stretched and an approximately 10-fold increase in cell surface area occurred. A549 cells exhibited a much larger increase in cell surface area than seen in 5,2 -FdU treated cells. The increase in cell surface area was much greater than that observed in BrdU treated DLKP and A549 cells.

Analysis of the selected differentiation protein markers by immunocytochemistry revealed that cytokeratins 8, 18 and 19 were induced in DLKP following 5,2 -FdU treatment. Increases in the cytokeratin filaments were also observed in A549 treated cells. Western blot analysis confirmed that A549 cells treated with CdU for 7- and 14-days that cytokeratins 8 was increased.

DLKP and A549 BrdU-treated cells were also examined immunocytochemically to determine any alterations in integrin expression. Analysis revealed that appeared to be marked increases both  $\alpha_2$ - and  $\beta_1$ -integrin subunits. EpCAM expression levels were also up-regulated in both cell lines following 5,2 -FdU treatment.

**Section 3.1 20      Summary of the effects of 5-Fluoro-5'-deoxyUridine (5,5'-FdU) on the differentiation status of DLKP.**

The ability of 5,5 -FdU to induce differentiation was also investigated DLKP cells treated with 10 $\mu$ M 5,5 -FdU for 7-days and investigated for morphological changes DLKP treated cells became very flattened and stretched The observed alteration in morphology after 5,5 -FdU treatment was comparable to the observed in BrdU treatments

Analysis of the selected differentiation protein markers by immunocytochemistry revealed that cytokeratins 8, 18 and 19 were induced in DLKP following 5,5 -FdU treatment 5,5 -FdU DLKP-treated cells were also examined immunocytochemically to determine any alterations in integrin expression Analysis revealed that appeared to be a moderate increase both  $\alpha_2$ - and  $\beta_1$ -integrin subunits EpCAM expression levels were also induced in DLKP following 5,5 -FdU treatment

**Section 3 1 21      Summary of the effects of 5-BromoUridine and 5-BromoUracil on the differentiation status of DLKP and A549.**

Toxicity profiles (results not shown) for 5-BromoUridine and BromoUracil in both DLKP and A549 cells revealed that it did not appear to be very toxic. A concentration of 70 $\mu$ M was chosen for the differentiation studies. Investigation of the morphological changes in DLKP and A549 cells treated with 5-BromoUridine and BromoUracil for 7-days did not reveal any obvious alterations in cell surface area. The cells did not acquire a flattened and stretched appearance as was seen in some of the other analogue treatments.

Immunocytochemical analysis of DLKP cells treated 5-BromoUridine and BromoUracil for 7-days appeared to show very little induction of the CK8, CK18 and CK19. Assessment of immunocytochemistry of the results revealed no major change in the expression level of  $\alpha_2$ -,  $\beta_1$ -integrins or EpCAM.

## ***Section 3.2*      DNA Microarrays**

### Section 3.2.1 DNA Microarrays

The success of the human genome project has allowed biologists to identify almost all the genes that are responsible for the genetic makeup of humans. The next important task is to assign function to the nearly 40,000 genes sequenced. The use of microarrays to analyse the gene expression on a global level has recently received a great deal of attention. In order to understand the complex mechanisms and networks involved in the control processes of normal and disease states of eukaryotic cells, it is no longer enough to focus on isolated pathways or single genetic events. Global transcriptional profiling using microarray techniques now offer the chance to develop a more complete understanding of gene function, regulation and interactions. The technique of microarray analysis has the huge advantage over other gene profiling methods in that mRNA isolated from a given cell, tissue or tumour can be used to prepare a labelled sample and hybridised simultaneously to a vast number of DNA sequences. Microarrays now offer great flexibility in the number of target sequences that maybe analysed per microarray. As few as a couple of probe sequences to as many as the nearly 40,000 genes of the human genome can now be analysed on one single microarray slide.

A wide variety of different microarrays platforms have been developed by both academic and commercial companies. The two main groups of microarrays currently in mainstream use; these are complementary DNA (cDNA) and oligonucleotides. Probes for cDNA arrays are generally printed onto glass or nylon slides at exact locations. The probes for cDNA (spotted) microarrays are prepared from products of the polymerase chain reaction (PCR) generated from cDNA libraries. Oligonucleotide microarrays on the other hand, are mostly 20-100mers which are synthesised *in situ*, either by photolithography onto silicon wafers or by ink-jet technology. One advantage oligonucleotide microarrays have over cDNA microarrays is the fact that the sequence used for the oligos can be designed to the most unique part of a given transcript, making it possible to discriminate between closely related genes or splice variants. The microarray gene expression studies which were performed in this body of work were

performed using Affymetrix® Human Genome U133A GeneChips® (Section 2 15)

### **Section 3 2 2 BrdU Array**

Three separate DNA microarray experiments were performed on DLKP cells treated with BrdU over a time course. These experiments have been labelled Exp 1, 2 and 3 for simplicity. The initial experiments, Exp 1 and Exp 2, were performed at the same time, therefore, the results from these two experiments will be discussed together. Also, these initial microarray experiments were performed using one biological sample from each time point, whereas, the third experiment, Exp 3, was performed in triplicate using biological replicates. And the results of Exp 3 will be discussed in a separate subsection.

#### **Section 3 2 2 1 BrdU Microarrays - Exp 1 and Exp 2**

In the preliminary two BrdU-treated DLKP microarray experiments, Exp 1 and Exp 2, hybridisations were performed using the Affymetrix U133A chips (Section 2 15). Cells were harvested and RNA isolated (as per Section 2 10) at the following time points of 0, 1, 3, 7 and 14 days in Exp 1 and 0, 1 and 7 days for Exp 2. These microarray experiments were performed using single samples from each time point. cRNA was prepared (Section 2 15 1) from total RNA which had been checked for quality, and shipped to the Conway Institute at University College Dublin, where it was hybridised to the Affymetrix® Human Genome U133A GeneChips®, and the chips scanned using the Affymetrix Chip scanner. This data was then sent back to us.

The resulting data sets were scaled and normalised as per analysis carried out by Rushton, J J, *et al*, (2003). In order to compare gene expression results in the microarray experiments performed, it was necessary to normalise the data obtained following scanning the microarray GeneChips. There are two main ways in which this type of normalisation is performed 'Per-chip' and 'Per-gene' normalisations (Reviewed in Section 2 15 1). This was performed using

Affymetrix Microarrays Suite v5.0 software, which scales all of the probe sets so that the average is 100 for each GeneChip. The average probe signal was calculated for each GeneChip and this was adjusted to 100 by multiplying by a scaling factor. By doing this for each GeneChip it makes the data easier to compare across different GeneChips in a given experiment.

Additional data analysis was performed using GeneSpring (Silicon Genetics). The data were normalised to the mean of the day 0 samples and then filtering was used to identify genes that were consistently up- or down-regulated in the day 1, 3, 7 or 14 day samples. The filter used was a 1.5 fold increase or decrease and the genes were also filtered using a 'Present' or 'Marginal' filter. A filter of 1.5-fold up or down was selected in these microarray experiments since it is generally thought that the expression levels of transcription factors do not alter dramatically in cells. It is thought that the control of gene expression is tightly controlled by small alterations in transcription factor expression levels. Gene lists were then generated for each of the two rounds of microarrays containing the gene name, accession number, Affymetrix Probe Id number and the fold increase/decrease of each gene found to be differentially expressed.

### **Section 3.2.2.2      Validation of Initial DNA Microarrays and Gene expression changes in BrdU-treated DLKP cells**

In order to validate the gene lists which were generated from the expression analysis performed using the GeneSpring analysis software package, and to demonstrate that the fold increase/decrease observed were real expression changes, a set of genes was selected from the gene lists generated. RT-PCR analysis was performed on these genes. In the majority of cases the results confirmed the trends observed in the microarray analysis. The following section contains the result for each of the selected genes. In each subsection a graph illustrating the fold increase/decrease found following microarray analysis, along with the corresponding RT-PCR result, is shown.

**Section 3 2 2 2 1      FSTL1**

FSTL1 is protein with similarity to follistatin, an activin-binding protein. It is known to contain an FS module, a follistatin-like sequence containing 10 conserved cysteine residues. FST1 is thought to be an autoantigen associated with rheumatoid arthritis. Following gene expression analysis, using GeneSpring analysis software, the FSTL1 gene was demonstrated to increase in BrdU-treated DLKP cells. It was noted, that after three days of exposure of the cells to BrdU, the level of expression of the gene started to increase to a maximum at 7-days. A decrease in FSTL1 was observed between day 7 and day 14 samples. This result was confirmed by RT-PCR analysis (Section 2 11), which showed a similar pattern of expression for the FLST1 gene.

**Figure 3 2.1** Microarray analysis (top image) showing fold increase of FSTL1 mRNA. RT-PCR analysis (lower image) confirming an increase in FSTL1 mRNA expression levels.

Section 3.2.2.2 2      FLH2

FHL2 belongs to the family of LIM proteins, which are known involved in protein-protein interaction and transcriptional regulation. Recent evidence has suggested that FHL proteins may act as co-regulators involved in the modulation of tissue-specific gene expression by interacting with different transcription factors. Such transcription factors include JUN and FOS and these associations have been shown to result in a powerful activation of AP-1-mediated transcription. Following gene expression analysis, an increase in the expression of FHL2 mRNA was observed in BrdU-treated DLKP cells. mRNA levels were to dramatically increase at day 7 to approximately 6.5-fold at 7 days. However, this increase was not maintained at day 14 where they were reduced to 4-fold higher than control cells. This result was confirmed by RT-PCR analysis, which showed a similar pattern of expression for the FHL2 gene.

**Figure 3.2.2** Microarray analysis (top image) showing fold increase of FHL2 mRNA. RT-PCR analysis (lower image) confirming an increase in FHL2 mRNA expression levels.

Section 3 2.2.2.3      TNFSF7

TNFSF7 belongs to the tumour necrosis factor (TNF) ligand family and this cytokine has been reported to play a role in the regulation of B-cell activation and IgG production. Microarray analysis revealed an increase in TNFSF7 transcript levels in drug-treated cells. It was found that after one day of exposure of the cells to BrdU that the level of expression of TNFSF7 mRNA increased gradually over the course of the experiment, to approximately 6.5-fold at day 14. This result was confirmed by RT-PCR analysis, which showed a similar pattern of expression for the TNFSF7 gene.

**Figure 3 2 3** Gene expression analysis (top image) showing fold increase of TNFSF7 mRNA. RT-PCR analysis (lower image) confirming an increase in TNFSF7 mRNA expression levels.

**Section 3.2.2 2 4      GPX3**

Microarray analysis revealed that an increase in GPX3 mRNA expression levels following exposure to DLKP to BrdU. It was demonstrated at day 1 the level of GPX3 mRNA levels increased by 4-fold to a maximum of approximately 7-fold after 3-days of exposure to the drug. A decrease in GPX3 mRNA was observed at day 7 and day 14 where mRNA levels had reduced to 5- and 3-fold, respectively. These results were confirmed by RT-PCR analysis, which showed a similar pattern of expression for the GPX3 mRNA expression levels.

**Figure 3.3.4** Gene expression analysis (top image) showing fold increase of GPX3 mRNA. RT-PCR analysis (lower image) confirming an increase in GPX3 mRNA expression levels.

Section 3 2 2 2 5      Zyxin

Zyxin is a low abundance phosphoprotein that is concentrated at adhesion plaques and along the actin filament bundles near where they insert at adhesion plaques. Zyxin has features of an intracellular signal transducer and may function as a scaffold for the assembly of multimeric complexes. These protein assemblages could mediate integrin-dependent signalling events that lead to cell differentiation or modulation of cyto-architecture. Microarray analysis revealed that an increase in Zyxin transcript levels in BrdU-treated DLKP cells. A 3-fold increase in Zyxin mRNA was observed in the day 1 sample and this increase was maintained up to day 7, where mRNA levels had to a maximum of approximately 3.5-fold. At day 14 a decrease in Zyxin mRNA expression levels was observed, but did not return to control levels. This result was confirmed by RT-PCR analysis, which showed a similar pattern of expression for the Zyxin transcript levels.

**Figure 3 2 5** Gene expression analysis (top image) showing fold increase of Zyxin mRNA. RT-PCR analysis (lower image) confirming an increase in Zyxin mRNA expression levels.

**Section 3.2.2.2.6 Spermidine/spermine N-acetyltransferase (Spd/Spn)**

Spermidine/spermine N-acetyltransferase is a highly regulated enzymatic protein is known induced by a variety of toxic agents, hormones and polyamines. It is also in belongs to a metabolic pathway which involves ornithine decarboxylase and S-adenosylmethionione decarboxylase. The combination of these enzymes fine tune intracellular polyamine concentration, underscoring the important role of these proteins in growth and cell survival. Following microarray analysis, Spd/Spn mRNA levels found to remain at a similar expression level as controls cells up to three days of exposure to BrdU. However, microarray analysis revealed a 4.5-fold increase in Spd/Spn mRNA levels following 7 days exposure to the drug, but this increase in transcript levels was reduced to approximately 3-fold at day 14. RT-PCR analysis confirmed the results generated following microarray expression analysis using GeneSpring software.

**Figure 3.2.6** Gene expression analysis (top image) showing fold increase of Spd/Spn mRNA. RT-PCR analysis (lower image) confirming an increase in Spd/Spn mRNA expression levels.

Section 3.2 2 2.7      Id2

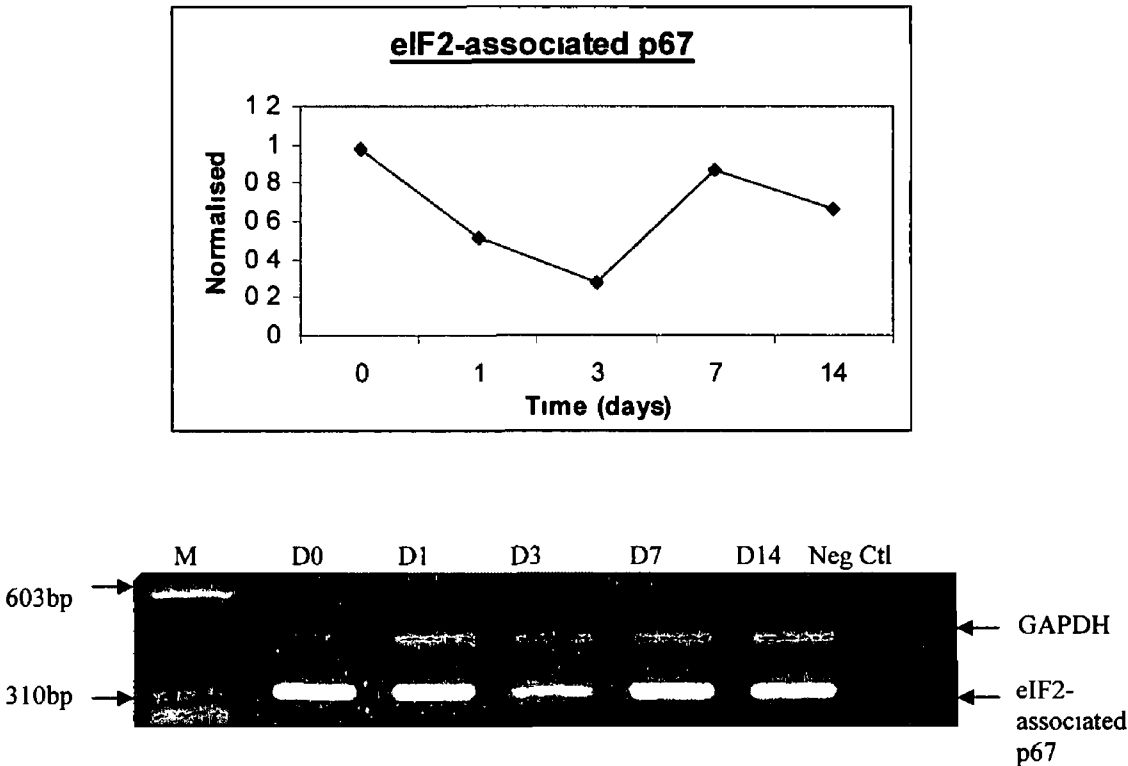

The Id family of four hehx-loop-helix (HLH) transcription factors (Id1, Id2, Id3 and Id4) act as dominant negative regulators of basic HLH proteins. Since many bHLH proteins positively regulate sets of genes during cell fate determination and cell differentiation, Id proteins are thought to inhibit the ability of bHLH proteins from binding DNA and inhibit cell differentiation. Although Id proteins traditionally have been viewed as negative regulators of differentiation, recent work has revealed much wider biological roles, and they are now thought to be important in development, cell cycle control and tumour biology. Microarray analysis revealed that Id2 transcript levels were increased to approximately 5.5-fold following exposure of cells to BrdU for 24 hours. However, over the remainder of the experiment Id2 mRNA levels declined to 2.5-fold day 7 and day 7. By day 14 transcript levels had returned to those of control cells. A similar pattern of expression was demonstrated following RT-PCR analysis for Id2 in BrdU-treated cells.

**Figure 3.2.7** Gene expression analysis (top image) showing fold increase of Id2 mRNA. RT-PCR analysis (lower image) confirming an increase in Id2 mRNA expression levels.

Section 3 2 2 2.8      eIF2-associated p67

Initiation of protein synthesis plays a central role in gene expression and is largely regulated at the level of formation of the initiation complex with the eukaryotic initiation factor 2 (eIF2), Met-tRNA, and the 40S ribosome. The rate of protein synthesis is regulated at the level of phosphorylation of the  $\alpha$ -subunit of eIF2, which is controlled by the cellular glycoprotein, p67. p67 protects the  $\alpha$ -subunit from phosphorylation by its kinases. Following microarray expression analysis, eIF2-associated p67 mRNA expression levels were shown to decrease at day 1 and day 3 in BrdU-treated DLKP cells and to increase to near control levels at the day 7. However, a decrease at day 14 decrease marginally was observed. RT-PCR analysis demonstrated a small decrease in eIF2-associated p67 mRNA in the day 3 sample, with the remaining time points exhibiting the same level of expression as control cells.

**Figure 3 2 8** Gene expression analysis (top image) showing fold increase of eIF2-associated p67 mRNA. RT-PCR analysis (lower image) confirming an increase in eIF2-associated p67 mRNA expression levels.

**Section 3 2 2 2 9      Immediate-early Response factor 3 (IER3)**

IER3 is a member of intermediate-early gene family of proteins that are thought to be critical for the control of cell proliferation and apoptosis in several cell types. Following gene expression analysis, using GeneSpring analysis software, the IER3 gene was shown to increase in BrdU-treated DLKP cells. It was found that after 1 day of exposure of the cells to drug that the mRNA levels of IER3 had increased to approximately 2-fold and increased further to 3.5-fold at day 7. At day 14 a reduction in transcript levels was observed, but did not return to that of control levels. RT-PCR analysis confirmed the microarray expression results obtained following GeneSpring analysis, however a increase in IER3 mRNA levels was demonstrated across all samples and no reduction in IER3 signal was found at day 14.

**Figure 3 2 9** Gene expression analysis (top image) showing fold increase of IER3 mRNA. RT-PCR analysis (lower image) confirming an increase in IER3 mRNA expression levels.

**Section 3 2.2.2.10      LOXL2**

A family of four proteins know as LOXL (LOXL 1-4) were recently identified and it has been suggested that these proteins are located in distinct intracellular and intranuclear locations, each with related but different functions that include cell growth control, tumour suppression, senescence and chemotaxis

Microarray analysis revealed an increase in LOXL2 transcript levels in drug treated DLKP cells. It was demonstrated that after 3 days of exposure of DLKP cells to BrdU mRNA expression levels of LOXL2 remained at control levels up to day 3, after which they were observed to increase to approximately 4-fold. However, at day 14 mRNA levels were reduced marginally to 3.5-fold. This result was confirmed by RT-PCR analysis, which demonstrated that LOXL2 transcript levels increased over the course of the experiment.

**Figure 3 2.10** Gene expression analysis (top image) showing fold increase of LOXL2 mRNA. RT-PCR analysis (lower image) confirming an increase in LOXL2 mRNA expression levels.

Following microarray expression analysis mRNA expression levels of CDKN1A were found to increase in drug-treated DLKP cells. Gene expression and RT-PCR analysis revealed a marked increase in CDKN1A mRNA expression levels after 24 hours of exposure of cells to BrdU and this increase was maintained over the experiment.

**Figure 3 2 11** RT-PCR analysis (bottom image) shows the level of CDKN1A mRNA following exposure of DLKP to BrdU

### **Section 3.2.2.3 DLKP BrdU Array – Exp 3**

The third DLKP BrdU microarray experiment, Exp 3, was performed using Affymetrix U133A GeneChips®. RNA was isolated (Section 2.10) from cells harvested after 0, 3 and 7 days exposure to BrdU (Section 2.7). This set of DNA microarrays were performed in triplicate using biological replicates. The isolated RNA was shipped to Affymetrix where the cRNA was prepared and hybridised to U133A GeneChips® and the chips scanned using an Affymetrix GeneChip scanner. The data was received back, and expression analysis was performed as described below.

The data set was normalised using the Affymetrix PLIER (Probe Logarithmic Error intensity Estimate) method in GREX. This normalisation method is recommended by Affymetrix for use on their GeneChips™. The PLIER method (Reviewed in Section 2.15.3) produces an improved signal by accounting for experimentally observed patterns in probe behaviour and handling error at the appropriately low and high signal values. Some of the advantages of using this method of normalisation included higher reproducibility of signal (lower coefficient of variation) without loss of accuracy and higher differential sensitivity for low expressors.

Having subjected the data set to the PLIER normalisation method, the data was then imported into GeneSpring analysis software (Silicon Genetics) and a new experiment was set up. As a result of using the PLIER method of normalisation, the data did not need to undergo 'Per Chip' normalisation in GeneSpring. In GeneSpring the samples were then normalised to the mean of the day 0 samples.

A filter was then applied to the data to select genes that had a 'Present' or 'Marginal' flag in three out of the nine samples. The filter also contained a condition that selected for genes that crossed a 1.5 fold threshold, up or down, in either the day 3 or day 7 samples.

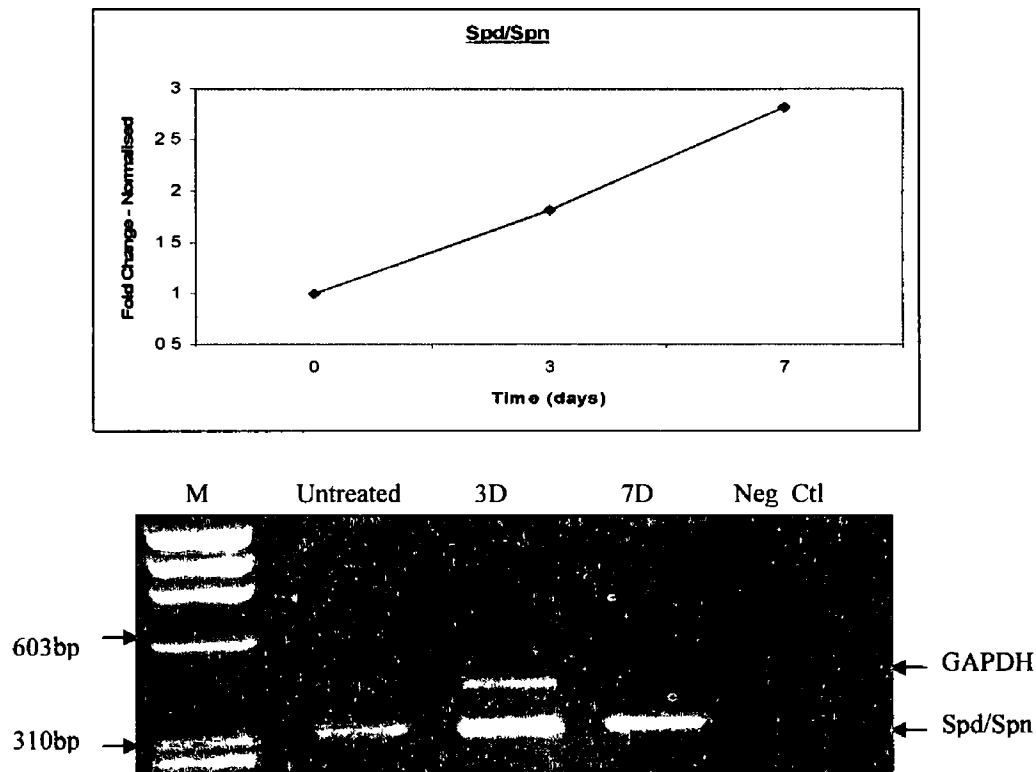

#### **Section 3 2 2.4      Validation of the DLKP-BrdU Exp 3 Microarrays**

In order to validate the gene lists, which were generated from the expression analysis carried out using GeneSpring, and to demonstrate that the fold increase/decrease observed were actual real expression changes, a set of genes were selected from the gene lists generated. RT-PCR analysis was performed on these genes. The expression patterns which confirmed the results that were obtained from the chip expression analysis.

The following section contains the result for each of the genes selected. In each subsection a graph illustrating the fold increase/decrease found following expression analysis, along with the confirmation RT-PCR result, is shown.

**Section 3 2 2.4 1      Spd/Spn**

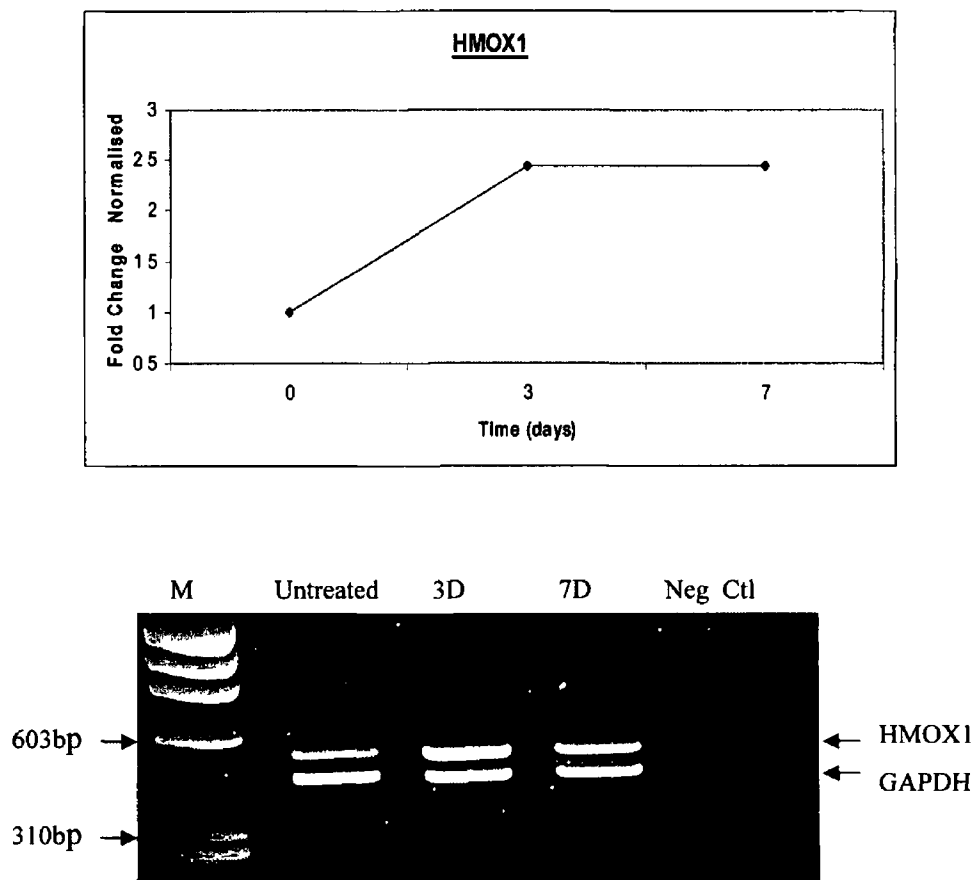

Spermidine/spermine N-acetyltransferase is a highly regulated enzymatic protein is known to be inducible by a variety of toxic agents, hormones and polyamines It is also in belongs to a metabolic pathway which involves ornithine decarboxylase and S-adenosylmethionine decarboxylase The combination of these enzymes fine tune intracellular polyamine concentration, underscoring the important role of these proteins in growth and cell survival Microarray analysis revealed an increase in Spd/Spn mRNA expression levels following treatment of DLKP cell with BrdU Spd/Spn transcript levels were shown to increase at day three to 1.8-fold and to 2.8-fold at day 7 RT-PCR analysis demonstrated an increase of several fold in Spd/Spn mRNA expression levels following three days exposure of DLKP to BrdU A slight reduction in Spd/Spn mRNA was observed in the day 7 sample in comparison to the day 3, however, Spd/Spn mRNA levels were still several fold increased when compared to control untreated cells

**Figure 3.2 12** The top graph illustrates the fold change in Spd/Spn mRNA following gene expression analysis RT-PCR analysis (bottom image) shows the level of Spd/Spn mRNA following exposure of DLKP to

Section 3.2.2.4.2 HMOX1

HMOX1 is one of two isoforms of heme oxygenase that is involved in catabolizing heme to biliverdin, carbon monoxide and free iron and is thought to be involved in iron homeostasis. Following gene expression analysis, HMOX1 mRNA levels were found to increase by approximately 2-fold in the day 3 sample and the expression level of this gene was maintained at this level in the day 7 sample. This result was confirmed by RT-PCR analysis which demonstrated a significant increase in HMOX1 mRNA expression levels across the experiment in comparison to untreated control cells.

**Figure 3.2.13** The top graph illustrates the fold change in HMOX1 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the level of HMOX1 mRNA following exposure of DLKP to BrdU.

Section 3.2.2.4 3      Id2

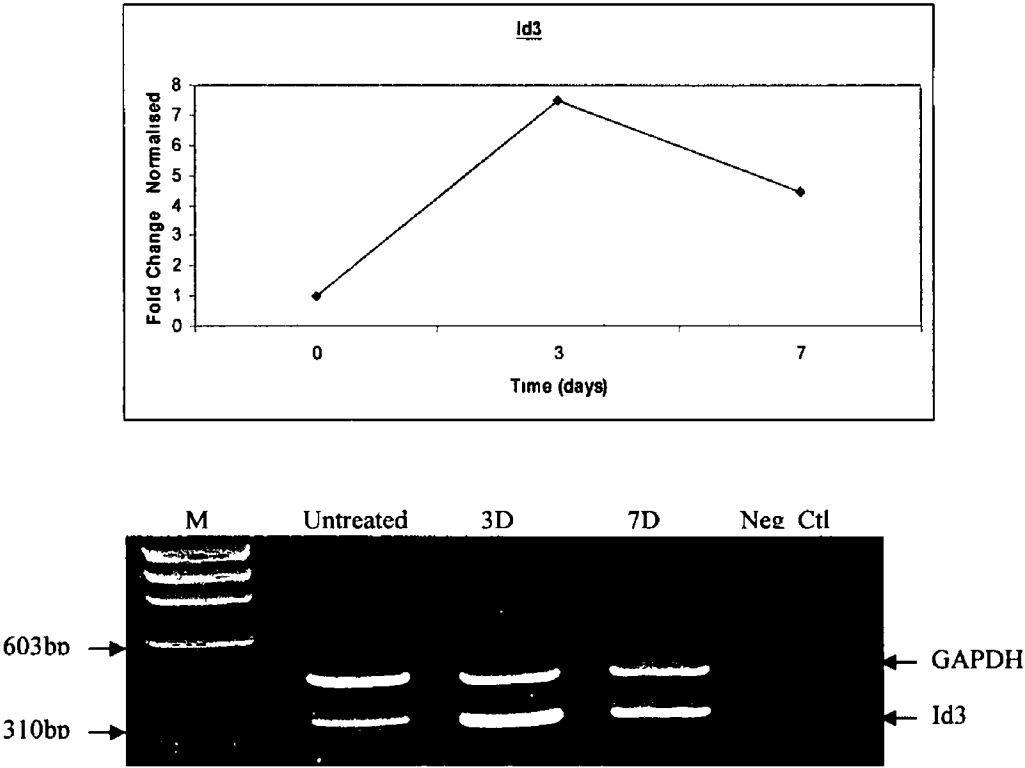

The Id family of four helix-loop-helix (HLH) transcription factors (Id1, Id2, Id3 and Id4) act as dominant negative regulators of basic HLH proteins. Since many bHLH proteins positively regulate sets of genes during cell fate determination and cell differentiation, Id proteins are thought to inhibit the ability of bHLH proteins from binding DNA and inhibit cell differentiation. Although Id proteins traditionally have been viewed as negative regulators of differentiation, recent work has revealed much wider biological roles, and are now thought to be important in development, cell cycle control and tumour biology. Microarray analysis revealed a 4-fold increase in Id2 mRNA transcript levels. At day 7 Id2 expression levels were found to decrease, but still remained approximately 2-fold higher than control cells. These results were confirmed by RT-PCR analysis which demonstrated a significant increase in Id2 mRNA levels in the day 3 and day 7 samples, with the day 7 samples showing a reduction in Id2 signal in comparison to the day 3 sample.

**Figure 3.2.14** The top graph illustrates the fold change in Id2 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the level of Id2 mRNA following exposure of DLKP to BrdU.

Section 3 2 2 4 4      Id3

The Id family of four helix-loop-helix (HLH) transcription factors (Id1, Id2, Id3 and Id4) act as dominant negative regulators of basic HLH proteins. Since many bHLH proteins positively regulate sets of genes during cell fate determination and cell differentiation, Id proteins are thought to inhibit the ability of bHLH proteins from binding DNA and inhibit cell differentiation. Although Id proteins traditionally have been viewed as negative regulators of differentiation, recent work has revealed much wider biological roles, and are now thought to be important in development, cell cycle control and tumour biology. Microarray analysis revealed a dramatic increase in Id3 mRNA transcript levels following exposure of DLKP cells to BrdU. A 7.5- and 5.5-fold increase in Id3 mRNA expression level was observed in the day 3 and day 7 samples, respectively. RT-PCR analysis demonstrated a similar pattern of expression for Id3.

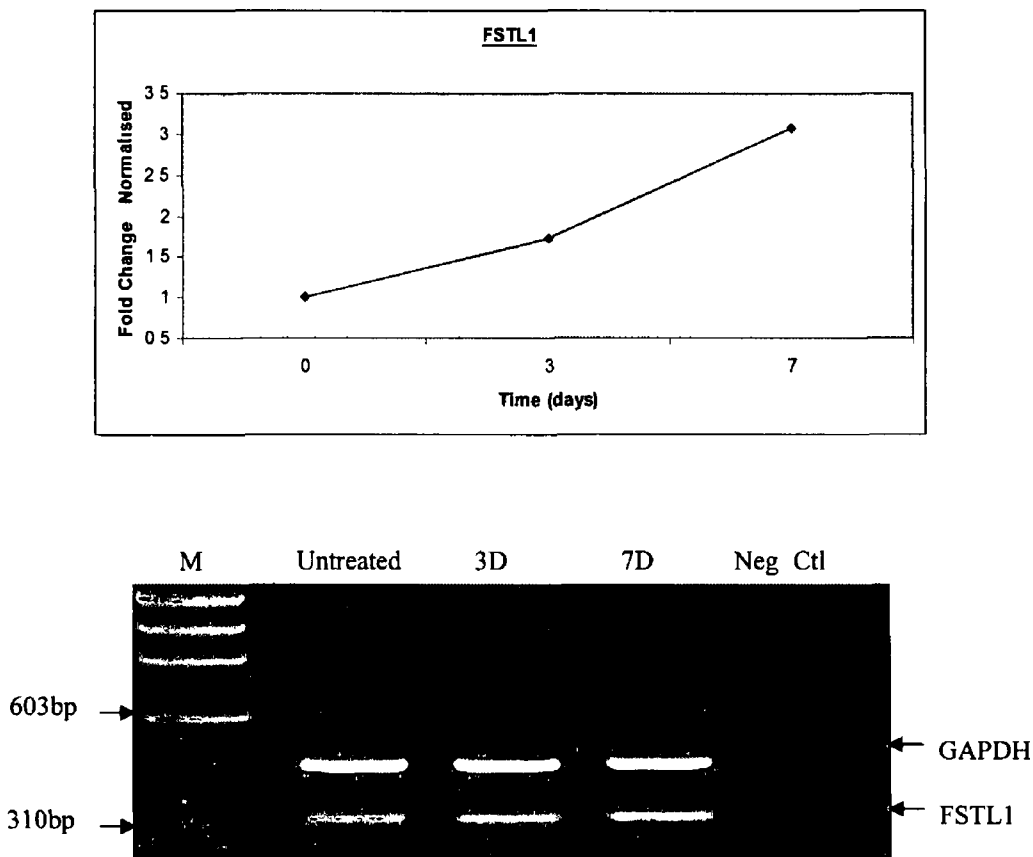

**Figure 3.2.15** The top graph illustrates the fold change in Id3 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the level of Id3 mRNA following exposure of DLKP to BrdU.

Section 3 2 2 4 5      FSTL1

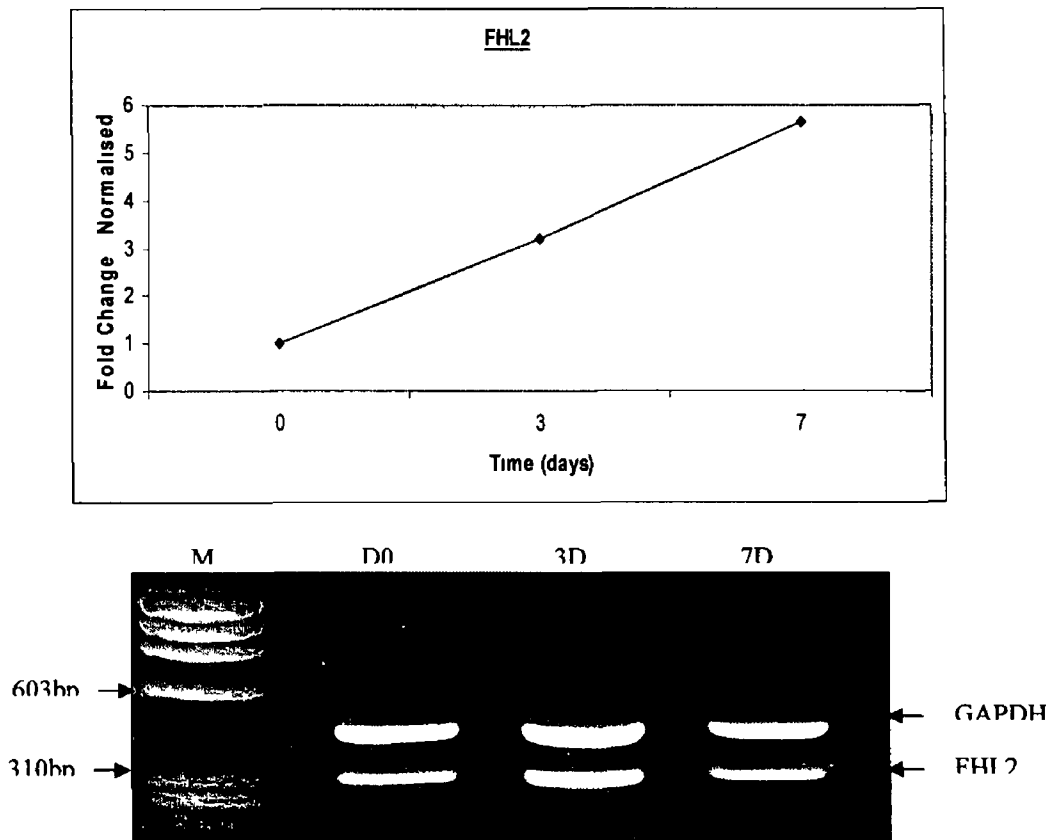

FSTL1 encodes a protein with similarity to follistatin, an activin-binding protein. It contains an FS module, a follistatin-like sequence containing 10 conserved cysteine residues. This gene product is thought to be an autoantigen associated with rheumatoid arthritis. Following microarray analysis using GeneSpring analysis software, FSTL1 mRNA expression levels were revealed to increase several fold after exposure to BrdU. Following three days treatment of DLKP with drug FSTL1 mRNA were shown to increase by 1.5-fold and increased further to approximately 3-fold by day 7. RT-PCR analysis (Section 2.11) confirmed the trend in FSTL1 mRNA expression observed in the microarray analysis.

**Figure 3.2.16** The top graph illustrates the fold change in FSTL1 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the level of FSTL1 mRNA following exposure of DLKP to BrdU.

Section 3 2 2 4 6      FHL2

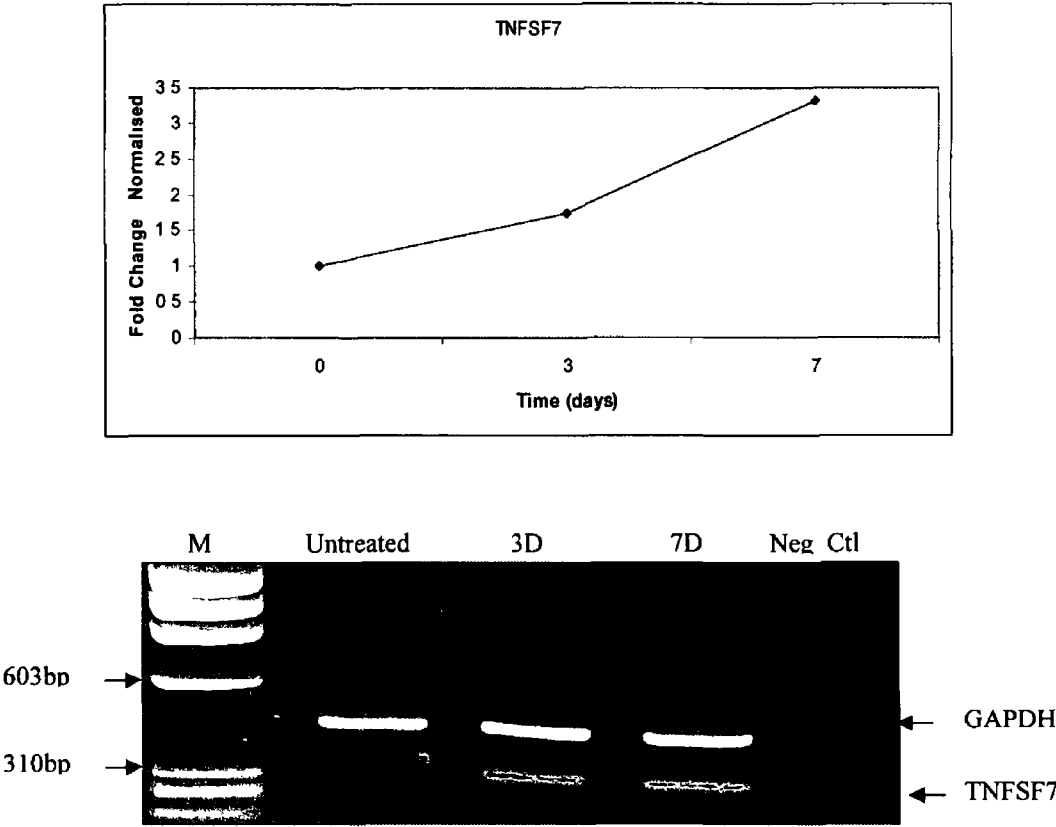

FHL2 belongs to the family of LIM proteins, which are involved in protein-protein interaction and transcriptional regulation. Recent evidence has suggested that FHL proteins may act as co-regulators involved in the modulation of tissue-specific gene expression by interacting with different transcription factors. Such transcription factors include JUN and FOS and these associations have been shown to result in a powerful activation of AP-1-mediated transcription. Microarray analysis revealed an increase in FHL2 transcript levels in drug-treated DLKP cells. A 3-fold increase in FHL2 mRNA expression levels was observed following three days exposure of cells to BrdU and expression levels of the gene increase further to 5.5-fold in the day 7 sample. RT-PCR analysis demonstrated a similar increase in FHL2 transcript levels as was observed in the microarray analysis.

**Figure 3 2 17** The top graph illustrates the fold change in FHL2 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the level of FHL2 mRNA following exposure of DLKP to BrdU.

Section 3 2 2.4 7      TNFSF7

TNFSF7 belongs to the tumour necrosis factor (TNF) ligand family and this cytokine has been reported to play a role in the regulation of B-cell activation and IgG production. Following microarray analysis, using GeneSpring analysis software, it was observed that the mRNA expression levels of TNFSF7 increase by approximately 1.5- and 3.3-fold in the day 3 and day 7 samples, respectively. This result was confirmed by RT-PCR analysis which demonstrated a similar increase in TNFSF7 transcript levels.

**Figure 3.2 18** The top graph illustrates the fold change in TNFSF7 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the level of TNFSF7 mRNA following exposure of DLKP to BrdU.

### **Section 3.2.2.5 Investigation of potentially co-regulated genes in BrdU-treated DLKP cells as identified using DNA microarrays**

Time course microarray experiments reveal information about the temporal transcription profile of spotted genes. Sets of genes with the same expression pattern can be grouped into clusters but the identification of molecular mechanisms responsible for co-expression requires further investigation. By using comparative promoter analysis it is possible to identify genes for which co-expression may be a result of co-regulation. The aim of this analysis is to find promoter features that may be potentially responsible for co-expression of differentiation related genes.

DLKP cells, exposed to the differentiation-modulating agent BrdU, undergo morphological change and the several epithelial markers of lung cell differentiations are induced. In order to analyse global changes the transcriptional profiles of BrdU-treated DLKP cells were examined using Affymetrix UA133 DNA microarrays. Following DNA microarray analysis the data generated was normalised and filtered (Section 2.15.2) and gene lists for up- and down-regulated differentially expressed genes were then generated.

#### **Section 3.2.2.5.1 Gene Clustering**

Effective comparative promoter analysis requires tightly clustered gene expression profiles. To generate tight clusters the gene lists were subjected to ANOVA analysis and the data from this microarray experiment was grouped into 13 clusters (Figure 3.2.19). In theory from analysis of clustered data sets it is possible to identify genes that are co-regulated and promoter models that are involved in the regulation of these clustered genes. One software package which is currently available for this type of analysis is the Genomatix Software Suite ([www.genomatix.de](http://www.genomatix.de)).

Clustering algorithms may be performed on microarray data sets to help identify genes that have similar patterns of gene expression and the results can be easily visualised. Hierarchical clustering has become one of the most widely used

techniques for the analysis of gene expression data. Clustering is an agglomerative approach in which single expression profiles are joined together until the process has been carried to completion. Simplified, hierarchical clustering works on the basis where a pair of genes that have the most similar expression pattern are found, these two genes are joined together and then the method identifies the next most similar pair of genes. This process continues until all of the genes are joined into one large cluster. Clustering of microarray data may only be carried out on data sets that have been normalised and there are several different variations on hierarchical clustering.

An alternative to hierarchical cluster is k-means clustering. In k-means clustering objects are partitioned into a fixed number of clusters. This process may be computationally intensive. K-means clustering is particularly useful when used with other techniques such as principal component analysis. Principal component analysis allows visual estimation of the number of clusters represented by the data.

The hypothesis behind clustering techniques is that genes in a cluster may share some common function or regulatory elements. However, classifications based on clustering algorithms are dependent on the particular methods used, the manner in which the data are normalised, and the manner in which similarity is measured. All of these factors can have a huge effect on the outcome of clustering analysis. Therefore, no single method of clustering is more or less appropriate to use on a given data set. Furthermore, use of one of more methods of clustering may in fact highlight differentiation relationships within a data set which consequently may be found to be important. Tools and techniques for analysis data sets are under continual development and the ultimate guide to the use of any data analysis method must be our biological understanding of the experiment under investigation.

A worked example for the identification of co-regulated genes in the BrdU Exp 3 microarray experiment is detailed in Section 4.6.

**Figure 3.2.19 Heat map of 732 differentially regulated genes in BrdU DNA microarray.** Following gene expression analysis of the DNA microarrays, the data set was subjected to statistical analysis and the gene lists then clustered. 13 clusters were then selected for further analysis. Clusters were chosen so that not more than approximately 150 genes were contained in each cluster.

### **Section 3 2 3 DLKP 5,2-FdU Arrays DNA Microarrays**

Affymetrix U133A human expression DNA microarrays were probed with RNA isolated from 5,2 -FdU-treated DLKP cells from a time course experiment. Cells were harvested after 0, 3 and 7 days exposure to the modulating agent (Section 2 7) and RNA isolated (Section 2 10). cRNA was then prepared (Section 2 15 1) and transported to the Conway Institute at University College Dublin, where it was hybridised to the U133A GeneChips™, and the chips were scanned using the Affymetrix Gene Chip scanner. The raw data was retrieved from the Conway Institute and the following analysis was performed on the data set.

The data set was normalised and filtered as has been described for in the BrdU Exp 3 microarray experiment (Section 3 2 2 3) using the Affymetrix PLIER (Probe Logarithmic Error intensity Estimate) method in GREX and using GeneSpring gene expression analysis software.

### **Section 3.2.3.1      Validation of the 5,2'-FdU DNA Microarrays**

In order to validate the gene lists, which were generated from the expression analysis carried out using GeneSpring, and to demonstrate that the fold increase/decrease observed were actual real expression changes, a set of genes were selected from the gene lists generated. RT-PCR analysis was performed on these genes. The expression patterns which confirmed the results that were obtained from the chip expression analysis.

The following section contains the result for each of the genes selected. In each subsection a graph illustrating the fold increase/decrease found following expression analysis, along with the confirmation RT-PCR result, is shown.

Section 3.2 3 1 1      Id2

The Id family of four helix-loop-helix (HLH) transcription factors (Id1, Id2, Id3 and Id4) act as dominant negative regulators of basic HLH proteins. Since many bHLH proteins positively regulate sets of genes during cell fate determination and cell differentiation, Id proteins are thought to inhibit the ability of bHLH proteins from binding DNA and inhibit cell differentiation. Although Id proteins traditionally have been viewed as negative regulators of differentiation, recent work has revealed much wider biological roles, and are now thought to be important in development, cell cycle control and tumour biology. Following microarray analysis in DLKP cells treated with 5,2 -FdU a significant increase in Id2 mRNA expression levels was observed. Id2 transcript levels increased to a maximum of 7.5-fold in the day 3 sample, and declined slightly to 4.8-fold at day 7. RT-PCR analysis confirmed the results of the microarray analysis performed and demonstrated a similar increase in Id2 mRNA levels.

**Figure 3.2.20** Top graph illustrates the fold change in Id2 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the actual level of Id2 at the various time points.

**Section 3.2.3.1.2      Id3**

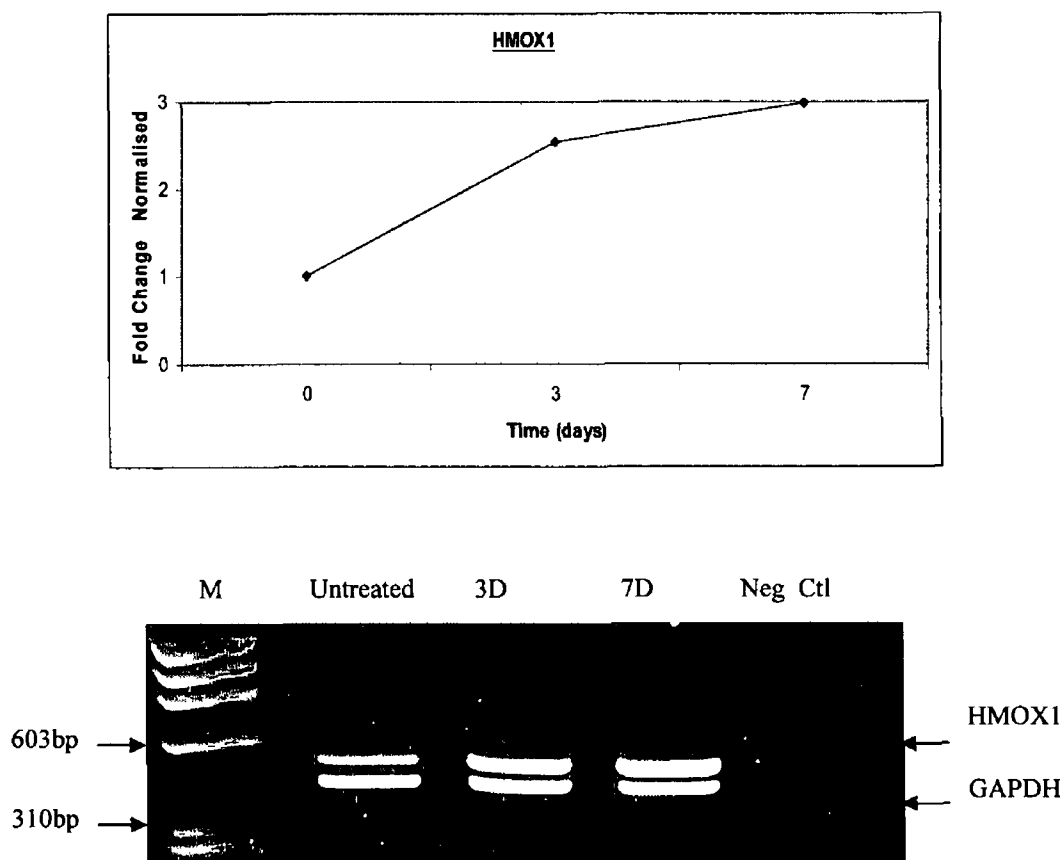

The Id family of four helix-loop-helix (HLH) transcription factors (Id1, Id2, Id3 and Id4) act as dominant negative regulators of basic HLH proteins. Since many bHLH proteins positively regulate sets of genes during cell fate determination and cell differentiation, Id proteins are thought to inhibit the ability of bHLH proteins from binding DNA and inhibit cell differentiation. Although Id proteins traditionally have been viewed as negative regulators of differentiation, recent work has revealed much wider biological roles, and are now thought to be important in development, cell cycle control and tumour biology. Microarray analysis revealed an increase in Id3 mRNA levels following exposure DLKP to 5,2 -FdU. A 7.5- and 6.4-fold increase in Id3 mRNA levels was observed in day 3 and day 7 samples, respectively. RT-PCR analysis confirmed this results and revealed a similar increase in Id3 transcript levels.

**Figure 3.2.21** Top graph illustrates the fold change in Id3 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the actual level of Id3 at the various time points.

**Section 3.2 3 1 3      Heme Oxygenase1 (HMOX1)**

HMOX1 is one of two isoforms of heme oxygenase that is involved in catabolising heme to biliverdin, carbon monoxide and free iron and is thought to be involved in iron homeostasis. Following microarray analysis a 2.5-fold increase in HMOX1 mRNA expression levels was observed following three days of exposure of cells to drug. A further increase in HMOX1 expression was found in the day 7 sample where the genes mRNA levels had increased to nearly 3-fold. RT-PCR analysis demonstrated a similar pattern of transcript levels for HMOX1.

**Figure 3.2.22** Top graph illustrates the fold change in HMOX1 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the actual level of HMOX1 at the various time points.

Section 3.2 3 1 4      FHL2

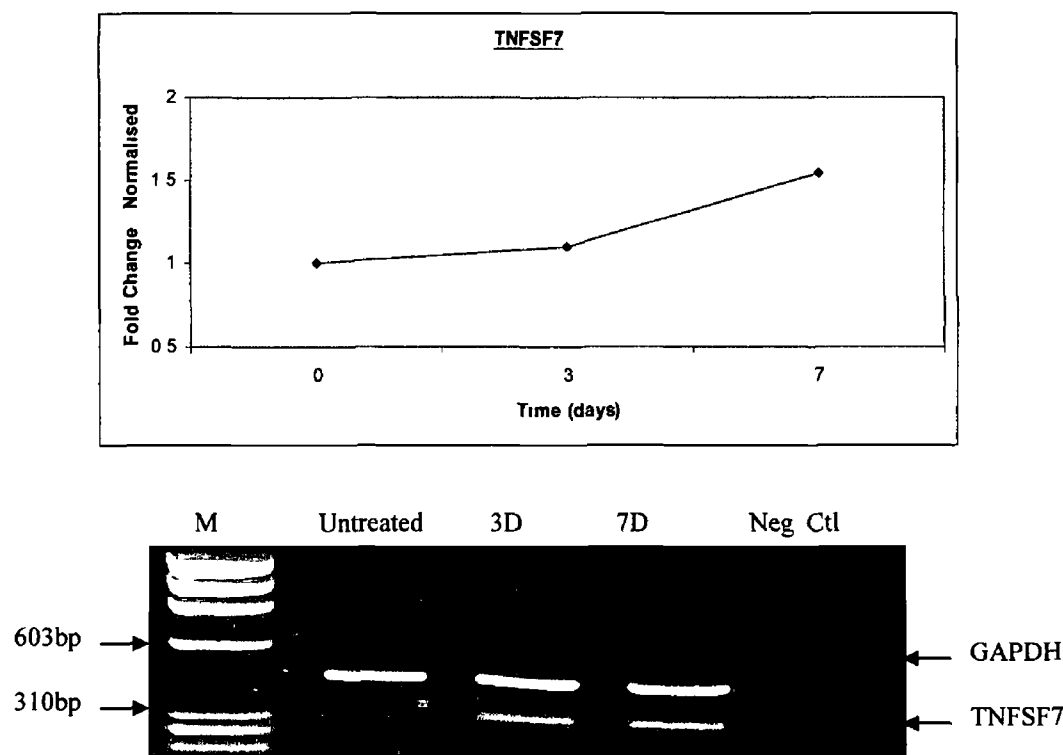

FHL2 belongs to the family of LIM proteins, which are involved in protein-protein interaction and transcriptional regulation. Recent evidence has suggests that FHL proteins may act as co-regulators involved in the modulation of tissue-specific gene expression by interacting with different transcription factors. Such transcription factors include JUN and FOS and these associations have been shown to result in a powerful activation of AP-1-mediated transcription. Following gene expression analysis, using GeneSpring analysis software, the FL1 gene was shown to increase in 5,2 -FdU-treated DLKP cells. Microarray analysis revealed an increase in FHL2 transcript levels in drug-treated cells. In the day 3 sample FHL2 mRNA levels were found to increased by 2.2-fold and levels were further increased to 2.9-fold in the day 7 sample. Confirmation of this result was demonstrated following RT-PCR analysis with revealed a similar increase in FHL2 mRNA expression levels in the day 3 and day 7 samples.

**Figure 3.2.23** The top graph illustrates the fold change in FHL2 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the level of FHL2 mRNA following exposure of DLKP to 5,2 -FdU.

**Section 3 2 3 1 5      TNFSF7**

TNFSF7 belongs to the tumour necrosis factor (TNF) ligand family and this cytokine has been reported to play a role in the regulation of B-cell activation and IgG production. Following microarray analysis the expression of TNFSF7 was demonstrated to increase to 1.5-fold in the day 7 sample, with a little change in mRNA expression levels at day 3. However, RT-PCR analysis reveals a significant increase in TNFSF7 mRNA transcription levels in both the day 3 and day 7 samples.

**Figure 3 2 24** The top graph illustrates the fold change in TNFSF7 mRNA following gene expression analysis. RT-PCR analysis (bottom image) shows the level of TNFSF7 mRNA following exposure of DLKP to 5,2 -FdU.

### **Section 3.2.4 DLKP IdU DNA Microarray**

Affymetrix U133 Plus 2 human expression DNA microarrays were probed with RNA from IdU-treated DLKP cells from a time course experiment. Cells were harvested after 0 and 7 days exposure to the thymidine analogue (Section 2.7) and RNA isolated (Section 2.10). This experiment was set up in triplicate using biological replicates. The RNA was quantified and shipped to Affymetrix where cRNA was prepared, hybridised to the GeneChips® and scanned using the Affymetrix Gene Chip scanner. The data was received back from Affymetrix for gene expression analysis.

As mentioned above, this experiment used the Affymetrix U133A Plus 2 whole genome GeneChips™ rather than the Affymetrix U133A GeneChips™, which had been used in the previous BrdU and 5,2 -FdU DNA microarrays. It is therefore more difficult to compare the results from the BrdU and 5,2 -FdU microarrays with data generated from the IdU microarrays. In order to get over this chip variation issue the IdU data sent was not put through the PLIER normalisation in GREX and an alternative normalisation method was applied.

The Gene Chip data was normalised 'Per Chip' by using the 50<sup>th</sup> percentile, using genes flagged as anything but 'Absent' in the calculation of the 50<sup>th</sup> percentile. The samples were then normalised 'Per Gene' to the mean of the day 0 samples. The data was then imported into the GeneSpring analysis software where a new experiment was setup.

A filter was then applied to the data to select genes that had a 'Present' or 'Marginal' flag in 3 out of the 6 samples. The filter also contained a condition that selected for genes that crossed a 1.5 fold threshold, up or down in day 7.

### **Section 3 2 5 Comparison of Up Regulated Genes between BrdU, 5,2'-FdU and IdU**

The BrdU, and 5,2'-FdU microarrays experiments were performed on Affymetrix human U133A GeneChips™, whereas the IdU experiment was performed using the U133 Plus 2GeneChips™. In order to compare these arrays a different form of normalisation was performed on the IdU data set than was described for the BrdU Exp 3 and 5,2'-FdU microarray experiments.

Since the chip types were different, they could not be combined in GREX for PLIER normalisation (as described in Section 2 15 3) and an alternative normalisation was used. The GeneChips® were normalised to the 50<sup>th</sup> percentile, using genes flagged as anything but 'Absent' in the calculation of the 50<sup>th</sup> percentile. The samples on the U133A GeneChips™ (BrdU and 5,2'-FdU microarrays) were then normalised to the mean of the day 0 samples. Because the IdU microarrays were carried out on a different Gene Chip type, the samples on this Gene Chip were normalised to the mean day 0 on the U133 Plus 2 chip, and not to the day 0 of the U133A Gene Chip.

Three pair-wise comparison experiments were then created, one for each of the three treatments and the appropriate day 0 sample. Gene lists were then generated and called 'Present' or 'Marginal' in three of the nine samples, in each pair-wise experiment, and that went either 1.5-fold up or down with drug treatment. The resulting gene lists from each drug treatment were then divided into up- and down-regulated differentially expressed genes.

In the BrdU experiment a total of 1,093 genes were identified as being differentially expressed. 812 of these genes were found to be up-regulated, and of 281 were to be down regulated.

In the 5,2'-FdU DNA microarrays a total of 2,147 genes were identified as being differentially expressed. Of this number 1,186 genes were found to be up-regulated, whereas 961 genes were found to be down-regulated.

In the case of the IdU DNA microarray experiment a total of 722 genes were identified as being differentially expressed. Of this number 471 genes were identified as being up-regulated, whereas 251 genes were found to be down-regulated. In the IdU DNA microarrays only two time points were chosen for analysis, 0 and 7 days. This may explain why a smaller number, 722 genes, were found to be differentially expressed in comparison to the BrdU and 5,2'-FdU microarrays where 1,093 and 2,147 differentially expressed genes were identified, respectively.

From analysis of the differentiation studies performed in the early part of this thesis (Section 3.1 and Section 4.2) it appeared that all the pyrimidine analogues investigated induced a similar pattern of differentiation. To explore these earlier studies further, it was decided to investigate common genes that may be potentially involved in the regulation of differentiation in the BrdU, 5,2'-FdU and IdU treatments. In order to identify common differentially expressed genes in these three drug treatments, up/down-regulated gene lists from the three microarray experiments (Appendix 7.1, Appendix 7.3 and Appendix 7.4) were overlapped using Venn diagrams (Figure 3.2.25 and Figure 3.2.26).

In the case of the up-regulated gene list it was found that a total of 179 genes were common to both the BrdU and 5,2'-FdU microarrays. 29 genes were identified as common to only the 5,2'-FdU and IdU microarrays, and 132 genes common to only the BrdU and IdU microarrays. A total of 93 up-regulated genes were found common between the BrdU, 5,2'-FdU and IdU microarrays.

In the case of the down-regulated gene lists it was found that a total of 105 genes were common to both the 5,2'-FdU and BrdU microarrays. 15 genes were common only to the 5,2'-FdU and IdU microarrays. A total 24 genes were identified as being common to both the BrdU and IdU microarrays. Only 9 genes were determined to be commonly down-regulated between the BrdU, 5,2'-FdU and IdU microarrays.

**Figure 3.2.25 Venn Diagram of Genes Identified as being Up-regulated in the BrdU, 5,2'-FdU and IdU DNA Microarrays.** The above Venn diagram illustrates the overlap of the genes determined to be up-regulated in all three microarrays experiments. The number in each overlapping section represents the number of up-regulated genes common to that section.

**Figure 3.2.26 Venn Diagram of Genes Identified as being Down-regulated in the BrdU, 5,2'-FdU and IdU DNA Microarrays.** The above Venn diagram illustrates the overlap of the genes determined to be down-regulated in all three microarrays experiments. The number in each overlapping section represents the number of down-regulated genes common to that section.

**Further analysis of these results is described in the discussion.**

### ***Section 3.3*      Transfections**

### Section 3 3 1 Overexpression of the transcription factor, *c-myc*

Several attempts were made to transfect DLKP and DLKP-SQ cell lines, both transiently (Section 2 14 4) and stably (Section 2 14 2), with an expression plasmid containing human *c-myc* cDNA insert

The plasmid appeared to readily transfect into both cell lines. In the case of the stable transfections, several clones were isolated from the mixed population of transfected cells. The clones were then assayed for up-regulation of *c-myc* mRNA and protein, however, no increase in either *c-myc* mRNA or protein levels were observed. It was thought that during the selection process the clones lost the overexpression of *c-myc* and that the surviving cells were as a result of resistance to geneticin. *c-myc* is widely known to induce apoptosis when up-regulated in many cell types, and this may also be a reason for the lack of overexpression seen in each round of stable clones generated.

Several rounds of *c-myc* transient transfections were also carried out. RNA and protein were harvested from the transfected cells at the following time points - 0, 24, 48 and 72 hours. In these transfections an increase in *c-myc* mRNA and a marginal increase in c-Myc protein were noted. However, the up-regulation of *c-myc* appeared to have a negative effect on all the other genes assayed for. It was suspected that the transient up-regulation of *c-myc* was inducing apoptosis, hence, shutting off these genes.

Gene Investigated	Transient	Stable
<i>c-myc</i>	↑mRNA ↑ Protein	- mRNA/Protein
YY1	↑ Protein	↑Protein
Mad1	↑ Protein

**Figure 3.3.3 Expression of YY1 in DLKP and DLKP-SQ Stably Transfected with c-myc.** YY1 expression in DLKP and DLKP-SQ cells stable transfected with a full length c-myc cDNA expression plasmid. An increase in YY1 protein levels was observed in some of the stable c-myc clones generated. 30µg of total protein was loaded per gel lane.

### **Section 3.3 1 2      c-myc Transient Transfections**

Several attempts at transiently transfecting a full length human c-myc expression plasmid into the DLKP-SQ cell line were carried out. Time points of 0, 24, 48 and 72 hours were selected for analysis. In order to investigate the effect the up-regulation of c-myc had in the cell line, several different genes were assayed for and the results are listed in the following sections

**Section 3.3 1 2.1 RT-PCR analysis showing the increase in *c-myc* expression in DLKP-SQ cell line transiently transfected with the pCMV · *c-myc* plasmid**

**(A)**

Lane 1 DLKP-SQ, Lane 2 DLKP-SQ *c-myc* 24h, Lane 3 DLKP-SQ *c-myc* 48h, Lane 4 DLKP-SQ *c-myc* 72h

**(B)**

**Figure 3 3 4 Expression of c-Myc in DLKP-SQ Transiently Transfected with *c-myc*.** (A) PCR analysis for *c-myc* expression demonstrate an increase in *c-myc* mRNA after 24 hours of transfection This increase in *c-myc* was maintained over the course of the 72 hour transfection (B) Western blot analysis showed that the c-Myc protein level was increased after 24h of transfection and was demonstrated to increase further at 72h 30μg of total protein was loaded per gel lane

**Section 3 3 1.2 2 Change in expression of Mad protein in DLKP-SQ transiently transfected with the pCMV.. c-myc plasmid.**

**Lane 1 DLKP-SQ, Lane 2 24h, Lane 3 48h, Lane 4 72h**

**Figure 3 3.5 Expression of Mad in DLKP-SQ Transiently Transfected with c-myc** Western blot analysis for Mad expression in DLKP-SQ cells transiently tranfected with the pCMV c-myc plasmid showed that the up-regulation of c-Myc resulted in the reduction of Mad protein in the transfected cells. It was observed from the analysed transfected cells that after 24h the level of Mad protein had been greatly reduced in comparison to the control untransfected DLKP-SQ cells. However, after 72h the level of Mad protrem was beginnig to return, but its expression was still very much reduced in comparison to control untransfected cells. 30µg of total protein was loaded per gel lane.

**Section 3 3.1 2 3 Change in expression of YY1 protein in DLKP-SQ transiently transfected with the pCMV. *c-myc* plasmid**

**Figure 3 3 6 Expression of YY1 in DLKP-SQ Transiently Transfected with *c-myc*** Western blot analysis for YY1 expression levels in DLKP-SQ cells transiently transfected with the pCMV *c-myc* plasmid showed that the YY1 protein slightly increased after 24h. This increase was noted also after 48 and a greater increase in YY1 was seen following 72 hours of transfection. 30µg of total protein was loaded per gel lane.

**Section 3 3 1 2 4 Change in expression of eIF4E RNA in DLKP-SQ cell line  
transiently transfected with the pCMV *c-myc* plasmid**

**Figure 3 3 7 Expression of eIF4E in DLKP-SQ Transiently Transfected with *c-myc*** Western blot analysis for eIF4E protein expression showed that there was an initial increase in the level of eIF4E protein in the transfected cells when compared to the untransfected DLKP-SQ control cells. However, after 48h this increase in eIF4E expression had return to the levels observed in the control cells

**Section 3 3 1 2 5 Change in expression of cytokeratin 8 RNA in DLKP-SQ transiently transfected with the pCMV *c-myc* plasmid**

**Lane 1** DLKP-SQ, **Lane 2** DLKP-SQ *c-myc* 24h, **Lane 3** DLKP-SQ *c-myc* 48h, **Lane 4** DLKP-SQ *c-myc* 72h

**Figure 3 3 8 Expression of Cytokeratin 8 in DLKP-SQ Transiently Transfected with *c-myc*** RT-PCR analysis of DLKP-SQ *c-myc* transiently transfected cells showed that upon the up-regulation of *c-myc*, the levels of CK8 where found to be decreased. It was noted after 48h the eIF4E signal has more or less been turned off and that following 72h the CK8 levels started to increase once again.

**Section 3 3 1 2 6 Change in expression of  $\beta_1$ -integrin RNA in DLKP-SQ transiently transfected with the pCMV- *c-myc* plasmid**

**Lane 1** Marker, **Lane 2** DLKP-SQ, **Lane 3** DLKP-SQ *c-myc* 24h, **Lane 4** DLKP-SQ *c-myc* 48h, **Lane 5** DLKP-SQ *c-myc* 72h

**Figure 3 3.9 Expression of  $\beta_1$ -integrin in DLKP-SQ Transiently Transfected with *c-myc*** RT-PCR analysis of DLKP-SQ *c-myc* transiently transfected cells showed that upon the up-regulation of *c-myc*, the levels of  $\beta_1$ -integrin were found to be decreased. It was noted that after 48h and 72h the level of  $\beta_1$ -integrin had been reduced to nearly half that of the control untransfected cells.

### Section 3.3.2 Overexpression of Yin Yang 1, YY-1

A plasmid encoding the human transcription factor, YY1 was transfected into the DLKP-SQ cell line and proved reasonably efficient to transfect. This plasmid was transfected both stably and transiently into the DLKP-SQ cell line.

Several stable highly over-expression clones were generated in two separate transfections experiments. From the initial experiment three over-expression clones were isolated from a mixed population of transfected DLKP-SQ cells. And from the second experiment several more stable clones were isolated. Overexpression of YY1 in the three clones was shown to up-regulate c-Myc at the protein level (Figure 3.3.11), however, *c-myc* mRNA levels appeared unaffected by the overexpression of YY1. An increase in Mad1 (Figure 3.3.12), a member of the c-Myc/Max/Mad network, was observed.

An increase in the translation factors eIF4E (Figure 3.3.13) and eIF2 $\alpha$  (Figure 3.3.19) was also noted in the three overexpressing clones. A significant increase in eIF4E protein levels was noted; however, due to problems with RT-PCR analysis of eIF4E, the effect of overexpression of YY1 on eIF4E RNA levels are not shown. Overexpression of YY1 also appeared to have an effect on the translation factor eIF2 $\alpha$ . A slight increase in eIF2 $\alpha$  was noted in the three stable clones generated (Figure 3.3.19). PCR analysis for eIF4e-binding protein-1 showed that there was no alteration in the expression of mRNA levels for this gene in any of the clones analysed.

The effect of overexpression of YY1 on cytokeratin expression was also investigated and it was found that there was no effect on the mRNA levels of cytokeratin 8 (Figure 3.3.14). However, some changes in the expression levels of both cytokeratins 18 (Figure 3.3.15) and cytokeratin 19 (Figure 3.3.16) were noted.

Unfortunately for some unknown reason, the YY1 clones lost all over-expression of YY1 during the freeze thaw back of the stable YY1 clones and due to time

constraints towards the end of this thesis it was not possible to generate more stable over-expression clones. Therefore, it was decided to transiently transfect the YY1 plasmid and in order to investigate further the role which YY1 plays in the regulation of differentiation in our cell system

A slight increase in eIF-2 $\alpha$  protein levels was observed in clone 4. The other two clones exhibited similar eIF-2 $\alpha$  as the DLKP-SQ control cells. 30 $\mu$ g of total protein was loaded per gel lane.

### **Section 3 2 2.2 Analysis RNA and protein changes in DLKP-SQ cells transiently transfected with the YY1 plasmid**

As mentioned earlier, the stable YY1 expressing clones generated from the transfection of the DLKP and DLKP-SQ cell lines lost YY1 over-expression for unknown reasons during cell freezing/thaw back process. Therefore, it was decided to further characterise the role that YY1 plays in our model system by transiently transfecting both cell lines with the YY1 plasmid.

DLKP and DLKP-SQ cells were transiently transfected with two different YY1 plasmids. The transfected cells were also analysed for alterations in expression levels of other proteins to elucidate what the effect the up-regulation of YY1 had.

Due to historical miss-labelling of the YY1 plasmid stocks these transfections were performed using two different YY1 vectors, each containing a full length human YY1 cDNA sequence. The initial transient transfections were performed using the plasmid described in Section 2 14, transfected into the DLKP-SQ cell line, while second set of experiments were performed using the His-tagged YY1 plasmid, transfected into DLKP. The reasoning behind the use of two different YY1 plasmids was due to historical miss-labelling of plasmids stocks in the laboratory. Both YY1 vectors used in this study contained a full length human YY1 cDNA sequence and only differed in the fact that one contained an added His-tag sequence.

From analysis of these transfections we demonstrate that transient YY1 over-expression up-regulated c-Myc protein levels, which is in agreement with the stable over-expression of YY1 in our earlier work. mRNA levels of *c-myc* were down-regulated in the transient transfections, whereas in the stable transfections the over-expression of YY1 was shown to have no effect of *c-myc* mRNA expression levels.

We also demonstrate that the transient over-expression of YY1 also has a negative effect on the mRNA of the translation initiation factor eIF4 $\alpha$ , but does

not affect the expression of other translation initiation factors such as eIF4E-binding protein-1 and Mnk2, a known kinase of eIF4E mRNA levels of cytokeratin 8 and 18 were also investigated and it was demonstrated that a slight decrease in cytokeratin 8 mRNA expression in DLKP-SQ cells after 24 hours of transfection with YY1 The transient over-expression of YY1 did not appear to have an effect on the mRNA levels of cytokeratin 18  $\beta_1$ -integrin levels were also investigated and mRNA levels of this gene were revealed to be significantly down-regulated after 24 and 48 hours of transfection However, expression levels for this gene and returned to near control levels after 72 hours of transfection

**Section 3.2.2.2.1 Change in expression of YY1 mRNA in DLKP-SQ transiently transfected with the YY1 plasmid.**

**Figure 3.3.20 YY1 mRNA Fold change in DLKP cells transiently transfected with YY1**

Taqman Real Time-PCR analysis for YY1 expression was performed on YY1 transiently transfected DLKP cells. It was demonstrated that following transfection YY1 mRNA transcript levels were 15.35-fold increase after 48 hours and had decreased to 6.75-fold at 72 hours.

**Section 3.2.2.2.2 Change in expression of *c-myc* RNA in DLKP-SQ transiently transfected with the YY1 plasmid.**

**(A)**

**Lane 1:** Marker, **Lane 2:** DLKP-SQ, **Lane 3:** DLKP-SQ::YY1 24h, **Lane 4:** DLKP-SQ::YY1 48h, **Lane 5:** DLKP-SQ::YY1 72h.

**Lane 1:** DLKP-SQ, **Lane 2:** DLKP-SQ::YY1 24h, **Lane 3:** DLKP-SQ::YY1 48h, **Lane 4:** DLKP-SQ::YY1 72h.

**Figure 3.3.21 Expression of *c-myc* in YY1 Transient Transfected DLKP-SQ.**

**(A)** RT-PCR analysis for *c-myc* mRNA revealed that *c-myc* was down-regulated after 24h and following 48h *c-myc* message had been fully turned off. However, after 72h the level of *c-myc* RNA was found to be increasing once again, but not back to control levels. **(B)** Western blot analysis showed no increase in *c-Myc* protein after 24h, however, an increase was seen at 48 h and this was maintained at 72 h of transfection. 30μg of total protein was loaded per gel lane.

**Section 3.2 2 2 3**      Change in expression of eIF2 $\alpha$  RNA in DLKP-SQ cells transiently transfected with the YY1 plasmid

**Lane 1** Marker, **Lane 2** DLKP-SQ, **Lane 3** DLKP-SQ YY1 24h, **Lane 4** DLKP-SQ YY1 48h, **Lane 5** DLKP-SQ YY1 72h, **Lane 6** Neg Control

**Figure 3 3 22 Expression of eIF2 $\alpha$  in YY1 Transiently Transfected DLKP-SQ** RT-PCR analysis for eIF2 $\alpha$  showed that eIF2 $\alpha$  was markedly down-regulated after 24h and 48h, when compared to the untransfected cells. It was noted that after 72h the level of eIF2 $\alpha$  had returned to that of the control untreated DLKP-SQ cells. Control GAPDH mRNA levels did not amplify in this reaction, and due to time constraints this PCR was not repeated.

**Figure 3.3.27 Expression of  $\beta_1$ -integrin mRNA in YY1 Transiently Transfected DLKP-SQ** RT-PCR analysis for  $\beta_1$ -integrin mRNA revealed that the level of  $\beta_1$ -integrin RNA was significantly down-regulated after 24h. In cells transfected for 48h the  $\beta_1$ -integrin message had nearly been fully switched off. However, after 72h the  $\beta_1$ -integrin message had almost returned to that of the control untransfected cells.

### **Section 3.2.2.3    Change in expression of Genes found regulated in BrdU Array in DLKP transiently transfected with the YY1 plasmid**

Following the DNA microarray experiments which were performed towards the end of this thesis, it was decided to investigate if YY1 played a role in the regulation of some of the genes demonstrated to be differentially expressed in the microarray experiments

Following RT-PCR analysis we demonstrate that transient over-expression of YY1 did in fact have a positive effect on some of the genes identified in the DNA microarray experiments. We show that the mRNA levels of FHL1, Id2, Id3 and HMOX1, to be increased. While YY1 over-expression did not appear to have an effect on FSTL1 mRNA levels

**Discussion**

#### 4.1 General Introduction

The lung is a complex organ consisting of over 40 different cell types (Plopper, 1996), whose development has been divided into four chronological stages; I) the pseudoglandular stage, II) the canalicular stage, III) the terminal sac stage and IV) the alveolar stage. While progress has been made in the developmental genetics in general, aided by huge developments in DNA microarray analysis and proteomic tools, the genetics of lung morphogenesis, the differentiation pathway and the genes involved in development of specific cell types are still largely unknown. The failure to identify a stem cell(s) of the lung (Emura, 1997) and the relative infancy of developmental genetics are part of the main problems in understanding the mechanisms regulating early development of the lung. We have been afforded the opportunity to study an *in vitro* model for early development using a very poorly differentiated lung cancer cell line, DLKP, which was isolated here at the NICB (Law, *et al.*, 1992).

DLKP is a poorly differentiated squamous carcinoma cell line which does not express keratin proteins or other epithelial markers such as epithelial-specific antigen or desmosomal proteins; despite being of epithelial origins (McBride, *et al.*, 1998). DLKP cells may represent a stem cell-like cell line of lung epithelial lineage which has the potential for both proliferation and differentiation. Also, the cells appear to be at a very early stage of differentiation, shown by the lack of expression of the simple epithelial keratins 8, 18 and 19, and can theoretically progress towards several different phenotypes.

Bromodeoxyuridine (BrdU) is a halogenated thymidine analogue that competes with thymidine for incorporation into DNA. BrdU has been found to modulate differentiation in a number of different cell types (Harding *et al.*, 1978). Specifically, BrdU has been reported in the literature to modulate differentiation in neuronal, muscle and haematopoietic lineages (Feyles *et al.*, 1991; Tapscott *et al.*, 1989; Yen *et al.*, 1987). It has been shown previously that this differentiation modulating agent is capable of inducing differentiation in our *in vitro* DLKP model system, and the lung adenocarcinoma cell line, A549, (McBride, *et al.*, 1999; Mcleady, PhD Thesis, 1997; O'Sullivan, PhD Thesis, 1999; Walsh, PhD

Thesis 1999, Doolan, PhD Thesis, 2001) Associated with this alteration in differentiation status of these two cell lines was an alteration in the expression levels of various proteins Protein expression of cytokeratins 8, 18 and 19, integrins  $\alpha_2$  and  $\beta_1$  (Section 3.1), the eukaryotic initiation factors eIF4E (Section 1.8 and Section 3.1.14) and eIF2 $\alpha$  (Doolan, PhD Thesis 2001) and the transcription factors Yin Yang 1 (Section 1.7.2) and c-myc (Section 1.7.1) were all up-regulated in DLKP and A549 cells when induced to differentiate by exposure to BrdU (Walsh, PhD Thesis, 1999) BrdU-induced differentiation of DLKP and A549 also resulted in the alteration of Ep-CAM protein expression (Section 3.1), along with global changes in the transcription profiles of the cells, which were investigated by DNA microarray experiments

In addition, immunocytochemical analysis of DLKP treated with BrdU for 7 days and then grown in the absence of BrdU for up to three months showed that these cells retained the pattern of keratin expression observed in BrdU-treated cells (Walsh, PhD, 1999) This result suggests that BrdU induces a pathway that causes irreversible differentiation of these cells

In this study, BrdU and other halogenated thymidine analogues, namely IdU, CdU, Bromouridine, Bromouracil, as well as 5-FU, 5,2 -FdU and 5,5-FdU, were investigated to determine if they had an effect on the differentiation status of both DLKP and A549 cell lines

## 4.2 Thymidine analogue-induced differentiation in epithelial cell lines

5-Bromo-2'-deoxyUridine (BrdU) has been reported to modulate differentiation in a number of different cell types, particularly its role in modulating differentiation in neuronal, muscle and haematopoietic lineages has been documented (Yen *et al.*, 1987; Sugimoto *et al.*, 1988; Valyi-Nagy *et al.*, 1993). We have demonstrated in our laboratory that BrdU treatment of DLKP and A549 cells induce these cells to differentiate. The mechanism(s) by which BrdU exerts its differentiation-modulating effects has not been elucidated. Several different theoretical models have been suggested to date (Section 1.4.1). It appears that the incorporation of BrdU into DNA is critical.

Results presented in this thesis demonstrate that following exposure of both DLKP and A549 cell lines to BrdU and the various other halogenated pyrimidine analogues a similar increase in the differentiation markers investigated was observed. Induction of cytokeratin expression was demonstrated in the DLKP system, with an up-regulation of cytokeratins observed in A549. However, not all the analogues induced/up-regulated the cytokeratins and integrins to the same level and a summary of these results are contain in Table 3.1 and Table 3.2.

In the DLKP and A549 systems, treatment with BrdU, IdU and CdU appeared to have a similar pattern of differentiation, with cytokeratins -8, -18 and -19 showing induction in expression. In DLKP cells increased expression of integrins,  $\alpha_2$  and  $\beta_1$ , were also demonstrated in our differentiation experiments.

Treatment of DLKP and A549 with 5,2'-FdU resulted in a dramatic alteration in the cell morphology, with the cells increasing in size to 3-4 times that of the control untreated cells. Induction of cytokeratin protein expression was noted in the DLKP system and an up-regulation found in A549 treated cells. Integrin and Ep-CAM protein expression was also noted in the two cell systems.

Bromouridine and Bromouracil did not seem to induce the differentiation markers to the same extent as the other halogenated thymidine analogues, though

some induction of cytokeratins was noted in treated DLKP cells. Interestingly, toxicity assays for these two analogues revealed that treatment with high concentrations of these drugs, of up to 70 µg/µl, had no effect on the growth of DLKP cells (results not shown). A small increase in expression of the cytokeratin proteins was seen in A549 treated cells with little change in  $\alpha_2$ - and  $\beta_1$ - integrin observed (Section 3.2.2.1).

In order to ensure that the alteration of the differentiation status of both DLKP and A549 was not as a result of simple toxic exposure, both cell lines were treated with Adriamycin for 7 days. Treatment with Adriamycin did not produce the same differentiating-modulating effects as was seen with BrdU and its analogues (Data not shown).

In summary, all the thymidine analogues investigated exhibited a similar induction in differentiation as was demonstrated previously with treatment of DLKP and A549 cells with BrdU (O'Sullivan, PhD 1999). The exact mechanism(s) by which these analogues induced the expression of the set of differentiation markers investigated in this study remain unclear. A surprising find was that all the analogues investigated demonstrated a similar overall pattern of cytokeratin and integrin protein expression. 5,5 -FdU, 5,2 -FdU and 5-FU are known to have a different biological mode of action than BrdU, and are known to inhibit DNA synthesis. However, treatment of DLKP and A549 with Adriamycin revealed no induction of cytokeratins or integrin proteins following 7 days exposure of cells to this drug. Therefore, it was concluded that the induction of the selected differentiation markers investigated by BrdU and the other pyrimidine analogues in our cell system was not as a result of toxic shock in the cells. In order to investigate these differentiation assays further DNA microarray analysis was performed on a subset of treatments and the results of these studies will be discussed in Section 4.5.

### 4.3 c-Myc Over-expression Studies

Epithelial cell proliferation and differentiation is a complex process. The regulation of genes encoding structural proteins, such as cytokeratins, during epithelial cell growth and differentiation is relatively well known. However, less is known about the roles of specific transcription factors (Lymboussakia, *et al*, 1996). Since the discovery of *c-myc*, the *myc* gene family and the proteins they encode have formed part of the research programme of many cancer research laboratories worldwide. However, despite the numerous studies performed or currently under investigation, the role and mechanism of action of the *c-myc* proteins still remain enigmatic. In fact, although recently large advances in understanding the role played by this oncogene and some of its binding partners have been achieved the data obtained appears extremely complex and in some cases contradictory. Many authors believe that oncogenes simply promote cell growth or cell death, and that they block cellular differentiation. Studies performed in this laboratory have shown results that contradict this view. In our differentiation model system we have shown that up-regulation of the *c-myc* oncogene may be of importance in the lung cell differentiation process and it is possible that critical genes such as *c-myc*, may play different roles depending on cell type.

Our research group has previously demonstrated that an increase in c-Myc expression is associated with the induction of differentiation, in both the DLKP and A549 cell lines, following treatment with BrdU (Walsh, PhD 1999). Western blot analysis revealed a significant increase in the levels of c-Myc protein during the differentiation of both epithelial cell lines. Along with the increase in c-Myc, an increase in eIF4E was also observed. eIF4E has been identified as one of the few known transcriptional targets of the *c-myc* proto-oncogene (Jones *et al*, 1996). Studies have shown that eIF-4E expression correlates with *c-myc* levels following growth induction and that overexpression of *c-myc* in rat embryo fibroblasts leads to an up-regulation of eIF-4E expression (Makhlouf, *et al*, 2001).

It may appear contradictory that both c-Myc and eIF4E are up-regulated during epithelial lung differentiation in the DLKP model since there have been extensive reports in the literature of the down-regulation of *c-myc* expression during differentiation (Yen and Forbes, 1990, Valyi-Nagy *et al* , 1993, Shimizu *et al* , 1994) correlated with growth arrest (Bennet *et al* , 1994) However, the roles of oncogenes such as *c-myc* and eIF4E in cellular differentiation are poorly understood

#### **4 3 1 Stable Over-expression of *c-myc* in DLKP**

In light of our earlier studies, which showed that there was a significant increase in c-Myc protein levels in both DLKP and A549 cells treated with BrdU (Walsh, PhD 1999), it was decided to transfect the DLKP and A549 cell lines with a full length human *c-myc* expression vector A549 is known to be a difficult cell line to transfect, following several attempts using different transfection techniques (Section 2 14 2 and Section 2 14 4) it was not possible to obtain over-expressing clones

DLKP and a clonal subpopulation of DLKP, DLKP-SQ, were both transfected (Section 2 14 2) with a full length human *c-myc* expression vector Several attempts were made to generate c-Myc over-expressing clones The plasmid appeared relatively easy to transfect into both the DLKP and DLKP-SQ cell lines Several stable clones were isolated from a mixed population, however, none of the clones isolated appeared to overexpress *c-myc* at the mRNA (Section 3 3 1 1 1) or protein level (Section 3 3 1 1 2) One possible reason for the lack of overexpression of *c-myc* may be due to the possible induction of an apoptosis pathway in cells over-expressing c-Myc and the clones isolated from the mixed population were cells that had become resistant to geneticin, but did not greatly over-express c-Myc

#### **4 3 2 Transient Transfection of DLKP-SQ with *c-myc***

As a result of the inability to generate stable over-expressing c-Myc clones in both the DLKP and DLKP-SQ cell lines, we decided to attempt to investigate the role that *c-myc* plays in differentiation of lung cells by transiently transfecting (Section 2 14 4) the DLKP-SQ cell line. The DLKP-SQ cell line was selected for the transient transfections simply because this subpopulation of DLKP is known to be easier to transfect, than DLKP.

RT-PCR analysis of transiently transfected DLKP-SQ cells revealed that the mRNA level of *c-myc* was significantly increased after 24h, 48h and 72h time points when compared to the untransfected DLKP-SQ parental cells (Section 3 3 1 2 1). An increase in c-Myc protein levels after 48 hours of transfection and a further increase at 72 hours was demonstrated (Section 3 3 1 2 1). Investigation of mRNA and in some cases protein levels of potential *c-myc* target genes was then performed, the results are described in the following subsections.

##### **4 3 2 1 YY1 Expression in *c-myc* transient transfections**

The YY1 transcription factor possesses the unusual ability to both positively and negatively regulate the expression of a number of genes which are thought to be important in cellular differentiation (Riggs *et al*, 1991) (reviewed in Section 1 7 2) and we have previously (Walsh, PhD Thesis, 1999) identified this transcription factor as an important factor in our differentiation assays. The unusual properties exhibited by this transcription factor allow it to regulate the expression of different genes in opposing fashion, making it a pivotal factor in the regulation of developmental gene expression. We have previously demonstrated that YY1 is up-regulated in DLKP and A549 cells treated with BrdU (Walsh, PhD Thesis 1999) suggesting that this transcription factor may indeed be a critical factor in the induction of differentiation on our *in vitro* cell systems.

Investigation of YY1 protein expression in the *c-myc* transient transfection experiments revealed an increase in this protein following the over-expression of

*c-myc* At 24 hours following transfection with the *c-myc* expression vector a increase in YY1 protein expression was demonstrated and this increase was maintained at 72 hours (Section 3.3.1.2.3). Due to problems with RT-PCR analysis for the YY1 gene, it was not possible to ascertain if the mRNA levels of YY1 were altered in these experiments. These results demonstrate that c-Myc had positive effect on the expression levels of YY1 in cell system.

#### 4.3.2.2 eIF4E Expression in *c-myc* transient transfections

eIF4E is a 25 kDa phospho-protein responsible for Cap-binding specificity in eIF4F complexes during eukaryotic translation initiation events. eIF4E is widely accepted as the limiting factor in translational initiation, particularly for mRNAs with complex 5' UTR's. The core promoter region of the eIF4E gene contains a pair of E-box consensus sequences, CACGTG, which corresponds to the *c-myc* binding sequence. The eIF-4E gene is one of the few known targets of the c-Myc protein. Studies have shown that eIF-4E expression correlates with *c-myc* levels following growth induction and that over-expression of *c-myc* in rat embryo fibroblasts leads to an up-regulation of eIF-4E expression (Makhlouf, *et al*, 2001) which is in agreement with studies that we have performed in this laboratory and results presented in this thesis. Examination of the transient over-expression of *c-myc* in DLKP-SQ revealed that eIF4E protein levels increased after 24 hours of transfection, but reverted back to levels of control cells following 48 hours (Section 3.3.1.2.4).

#### 4.3.2.3 Mad expression in *c-myc* transient transfections

The Myc/Max/Mad family of transcription factors plays a fundamental role in the regulation of cell proliferation, oncogenic transformation, and cell differentiation. However, it remains unclear whether different heterodimers, such as Myc/Max and Mad/Max, recognize the same or different target genes *in vivo*. c-Myc and Mad1 belong to a superfamily of interacting proteins that regulate cell growth and differentiation. Myc, Max, Mad1, Mad2 (Mx1), Mad3, Mad4 and Mnt are all members of this family. In order for Myc to exert its cellular function it requires dimerization with another protein. Blackwood and Eisenman (1991)

undertook a study to try and uncover a binding partner required for *c-myc* functionality and subsequently they identified a small, novel protein which they named Max. Sequence analysis showed that Max was similar to *myc* in that it also contained a bHLH and leucine zipper motifs. The structure of Max appeared to be extremely simple, comprising of only 160 amino acids, 60 of which constitute the DNA-binding/dimerization domain (Cole, 1991). Max has been found to be a very stable protein and appears to be constitutively expressed in resting as well as proliferating cells. In proliferating cells, all newly synthesised *c-myc* is found associated with Max, suggesting that *c-myc* is rate-limiting in the formation of *c-myc*-Max dimers.

Further work was carried out by Ager and Eisenman (1993) to investigate Myc's and Max's ability to interact with other proteins. The fact that the highly stable Max protein is present at times when *myc* is not expressed, prompted Eisenman and Ager to examine further the possibility that Max might associate with other proteins. This group isolated a Max-binding protein which in turn they named Mad (Ager and Eisenman, 1993).

The Mad protein is made up of a family of four closely related proteins: Mad1, Mx1 (Mad2), Mad3 and Mad4. When Mad proteins are over-expressed in cells, they inhibit proliferation and apoptosis and suppress cell transformation not only by *myc*, but also by a variety of oncogene factors (Zhou and Hurlin, 2001). Transcriptional repression function of Mad proteins corresponds to its biological activity which is in direct opposition to that of *myc* proteins.

The expression levels of Max were not investigated in the *c-myc* transfection experiments, nor how the DLKP-treated with BrdU affects the expression levels of Max or Mad proteins. Results presented in this thesis demonstrate that *c-Myc* protein over-expression has a negative effect on the expression of Mad1 protein (Section 3.3.1.2.2). The reason why overexpression of *c-Myc* decreased the expression levels of Mad1 proteins is not clear. However, in terms of cell function it is not surprising that increased expression of *c-Myc* would have a negative effect on the expression levels of Mad proteins, given that these two

proteins have been demonstrated to have conflicting roles in cellular differentiation.

#### 4.3.2.4 $\beta$ 1-Integrin Expression in *c-myc* transient transfections

Integrins form a large family of heterodimeric transmembrane glycoproteins that bind to components of the extracellular matrix. They are versatile adhesion receptors expressed by almost every cell type. In addition to mediating cell adhesion, integrins are known to function as signalling receptors, participating in a diverse array of cellular events including spreading, migration, proliferation, differentiation and apoptosis (Debhar, 1999). Integrins also appear to be important for normal differentiation in most cell types. Their role in differentiation of epidermal stem cells has been well established (Watt, 1998).

Cell adhesion promotes cellular proliferation through the regulation of gene expression, including the immediate early genes. However, the precise role of cell adhesion in the regulation of the *c-Myc* proto-oncogene is not clear, and the adhesion-dependent signalling pathway(s) regulating the expression of *c-Myc* has yet to be defined.

Our research group has previously demonstrated that treatment of DLKP and A549 with the differentiation-modulating agent, BrdU, resulted in increase expression of  $\beta$ 1-integrin protein (Meleady, and Clynes, 2000). An increase in *c-Myc* was also observed in these cells (Walsh, PhD, 1999). Interestingly, in the transient transfection of the DLKP-SQ cell line with *c-myc*, a slight decrease in the mRNA levels of  $\beta$ 1-integrin was observed. It has been previously been reported in the literature that constitutive expression of *c-Myc* in keratinocytes causes a reduction in  $\beta$ 1-integrin expression levels. Our study of the transient over-expression of the *c-myc* gene agrees with these studies (Section 3.3.1.2.6). However, this does not explain how the expression levels of  $\beta$ 1-integrin are increased in BrdU-treated DLKP and A549 cells in which *c-Myc* levels are increased. It is possible that the treatment of these cell lines with BrdU induces  $\beta$ 1-integrin proteins via some other pathway way which is independent of

regulation of c-Myc. Another reason for this disparity between the BrdU-treatments and the *c-myc* transient over-expression studies potentially could be related to c-Myc phosphorylation. In these experiments the phosphorylation status of c-Myc has not been investigated. Future work is required to examine if the activity of c-Myc is a result of kinase-related effects in BrdU-treated cells.

In summary, we have found that it was not possible to generate stably over-express c-Myc in the DLKP cell line, but we have demonstrated that the transient over-expression of c-Myc increased levels of YY1 and eIF4E protein expression levels were increased in these transient experiments. Our results agree with published data where up-regulated c-Myc expression levels have been reported to increase the expression of eIF4E protein levels (Makhlouf, *et al*, 2001). Further work is required to investigate the exact role *c-myc* plays in our model differentiation system. The over-expression of *c-myc* may indeed be involved in the regulation of other important differentiation-related genes not investigated in these studies. Genes that may warrant further investigation maybe those which we have identified as being differentially expressed and thought important in the regulation of differentiation by BrdU, 5,2 -FdU and IdU, following DNA microarray analysis (Section 3.2 and Section 4.5). In view of the fact that the microarray experiments performed in this thesis were conducted after this set of *c-myc* over-expression studies, and due to time constraints, it was not possible to investigate if *c-myc* was involved in their regulation of expression.

#### 4 4 Yin Yang 1 Over-expression Studies

The Yin Yang 1 (YY1) transcriptional regulator is thought to be of critical importance in the control of normal development (Riggs *et al* , 1991) (reviewed in Section 1 7 2) YY1 possesses the unusual property of regulating transcription in three ways In different cellular contexts, YY1 has been shown to activate, repress or initiate transcription of a number of cellular genes These opposing roles in the regulation of gene expression make YY1 a pivotal factor in the regulation of developmental gene expression YY1 is ubiquitously expressed transcription factor that is thought to play an important role in the regulation of many cellular and viral genes through the consensus *cis* recognition sequence (Yao, *et al*, 1998) It has been reported previously to up-regulate genes such as *c-myc* (Riggs *et al* , 1993, Lee *et al* , 1994) Previous investigation in our laboratory of the DLKP and A549 cell lines showed elevated expression of YY1 protein upon treatment with BrdU in both cell lines (Walsh, PhD 1999) BrdU has also been shown to up-regulate the levels of YY1 in embryonic myoblasts (Lee *et al* , 1992), further confirming work previously performed in this laboratory It appears that YY1 may play an important role in the control of normal differentiation and development, due to its unusual ability to differentially regulate expression of various genes

Despite the large number of genes found to be potentially regulated by YY1 and the increasingly large number of proteins that are claimed to interact with YY1, little is known concerning how YY1 itself is regulated YY1 has also been linked to cellular growth and differentiation One study by Lee *et al* (1992) demonstrated that the level of YY1 activity changes during myoblast differentiation It has been shown that YY1 levels increase rapidly in quiescent NIH3T3 cells in response to serum and insulin-like growth factor 1 treatment (Shi, *et al*, 1997) YY1 DNA binding activity has also been shown to be regulated during differentiation For example, YY1 DNA binding decreases during differentiation of human teratocarcinoma cells (Liu, *et al* , 1994)

In view of its pleiotropic activities, it is not surprising that association of YY1 with other proteins appears to be important in determining the activity of YY1

YY1 was first cloned because of it was found to bind to an E1A sensitive site in the Adenoassociated virus (AAV) P5 promoter YY1 has also been shown to associate with another transcriptional activator Sp1, YY1 and Sp1 together activate transcription in a synergistic manner (Lee, *et al* , 1993, Seto, *et al* , 1993) Also, studies using the P5 promoter in an *in vitro* system indicated that YY1 TFIIB and Pol II are sufficient to initiate transcription

YY1 has been demonstrated to increase the transcription from the P1 and P2 promoter of the *c-myc* gene (Riggs *et al* , 1993) In addition, it has been revealed that YY1 associates with the c-Myc protein itself (Shrivastava, *et al* , 1993) In co-transfections carried out by Shrivastava, *et al* (1993), over-expression of c-Myc inhibits both the transcriptional activation and repression abilities of YY1 YY1 is thought to compete with Max (Section 1 7 1 1), excluding it from association with c-Myc (Shrivastava *et al* , 1994) Since the 201-343 amino acid region of YY1 is required for association with c-Myc and is also required for association with Sp1 and E1A, c-Myc may inhibit YY1 activity by interfering with its ability to associate with other transcription proteins Studies have shown that c-Myc interferes with the ability of YY1 to contact the basal transcription factors TATA-binding protein (TBP) and TFIIB

c-Myc levels vary in response to many mitogens and growth signals and it may be that the varying levels of c-Myc modulate YY1 activity *in vivo* There has been some speculation that one function of the c-Myc oncogene is to modulate the expression of YY1-dependent developmental genes by virtue of its association with YY1 (Liu, *et al* , 1996) In co-transfection experiments, *c-myc* expression was able to reduce YY1 activating function from eight-fold in the absence of co-expressed *c-myc* to two-fold in its presence (Shrivastava, *et al* , 1993) In light of YY1s ability to activate *c-myc* gene transcription, association between these two proteins may form the basis of an auto-regulatory mechanism that controls the expression and activity of both proteins (Grignani, *et al* , 1990), preventing excessive loss of growth control during periods of elevated c-Myc expression

#### 4.4.1 Role for YY1 in regulation of differentiation in DLKP

Previous work performed by our research group showed that the differentiation-modulating agent, BrdU, was capable of inducing differentiation in our *in vitro* DLKP cell system and the lung adenocarcinoma cell line, A549 (McBride S., *et al.*, 1999; Meleady P., PhD Thesis 1997; O'Sullivan F., PhD Thesis 1999; Walsh D., PhD Thesis 1999; Dolan P., PhD Thesis 2001; Meleady and Clynes, 2001a; Meleady and Clynes, 2001b). It was also proposed by work performed by Walsh (PhD Thesis, 1999) that YY1 may play a critical role in the control and induction of differentiation in our model system. To investigate if YY1 is indeed a critical factor in this model differentiation process it was decided to transfect the cell line, DLKP, and a clonal subpopulation, DLKP-SQ, with an YY1 expression vector.

Stable highly over-expression YY1 clones were generated from the transfection of DLKP-SQ cells with a full length YY1 expression vector. Preliminary characterisation on the effect of the over-expression of the YY1 transcription factor was performed on these clones. Unfortunately, during the freezing and thaw-back, the cells lost the over-expression of YY1 gene.

Western blot analysis of the isolated over-expressing YY1 clones revealed a significant increase in expression of YY1 protein in comparison to the untransfected parental cell line (Section 3.2.2.1.1). As a result of difficulties experienced generating effective RT-PCR primers, it was not possible to investigate the YY1 mRNA levels in the isolated over-expression clones.

In order to characterise the DLKP-SQ YY1 clones, the expression levels of several genes were investigated at both the mRNA and protein level in an attempt to determine if the over-expression of YY1 plays an important role in our differentiation system. In studies performed by Walsh (PhD Thesis, 1999), it was demonstrated that BrdU-treatment of DLKP increased the expression of YY1 and c-Myc proteins; indicating that these two proteins may be two important transcription factors in this differentiation model system. Also, YY1 has been reported in the literature to associate with c-Myc; therefore, we investigated the

expression levels of c-Myc in our YY1 to determine if YY1 played a role in the regulation of *c-myc*. RT-PCR analysis for *c-myc* was performed on the clones (Section 3 2 2 1 2) revealing no change in expression of *c-myc*. However, Western blot analysis demonstrated that there was a marked increase in c-Myc protein levels within the YY1 clones (Section 3 2 2 1 2). It appears that the up-regulation of YY1 had no effect on *c-myc* expression at the RNA level, but did cause an increase in c-Myc protein expression.

In addition to c-Myc, Mad1 protein levels were investigated in the YY1 over-expressing clones. Mad1 protein is reported to be expressed in resting and differentiating cells and is a known antagonist of c-Myc. The expression of c-Myc and Mad proteins is tightly controlled and their relative concentrations are critical parameters in the regulation of cell growth. Western blot analysis for Mad1 protein in the YY1 clones revealed that the level of Mad1 was increased, with Clone 4 exhibiting the greatest increase in expression (Section 3 2 2 1 3).

The effect of over-expression of YY1 on members of the family of eukaryotic translation factors (eIFs) were also investigated in this study. It was found that over-expression of YY1 up-regulated the mRNA expression levels of eIF2 $\alpha$  (Section 3 2 2 1 10) in all clones when compared to the untransfected parental cell line, DLKP-SQ. mRNA levels of Mnk2, a known eIF4E kinase, were examined. It was demonstrated that over-expression of YY1 in this cell model system had no effect on the mRNA levels of Mnk2.

Western blot analysis for eIF4E in the YY1 clones was performed revealing that a substantial increase in the level of eIF4E protein (Section 3 2 2 1 4). All clones exhibited a marked increase in eIF4E protein, however, Clone 4 showed the greatest change. Immunocytochemical analysis of the clones revealed that the over-expression of YY1 also increased the expression of Ornithine Decarboxylase (results not shown) which is known to be translationally regulated by eIF4E over-expression. Due to problems with RT-PCR primers it was not possible to investigate if the mRNA levels of eIF4E were altered in these clones. An increase in the expression of eIF4E protein levels was also demonstrated in

BrdU-treated DLKP cells eIF4E has also been reported as a target for c-Myc and over-expression of c-Myc has previously been shown to up-regulate eIF4E protein levels (Makhlouf, *et al* , 2001), which was confirmed here Also, an increase in eIF4E protein expression was demonstrated in the treatment of A549 cell lines (Section 3 1 14) with BrdU and this further confirms the fact that YY1 maybe playing role in this differentiation system

Other members of the translationally machinery were investigated, these included Mnk2, eIF4E-BP1 and eIF2 $\alpha$  RT-PCR analysis of eIF4E-binding protein-1 revealed that there was no change in mRNA expression in any of YY1 over-expressing clones RT-PCR analysis for eIF2 $\alpha$  revealed an increase in mRNA levels in the clones Western blot analysis also demonstrated an increase in eIF2 $\alpha$  protein levels

In our studies we demonstrate that the over-expression of YY1 in our system had an effect on some of the translation machinery of the cell In particular, a major increase in the expression eIF4E protein levels was demonstrated along with an increase in the expression of eIF2 $\alpha$  mRNA and protein levels eIF2 $\alpha$  is a subunit of eIF2 and is involved in the recruitment of the initiator tRNA (Met-tRNA) to the 40S Ribosomal subunit, in the initiation process of translation (Colhurst *et al* 1987) It has been suggested that eIF2 $\alpha$ , along with eIF4E, may possibly be a limiting factor in initiation of protein synthesis Under conditions of elevated eIF4E expression, translation of complex or repressed mRNAs have been shown to be initiated more frequently, and can compete more efficiently for eIF2 $\alpha$ , becoming translated at the same rate as 'normal' mRNAs The over-expression of these two important initiation factors may thus be playing important roles in the induction of cytokeratin protein expression in the YY1 over-expressing clones

We also examined by RT-PCR analysis  $\beta_1$ -integrin mRNA expression levels in the YY1 over-expressing clones and demonstrated that there was no change in the level of expression of  $\beta_1$ -integrin mRNA (Section 3 2 2 1 1 8) However, Western blot analysis revealed that upon up-regulation of YY1 protein,  $\beta_1$ -

integrin protein levels appeared to be down-regulated (Section 3.2.2.1.1.8). As mentioned earlier up-regulation of c-Myc protein has been shown to have an inhibitory effect on the expression levels of  $\beta_1$ -integrin. In our *in vitro* system we have demonstrated that associated with the over-expression of YY1 protein, is an associated up-regulation in the expression levels of c-Myc protein. This up-regulation in c-Myc protein may explain why a decrease  $\beta_1$ -integrin was observed in the YY1 over-expression experiments. Also, as for c-Myc, YY1 over expression may have a different affect on the expression of certain genes, and the expression pattern of these genes may vary when compared to BrdU-treatment of cells.

Immunocytochemical analysis performed by Derek Walsh (PhD Thesis, 1999) demonstrated that the over-expression of YY1 in DLKP induced cytokeratin expression in the cell line. In order to investigate if YY1 over-expression altered the mRNA expression of these proteins, RT-PCR analysis was performed for cytokeratins 8, 18 and 19. This analysis revealed that the level of mRNA of cytokeratin 8 remained unaffected by the over-expression of YY1 (Section 3.2.2.1.5). However, the mRNA levels of both cytokeratin 18 and 19 (Section 3.2.2.1.6 and Section 3.2.2.1.7) were both increased, indicating that YY1 maybe involved in the regulation of their expression. For some unknown reason the stable YY1 clones generated in this study lost their YY1 over-expression during freeze/thaw back. Several clone stock banks were prepared, however when these stocks were re-cultured, Western blot analysis revealed that the clones had lost all over-expression of YY1 protein. Due to time constraints in this thesis, it was not possible to ascertain if the protein levels of these three cytokeratins were also altered and some further work needs to be performed to address this.

## Section 4.4 2 Transient Over-expression of YY1

Due to time constraints towards the end of thesis and problems with the YY1 plasmid, it was not possible to generate more stable over-expressing YY1 clones. Therefore, it was decided to transiently transfect the DLKP and DLKP-SQ cell lines with a YY1 expression vector for up to 72 hours in order to further investigate the potential role that YY1 plays in our model differentiation system. The initial transient transfections were performed with the YY1 expression vector described in Section 3 2 2 2 while the DLKP YY1 transient transfections were carried out using the vector described in Section 3 2 2 2. Both YY1 plasmids contain a full length human cDNA gene.

From analysis of the transient over-expression of YY1 experiments it was found the YY1 mRNA levels were increased several fold following 72 hours of transfection (Section 3 2 2 2 1). Unfortunately, due to continual problems sourcing anti-YY1 antibody from Santz Biotech, it was not possible to examine the protein levels of YY1 in these experiments. Transient over-expression of YY1 appeared to have a negative effect on the expression levels of *c-myc* mRNA, and analysis revealed that the *c-myc* signal was complete shutoff after 48 hours, but were found to increase again after 72 hours, but not back to control levels (Section 3 2 2 2 2). However, Western blot analysis demonstrated that c-Myc protein levels were increased upon the over-expression of the YY1 gene (Section 3 2 2 2 2). From analysis of the stable over-expression YY1 experiments in DLKP-SQ cells (Section 4 4 1), results demonstrated that the mRNA levels of *c-myc* were unchanged by the over-expression of YY1 protein, however c-Myc protein expression levels were increased in the YY1 clones.

The YY1 transient over-expression studies performed confirmed that YY1 up-regulation in our cell system is capable of increasing c-Myc protein expression. The disparity in the effect of YY1 over-expression on *c-myc* mRNA levels maybe explained by dosage levels of the YY1 gene in the transfected cells. The over-expression of YY1 achieved in the transient experiments maybe much higher than the levels obtained in the stable clones, and the differences in the

levels of YY1 expression may have a bearing on the expression of *c-myc* mRNA in these experiments. Further analysis is required to confirm this hypothesis.

The effect of transient over-expression of YY1 on members of the translation initiation factors was also investigated. These experiments confirmed results of the stable over-expression experiments where YY1 was demonstrated to have no effect on expression levels of eIF4E-binding protein-1 and Mnk2 (Section 3.2.2.2.4 and Section 3.2.2.2.5). In the stable YY1 clones it was found that the protein expression levels of eIF2 $\alpha$  were increased, however, the mRNA levels for this gene were not investigated. The results from the transient over-expression of YY1 revealed that the mRNA levels for eIF2 $\alpha$  were greatly reduced after 24 hours of transfection, but after 72 hours returned to control levels. Unfortunately, due to time constraints it was not possible to investigate the protein levels of eIF2 $\alpha$  in these transient experiments.

$\beta$ 1-integrin mRNA levels in the YY1 transient transfection experiments were also investigated. The results of this analysis revealed a marked reduction in the expression of  $\beta$ 1-integrin mRNA upon up-regulation of YY1, with virtually all  $\beta$ 1-integrin mRNA signal shutoff following 48 hours of transfection with YY1. However, 72 hours after transfection the mRNA expression levels of  $\beta$ 1-integrin had almost returned to that of the control, untransfected cells. These results in part contradicted the RT-PCR analysis performed on the YY1 stably over-expression clones, which showed no apparent change in  $\beta$ 1-integrin mRNA levels (Section 3.2.2.2.8). Western blot analysis demonstrated a marked reduction in  $\beta$ 1-integrin protein levels. In both the YY1 stable and transient over-expression studies we have demonstrated that YY1 is capable of up-regulating c-Myc protein levels in your system. Therefore, it is plausible to assume that this up-regulation in c-Myc protein levels may potentially be regulating the levels of  $\beta$ 1-integrin. The regulation of  $\beta$ 1-integrin by c-Myc has previously been reported.

The effect of YY1 over-expression on the mRNA expression of cytokeratin 8 and 18 was examined. It appeared that YY1 over-expression had no major impact

the mRNA levels of these two cytokeratins. These experiments were performed at the end of this thesis and due to time constraints it was not possible to investigate if transient YY1 over-expression induced cytokeratin protein expression, as was demonstrated by our research group in stable YY1 over-expression clones (Walsh, PhD Thesis, 1999)

In summary, we have demonstrated that the stable and transient over-expression of the YY1 transcription factor in our cell system is capable of inducing a similar pattern of genes as were found altered in BrdU-treated DLKP cells. We demonstrate that both BrdU-treatment of DLKP and the over-expression of YY1 protein both increased the expression levels of c-Myc and eIF4E proteins. These results suggest that these two genes may be playing a critical role in the regulation of the differentiation pathway induced in DLKP by BrdU.

## 4.5 DNA Microarray Analysis

Temporal and spatial control of gene expression by transcription factors is the hallmark of development. The program of lung development from the beginning is directed by the activity of key transcriptional factors. DNA microarrays which permit assessment of gene expression patterns on a global level have become increasingly available. Initial work in this study demonstrated that a range of thymidine analogues, including BrdU, IdU and 5,2 -FdU (Section 4.2), were capable of inducing differentiation-related proteins in our DLKP and A549 cell line model systems. Analysis of DLKP cells treated with these three thymidine analogues illustrated that they all induced a similar pattern of differentiation-related genes (Section 4.2). All three analogues altered the morphology of DLKP upon treatment for 7 days. In particular, the expression of cytokeratins 8, 18 and 19 proteins were induced following exposure of cells to the thymidine analogues (Section 3.1). To investigate the global changes that occurred in DLKP cells treated with BrdU, 5,2 -FdU and IdU, DNA microarray analysis was performed using Affymetrix U133A GeneChips® (Section 2.15). The aim of this analysis was to identify patterns of gene expression changes in all three thymidine analogue treatments and also to identify common gene alterations between the three DNA microarrays performed, thereby possibly identifying genes which may be potentially regulatory in the pathway of differentiation induced by these three analogues.

The first DNA microarrays to be performed were microarrays on BrdU-treated DLKP cells. Three separate microarray experiments, labelled Exp 1, Exp 2 and Exp 3, were performed. In the initial experiments, Expt 1, time points at 0, 1, 3, 7 and 14 days and in the Expt 2 experiment time points of 0, 1 and 7 days were chosen for analysis (Section 3.2.2.1). These initial microarray experiments were carried out using single samples from each time point. Gene expression analysis on data sets was carried out as per Rushton *et al* , (2003). In Exp 1 over 9,100 genes were identified as being differentially expressed in the experiment, whereas in Exp 2 approximately 3,500 genes were identified. A large difference in the numbers of genes identified as being differentially expressed between

these two experiments maybe due to the fact that 5 experiment time points were chosen in Exp 1. In Exp 2 only time points at 3 and 7 days were chosen.

Following gene expression analysis on these data sets, a list of differentially expressed up- and down-regulated genes was created. From this list, ten genes were selected and RT-PCR analysis was performed in order to verify the gene expression analysis results. The genes were selected on the basis of being the most robust and the most reliably consistent in the two experiments. The ten selected genes were then confirmed by RT-PCR analysis in order to validate the microarray data sets.

Expt 3 was performed in triplicate using biological replicates and time points of 0, 3 and 7 days were chosen (Section 3.2.2.3). Since this experiment was performed using biological triplicates, the promoter analysis (Section 3.2.2.5 and Section 4.6) for this thesis was focused on this experiment. In this experiment following gene expression analysis a total of 1,093 genes were identified as being differentially expressed (Appendix 7.1). 812 of which were demonstrated as being up-regulated, whereas 281 genes were identified as being down-regulated at day 7.

In the 5,2 -FdU microarray experiment, total of 2,240 genes were identified as being differentially expressed across the experiment (Appendix 7.3). At day 7, 1,186 of these genes were shown to be up-regulated and 961 genes down-regulated. The total number of differentially expressed genes identified in the 5,2 -FdU array found to be almost twice that of the 3 BrdU array. In the case of the IdU microarray 722 genes were identified as being differentially expressed, 471 of which were found to be up-regulated at day 7, with a further 251 down-regulated.

Exp 3 of the BrdU microarrays, the 5,2 -FdU and IdU microarrays were performed towards the end of this thesis and as a result time did not allow for

RT-PCR validation of wide set of genes identified as being differentially expressed. However, the ten genes used to validate the initial BrdU arrays, Exp 1 and Exp 2, also emerged following analysis of the third BrdU microarray, Exp 3, and the 5,2 -FdU microarray. These ten genes were used to validate the BrdU (Exp 3) and 5,2-FdU. However, not all of these ten were found up-regulated in the IdU microarrays, therefore only a subset of these were used to validate this microarray.

#### **4.5.1 Comparison of the BrdU, 5,2 -FdU Microarray and IdU DNA Microarrays**

Venn diagrams of differentially expressed genes were created in order to identify genes that were commonly up-regulated at 7 days between the Exp 3 BrdU, 5,2 -FdU and IdU microarrays (Section 3.2.5). 179 up-regulated genes were shown to be common to BrdU and 5,2 -FdU only, 132 up-regulated genes were found common to BrdU and IdU only, and a further 29 genes common only to IdU and 5,2 -FdU. A total of 93 up-regulated genes (Appendix 7.5) were identified as being common to all three treatments.

Similar to the up-regulated genes, the lists of differentially expressed down-regulated genes from the BrdU, 5,2 -FdU and IdU microarrays were overlapped using a Venn diagram in order to identify genes that are commonly down-regulated between the three treatments. From the Venn diagram 105 down-regulated genes were found to be common to both the BrdU and 5,2 -FdU microarrays. It was observed that 24 genes were commonly down-regulated between BrdU and IdU, with a further 15 genes common to 5,2 -FdU and IdU only. A total of 9 genes were identified as being down-regulated between all three microarray experiments.

It should also be noted that BrdU treatment of DLKP cells differentiate in response to treatment with BrdU. Therefore one would expect some 'noise' from undifferentiated cells. Also, the low percentage of cells induced to differentiate

in the BrdU differentiation assays agrees with the finding of relatively few genes found to overlap between the three microarray experiments.

#### **4.5.2 Identification of biological themes with EASE**

High density microarray experiments have enabled the discovery of global patterns of biological responses to experimental conditions. Huge amounts of effort have been placed on issues such as data normalisation and statistical testing of genes that are significantly clustered on the basis of expression profiles. The net result of these efforts is the creation of one or more often very long lists of differentially expressed genes. However, one area of microarray analysis that requires attention in trying to make biological sense of these lists is of identification of biological themes from the gene lists. Annotating genes from such lists can be extremely laborious using internet-based databases or manual literature searches. Even after performing such searches, it can be difficult to identify biological themes from the gene list in order to make sense of the microarray data. Expression Analysis Systematic Explorer (EASE) is a publicly available software application (<http://david.niaid.nih.gov/david>) that can be used for the determination of biological themes from lists of genes.

The main focus of the differentiation studies performed in this body of work was to identify genes that were common to all three thymidine analogues, BrdU, 5,2'-FdU and IdU, since all three induce similar patterns of differentiation. A total of 93 genes (Appendix 7.5) were identified as being up-regulated between the three microarray experiments. In order to identify biological themes within this set of 93 genes, they were entered into EASE.

Not surprisingly, due to the effect these thymidine analogues have on the cell, some of the categories that featured strongly in this analysis included cell death and apoptosis categories. However, other groups which featured heavily in the statistical scoring in the EASE analysis were the categories of morphogenesis, organogenesis and development (Table 4.1).

**Table 4.1** This table details the 20 genes categorised by EASE has being involved in ‘Development’

A total of 20 (Table 4 1) of the 93 (Appendix 7 5) up-regulated genes common to all three microarrays fell into the development category, a subset of the more interesting genes are described in the following subsections

#### 4 5 2 1 Id family

The Id family of four helix-loop-helix (HLH) transcription factors (Id1, Id2, Id3 and Id4) act as dominant negative regulators of basic HLH proteins. The four Id proteins share a homologous HLH domain, but lack the basic DNA binding domain. Id proteins act to sequester bHLH proteins by forming inactive dimers to prevent binding of bHLH proteins to E-box sites (Chaudhary *et al* , 2000)

Two genes from the Id family of transcription factors, Id1 and Id3, were found following EASE analysis, in the development category and were common to all three DNA microarray experiments. **The expression of Id1 mRNA was found**

to be up-regulated in all three microarray experiments: 4.8-fold in BrdU, 3.6-fold in 5,2'-FdU and 1.6-fold in the IdU microarray. The mRNA expression levels of the Id3 family member was increased by 7.5-fold in the BrdU microarray, 7.9-fold and 1.6-fold in the 5,2'-FdU and IdU microarrays, respectively.

Two other Id family members, Id2 and Id4, were also found up-regulated in the DNA microarray experiments. However, EASE did not classify these two family members in to the 'Development' category. The expression of Id2 mRNA was increased to 3.9-fold in both the BrdU and 5,2'-FdU microarray and 1.5 fold in the IdU microarray. The expression levels of Id4 mRNA were increased to 4.4-fold and down to 2.7-fold at day 3 and day 7, respectively, in the BrdU microarray. In the 5,2'-FdU microarray experiments the mRNA levels of Id4 were found to be 3.2-fold and 3.9-fold at day 3 and day 7 respectively. And in the IdU microarray the expression of Id4 mRNA was found to increase to 2.1-fold following 7 days of exposure to the analogue.

The different Id members have been localised to different chromosomes and show marked differences in their pattern of expression and function (Fong *et al.*, 2003). Although the family members are similar in the HLH domain, the regions outside this sequence are distinct from each other. It is thought that this variance between the four family members may determine their tissue specific function, as well as the binding specificity for particular bHLH proteins. Since many bHLH proteins positively regulate sets of genes during cell fate determination and cell differentiation, Id proteins are thought to inhibit the ability of bHLH proteins from binding DNA and inhibit cell differentiation.

Although Id proteins traditionally have been viewed as negative regulators of differentiation, recent work has revealed much wider biological roles, and are now thought to be important in development, cell cycle control and tumour biology. In general, the Id proteins are expected to have overlapping function because of their ability to form non-functional dimers with differentiation-inducing bHLH proteins. Recent studies suggest that this may not be true, and some Id proteins may, in fact, be required to induce and maintain the

differentiation state of a particular cell (Lui, *et al* , 2000, Cooper and Newburger, 1998) It has been demonstrated that Id2 may act as inhibitor of proliferation and is required for the determination and maintenance of the differentiated state of alveolar epithelial cells (Liu *et al* , 2000) The constitutive expressions of Id2 and Id3 mRNA in Sertoli cells suggests that these proteins may have a significant role in maintaining Sertoli cell function (Chaudhary *et al* , 2000) Chaudhary *et al* (2000) have shown that post-mitotic and differentiated Sertoli cells express high levels of Id proteins This pattern of Id2 and Id3 expression agrees with the results presented in this study, where we show a significant increase of both genes in differentiating lung epithelial cells

In several epithelial cell types, the expression of this family of proteins has been positively correlated with proliferation (Barone *et al* , 1994) They are often up-regulated in proliferating and undifferentiated cells, and down-regulated upon induction of differentiation (Norton *et al* , 1998) Ectopic expression of Id proteins has also been shown to block differentiation functions in a number of cell types by sequestering cell-specific bHLH transcription factors (Melnikova and Christy 1996, Shoji *et al* , 1994) Experiments presented in our study show that mRNAs for the Id family members are up-regulated in DLKP cells induced to differentiate following treatment with halogenated pyrimidine analogues Therefore, we suggest that the Id family of transcription factors may potentially play an important role in the control of differentiation-related genes in our model cell system However, further work is required to elucidate the exact role this family of proteins plays in our differentiation system

#### **4.5.2.2 Glypicans**

Glypicans are a family of six glycosylphosphatidylinositol-anchored cell surface heparan sulfate proteoglycans implicated in the control of cellular growth and differentiation, which have been localized to rafts and caveolae (Fransson 2003) Glypicans are selective regulators of ligand-receptor binding and have been reported to control cellular growth and development In recent years it has become apparent that proteoglycans serve in several major developmental signaling-pathways It is now thought that several secreted and cell surface

molecules participate indirectly in growth-factor signaling, by influencing the interactions between growth factors and receptors. The evidence is particularly strong for the pathways supported by FGFs, Wnts and BMPs, which all involved in a wide variety of developmental pathways (De Cat and David, 2001)

Proteoglycans are proteins, substituted with glycosaminoglycans. These glycosaminoglycans bind to growth factors, extracellular matrix molecules, enzymes, protease inhibitors and many other proteins. They are predominantly located on the cell surface. Two major families of proteoglycans have been identified: the syndecans and the glypicans. Syndecans are transmembrane proteoglycans, whereas glypicans are attached to the cell surface. Syndecans and glypicans show differential expression and have been found to be highly regulated during development. The structures of the individual glypicans are extremely well conserved across the species. It is not currently known if the glypican family members share common functions (De Cat and David, 2001)

Given the ability of glypicans to regulate the activity of cellular growth, this family of proteins has also been associated with some cancers. Recent reports have showed that changes in their expression patterns maybe linked with tumour progression. One such study established a connection between glypican 1 and pancreatic cancer, where the expression of this protein was significantly up-regulated (Kleef *et al* , 1998). **In our study we found that the expression of glypican-4 mRNA was increased by 1.6-fold at day 7 in the BrdU microarray, to 1.7-fold in both the 5,2'-FdU and IdU microarrays, respectively.** The exact role that the glypicans play in our differentiation system remains unclear and further work is required to ascertain their exact role in the control of differentiation in the DLKP cell line.

Following EASE analysis of the BrdU, 5,2'-Fdu and IdU microarray data sets, one interesting gene identified in the development category was KLF4. **Analysis of the microarray experiments revealed that the expression of KLF4 mRNA was increased 1.8-fold in BrdU-treated DLKP cells, 2.8-fold in 5,2'-Fdu and 2.2-fold in IdU-treated DLKP cells following 7 days exposure**

Kruppel-like factors (KLFs) are DNA-binding transcriptional regulators that play a diverse role during differentiation and development. The KLFs are zinc finger transcription factors, expressed in the epithelia of the skin, lungs and gastrointestinal tract as well as in many other organs. Members of this family include erythroid (EKLF), lung (LKLF), basic (bKLF) and gut (GKLF, also known as KLF4).

KLF4 has been the most thoroughly investigated family member with respect to its role in cellular differentiation. This gene has been shown to be important in the gastrointestinal tract and colon epithelium, where the gene is thought to regulate cell growth and differentiation. Shie *et al* (2000) demonstrated that the expression of KLF4 mRNA is significantly decreased in neoplastic colonic tissues including adenoma and carcinoma and they have suggested that down-regulation of KLF4 may contribute to malignant transformation of the colon. In this study, Shie *et al* (2000) showed that constitutive over-expression of KLF4 in human adenocarcinoma cells resulted in a decrease in [<sup>3</sup>H]thymidine uptake, whereas inhibition of KLF4 led to an increase in DNA synthesis, suggesting that KLF4 may play an essential role in controlling growth arrest in the colon. This trend in KLF4 expression was confirmed in another study by Shields *et al* (1996) who demonstrated that KLF4 mRNA levels were significantly decreased in proliferating NIH 3T3 cells. The exact mechanism by which KLF4 exerts its effect is not fully understood. Shie *et al* (2000) reported that the expression of KLF4 is closely related to that of CD1 and CD1-associated kinase activity and that KLF4 in fact suppresses the CD1 promoter activity.

Earlier work in this study examined the effect of the differentiation modulating agent, BrdU, and the various other halogenated thymidine analogues (Section 3.1 and Section 4.2) had on the differentiation status of both DLKP and A549. Markers of differentiation that were investigated in these assays included a group of intermediate filaments known as cytokeratins. These proteins are known to be important in cellular differentiation and cytoskeleton organisation and have been subdivided into two main types. The acidic type I is comprised of cytokeratins 9-20, whereas the basic type II include 1-8 (Section 1.5). One cytokeratin in particular, K19, has no known basic type II keratin partner, although its expression is often found in cells that express K8 (Quinlan *et al*, 1985). We have also demonstrated that the expression of K8 and K19 protein levels are induced in our differentiation studies of both DLKP and A549 cells (Section 4.2).

Regulation of cytokeratin expression in the differentiating stratified squamous epithelium is governed by a complex interplay of both ubiquitous and tissue-specific transcription factors. Little is known about the regulation of K19 expression. Brembeck and Rustig (2000) reported that KLF4 and Sp1 modulate K19 promoter activity in a tissue-specific manner. The role of Sp1 in the regulation of cytokeratins has been described previously. The promoter of corneal-specific K3 gene is regulated by an overlapping Sp1/Api2 site and endogenous levels of Sp1 and Api2 define K3 gene transcription in differentiating corneal epithelial cells (Chen *et al*, 1996). The transcription of K5, K16, K17 and K18 has all been shown to be under the control of Sp1 (Ohtsuki *et al*, 1993, Magaldi *et al*, 1993, Gunther *et al*, 1995).

The KLF family of transcription factors had been phylogenetically linked to the Sp1 family. Brembeck and Rustig (2000) in their study revealed that both Sp1 and KLF4 act positively on an overlapping Sp1/KLF4 site in the K19 promoter with preferential binding by KLF4 and postulated that the endogenous levels of Sp1 and KLF4 are important determinants in binding to this element. In their study they showed that KLF4 contributes to the tissue-specific transcriptional regulation of K19 expression. KLF4 appears to play an important role in cell-specific differentiation by activating K19 expression, which they demonstrated to be influenced by Sp1 in stratified squamous epithelial cells but is relatively

independent of Sp1 in pancreatic ductal epithelial cells. Therefore, it is possible that KLF4 and Sp1 modulate K19 expression differently, in that Sp1 is important developmentally and KLF4 directs cell fate decisions during differentiation.

Jenkins *et al* (1998) also reported that KLF4 increased the transcriptional activity of keratin 4 and Epstein-Barr virus ED-L2 promoters and suggested that KLF4 may function as a transcriptional activator in the oesophageal squamous epithelium to regulate cell differentiation. It is also possible that KLF4 may function as either an activator or repressor of transcription and that this property is promoter or cell type specific (Yet *et al*, 1998). Is it possible that KLF4 is involved in the regulation of cytokeratin expression levels in our cell system? In order to answer this question the factors involved in the regulation of KLF4 itself require investigation.

#### **4.5.2.3.1 Regulation of KLF4**

The transcriptional regulation of KLF4 itself is poorly understood and it was recently shown by Chen *et al*, (2000) that IFN- $\gamma$  enhanced its expression. IFN- $\gamma$ , a pleiotropic cytokine with antiproliferative and immuno-modulating activities, has been shown to exert its functions by enhancing transcription of IFN- $\gamma$ -responsive genes such as IRF-1, FcR1 and Ly6-1A/E. These genes, in general, share many common features, for example, their expression is mediated by tyrosine phosphorylation of latent pre-existing STAT1 and their promoters contain an IFN- $\gamma$ -activation sequence that binds specifically to phosphorylated STAT1 (Chen *et al* 2002). A study performed by Chen *et al* (2002), established the molecular mechanism by which IFN- $\gamma$  induced KLF4 expression in colon cancer cells. This was accomplished by demonstrating that IFN- $\gamma$  increased KLF4 and IRF-1 mRNA levels in a similar fashion. Wong *et al* (2002) demonstrated that the induction of IRF-1 by IFN- $\gamma$  was STAT1-dependent and that the expression of the STAT1 gene depended on IRF-1. Together, these data suggest that IFN- $\gamma$ -induced KLF4 expression was mediated through STAT1 and this theory was further supported by findings showing that the effect of IFN- $\gamma$  on KLF4 or IRF-1 gene expression was completely abolished in STAT1-deficient cells.

#### 4 5 2 3 2      **STAT1 regulation of gene expression in response to IFN- $\gamma$**

The transcription factor STAT-1 is activated by the tyrosine phosphorylation mediated by JAK family kinases during cellular responses to cytokine or growth factor signalling. STAT-1 directly regulates the expression of key proteins in controlling the cellular processes of growth arrest of p21 (also known as CDKN1A) and cell death via expression of caspases (Wong *et al* , 2002). **In our study it was observed that p21 mRNA was up-regulated 4.9-fold in the BrdU microarray, 2.5-fold in 5,2'-FdU microarray and 2.2-fold in IdU-treated DLKP cells, after 7 days exposure.** STAT-1 is also thought to be an essential element in a range of different transcription factor complexes. The two most commonly identified are GAF and ISGF3, which are involved in the signal transduction pathways of type I and II IFNs, respectively (Stark *et al* , 1998, Decker *et al* , 1997).

Genetic and biochemical analyses have revealed the importance of the protein tyrosine kinase Jak1 and Jak2 and the transcription factor STAT1 in IFN- $\gamma$ -dependent signalling. Upon ligand binding, the receptor oligomerises and Jak1 and Jak2 are activated, leading to the phosphorylation of tyrosine 440 of the IFN- $\gamma$  receptor subunit 1 (INFR1) of the receptor, which provides a docking site for STAT1. STAT1 then is phosphorylated on tyrosine 701, leading to its dimerisation and translocation to the nucleus, where it binds to the gamma-activated sequence (GAS) elements of promoters to regulate expression of downstream genes (Rama *et al* , 2001). **In our study we found that expression of Jak2 was increased by 1.7-fold in the DLKP IdU microarray experiment and increased by 1.8- and 2.2-fold at day 3 and day 7 in the 5,2'-FdU microarray experiment, respectively.** Therefore, Jak2 potentially may be involved in the phosphorylation of STAT1 in our model system.

Wong *et al* (2002) proposed a role of IRF-1 in the regulation of STAT-1 expression. They found that STAT-1 regulates the IRF-1 gene promoter and suggested that both gene products form a feedback loop that acts to regulate cellular responses to IFNs, such as IFN- $\gamma$ . **In this study we found that STAT-1 mRNA was increased 1.8-fold in both the BrdU and IdU microarrays and**

**1.6-fold in the 5,2'-FdU-treated DLKP cells** These results indicate that STAT-1 may indeed be playing a role in the regulation of IFN- $\gamma$  which in turn may potentially be controlling the expression levels of KLF4 in our differentiation model system. The expression levels of IFN- $\gamma$  in the BrdU, 5,2'-FdU and IdU microarray experiments are unknown. One proposed reason that they may not have been identified by microarrays analysis may be as result of less than optimal probe design by Affymetrix. Affymetrix do not quality control each probe set and we know from other experiments that genes which we know are up-regulated at the mRNA levels are not detected by Affymetrix GeneChips. However, from analysing the microarray data sets it would seem probably that IFN- $\gamma$  is in fact up-regulated in treated DLKP cells. The expression of other genes that are known targets of IFN- $\gamma$ , such as IRF-1 and Interleukin 18 have been demonstrated as being increased several fold in the microarray experiments.

It should be noted here that the Affymetrix GeneChip system has many advantages over other platforms currently available on the market. However, this system does have some drawbacks. Through out this study we have identified some failing in probe design, where the system has not identified genes that we know from previous studies to be altered following exposure of DLKP cells to BrdU. Some of these genes include YY1, *c-myc* and  $\alpha_2$ -integrin. We have previously shown these genes in particular have increased mRNA and protein levels following treatment with drug.

**Figure 4.1** Schematic of the proposed regulation of cytokeratin expression in BrdU-, 5,2'-FdU- and IdU-treated DLKP Cells. STAT-1 is activated by phosphorylation mediated by the Jak kinases. Phosphorylated STAT-1 translocates to the nucleus where it is proposed to be involved in the regulation of KLF4 and IRF-1 gene expression. It is suggested that up-regulation of KLF4 increases the transcription of certain genes such as the cytokeratin. IRF-1 and STAT-1 form a feedback loop that acts to regulate the cellular responses to stimuli such as  $INF\gamma$ .

#### 4 5 2 3 3      Potential role for YY1 in regulation of IFN- $\gamma$

The nuclear factor of activated T cells (NFAT) originally described as an essential transcription factor for IL-2 gene expression in T cells, is thought to play a major role in the coordinating transcription of a number of cytokines. Recent studies have demonstrated that the cytoplasmic NFAT components belong to a large family of regulatory transcription factors comprised of at least four members, NFAT 1-4, which are differentially expressed. In T cells NFAT1 is expressed in both unstimulated and stimulated cells, whereas NFAT2 is expressed primarily in activated cells (Sweetser *et al* 1998).

Some studies have shown that NFAT1 (also known as NFATC2) may function in the regulation of the IFN- $\gamma$  promoter. Sweetser *et al* (1998) demonstrated that two strong NFAT binding sites were required for maximal expression of the IFN- $\gamma$  reporter construct containing 538 bp of the IFN- $\gamma$  promoter. Also in this work, the group showed that YY1 did not mediate inhibition of basal IFN- $\gamma$  expression. Previous studies suggested that YY1 suppresses IFN- $\gamma$  promoter function in Jurkat T cells by interacting at two regions within a silencer element located between the NFAT-binding sites (Ye *et al*, 1996). In contrast to this Yen *et al* (1996), Sweetser *et al* (1998) demonstrated that proteins binding to the NFAT and YY1 sites on the IFN- $\gamma$  promoter may serve to initiate expression of IFN- $\gamma$  in primary splenocytes. Although YY1 has been shown to interact with many other transcriptional regulators, interaction with NFAT proteins has not yet been demonstrated.

The mechanisms by which YY1 induces transcriptional activation of cellular genes such as *c-myc* and how proteins modulate the activating and repressive activities of YY1 remain yet unclear. And this is the case of the effect of YY1 on the IFN- $\gamma$  promoter, however, this transcription factor is thought to play a complex and context-dependent role in the regulation of IFN- $\gamma$  expression.

#### **4.5.2.3.4 YY1 transient over-expression versus BrdU-treatment in DLKP cells**

Following DNA microarray analysis performed on DLKP-treated cells with BrdU, 5,2 -FdU and IdU (Sections 3.2 and Section 4.5) it was decided to investigate if some of the differentially expressed genes identified in these microarrays experiments were also altered following the transient over-expression of YY1. RT-PCR analysis revealed that the transient over-expression of YY1 did in fact up-regulate the expression of Hmox1, Id2, Id3 and FHL1 mRNAs (Section 3.2). However, further RT-PCR analysis for FSTL1 mRNA expression demonstrated that YY1 over-expression had no effect on expression levels of FSTL1 (Section 3.2).

Promoter analysis on these four genes was also performed (Section 2.16). Interestingly, this analysis demonstrated that the promoter sequences of the Id2 and FHL1 genes both contained binding motifs for the Sp1 and KLF4 transcription factors. Analysis on the BrdU, 5,2 -FdU and IdU microarrays demonstrated that KLF4 and the Id family of transcription factors may potentially play an important role in the induction of differentiation in our DLKP model system. We have earlier discussed (Section 4.5.2.3.3) how YY1 has been shown to regulate the expression levels of IFN- $\gamma$  in certain cell types and how in turn IFN- $\gamma$ , as well as STAT-1, are involved in the regulation of KLF4. In previous studies, YY1 has been demonstrated to associate with the transcription factor Sp1 and the association of these two factors has been shown to activate the transcription of a number of cellular genes (Section 1.7.2). Therefore, it is plausible to hypothesise that YY1 is in fact a major controlling factor in the regulation of differentiation induced in our DLKP model system by BrdU, as previously suggested (Walsh D, PhD Thesis, 1999).

**Figure 4.2 Hypothesised Involvement of YY1 in the Regulation of IFN $\gamma$**

It is hypothesised that YY1 may be involved in the regulation of expression of IFN- $\gamma$ , and that IFN- $\gamma$  then stimulates the phosphorylation of STAT-1, mediated by Jak, which results in the activation of transcription of KLF4.

## **4 5 2 3 5      Other genes identified in the development category included FGF-2 and LY6H**

### **Fibroblast Growth Factor-2**

Fibroblast growth factors (FGF) make up a large family of polypeptide growth factors that are found in a wide variety of organisms. In vertebrates, 22 members have been identified and are thought to be highly conserved in both gene structure and amino acid sequence. Most FGF genes are found distributed around the genome (Ornitz and Itoh, 2001). The members of this family of proteins are differentially expressed in many tissue types, but the patterns and timing of expression differ. Some FGFs are expressed exclusively during embryonic development (FGF 3, 4, 8, 15, 17, and 19), whereas others are expressed in embryonic and adult tissues (FGFs 1, 2, 5-7, 16, 18 and 20-23).

In our differentiation system, DNA microarray analysis revealed that FGF-2 mRNA levels were increased in the BrdU, 5,2 -FdU and IdU microarrays. The expression of FGF-2 mRNA was found to be increased to 1.6-fold in all three arrays. The expression patterns of FGFs suggest that they have important roles in development. They are often involved in the direct signalling across epithelial-mesenchymal boundaries (Hogan 1999), the expression of each family member is thought to be tightly controlled. However, the exact mechanisms regulating FGFs activity *in vivo* are not yet fully understood. The roles which FGFs play in development have also yet to be determined.

### **LY6H**

The ly6 family of molecules was first identified in mouse and are a class of glycosylphosphatidylinositol-anchored cell surface glycoproteins. Highly restrictive patterns of expression of Ly6 genes in specific subpopulations of murine myeloid and lymphoid cells established Ly6 molecules as markers for T-cell differentiation and for hematopoietic stem cells.

Murine Ly-6 molecules are a family of cell surface glycoproteins which have interesting patterns of tissue expression during haematopoiesis from multipotential stem cells to lineage committed precursor cells, and on specific leucocyte subpopulations in the peripheral lymphoid tissues. These interesting patterns of tissue expression suggest an intimate association between the regulation of Ly-6 expression and the development and homeostasis of the immune system. Ly-6 molecules are low molecular weight phosphatidyl inositol anchored glycoproteins with remarkable amino acid homology throughout a distinctive cysteine rich protein domain that is associated predominantly with O-linked carbohydrate. These molecules are encoded by multiple tightly linked genes located on chromosome 15 which have conserved geneomic organization. The *in vivo* functions of Ly-6 molecules are not known although *in vitro* studies suggest a role in cellular activation.

Ly6H appeared to play a role in the differentiation pathway induced in DLKP suggesting that following the treatment with BrdU, 5,2'-FdU and IdU. **It was observed that the mRNA expression levels of this gene was increased to 2.0- and 1.9-fold in the BrdU and 5,2'-FdU microarrays, and to 1.7-fold in the IdU experiment following 7 days exposure of DLKP to each of the analogues.**

#### 4.6 Investigation of potentially co-regulated genes in BrdU-treated cells

Time course microarray experiments reveal information about the temporal transcription profile of genes. Sets of genes with the same expression pattern can be grouped into clusters but the identification of molecular mechanisms responsible for co-expression requires further investigation. By using comparative promoter analysis it is possible to identify genes for which co-expression maybe a result of re-regulation. The aim of this analysis was to find promoter features that are potentially responsible for co-expression of different genes.

DLKP cells exposed to the differentiating-modulating agent, BrdU, undergo morphological change and several epithelia markers of lung cell differentiation are induced. In order to analyse global changes, the transcriptional profiles of BrdU-treated DLKP cells were examined using Affymetrix U133A DNA microarray GeneChips®. Following DNA microarray data was normalised and passed through various filters, as described in Section 3.2.2.3. Effective comparative promoter analysis requires tightly clustered gene expression profiles. To generate tight clusters the gene lists were subjected to ANOVA analysis (Section 3.2.2.5).

It is beyond the scope of this thesis to analyse all the clusters from the BrdU array for co-regulated set of differentially expressed genes. Therefore, it was decided to select one cluster and to demonstrate how it is possible to identify potentially co-regulated genes using the Genomatix Suite software ([www.genomatix.de](http://www.genomatix.de)). In this worked example genes contained in Cluster 5 were chosen. The decision to choose Cluster 5 was made because genes contained in this cluster were found to be up-regulated following three days exposure to BrdU and remained at this level after 7 days.

A total of 115 genes were contained in Cluster 5 and were imported into the Genomatix BiblioSphere software package (Section 2.16) and were filtered using 'Biological Processes' Gene Ontology filter. After applying GO filter the genes were categorised as illustrated in figure 4.3 and ranked according to z-score. 15

genes (Table 4.2) were found to be classified into the ‘Development’ category and had a z-scoring of 1.68. These were chosen for further analysis. The hypothesis behind is experiment was that co-expressed genes that are involved in the same biological process may potentially be co-regulated at a promoter level. We could have classified the genes based on involvement in other cellular processes such as disease or molecular function alternatively, but since the overall aim of this thesis in the investigation of genes involved in cellular differentiation it was decided to select the ‘Development’ category.

**Table 4 2** 15 genes contained in 'Development' Category

The promoters for each of these 15 genes were retrieved using Genomatix Gene2Promoter software packages and the promoter regions of the 15 genes were then searched for a common framework of transcription factor binding sites 500 bps upstream of the transcriptional start site, for each of the genes was analysed Following this analysis, several models were identified The model illustrated below (Figure 4 4) was chosen on the basis that it contained an E box transcription factor matrix Previous work in this laboratory has suggested that *c-myc* may play an important role in the control of the differentiation pathway of BrdU-treated DLKP cells (Walsh, PhD Thesis 1999) *c-Myc* is known to contain an E box binding motif (Section 1 7 1 1)

The model chosen (Figure 4 4) contains three transcription factor elements MAZF, ZBPF and Ebox, were found in 6 (40%) (Figure 4 4) of the 15 gene promoters from the 'Development' category

**Figure 4.4** Binding sites for MAZF, ZBPF and Ebox in the upstream promoter regions of EPAS1, MYH9, TMP1, TMP2 COLA1 RPS6KA6.

#### 4.6.1 Role for MAZF, ZPF and EBOX Regulation of other human promoter sequences

In order to investigate the specificity of the promoter model containing MAZF, ZBPF and E box this model was searched for in all known human promoter regions. This was performed by using Genomatix ModelInspector program. From this analysis it was found that the promoter model occurs in 94 human gene promoter sequences, two of which are involved in regulation of protein biosynthesis (eIFG1 and PRKAA1). Another set of genes whose promoters also contain this model transcription factor framework are these involved in the protein kinase cascade. Included in this list of genes were STK17B, ADRA2C, PRKAA1, F2R and RPS6KA2 (Figure 4.5).

**Figure 4.5** Evaluation of ModelInspector Matches

Interestingly, one gene, STK17A, whose closely related family member STK17B promoter region was found to contain the proposed transcription factor model motif; was also found in cluster 5. From DNA microarray analysis we found that STK17A mRNA expression levels were increased by 1.7- and 1.9-fold at day 3 and day 7, respectively, in the BrdU Exp. 3 microarray experiments. STK17B expression levels were also found increased in the DLKP BrdU Exp. 3 microarray experiment. At day 3 and day 7 the mRNA expression levels of this gene was found to be 1.7- and 1.8-fold increased, respectively. This may be further evidence that the transcription factor model system that we have identified in this example may indeed be biologically relevant.

Further experimental work is required to confirm the model transcription factor framework identified in this example. Also, in this example only one cluster from the BrdU Exp. 3 microarray data set was investigated and genes contained in this cluster were found up-regulated at day 3 and remained up-regulated at day 7. Genes whose expression levels increase and decrease across the experiment and genes that are down-regulated at day 3 and day 7 may be investigated for co-regulation. The work required to investigate further potentially co-regulated genes in the differentiation experiments, is beyond what is possible in the time allotted for this thesis and further work may identify other interesting models

systems that are responsible for the gene expression patterns observed in our *in vitro* differentiation model system

In light of this it is clear that the results generated in these microarray experiments could be extensively mined in the manner demonstrated to reveal countless groups of potentially co-regulated genes. The breadth of this analysis was beyond the scope of this thesis, therefore, it was decided to illustrate the powerful use of this type of analysis in one cluster of the DLKP BrdU microarray experiment. The process just described is an iterative one and further work could potentially generate additional interesting transcription factor frameworks

#### **4.7 Summary**

Experiments performed in this study have demonstrated that the pyrimidine analogues investigated induce a very similar gene expression changes and differentiation pattern, in drug-treated DLKP and A549 cell lines. These alterations in gene expression are reflected in a common set of transcriptional gene changes, as well as drug-specific changes. We have identified a whole host of additional differentially expressed genes following BrdU exposure, as well as in 5,2 -FdU and IdU-treated DLKP cells by DNA microarray analysis. And have validated some of these gene expression alternations by RT-PCR

It has also been shown in this thesis that YY1 is directly capable of regulating some, but not all, of the genes altered following BrdU exposure. The results of these studies further the hypothesis put forward by Walsh (PhD Thesis, 1999), which suggested that YY1 potentially plays a key role in the regulation of differentiation in our *in vitro* model system

We have analysed all these results and discussed some possible models for the observed transcriptional alternations induced in our cell systems upon induction of differentiation and suggest some experiments to future work

## ***Section 5.0*      Conclusions and Future Work**

## 5.1 Conclusions

### ❖ Pyrimidine Analogues Induce Differentiation in DLKP and A549 cell lines

This project began, as an investigation into the mechanism(s) by which the differentiating/modulating agent, BrdU, is able to alter the differentiation status of epithelial lung cells. A range of pyrimidine analogues, as well as BrdU, namely IdU, CdU, BromoUracil, BromoUridine, 5-FU, 5,2 -FdU and 5,5 -FdU, were also investigated to determine if similar differentiation effects were seen with these analogues as was seen with BrdU-treated DLKP and A549 cells.

Our results demonstrate a common differentiation effect of all the pyrimidine analogues in both the DLKP and A549 cell lines. The ability of these analogues to induce differentiation in both cell lines was assessed by examining their effect on protein expression levels of cytokeratin 8, 18 and 19,  $\alpha$ 2-integrin,  $\beta$ 1-integrin and Ep-CAM. This study has shown that these proteins are induced in DLKP cells and are increased in A549 cells following exposure to these analogues.

### ❖ cDNA Transfection of *c-myc* and YY1 into DLKP

In light of work performed in our laboratory which demonstrated that BrdU treatment of DLKP and A549 cells significantly increases in the expression of *c-myc* and YY1 (Walsh, PhD Thesis, 1999). It has been suggested that these two transcription factors may potentially be important key regulators of differentiation in our cell system. Therefore, it was decided to transfect full length human *c-myc* and YY1 cDNAs into the DLKP cell line in order to determine if their over-expression induced similar patterns of gene expression as was demonstrated in BrdU-treatment of DLKP.

Attempts to stably over-express the *c-myc* expression vector in our DLKP cell line proved unsuccessful. Clones isolated from a mixed population of cells did

not exhibit any significant up-regulation in either *c-myc* mRNA or protein levels. Therefore, it was decided to transiently transfect the vector in order to determine if *c-myc* was a key regulator of differentiation. We demonstrated that the transient over-expression of *c-myc* had a positive effect on YY1 and eIF4E protein expression levels which is in agreement with results obtained from the treatment of DLKP cells with BrdU.

Over-expression of the transcription factor YY1, into DLKP cells also resulted in a significant increase in the expression levels of c-Myc and eIF4E proteins. Also associated with the transient increase in YY1 levels was a increase in genes which were identified as differentially expressed in the DNA microarrays performed in this study. We show that mRNA levels for FHL1, Id2, Id3 and HMOX1 are all increased in YY1 transiently transfected cells. This provides further evidence that YY1 is indeed an important factor in the regulation of differentiation and that YY1 transfection and BrdU treatment of the DLKP cell line may induce a similar pattern of differentiation in our cell system.

#### ❖ DNA Microarray Experiments

DNA microarrays were also performed on DLKP cells treated with 5,2'-FdU, IdU and BrdU in order to examine global transcriptional changes which occur in DLKP cells following exposure to these differentiation-inducing drugs. 93 up-regulated differentially expressed genes were identified as common to all three microarray experiments. These genes were further investigated in order to determine their involvement in the process of differentiation in our cell system. These 93 genes were subjected to EASE analysis, which we used, helped to identify biological patterns in the gene list. Following this analysis we narrowed our focus on a subset of the 93 genes which are thought to be involved in cellular development. We propose that the Id family of transcription factors may be important regulators of differentiation in our cell models. This family of helix-loop-helix transcription factors has also been demonstrated as being a central regulator in the differentiation of other types of epithelial cells, besides the lung. These studies provide evidence that Id proteins may in fact be significant

controllers in our system and we suggest that these transcription factors may indeed have a wider role to play in cellular process than traditionally thought

Another finding from the microarray experiments performed in this thesis was the involvement of the transcription factor, KLF4. KLF4 has been shown to be important in the gastrointestinal tract where the gene is thought to regulate cell growth and differentiation. This gene has also been associated with the regulation of cytokeratin expression in other cell systems and from the results of this thesis we hypothesize that this transcription factor could potentially be involved in the regulation of cytokeratin expression in BrdU-treated DLKP cells.

From our microarray experiments we propose a role for KLF4 in the regulation of cytokeratin expression in our differentiation system. We hypothesize that KLF4 mRNA levels are increased mediated by the phosphorylated STAT-1 and IFN $\gamma$  and IRF-1. We also suggest a possible role for YY1 involvement in the regulation of IFN $\gamma$  within the cell. The involvement of YY1 in this model is further strengthened following promoter analysis of a subset of genes identified as differentially expressed in the DNA microarray experiments. As mentioned earlier we have shown that YY1 is capable of inducing the expression of FHL1, Id2, Id3 and HMOX1 in DLKP cells following transient over-expression studies. We demonstrate that the promoter sequences of Id2 and FHL1 genes both contain binding motifs for Sp1 and KLF4 transcription factors, which provides further evidence for important roles for both YY1 and KLF4 in our proposed model.

## Future Work.

The work described in this thesis has identified a number of key factors and the mechanism(s) that maybe critical in the control of differentiation of lung epithelial cells. Areas that would be of interest for further study may include

### 1 YY1 Transfections

- DNA Arrays and Protein Arrays Perform DNA arrays on stable YY1 clones. Investigate of YY1 over-expressing clones by DNA microarray analysis may provide further leads and help to identify gene targets for this unusual transcription factor. Comparison of the results of YY1 and the microarray experiments performed on pyrimidine-treated DLKP cells may identify common regulatory genes in our *in vitro* lung differentiation model. Investigate on the altered protein profiles in YY1 transfected cells may also be of interest. The use of new protein arrays, as provided CIPHERGEN SELI-TOF system, may generate interesting leads for further investigation.
- DIGE 2D electrophoresis Analysis experiments on stable YY1 clones using DIGE analysis may also aid in the identification of proteins thought to be under either the activation or repression control of YY1.
- Immunocytochemical and *in-situ* hybridisation studies using tissue sections from early lung and carcinoma samples may be used to identify the *in-vivo* relevance of factors, such as YY1, shown to be involved in differentiation in our *in-vitro* model.
- In order to determine the percentage of transfect cells in the YY1 transient transfections co-transfection of the YY1 plasmid along with GFP or  $\beta$ -Gal should be performed.

## **2. c-Myc Transfections**

- In order to investigate further the role which *c-myc* plays in our model differentiation system and to overcome the difficulties experienced in this study with stably transfecting the *c-myc* vector into the DLKP cell line, transfection with an inducible *c-myc* plasmid may offer an alternative approach
- Further work is required to confirm the hypothesis that overexpression of *c-myc* in our model system does in fact induce apoptosis RT-PCR and Western blot analysis for pro-apoptotic factors should be performed

## **3 Thymidine Analogues and DNA Microarrays**

- Quantitative RT-PCR analysis confirm the microarray results using Real Time-PCR
- Transfection of KLF4 into the DLKP cell line From the results presented in this thesis it appears that KLF4 may be an important transcription factor in the regulation of cytokeratin expression in our cell system Therefore, it would be interesting to transfect a full length human cDNA for this gene into DLKP cells to investigate if it is possible to mimic the gene expression pattern with KLF4 over-expression as was demonstrated in pyrimidine-treated DLKP cells
- DNA microarray analysis generates vast amounts of data, analysis of some of which is only possible in the time provided for the completion of this thesis In this study only up-regulated genes were investigated Down-regulated genes may also play an important role in the regulation of cellular process and differentiation, therefore, warrant further investigation It is possible that the microarray data sets generated in this body of work could yet reveal more interesting

genes and pathways involved in the regulation early lung differentiation, if re-mined

- Further microarray analysis could reveal interesting targets for siRNA experiments. It would be interesting to know down key genes that are potentially regulating the process of differentiation in our cell system.
- Promoter analysis. In this study we demonstrated the possible use of promoter analysis software for the identification of potentially co-regulated genes in the BrdU microarray experiments. As mentioned, this process is iterative, and is beyond the scope of this thesis to fully mine the data to its full potential. Similar analysis of clusters is possible for the 5,2'-FdU and IdU microarray experiments. In light of the model transcription factor framework identified in this thesis, it is clear that other framework models of more significant importance may yet be identified from the microarray data sets.
- DIGE 2D electrophoresis and protein Arrays. Comparison of control versus treated cells, using DIGE 2D electrophoresis and protein arrays may help to identify proteins that may be up- or down-regulated in our model system for lung cell differentiation. Unknown proteins may then be tentatively identified using Mass Spec analysis.

## **7 4    Appendix E – Differentially Expressed Genes Identified in IdU DNA Microarray Experiment**

List of differentially expressed genes identified from microarray analysis of IdU  
microarray experiment    Genes listed are sorted by Affymetrix ID number

## **7 6      Appendix E – EASE Analysis**

This appendix contains part of the results generated following subjecting the 93 up-regulated genes identified as common to the BrdU, 5,2 -FdU and IdU DNA microarray experiments. Due to size constraints only part of the EASE report is listed in this Appendix.

System	Gene Category	List Hits	List Total	Population Hits	Population Total	EASE score	Bonferroni	Bootstrap within system	Gene identifiers	Affymetrix probesets
