#### Introduction

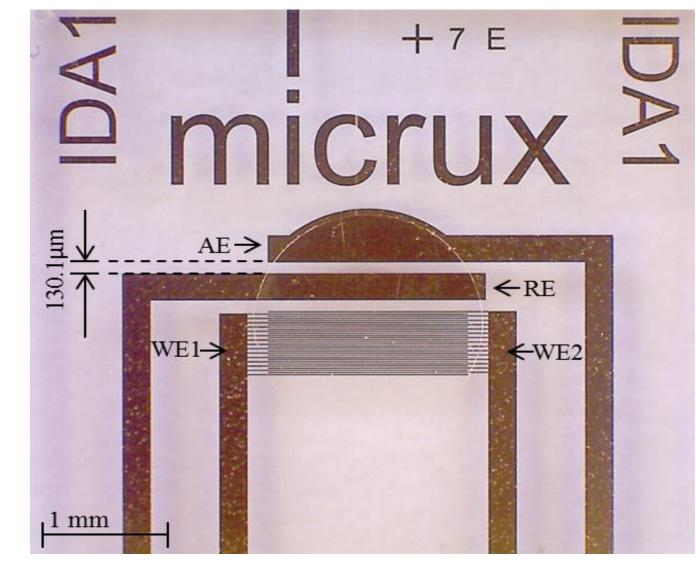

Wearable chemical sensors have the potential to provide new methods of non-invasive physiological measurement. This work presents the design of two realtime sweat sensing platforms to analyse sweat loss and composition. The first method uses ion selective electrodes (ISEs) to detect the sodium content in sweat. The second method uses capacitively coupled contactless conductivity detection (C4D) to measure the conductivity of sweat, which is highly correlated to the sodium chloride content.

#### Background ISEs

The ISEs used in this study are prepared by screen printing. An appropriate solid contact material is interposed between the carbon layer and the dropcast outer membranes of the ion-selective & reference electrodes. The selective response of the ion-selective membrane is due to the presence of an ionophore, while the reference membrane is insensitive to changes in the sample composition.

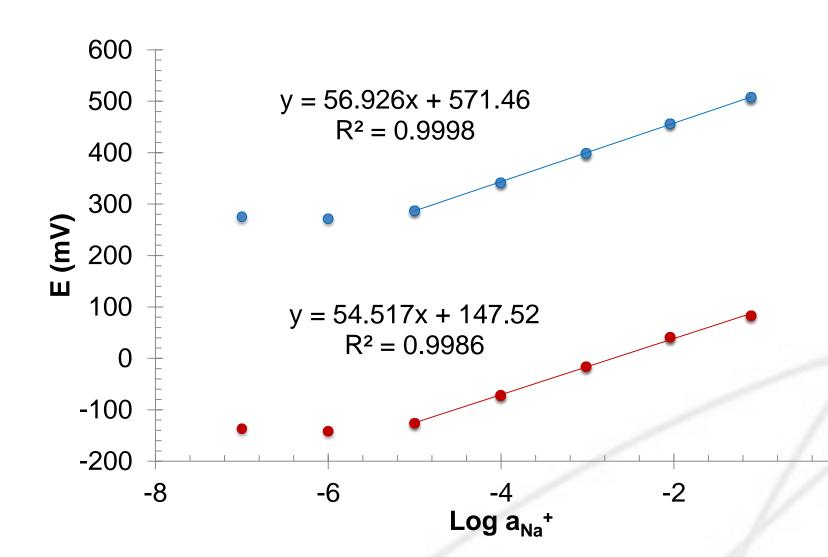

#### C4D

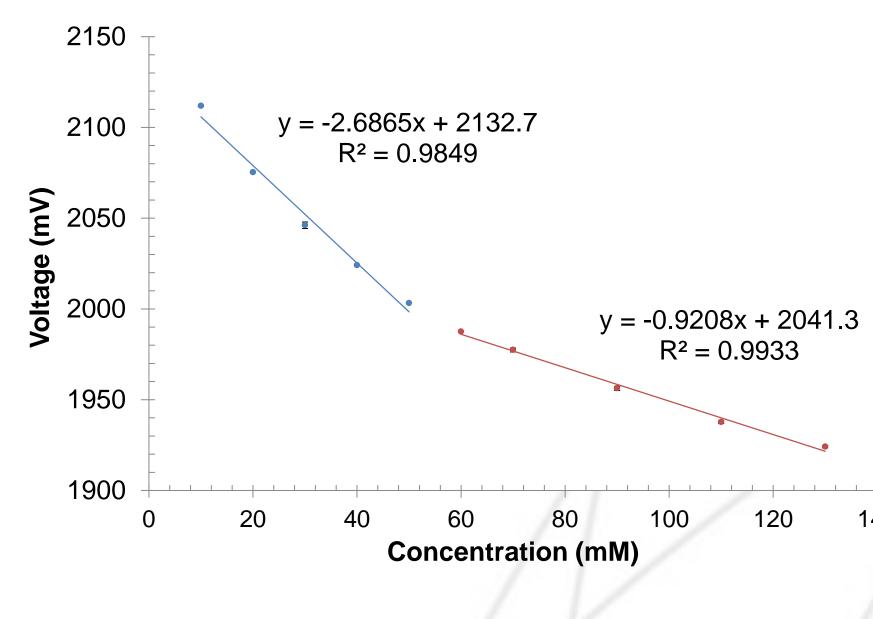

A TraceDec C4D system was used to determine the conductivity of a range of NaCl solutions using a thin-film interdigitated Micrux microarray electrode. The applied frequency, voltage and gain were adjusted for maximum sensitivity. The auxiliary electrode (AE) and reference electrode (RE) were used for all measurements.

### Calibration **ISEs**

Average calibration of 3 Na-ISEs standard double liquid Ag/AgCI reference junction miniaturised electrode and a solid contact reference electrode realised on a screen printed substrate.

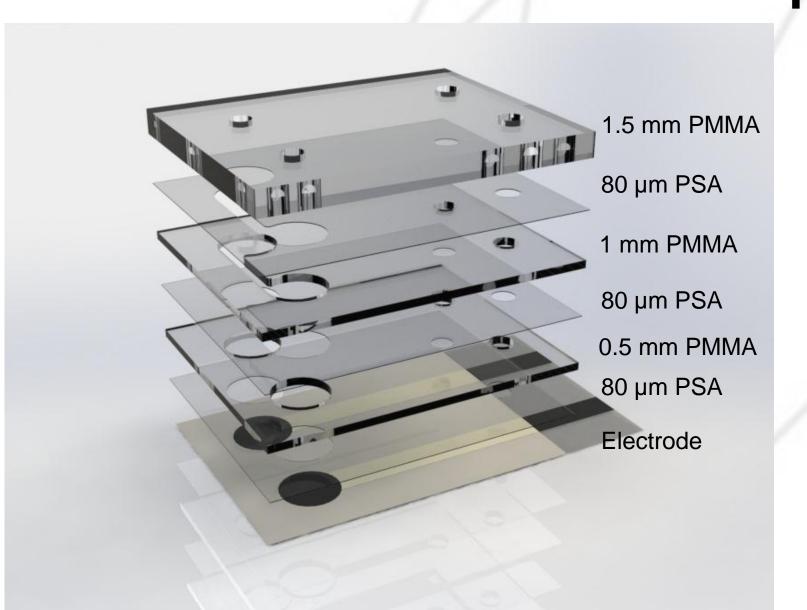

## Micrux Electrode

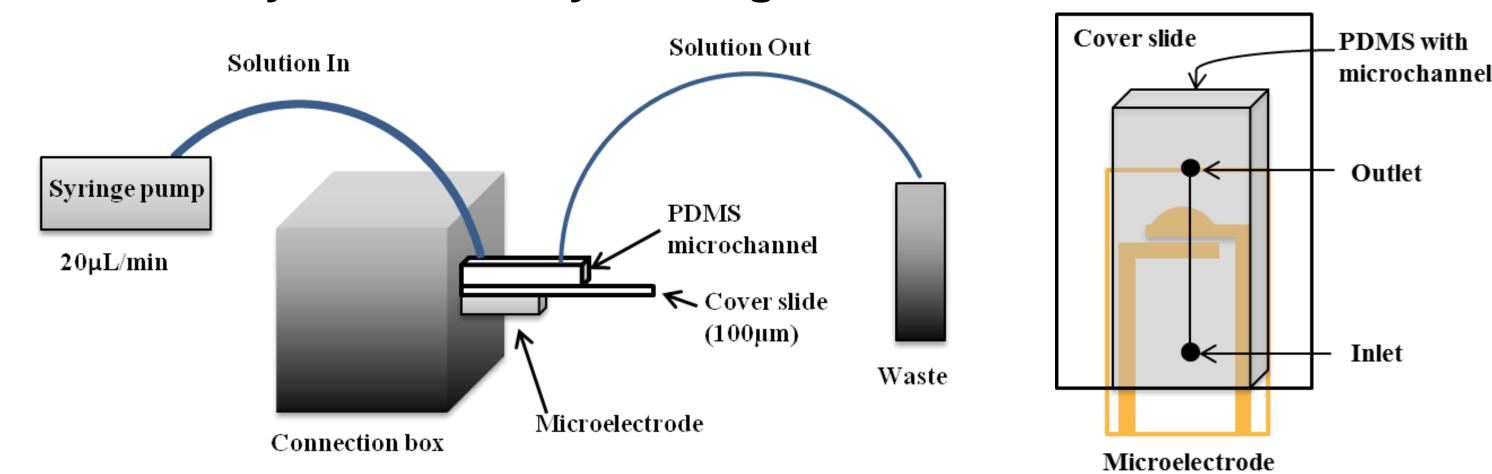

Micrux chip A gold was with 10-130 calibrated mM solutions of NaCl with a flow  $20 \mu L/min.$ rate of Two distinct linear ranges sustained; 10-50 mM and 60-130 mM. NaCl concentration variations over the normal range (<60 mM) and elevated values associated with cystic fibrosis (>60 mM) can be clearly distinguished.

### Microfluidic Potentiometric Strip

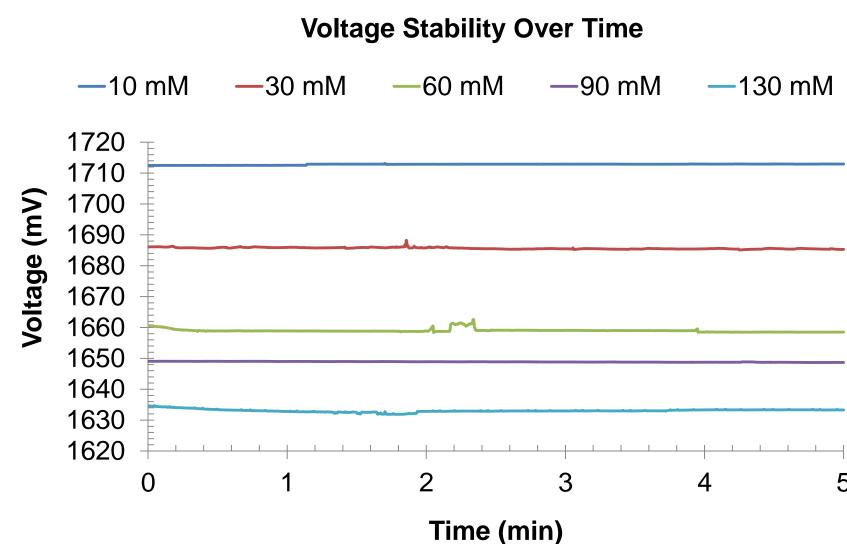

Expanded view of the different layers used to realise microfluidic chip that was mounted the of on top This potentiometric strip. configuration allows sweat to be collected through a Mega-Duct sampler directly connected to the microfluidic channel.

#### **Laboratory Conductivity Testing**

measurements were taken minute over intervals to measure time. The stability over relative standard deviation for the 5 solutions was calculated to be between 0.0017%-0.0860% n=5940.

#### **On-body Testing ISEs**

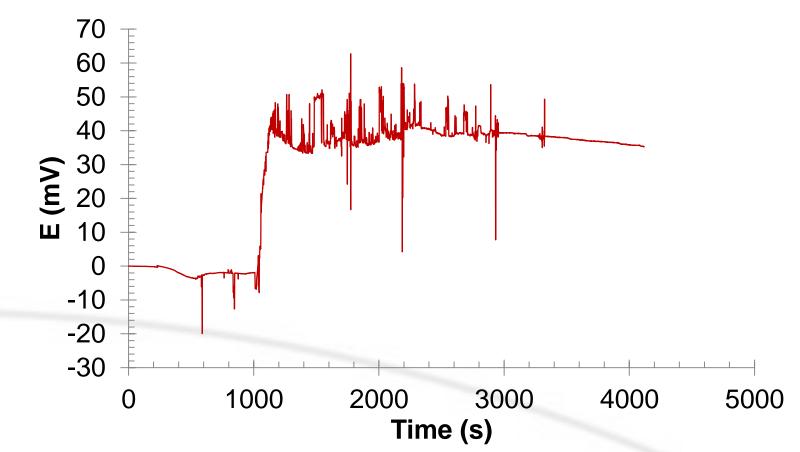

Electronics board

Sweat Chip

**Battery** 

Harvesting

The potentiometric strip was integrated into a wearable device using a Mega-Duct to deliver the sample to the electrode. Real-time tests were carried out measuring the real-time potential variation during a stationary cycling trial.

#### **Future Work ISEs**

**EB** 

# Connection to Electronics **Bluetooth Communication** Back Outside Sensory Area Laminate **Integrated Sweat**

**Conductivity Sensor** 

Conclusions

Wearable sensors open the door to continuous monitoring for sports, exercise and health applications. These types of sensors have the potential to prevent injury, decrease rehabilitation time and reduce medical costs. Eventually, it is conceivable to integrate multiple sensors into one garment for whole body wellness monitoring.
