Summing up, we concluded that only 27 out of the 57 problems could be classified as challenging (high mathematical cognitive demand and three out of the five key competences). It should be noted that ten problems met the criterion for high cognitive mathematical demand, but not the criterion of developing three out of the five key competences. Figure 1, presents a decision-making problem provided by one of the participants, which fulfilled all the criteria of our suggested model.

CONCLUSIONS

In this paper we proposed a model for assessing challenging mathematical problems based on mathematical features as well as other key competences. We suggested that a mathematical challenging problem should encompass high cognitive demand and at the same time enhance at least three out of the following key competences: digital, social, communication in mother tongue, learning to learn and sense of initiative. This proposed model is in line with the definitions and characteristics of challenging mathematical problems suggested by other researchers (e.g., Hiebert et al., 2005; Hsu, 2013; Powell et al., 2009; Silver et al., 2009; Stein & Lane, 1996).

The postgraduate problem solving course allowed a group of in-service teachers to develop abilities to design challenging tasks up to a certain extent. Almost half of the proposed problems appeared to be able to develop highly mathematically cognitive tasks which incorporated at least three other key competences. However, it seemed that the in-service teachers of the study had a greater difficulty to develop mathematical challenging problems that promote "digital competence" and "learning to learn". Therefore, future studies should aim to investigate the way in which we may empower teachers to develop challenging mathematical problems which enhance students' key competences.

Heuristics and mental flexibility in the problem solving processes of regular and gifted fifth and sixth graders

Benjamin Rott

University of Duisburg-Essen, Faculty of Mathematics, Essen, Germany, benjamin.rott@uni-due.de

This study reports on a mixed-methods design analyzing the problem solving processes of gifted and regular fifth and sixth graders (age 10–12). The analysis focuses on heuristic techniques, indicating that the regular pupils need more heuristics to be equally successful as the gifted ones. This finding is explained by the theory that heuristics can be used by the regular students to compensate a lack of mental flexibility.

Keywords: Mathematical problem solving, heuristics, intellectual flexibility.

INTRODUCTION

Within problem solving, which is a very important part of mathematics, heuristics play an integral role. It is generally assumed that the use of heuristics is related to problem solving with successful problem solvers using a greater number and variety of heuristics than less successful ones. But there are still some issues unresolved as these results have mostly been obtained with regular students. The number and appearance of heuristics in the processes of gifted or creative problem solvers might differ from those of regular problem solvers. In this article, the problem solving processes of two groups of fifth and sixth graders are analyzed and compared: one group consists of pupils from regular lower secondary schools while the other group consists of pupils that have been very successful at mathematical competitions.

THEORETICAL BACKGROUND

The theoretical framework of this article focuses on an integral aspect of mathematics that is important for gifted as well as for regular students: on mathematical problem solving and particularly on the use of heuristics in problem solving. After justifying the classification of gifted students by their participation in competitions, different aspects of problem solving are discussed. This implies the use of heuristics, their function of compensating a lack of intellectual flexibility, as well as reports on their trainability.

Mathematical competitions provide the opportunity for students to actively engage in mathematical problem solving and to compete with other problem solvers. Successful participants of such competitions are mostly mathematically gifted and talented students (Bicknell & Riley, 2012); a fact which should be true especially for younger students as they have less opportunity (only regarding their age) to compensate missing talent by training. Classifying the successful participants as gifted also fits Renzulli's (1978) classical definition of giftedness as these students show above-average abilities as well as task commitment and creativity by solving the problems posed at mathematical competitions.

The term "problem solving" has different meanings ranging from solving routine tasks to working in perplexing or difficult situations (e.g., Schoenfeld, 1992). This article refers to the latter interpretation, problem solving as working on non-routine tasks. This implies that the attribute "problem" depends on the solver, not on the task. A task is a problem for a person that does not know any procedures or algorithms to solve it. Instead of algorithms that just have to be followed step by step, heuristics can help solving problems by ordering or reducing the search space and by helping to generate new ideas (Rott, 2014). In this article, heuristics are considered as methods, mental tools, or mental operations such as "working backwards" or "drawing a figure". The use of heuristics is thoroughly discussed by Schoenfeld (1992) in general and by Engel (1998) who focuses on mathematical competitions.

Bruder (2003) and Bruder and Collet (2011) – drawing on the work of the psychologists Lompscher and Hasdorf – describe the qualities of creative and intuitive problem solvers: One main characteristic of these problem solvers is their intellectual flexibility that allows them (amongst others) to easily consider different aspects and to focus on important parts of problems. Bruder then divides intellectual flexibility into five groups of actions, namely Reduction, Reversibility, Consideration of Aspects, Change of Aspects, and Transferring. For the actions of each group of intellectual flexibility, she presents heuristic actions that are able to help less flexible problem solvers overcome their lack of intuitive problem solving skills. For example, the intuitive skill of structuring facts can be compensated by creating a table; the intuitive skill of reversing relationships can be substituted by working backwards.

Research results regarding the trainability and use of heuristics can be summarized as follows: In the 1960ies and 70ies there have been several studies in America showing (often weak) positive correlations between the use of heuristic strategies and performance on ability tests as well as on specially constructed problem solving tests (Schoenfeld, 1992). Newer studies support this supposed relationship between the use of heuristics and success in problem solving (e.g., Komorek et al., 2007; Rott, 2012). Most of these studies did not only measure the number of heuristics used and the participants' success in problem solving, but also conducted some sort of training. The results show consensually that usage of heuristics can be accomplished by training. However, these trainings have often been limited to small groups of problems with unknown transferability of strategies to other problems (cf. Schoenfeld, 1992); additionally, these trainings have been limited to regular (school and university) students without specifically addressing gifted students. The findings of these studies seem to support the claim of Bruder that learning heuristics can (at least partly) compensate the abilities of intuitive problem solvers in regular students. But we do not know enough about the abilities of creative or gifted problem solvers to really draw such conclusions.

The *research intention* of this article is to further explore the problem solving abilities of gifted students and to compare them to those of regular students. Can these two groups be distinguished by the number and appearance of the heuristics in their processes? In the short run, such a comparison can help us to better understand the way in which heuristics work. In the long run, this research can help us to better teach problem solving in schools (for gifted and regular students).

DESIGN OF THE STUDY

The aim of the research presented in this paper is to explore the problem solving behavior of fifth and sixth graders (aged 10 to 12) by analyzing and comparing the processes of two groups of pupils: novices and experts[1].

"Novices": The so-called novices were regular pupils from secondary schools in Hanover, Germany that took part in the first four terms of the support and research program MALU[2] for fifth graders, which lasted from November 2008 to June 2010 (with 10 – 15 pupils each term). These pupils came to the University of Hanover once a week for 1.5 hours and worked on problems for about half of this time. Ability tests and a consideration of school grades as selection criteria ensured a mixture of pupils that can be classified as "non-gifted".

"Experts": The so-called pupil experts were successful participants of mathematical competitions, namely of the final round of the German Mathematical Olympiad[3] in 2009/10 (8 pupils of grade 5 and 6) and price winners of the Mathematical Kangaroo[4] in 2009 (2 pupils of grade 6). As very successful problem solvers at a young age, these pupils are considered to be

1 The use of the terms „non-gifted" and "gifted" is mostly avoided in this context because of possible negative connotations of "non-gifted" and because there was no official test to ensure the "gifted" status of the pupil experts – however, the second group meets the criterion of "reproducible superior performance" for expertise.

2 Mathematik AG an der Leibniz Universität which means Mathematics Working Group at Leibniz University

3 The German Mathematical Olympiad consists of four rounds: (1) tasks to be solved at home to qualify for (2) a written tests at schools (180 minutes for grades 5 and 6). The best 200 students of all grades qualify for (3) the final round of the federal state which takes place at a central place. And the 12 winners of those state finals are invited to the final round of all German states – but this round is only for students of grade 8 and higher.

4 An international competition which consists of 30 tasks (75 min); 5 to 6 % of the German participants receive prices.

"gifted". They were asked to take part in this study at the venue of the Olympiad and the school of the Kangaroo winners; the pupils did so voluntarily and have not worked with their video-partners beforehand.

To explore the pupils' problem solving behavior, their processes were videotaped. To ensure uninfluenced problem solving attempts, the pupils worked without interruptions or hints from the researchers. For the same reason the pupils were not trained to think-aloud or interrupted by interview questions; instead, they were asked to work in pairs to enable an insight into their thoughts through their natural communication. Three problems were selected for the comparison (see Figure 1).

METHODOLOGY

To analyze the problem solving processes as well as the products (everything that had been written down or sketched during those processes) of both groups of pupils, a mixed methods design has been chosen. This allows for detailed analyses of singular processes as well as an overview of all the data.

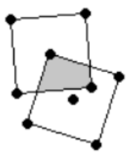
Product Coding: The pupils' products were graded in four categories of success: (1) *No access*, when they showed no signs of understanding the task properly or did not work on it meaningfully. (2) *Basic access*, when the pupils mainly understood the problem and showed basic approach. (3) *Advanced access*, when they understood the problem properly and solved it for the most part. And (4) *full access*, when the pupils solved the task properly and presented appropriate reasons, if necessary.

This grading system was customized for each task with examples for each category. Then, all the products were rated independently by the author and research assistants. After calculating Cohen's kappa ($k > 0.85$ for each task), the few products with differing ratings were discussed and recoded, reaching consensus every time.

Process Coding – Heuristics: Occurrences of heuristic techniques (like *drawing a figure* or *examining special cases*) were coded using a manual that was developed for analyzing videotaped problem solving processes (see Table 1); that development was based on empirical processes as well as on related research literature (Koichu et al., 2007, being the most noteworthy influence; see Rott, 2012, for details). The coding procedure is a sort of qualitative content analysis (cf. Mayring, 2000) which helps ensuring its reliability and objectivity and makes it suitable for qualitative as well as quantitative analyses.

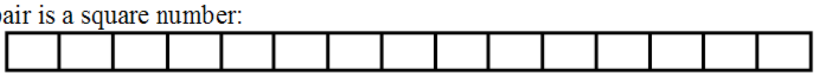
All videos were coded independently by several researchers, who first identified points of time in the processes where heuristics were used and then characterized the heuristics afterwards. In accordance with the TIMSS 1999 video study (cf. Jacobs et al., 2003, p. 103 f.), the "percentage of agreement" approach

Beverage Coasters
The two pictured squares depict coasters. They are placed so, that the corner of one coaster lies in the center of the other.



Examine the size of the area covered by **both** coasters.
[Idea: Schoenfeld (1985, p. 77): *Mathematical Problem Solving*. Orlando, Florida, Acad. Press.]

Marco's Number Series
Marco wants to arrange the numbers from 1 to 15 into the caskets so that the sum of every adjoining pair is a square number:



For instance, if there are the numbers 10, 6, 3 in three consecutive caskets, the 6 adds up to a square number with its left (10+6=16) and its right neighbor (6+3=9).
How could Marco fill-up his 15 caskets?

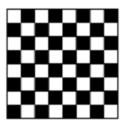
Squares on a Chessboard
Peter loves playing chess. He likes playing chess so much that he keeps thinking about it even when he isn't playing. Recently he asked himself how many squares there are on a chessboard. Try to answer Peter's question!



[Idea: Mason, Burton, & Stacey (2010, p. 17): *Thinking Mathematically*. Dorchester, Pearson, 2. ed.]

Figure 1: The three problems selected for the study

Code	Description	Examples
Drawing a figure	Drawing a figure, a graph, or a diagram.	**Coasters**: a drawing of possible positions of the two squares. **Number Series**: drawing a diagram of numbers with possible neighbors.
Auxiliary elements	Introducing auxiliary elements like auxiliary lines or additional variables.	**Coasters**: drawing auxiliary lines to indicate area. **Chessboard**: drawing borders of squares to illustrate their size or count them.
Special cases	Assigning special values (like 0 or 1) to algebraic problems or examining special positions in geometric problems.	**Coasters**: positions of the two squares which make it evident that the marked area amounts to one fourth of a square.
Mental flexibility	"Thinking outside the box"; special ideas and activities that are not captured by other heuristic categories	**Coasters**: (mental) rotation of the squares. **Number Series**: flexible way of adding numbers to both sides of the series. **Chessboard**: easily identifying the possible overlap of squares bigger than 1x1.

Table 1: An extract of the heuristics coding manual

(Bakeman & Gottman, 1997, p. 59)[5] was used to compute the interrater-reliability of randomly chosen videos (40 % of the processes). More than $P_A = 0.7$ for identifying points of time in the videos with heuristics and more than $P_A = 0.85$ for characterizing the heuristics was achieved. After calculating the reliability, all differing codes were analyzed and recoding consensually (100 % of the processes).

Pupils' products were coded individually with the result that in 6 of the 55 processes discussed here the two members of a pair obtained results with differing product ratings. To manage the data, for each pair the better result was chosen to further work with. The heuristics in the pupils' processes have also been coded individually. The numbers given here represent the number of different heuristics noticed for each pair; for example, when one member of a pair drew a figure while the other one didn't do so, this heuristic was counted for the pair.[6]

RESULTS

Quantitative results

The evaluation presented here starts quantitatively by comparing some statistical results regarding the product and process codings of both groups. Looking at the novice group (i.e., the regular, non-gifted pupils), the results are distributed widely among the four product categories in all three problems indicating no ground or ceiling effects. As expected, the pupil experts are significantly more successful ($c^2 = 14.54$; $p < 0.001$), scoring exclusively in categories 3 or 4.

For the novices, the number of coded heuristics is related to the success in solving the problems with mean scores of 1–3 heuristics in less and 3–5 heuristics in more successful processes (see Table 2 for details). There are significant Spearman rank-order correlations[7] for the Coasters ($r_s = 0.69$; $p < 0.01$), the Number Series ($r_s = 0.78$; $p < 0.001$), and the Chessboard ($r_s = 0.99$; $p < 0.05$) problems as well as for all three problems ($r_s = 0.72$; $p < 0.001$) combined. This finding is in accordance with research on the topic and the values mostly match the correlations reported by Komorek and colleagues (2007); this result meets the expectations as the use of heuristics should be helpful in solving problems.

However, there are successful processes with only one or two heuristics as there are unsuccessful ones with three or more. Some pairs picked a heuristic and used it to solve the problem outright; on the other hand, heuristics did not help every time. As expected, there is no straight "the-more-the-better" rule for the use of heuristics.

For the pupil experts, there is no such correlation between the number of heuristic techniques and suc-

5 Chance-corrected measures like Cohen's kappa are not suitable for this calculation, as there is no model to calculate the agreement by chance for a random number of heuristics distributed randomly over the course of the process.

6 Please note that in previous publications from the MALU data pool (e.g., Rott, 2012), the individually coded results have been reported. This time, the pair data is reported, therefore the numbers do not match those from previous articles.

7 As the product categories yield only ordinally scaled data, no Pearson correlation coefficient was calculated. The web-tool by R. Lowry (http://vassarstats.net/corr_rank.html) also provides a way to calculate the significance level for n < 10.

		Beverage Coasters		Marco's Number Series		Squares on a Chessboard	
		heu	count (%)	heu	count (%)	heu	count (%)
NOVICE	$\bar{x}_{cat1}$	2.00	6 (37.5)	0.33	3 (18.8)	0.00	5 (55.6)
	$\bar{x}_{cat2}$	3.80	5 (31.3)	1.00	3 (18.8)	2.00	2 (22.2)
	$\bar{x}_{cat3}$	5.33	3 (18.8)	3.33	6 (37.5)	3.50	2 (22.2)
	$\bar{x}_{cat4}$	5.00	2 (12.5)	4.00	4 (25.0)	---	0 (0.0)
EXPERT		heu	count (%)	heu	count (%)	heu	count (%)
	cat. 1/2	---	0 (0.0)	---	0 (0.0)	---	0 (0.0)
	$\bar{x}_{cat3}$	3.00	4 (80.0)	---	0 (0.0)	2.00	1 (25.0)
	$\bar{x}_{cat4}$	3.00	1 (20.0)	2.40	5 (100.0)	2.67	3 (75.0)

Table 2: Results of the heuristic coding for the pupil novices and experts

cess (r_s = -0.06; p = 0.84), but this can be explained by ceiling effects. Surprisingly, opposed to the vague "the-more-the-better" rule, the experts use significantly *less* heuristics compared to equally successful novices (i.e., pairs that reached product categories 3 or 4) (t = 2.73; p = 0.01).

Table 2 summarizes some statistical data of both groups. Column "count (%)" shows the number of pairs for each of the four product categories. Column "heu" shows the mean numbers of heuristics coded in the processes for each product category. The experts use less heuristics for each problem in the product categories 3 and 4.

Qualitative results

To further explore this surprising result – better problem solvers use less heuristics – the processes are analyzed qualitatively in the following paragraphs. Coded heuristic actions are indicated with *italics*.

The first (abbreviated and smoothed) example deals with the Coasters problem. After reading the problem formulation, the novices Hannelore and Lucy start to *measure* the length of the sides of the squares to somehow calculate the requested area; Hannelore also *introduces notations* to points in the given figure. They soon notice that their first approach does not work and start to question whether the squares could be arranged in another way. Lucy then *draws figures*, among them a *special case* in which the size of the area is easily identified (see Figure 2). They return to the given figure and start adding *auxiliary lines* to indicate a *decomposition* (see Figure 2). Lucy notices that she could "cut off" a triangle and add it at the other side to regain the special case. She concludes that the area is always as big as in the special case. They then do not write down "a fourth of a square" but calculate the size of the requested area. Overall, they worked nearly 12 minutes on this problem.

Bernd and Tobi, two of the pupil experts, worked on this problem for 2 minutes. After reading, Bernd says: "Wait, this is exactly one fourth. Because you can push it over there, so that you get exactly four parts." (*mental flexibility*) Tobi quickly agrees and they request the next problem without further justifying their solution. Bernd's recognition can be interpreted as Consideration of Aspects within the framework of intellectual flexibility, because he "recognize[s] the correlation of facts and [is] easily able to vary them." (Bruder, 2003, p. 17)

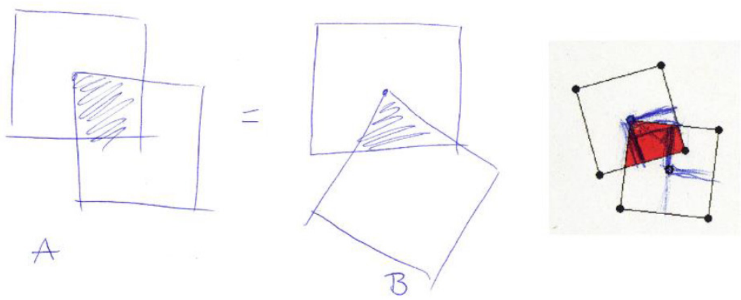


Figure 2: Lucy's figures working on the Coasters problem

The second comparison of novice and expert processes deals with Marco's Number Series. It takes the novices Birk and Janus more than 30 minutes to solve this problem. They start with "1, 3, 6, 10, 15" and are stuck, because there is no number left to add to 15 (they try

21 but reject this idea quickly). They start new rows with different numbers, always adding numbers to the right end until they get stuck and start anew. To keep track of the numbers they had already used, they keep a list of all numbers from 1 to 15 to cross out (*tool of systematization*). In this period, they occasionally use *backtracking*, i.e. deleting the last number(s) to continue with a different number instead of starting a new row. After more than 20 minutes, Birk introduces a new idea; he *creates a table* with all possible combinations of two numbers smaller than 16 adding up to a square number. This way, he realizes that the numbers 8 and 9 only have one possible neighbor each and have to start and end the row (*looking for patterns*). Shortly after this realization, they solve the problem.

It took the experts Robert and Lasse about 5 minutes to solve this problem. They immediately start with a list of numbers to cross out (*tool of systematization*) and begin their first row with the given example, "3, 6, 10". Instead of only adding numbers to the right, they work on both sides of the row (*mental flexibility*). To the right, they add "15, 1, 8". Finding no neighbor for the "8", they do not restart, but complete the row on the left side: "13", "12", "4", "5", "11", "14", "2", "7" and "9". Within the framework of intellectual flexibility, this idea can be interpreted as Change of Aspects, because "[b]y intuition they consider different aspects of the problem which avoids or overcomes getting stuck." (Bruder, 2003, p. 17)

Of course, these two examples are more obvious than the majority of the processes; they have been selected to illustrate an argument. However, the appearance of *mental flexibility* seems to be a distinguishing factor between novice and expert processes as this code appears significantly more often in the experts' processes: overall, mental flexibility appears in 15 of 43 novice processes compared to 10 of 14 expert processes ($c^2 = 5.73$; $p = 0.017$); this trend continues at the level of individual problems (Coasters: 8/16 compared to 3/5; Number Series: 6/16 compared to 4/5; Chessboard: 1/9 compared to 3/4).

The experts need less heuristics because of their mental flexibility. In other words, the novices that are not that flexible need more heuristics (and more time) to get similar ideas. This finding supports the claim of Bruder and Collet (2011) that a lack of intellectual flexibility can be compensated by the use of heuristics. For example, not being able to imaginary rotate the squares in the Coasters problem, most of the novices draw figures of squares in different positions.

DISCUSSION

The quantitative analysis of the regular pupils' problem solving processes showed a significant moderate to high correlation between the number of heuristics in those processes and the pupils' success. This result is in accordance with the literature as a vague "the-more-the-better" rule according to the number of heuristics has been reported many times. Surprisingly, this result does not apply to the group of gifted pupils (successful participants of mathematical competitions, i.e., "experts") whose processes have also been analyzed. These pupils have been more successful than the regular ones (as expected) but used significantly less heuristics than equally successful pupils of the first group. A qualitative comparison of the processes of both groups revealed an explanation for this finding: the experts' processes contained a significantly higher number of actions coded as "mental flexibility" than those of the novices (regular pupils). This finding can be explained by the theory of Bruder and Collet (2011). The lack of intellectual flexibility of the regular students (compared to the experts) can at least partly be compensated by the use of heuristics.

This has implications for practicing and teaching problem solving. Of course, intuitive problem solvers have an advantage working on problems as "the active intuition might be the most important device for discoveries, e.g. the sudden realization of analogies can only be thought of as an intuitive event." (Winter, 1989, p. 177, translated by the author) But not-so-intuitive problem solvers might overcome their disadvantage by learning and practicing heuristic techniques.

Of course, there are limitations to this study: Firstly, the group sizes are quite small; especially the group of the pupil experts consists of only ten pupils. A bigger number of both regular and gifted pupils would be desirable to see if the observed patterns can be confirmed. Secondly, the pupils have worked in pairs to enable access to their thoughts through their natural communication. This might have influenced their problem solving behavior and it might be problematic to generalize the findings of this study to individual problem solving behavior of regular and gifted pupils.

Further studies need to evaluate whether the actions of “mental flexibility” are a genuine part of gifted pupils’ problem solving behavior or whether being “mentally flexible is a learned (and thus learnable) ability these pupils picked up when participating in and training for mathematical competitions. It might be that the actions coded as “mental flexibility” are a combination of heuristics which are performed mostly cognitive and so elaborate that they are unidentifiable for the raters observing the problem solving processes of the pupil experts.

It would be interesting to see whether a follow up study with older students might provide a clearer distinction between regular and gifted students and similar results.

Designing tasks for mathematically talented students

Maike Schindler[1] and Julia Joklitschke[2]

1 Örebro universitet, Institutionen för naturvetenskap och teknik, Örebro, Sweden, maike.schindler@oru.se
2 Ruhr-Universität Bochum, Bochum, Germany

For the Design Research project presented, a learning environment for mathematically talented and interested 7th-grade students was investigated. The results show that the subject matter of graph theory offers both opportunities and means for students to develop their abilities. The data analysis showed likewise how the tasks might be modified in order to impose on their potential and thereby foster students' abilities of a formalized perception and pervasion of mathematical information and of generalization.

Keywords: Talented students, Design Research, RME, task design, graph theory.

INTRODUCTION

Mathematical potential and talent is one of the topics in mathematics education research increasingly attracting attention (Leikin, Karp, Novotna, & Singe, 2013) – with good reason. Not only since PISA and TIMSS – which have impressively revealed the heterogeneity of students within countries and even within single school types – the huge variety of students' abilities is well-known. However, there is only a small number of investigations that show how high-achievers can be supported in order to develop their potential (cf., e.g., Kießwetter & Rehlich, 2005). In the context of mathematics education research, there are certain findings regarding the abilities and characteristics of mathematically talented students (e.g., Krutetskii, 1976). These constitute a stepping stone for the investigation at hand: On the basis of the existing results, a Design Research project (cf. Gravemeijer & Bakker, 2006, p. 1) was conducted in order to develop and refine a learning arrangement for a group of mathematically talented and interested students and to assess, for a concrete subject matter – namely graph coloring –, how mathematically talented students can be challenged and, at the same time, supported in their specific abilities. Therefore it was one main goal to get insights into the abilities and possible difficulties of the students, which are being focused in this paper.

THEORETICAL BACKGROUND

Mathematically talented students and their abilities

One of the most important investigations in the field of abilities of mathematically talented students was conducted by Krutetskii (1976). He found four components being constitutive for mathematical abilities during school age: *Obtaining mathematical information*, i.e. "the ability for formalized perception of mathematical material, for grasping the formal structure of a problem" (Krutetskii, 1976, p. 350); *Processing mathematical information*, which comprises, among others, "the ability for rapid and broad generalization of mathematical objects, relations, and operations" (Krutetskii, 1976, p. 350); *Retaining mathematical information*, meaning memorizing mathematical approaches etc.; and a *General synthetic component*, connecting and interrelating all other components and forming a mathematical cast of mind. Mathematically talented students can be characterized by possessing these abilities to a great extent. Therefore Krutetskii's categories should be considered when learning environments and tasks for these students are being designed.

In the investigation presented, the focus was – on the one hand – on the students' ability to *mathematize* situations and – on the other hand – on their ability to *generalize*, which means being able to (a) recognize similar situations and (b) handle the generalized solution in these situations (Krutetskii, 1976, p. 237). It was investigated in how far the students were able to mathematize and generalize when handling the tasks of the developed learning environment.

Task design and realistic mathematics education

For refining and (re-)designing our learning environment, we focused especially on students' abilities to *mathematize* and *generalize* (see above). In our project, research was not supposed to be separated from a practical perspective, on the contrary: research and design were closely interwoven (Gravemeijer & Bakker, 2006). The Design Research alignment meant a focus on *task design*, which is of significant importance in mathematics education (Drijvers, Boon, Doorman, Bokhove, & Tacoma, 2013). However, the terms *task* and *task design* vary widely (Watson et al., 2013). The aim of our investigation was to develop and refine *tasks* in their meaning of being "what students are asked to do. Then 'activity' means the subsequent mathematical (and other) motives that emerge from interaction between student, teacher, resources, environment, and so on around the task" (Watson et al., 2013, p. 11). In our case, *task design* means the design of tasks for the above-mentioned purpose as well as possible oral impulses of the teacher and corresponding material.

The design of the learning environment within our investigation is being guided by the domain-specific instruction theory of *Realistic Mathematics Education (RME)*. RME "itself is the result of a long history of design research in the Netherlands" (Gravemeijer & Bakker, 2006, p. 2).

"According to RME, mathematics should be seen as an activity (Freudenthal, 1973), and students, rather than being receivers of ready-made mathematics, should be active participants in the educational process, in which they develop mathematical tools and insights by themselves" (Drijvers et al., 2013, p. 56).

Mathematical learning should – according to RME – originate from problem situations in realistic contexts, which do not necessarily need to be from the real world (Van den Heuvel-Panhuizen, 2005, p. 2). Based on their activity within these situations, students use their individual concepts in order to handle situations and therefore extend them. In our project, students were supposed to handle the presented tasks and hence the mathematical information (cf. Krutetskii, 1976, see above), and thereby apply their mathematical concepts, develop them and generalize them for being able to apply them in different situations (Krutetskii, 1976).

Graph theory as subject matter for mathematically talented students

The application of graph theory as a subject matter for talented students offers different advantages. Most of these are connected to the large applicability and therefore its huge potential for fostering students' creativity (cf. Leuders, 2007).

In graph theory, the notion of *graph* is fundamental: "A graph G consists of a finite set V, whose members are called vertices, and a set E of 2-subsets of V, whose members are called edges" (Biggs, 1985, p. 158; partially highlighted in the original). As graphs represent networking structures, they can be visualized by points and connecting lines between two points. Especially *graph coloring* is a central scope of application in the focus of our study. "A vertex-colouring of a graph $G = (V, E)$ is a function $c: V \to \mathbb{N}$ with the property that $c(x) \neq c(y)$ whenever $\{x, y\} \in E$. The chromatic number $\chi(G)$ is defined to be the least integer k for which there is a vertex-colouring of G using k colours" (Biggs, 1985, p. 172). Due to graph coloring, we can distinguish adjacent vertices and, thereby, create disjoint partitions of vertex-sets.

Research questions

In this Design Research project, the following questions were at the core of the research interests (based on Krutetskii, 1976). These are:

1) To what extent are the talented students able to *mathematize* the realistic problem situations in the given tasks?

2) In how far are they able to recognize the similarity of different situations and *generalize* their solutions?

On the basis of these questions, it is considered how the task design can be refined in order to optimize the learning processes.

DESIGN OF THE INVESTIGATION

Designing the tasks

We developed tasks, according to two kinds of problem situations (cf. Joklitschke, 2014). The first kind of problem situations is rather abstract. Here, a concrete problem situation may be the assignment of persons to different groups. Persons can be represented by vertices – and the do-not-like-relation by edges. If the vertices are being colored, the colors signify the emerging groups. The number of colors then represents the number of groups. A second field of application addresses problem situations with rather geometrical visualizations, for instance the coloring of maps. Here, the dual graph is needed, which includes the information about adjacent areas: every area is represented by a vertex, and adjacent areas are visualized by an edge (cf. Leuders, 2007, p. 141). By finding the chromatic number, we get to know how many colors are needed.

Our tasks comprised certain subtasks and were supposed to serve for a 90 minutes lesson. Two of them are being focused in this paper. As we assumed problem situations with a geometrical representation to be easier to grasp for the students (see Bronner, 2014), the first task was a map task. Students were supposed to find the minimum number of colors for coloring the 16 federal states of Germany (see Leuders, 2007, pp. 132ff, Figure 1). The second task, then, comprised a problem situation without geometrical visualization (cf. Leuders, 2007, pp. 133f). We chose the context of the soccer world championship with national supporters who are – due to rivalries – supposed to be accommodated in different places (Figure 1).

Implementation and data collection at school

The developed tasks were investigated in a group of eleven 7th-graders – aged twelve or 13 – at a German secondary school. This group had already been active for two years and was supposed to give mathematical talented and interested students the opportunity to enhance their abilities. The selection of the students for this course depended on their performance in mathematics (according to the teachers' assessment) and their motivation to participate. Since this course was already well-established, all students had experience in the field of graph theory: They had worked on realistic problem situations (shortest path problems, spanning trees and Euler graphs, developing algorithms) beforehand. The students were used to work in small groups on open problems and to generate the mathematical contents by themselves.

In this investigation, the students worked in groups of four (or three) as they were used to. The group work took 90 minutes. The group work of all groups was videotaped. The analysis focused on one "focus group" because here, the students communicated a lot so that the analysis could be undertaken on a profound empirical base. The videos were transcribed.

The four students of this focus group were additionally interviewed in semi-structured partner post interviews. Here, every group got the same tasks and questions. The students were interviewed in pairs of two as this was expected to foster their communication and give them safety. The interviews took place two weeks after the group work. The interview guide comprised questions on the approaches that the students had worked on before as well as two new, but analogous problem situations (one problem regarding map coloring and one problem regarding partitioning). The

Task 1: Color selection

GeoPaint Inc. wants to include a colored map of Germany with its federal states in their assortment.

a) What should the company consider? Note the necessary criteria and try to color the map.

b) As the company has to order each color separately, the map gets cheaper when they use as few colors as possible. How many colors are needed?

c) In order to develop a computer program that helps designing the colored map, GeoPaint has to create an illustration that represents the neighborhood of the federal states. How could such an illustration look like?

Task 2: A Peaceful World Championship

At the soccer world championship 2014, many European teams compete. But the national supporters partly do not stand well with each other. Therefore, fans with a special rivalry shall be accommodated in different locations. Now, the organizing committee has to find a suitable allocation of the national supporters. These are the conditions:

- German supporters do not stand well with fans from the Netherlands and England.
- ...

How many locations do the organizers need to ensure a peaceful meeting? How can you represent the problem adequately?

Figure 1: "Map coloring task" and "Soccer world championship task"

semi-structured interviews – which allowed not only to inquire their approaches to the same tasks, but also to go into detail to see certain differences between the pairs, especially in their inferential reasoning – took 30 minutes each. The students were supposed to comment on their approaches by thinking aloud. The interviews were videotaped and transcribed afterwards. For the data analysis, both, the transcripts of the group work and of the interviews, were taken into account.

ANALYTICAL FRAMEWORK

For investigating students' individual approaches, we used a framework that arises from a philosophical perspective, founding on ideas of Kant, Frege, Wittgenstein, Heidegger, and Brandom's (1994) theory of *semantic Inferentialism*. Based on these philosophical notions, a theoretical and analytical framework was developed for mathematics education (e.g., Schindler, 2014), whose applicability has been shown for different subject matters (e.g., Schindler & Hußmann, 2013). The philosophical background signifies that individual approaches and students' concepts can only be understood in their use, i.e. in reasoning processes. Therefore, the data analysis is being conducted on the basis of three crucial analytical elements, which are: individual commitments, inferences and focuses (see below).

The concept of *language game* plays an important part in the theoretical background. For our analysis it is important to analyze the use of concepts in these language games, since concepts and their meaning can – in this holistic perspective – only be understood by means of the role that they play here: "grasping a concept involves mastering the properties of inferential moves that connect it to many other concepts" (Brandom, 1994, p. 89). The basic elements in this framework are propositions that individuals hold to be true and explicate, like for example "Four colors are enough to color the map". These individual *commitments* constitute the building blocks in our data analysis, which is carried out turn-by-turn on the basis of the transcripts at hand.

Furthermore, the reasoning process itself is being analyzed, as it is crucial for reconstructing students' understanding. *Inferences* embody the reasoning process, as they constitute the relation between commitments if a student entitles a commitment with another commitment, like e.g. "Five colors are one too many, thus four colors are enough to color a planar graph". For our data analysis, it is important that these inferences, as well as the commitments, do not have to be formally correct but to be held as true by the individual student. Besides commitments and inferences, *focuses* – as individual categories that are used to pick up, select and handle the information at hand – are being reconstructed in our data analysis. Students can – consciously or not – utilize e.g. concepts, properties, or other entities as categories, such as the number of colors and partitions. Via the analysis of these three elements (students' focuses, the commitments and inferences), we analyzed how students mathematize the realistic situations and in how far they are able to generalize (see results).

RESULTS

An insight into students' mathematization process

In general, the analysis revealed that students showed an enormous performance handling the maps task and mathematize the information at hand. First, they focused on painting the map with colored pencils. While doing so, they did not yet gain access to the formal structure of the problem and some stuck to the real-world conditions of the problem situation. For example, they committed to "The company can blend colors, then they do not have to buy so many of them". During their work, their focus became more and more structure-oriented. It was only when they started with the task to support a computer program (see task 1c, Figure 1), that they focused on graphs for the first time.

Sasha:	Well, we have to do this with a graph, right?
Tim:	Yes. I already worked on two or three graphs, but they do not yet work out.
Klara:	(reading the task out loud) The neighbors of federal states...
Sasha:	Yes, let's see.
Klara:	So, simply a graph?
Sasha:	Yes.

In this excerpt, Sasha at once commits that they can focus on a graph. Tim agrees and therefore acknowledges Sasha's commitment. Klara seems to be in doubt if this focus is adequate, as she asks "Simply a graph?".

But after Sasha's conclusive confirmation, everyone of them starts drawing a graph (focus: graph).

In this dialogue, it is interesting that all students immediately focused on an *edge* representing a neighborhood, which is adequate from a mathematical perspective, as it implies constructing the dual graph (Figure 2). As Leuders (2007, p. 140) shows, it is also possible to choose the borders to represent the edges and the vertices to represent the "corners" of three countries bordering. But the students seemed to immediately realize that "it is not of interest to know the exact shape of country's frontiers [...], but only to know who is adjacent to whom" (Leuders, 2007, p. 138, translated by M.S./J.J.). During their prolonged activity, in which they constructed the dual graph, they focused on the numbering of the countries, i.e. vertices, in order to keep track of the neighborhoods and to communicate about them more easily. The focuses on (dual) graphs, on numbering, on edges representing the neighborhood reveals that the mathematization process was successful in the first task.

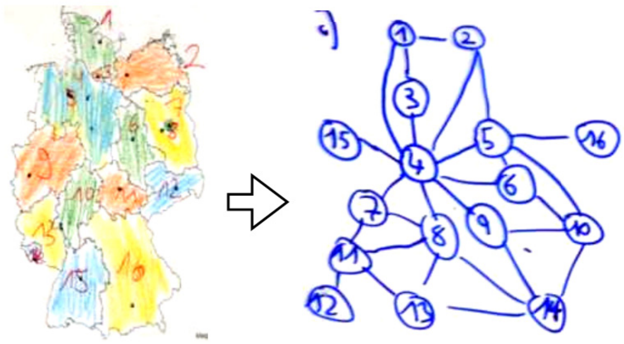

Figure 2: Students' drawings

Similarity recognition and generalization

The second task on the soccer world championship and national supporters represented more of a challenge for the students. Here, they had much more trouble to capture the formal structure of the problem situation and to recognize the similarity to the first task. When dealing with the task, students proceeded intuitively and tried splitting the supporters into distinct groups.

Alex: Well, we can definitely put Russia, Greece and Switzerland together.
Tim: I suggested the same.
Alex: Because they do not oppose each other.
Tim: With whom does Germany *not* get on well? Germany does not get on well with the Netherlands and England, but they get on well with Spain and France, don't they? Yes, Germany does not get along with the Netherlands. Therefore, I would put Germany together with Spain and France.

In this heuristic approach, the students' common focus is on dividing the sets of supporters into groups. In mathematical terms, it is the concept of partition, and the idea is to find an optimal (i.e. smallest possible) partition. The students justify their partitioning via harmonies or compatibilities.

In this excerpt of the group work, the students focused on splitting the sets of supporters (i.e. building partitions) and on the number of locations needed. They did not mention that the formal structure of this problem is similar to the first one; that the sets of supporters can be depicted – just like the countries – as vertices and the rivalries as edges – just like the borders. They did not seem to realize that both problem situations are about objects and their (binary) relations to each other and that the mathematization is obvious (cf. Leuders, 2007, p. 138). On the contrary, the focuses of the students in our investigation remained in the real-world situation in the second task. When the teacher tried to help students focusing on graphs, they disliked this focus and committed for instance to "But that would only be the same that we did with the other approach" or "That only brings the same result that we can find otherwise". They did not see a reason for focusing on graphs.

Then, in an additional, further task, students were confronted with a problem situation that dealt with four groups of national supporters, which each have a rivalry against each other. Here, students were again *explicitly* asked if it is possible to depict this with a graph and if there are edges, which necessarily have to cross over each other.

Tim: Well, I have drawn one without crossings. Where one can see that everyone hates everyone. (...)
Sasha: Huh? How do you want to draw that with a *graph*?
Tim: Four points and connect them one to each other. (...)

Sasha: But how do you want to draw *rivalry* with a graph?
Tim: Well, because if they are connected then they do not like each other. And here, everyone is connected to everyone.
Sasha: But this is actually the other way round!
Alex: Yes, I would also say that...
Tim: Yes, okay. So, simply four points. That also works. (...)
Sasha: (while writing, talking to himself) Mhm, but that's right.

Here, we see that the students acknowledge the focus on graphs. Tim directly seems to generalize – probably unconsciously – the idea of *dissociation represented as edges* from the first task (boundaries as edges) to the second task (rivalry as edges). Sasha and Alexander, however, are obviously not convinced: Sasha asks for reasons and explanations, but Tim's reasoning is not convincing for them. Instead, the group focuses on *compatibility as edges* – and not on the similarities between the two kinds of dissociation and of the two problem situations. When writing his findings down, Sasha then acknowledges Tim's focus: Afterwards, he continues drawing dissociation as edges – but this does not become subject of discussion anymore. Sasha's final commitment as well as his drawing might indicate a generalization process.

In the post interview, however, neither Tim nor Sasha saw the similarities between the geometrical and the abstract problem situation. The frequent changes of focuses as well as the low level of inferential reasoning during the lecture series go hand in hand with the lacking generalization. However, an impulse of the interviewer encouraged the similarity recognition in one case (Sasha). This was initiated by the interviewer's explicit focus on similarities between the maps problem and the problems with the football supporters.

Interviewer: Are there any similarities between the two problem situations?
Sasha: (Looking straight ahead, then looking out of the window, beginning to smile and looking back to the interviewer) Yes. Because here (pointing onto the map), adjacent countries were supposed to have different colors. And here, it is effectively the same. Because, then the colors are the locations, and the locations just differ from each other.

The interviewer's question seems to foster the student's similarity recognition: After thinking about the question, he affirms the similarity. The inferences that he makes underpin that he understands the reason: He is able to see the functional similarity of countries and locations and commits to "The colors are then the locations". This indicates that students *are* able to focus on graphs and on coloring in problem situations without geometrical visualization, but this needs specific support.

Consequences for the task design

Task 1: One of the prominent results revealing from the above-mentioned data analysis is that the mathematization process was fostered by the sub-task to think of an illustration for a computer program. Here, students were able to focus on graphs easily. This was very useful for systematic approaches in which the students focused more structurally and systematically and thus fostered the mathematization process. This indicated that this task does not need modifications in this regard.

Task 2: It was not easy for the talented students in our investigation to grasp the formal structure of a graph in problem situations, which do not have a geometrical visualization. On the one hand, this indicates that these tasks have a huge potential for talented students to exert themselves, because it was shown that these students can gather the mathematical structure when having the right focuses. On the other hand, the analysis reveals that the tasks and even the impulses of the teacher did not prompt the students to perceive the structure and to generalize their focuses and commitments from the geometrical problem situations. In order to foster these abilities in this context even more, the task has to be modified: There have to be more reflective aspects that make the students think of similarities. Possible impulses would be e.g. "Look for similarities of both problem situations. Is it possible to solve the second task with the same strategy that you used in task 1?". For generalization purposes, it seems to be important for the students to recognize the *focus on dissociation* in both kinds of problem situations. But without a profound inferential reasoning, even the right focus is not sufficient for students' similarity recognition and especially their generalization.

CONCLUSION

The overall aim of the empirical investigation at hand was to explore the students' approaches and abilities (esp. mathematization and generalization) for refining the design of a learning environment.

The results indicate that the students were able to perceive mathematical information and the structure of problem situations formally (cf. Krutetskii, 1976). But this ability strongly depended on the tasks presented. It was manifested as highly-developed in problem situations which had a geometrical visualization, whereas in problem situations without a direct geometrical visualization, students were less able to see the mathematical structure. In the consequence, it was not easy for the students to generalize their focuses from a problem situation with a geometrical visualization to one without the latter. Our findings indicate that Krutetskii's framework constitutes a profound basis for developing tasks for talented students: On the one hand, the students showed the abilities to a certain extent, on the other hand, it was shown how these abilities can be fostered even more.

The results of the investigation revealed many aspects which can be used for optimizing the tasks and support students in their specific abilities: for instance, giving adequate impulses that lead students to focus on graphs; and fostering a purposeful and conscious reflection about similarities of problem situations much more explicitly.

Problem posing: Students between driven creativity and mathematical failure

Florence Mihaela Singer[1], Ildikó Pelczer[2] and Cristian Voica[3]

1 University of Ploiești, Ploiești, Romania, mikisinger@gmail.com

2 Concordia University, Montreal, Canada

3 University of Bucharest, Bucharest, Romania

We explore behaviors of high achievers 10 to 16 years old during a problem modification process by looking at the ways students vary the constraints of a given problem. We found that these children swing between low amplitude driven creativity and failure to pose mathematically consistent problems when it comes about understanding the deep structure of mathematical concepts and strategies.

Keywords: Problem posing, problem modification, constraints, mathematical creativity, endogenous and exogenous transformations.

INTRODUCTION

We exposed students from grades 4 to 10 to a problem posing context. We were interested in this case to see how mathematical creativity manifests in students and what is (if any) the relationship between their creative approaches and the quality of the mathematics problems they generate.

In general, in problem-posing contexts, students are stimulated to make observations, experiment through varying some parameters, and devise their own new problems (Singer, Ellerton, Cai, & Leung, 2013). In this paper, we accept that problem posing refers to the generation of (completely) new problems, and to the re-formulation/ modification of given problems (Silver, 1994). We specifically address here the context of problem modification.

Previous studies have shown that, in problem posing situations, mathematically able students tend to vary a single parameter in order to ensure the control over the relationships among all the elements of a posed problem, even when they make interesting generalizations. This tendency of small-step variations was interpreted as a student's need to keep as coherent and consistent as possible his/her proposals by controlling (sometimes unintentionally) the consequences of the proposed changes (Singer, 2012a; Voica & Singer, 2013). In a problem-modification study, Singer, Pelczer and Voica have shown that the capacity of a student to pose coherent and consistent changes of a problem and to understand the (mathematical) consequences of these changes proves student's capability for deep transfer creative approaches (Singer, Pelczer, & Voica, 2011). Therefore, this capability could predict mathematical creativity, which has been characterized as being different from general creativity (e.g., Piirto, 1999).

In describing mathematical creativity, we use a framework based on cognitive flexibility, which is characterized by: cognitive novelty, cognitive variety, and changes in cognitive framing (e.g., Voica & Singer, 2013). In a problem-modification context, we consider that a student proves cognitive flexibility when she or he poses different new problems starting from a given input (i.e. cognitive variety), generates new proposals that are far from the starting item (i.e. cognitive novelty), and is able to change his/her mental frame in solving problems or identifying/discovering new ones (i.e., change in cognitive framing).

In addition, these studies have shown that the more the student advances in the abstract dimension of a given problem, the more mathematically relevant are his/her newly obtained versions. It seems that the students who are cautious and minimally change the problem are in fact mathematically advanced students who show proper insights on some mathematical concepts that exceed their age level. Actually, they pay careful attention to controlling the values of the variables, as mathematicians usually do. These studies conclude that a feature of mathematical creativity, at least for the students involved in the research (10–16 years old), is a type of cognitive flexibility characterized not so much by novelty, but by incremental representational changes in cognitive frames (Singer, 2012b; Voica & Singer, 2013).

In the present study, we start from the assumption, suggested by previous experimental research (e.g., Voica & Singer, 2014), that problem posing (and its particular case – problem modification) is a useful context for identifying mathematical creativity, and we try to go further in determining correlations between students' mathematical creativity and the quality of their posed problems. Thus, we are trying to answer the question: What are the gains and the losses from the view of creativity, when students do mathematical problem posing?

METHODOLOGY

The sample of this study consists of students from grades 4 to 10 (10–16 years old), participants in a summer camp organized for the winners of a large-scale two-round competition (Kangaroo). The camp participants, representing the top 0.2% from a total of about 150 000 participants at the competition, are considered high achievers in mathematics. During this summer camp we launched a call for problems. The participants had to choose a problem from a list of three problems (given as reference points) and, after solving it, to pose three problems based on the starting reference problem: one simpler, one similar, and one more difficult. In addition, the students were supposed to write down the solutions of their posed problems and to explain how their proposals fit the requested criterion (simpler, similar, etc.). We used therefore a structured problem-posing situation (in the terminology of Stoyanova and Ellerton, 1996). Students had 3 days to formulate their answers. In all, 57 students submitted problems.

Each of the posed problems was evaluated by two independent evaluators who assessed it based on a set of criteria: correctness and completeness of the problem formulation and the proposed solution, originality of the text, and clarity of explanations. Based on this primary evaluation, we invited a few participants for interview. Among the selected students were those whose problems were highly ranked by the evaluators. We also invited for interview two students who posed problems considered with potential for further development. In all, 20 students were interviewed. The interviews were based on a general protocol concerning issues such as: What are the similarities/differences between the posed problem and the starting one? What other problems are possible to pose? What make you think to such approach?

The interviews were carried out with two students at a time, thus creating a context for interactions between the children. This helped us to reveal students' ideas through discussions with their peers (Vygotsky, 1978) and to get consistent feedback on their problem posing strategies and their level of mathematical understanding. The interviews were video recorded.

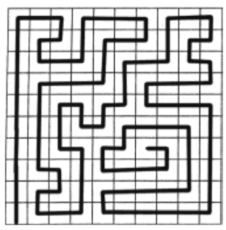
We focus the present paper on the problems generated by the students who have chosen the first problem in the given list (problem 1 below). Consequently, our sample consists of those 19 students (out of which 6 have participated in the interview sessions). The analysis that we do is a qualitative one, mainly based on students' written submissions. Because of the reduced dimension of this paper, we just present a holistic view on students' comments during the interviews to highlight our main conclusions.

CONTEXT

The starting problem

The following problem was initially given to students as a reference point: we will identify it as *the starting problem.*

Problem 1. The 10 × 10 grid is formed out of squares of 1dm. We glue a ribbon as shown in the image. What is the length of the ribbon?



A. 99 dm; B. 99.5 dm; C. 100 dm; D. 100.5 dm; E. 20 dm

We have chosen this problem from the Kangaroo contest to have statistical information on its degree of difficulty. In the competition, this problem was administered to a group of 5659 students from the 5th and the 6th grades. The Kangaroo contest takes place in two rounds and the participants have to answer 30 multiple-choice questions in 75 minutes; therefore,

	A	B	C	D	E	NA
Grade 5 (3278 participants)	10.2	18.5	37.2	8.9	7.7	17.5
Grade 6 (2381 participants)	10.4	25.1	33.9	7.7	7.0	15.8

Table 1: Frequencies of answers to the starting problem in the Kangaroo competition (Correct answer is B. NA stands for no-answer)

optimizing solution strategies is essential in obtaining a good score.

Statistical data about the performance of students participating in the Kangaroo contest show that they perceived the starting problem as difficult: this conclusion follows from the relatively low percentage of correct responses to this problem (see Table 1), the percentage of students that preferred not to answer this question, and the percentage of correct answers obtained by this cohort to other problems (around 75%). Even if we take together answers B and C (concluding that about half of the students had an insight concerning a strategy to optimize the solution to this problem), we can still conclude that the problem was perceived as difficult.

Components of a problem

To better understand the discussion that follows, we detail the components of the starting problem based on the methodology introduced by Singer and Voica (2013). In general, the text of a problem contains: a background theme, (numerical) data, operators (or operating schemes), constraints over the data and the operators, and constraints that involve at least one unknown value of a parameter (Singer & Voica, 2013). The background theme represents, briefly said, what is about in the problem. In our case, the background theme is represented by a grid and a trajectory marked on it. The background theme is characterized by one or more parameters: in our case, the parameter is the shape of the trajectory (of the ribbon). The data are (numerical or literal) values associated to these parameters: in the above problem, these are represented by the number of squares and their dimensions. The operating schemes are actions suggested by the text: here, these are the way of crossing, and the measurement of the trajectory. The constraints imposed on the data and the operators are restrictions that state the relations of the background theme with the data and the operating schemes. In the starting problem, some of the constraints are of *local* nature: for example, "the trajectory" unites the centers of the squares and crosses a square in one of the two modalities shown in Figure 1 (eventually rotated).

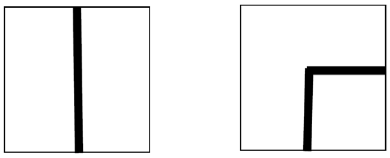


Figure 1: Local constraints for building the trajectory in problem 1

Other constraints are *global*, such as the filling condition – i.e. that the ribbon goes across each cell of the square. These constraints, in combination, allow a quick identification of the answer, since 99 out of 100 squares are crossed and the last one is only half marked (therefore, the correct result is 99.5). We believe that the difficulty of the problem comes from the fact that the solvers did not totally understand the local and the global constraints; usually, they try to perform sequential additions of the ribbon length, which can lead to miscalculations or to abandoning the problem because of the time limit crisis.

The starting problem contains two kinds of constraints: essential in-depth constraints that give the core-structure of the problem, and superficial constraints. The essential constraints manifest at both local and global levels: the global constraint refers to the grid coverage, which combined with the local algorithm (the trajectory crosses the squares in the midpoints of their sides following two different patterns, and there are no self-crossings) allows an optimal solution (as time is concerned). Superficial constraints refer to the dimension of the grid, the shape of the grid (including the base element of the grid), and to the particular path chosen within the grid.

Transformations

We classified the modifications made by the students when they developed a new problem in two categories: *exogenous* and *endogenous* transformations. The terms originate from the system theory, where endogenous transformations are transformations between models expressed in the same language, and exogenous ones are transformations between models expressed using different languages (Mens & Van Gorp, 2006). In problem modification (PM) situations, we consider that a student makes endogenous transformations when he/she uses the same types of operating

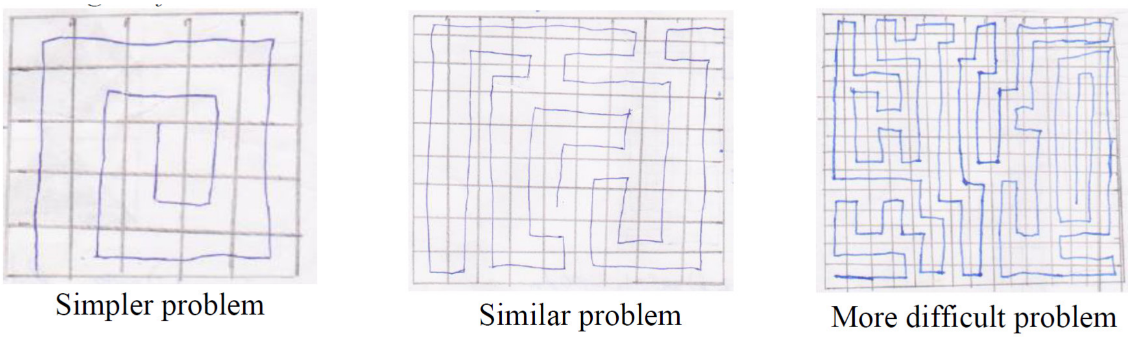

Figure 2: The drawings made by Victor (grade 4) in posing new problems

schemes and constraints as in the starting problem (i.e. makes a new mathematical problem using the same language - the same mathematical concepts as those of the starting problem); otherwise, we consider that the student makes an exogenous transformation. In other words: the endogenous transformation acts only on already present components in the starting problem, while an exogenous transformation will bring new components into the generated problem.

RESULTS

We present our analysis based on some illustrative examples.

Example 1. Victor (grade 4) proposed three problems based on the drawings contained in Figure 2. In all these problems, Victor formulated the same question: *What is the length of the ribbon?*

One can observe that Victor varies the dimensions and the shape of the trajectory. For the last problem (most difficult), Victor avoids two of the squares – therefore, he renounces to the complete coverage of the grid, but he keeps the same type of optimal strategy of solving. The transformations performed by Victor are endogenous: he poses a new problem using elements that exist in the starting problem.

Example 2. Doina (grade 8) based her posed problems on the patterns presented in Figure 3. She put the same requirements for all her problems: finding the length of the drawn broken line. Doina specifies in her problem texts the geometrical properties of the base cell (rhombus, in the first case; regular hexagon in the second; and equilateral triangle in the third). She is very careful in characterizing the local constraints; for example, in the last posed problem, she clarifies the fact that the ribbon crosses the centers of gravity of some of the triangles.

Overall, Doina kept both the local and global defining characteristics unchanged and modified only the layout and the basic element in the tessellation. The modifications took into account the unique association between each cell(s) and measure unit, the nature of the trajectory (no crossings) and the complete coverage of the grid, conditions that allow the optimal solution.

We can observe in this case cognitive flexibility in changing elements without changing the deep structure of the initial problem (solution). This case also illustrates endogenous transformations – since only the elements already present in the initial problem are manipulated.

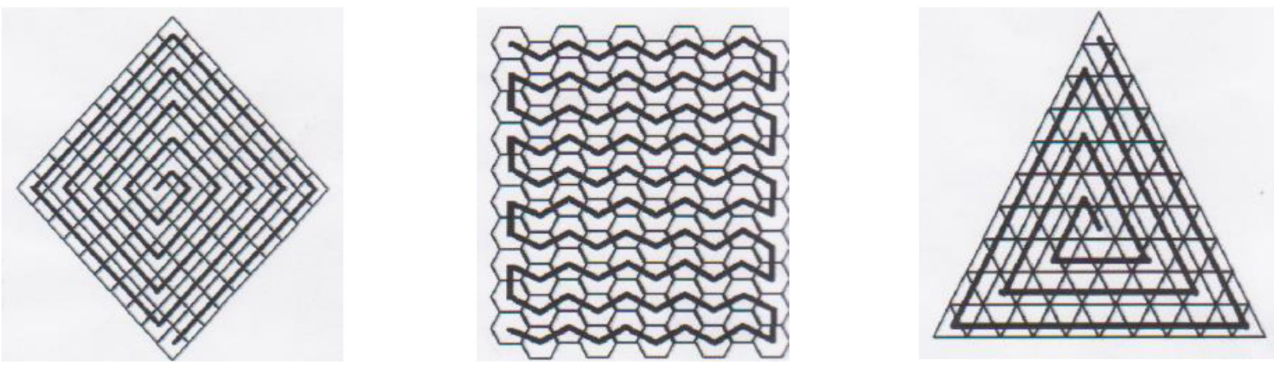

Figure 3: The drawings made by Doina (grade 8) in posing new problems

Example 3. The following problems were proposed by Silviu, a grade 9 student.

Simpler: Dan wants to cut out a shuttle from a textile covered by a square grid (Figure 4a). If the side of a square is 2, what is the remaining surface after the shuttle was cut out?

Similar: An ant crossed a piece of cake of an equilateral triangle shape with the side of 5cm. What is the length of the trajectory marked in the image (Figure 4b)?

More difficult (simplified phrasing): There are four animals competing on square-grid paths (Figure 4c); their speed is given in terms of relations between them. The question is on the order of arrival of the animals.

The "similar" problem has an exogenous modification on the global constraint. Although the student considered this proposal similar to the given problem, this is actually very different when its nature is considered: the only available strategy for solving is the counting of the line segments (two different kinds). Consequently, the student failed to use an optimized algorithm to solve this problem.

Silviu's simpler and more difficult problems suppose also exogenous transformations. By adding new elements, the requirements changed, and the difficulty remains to be judged based on the amount of calculations to perform. By an exogenous transformation, the new problems are much farther from the given one, but they become procedural, as global solving is not possible.

Example 4. The following problems were proposed by three students (Mircea, Andrei, and Nguyen, grade 5), who decided to work as a group.

Simpler: A monkey wants to reach bananas. In the 7 x 9 square below the route is indicated (Figure 5a). Knowing that the side of a square is 5m and the monkey crosses 19m in 5 minutes, find how long does it takes the monkey to reach the bananas.

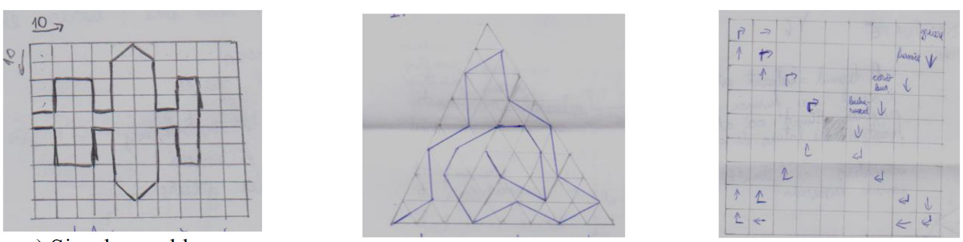
Similar: Ballerina lost her ribbon in the maze. The ribbon is represented in the square grid (Figure 5b). Knowing that the side of a small square is 3m, find the length of the ribbon.

More difficult: A maze is between the houses A and B. Jack wants to go from A to B, so he takes a string to indicate his way to go. On the 11 × 11 square grid below the Jack's travel is drawn (Figure 5c). Knowing that a square has a side of 1.2m, find the properties of the number that shows the length of the road.

In their proposals, the three students renounced to the local constraints (the similar and more difficult problems have cross-overs), but also to the global constraints (the trajectory doesn't fill in the grid). In addition, the problems contain a series of external elements meant to increase the degree of difficulty. For example, they requested to calculate the time needed for crossing the given path (simpler problem) or the fact that problem 3 contains a reference to an 11 × 11 grid, although the given image contains a 11 × 12 grid (consequently, the last column should be ignored).

DISCUSSION

The data reported above highlight two situations. Some of the students vary superficial constraints by making endogenous transformations. For example, Victor (example 1) modifies the size of the grid and the shape of the trajectory, while Doina (example 2) modifies the generator element of the grid. In these cases, the students strictly follow the starting prob-



a) Simpler problem b) Similar problem c) More difficult problem

Figure 5: The drawings made by Mircea, Andrei, and Nguyen for the posed problems

lem's structure and pose coherent and consistent problems that respect the nature of the given problem.

Some other students use their knowledge of advanced mathematical procedures and techniques to pose problems based on exogenous transformations. In these cases, the proposals are farther from the starting model, but at the expense of a lesser level of generalization. This is visible in the situations where students vary global constraints, as in the case of Silviu (example 3), or in the case of Mircea, Andrei, and Nguyen (example 4). In these cases, students introduce independent variables – that is, they perform exogenous transformations on the starting problem. In spite of their efforts to make their problems more difficult, they just increase the amount of procedural computations, but not the mathematical quality of the problem, measured by its mathematical consistency. Their interviews also revealed that they actually have limited understanding of the starting problem: this fact had an effect on their posed problems, which they were not able to solve using an optimal solution, but just making step-by-step procedural calculations.

Before getting to a final conclusion, we may consider that other factors could be at play in our analysis. The problems were posed for a problem-posing competition, and the students knew that the "value" of their problems would be judged. It might be that some students preferred to keep the structure of the starting problem, because it was already considered as being "valuable" (as it was a problem included into a real contest). Consequently, in appreciating the problems posed by students we need to consider their personal beliefs about what makes a good problem, as well as their ability to identify the problem structure and the mechanisms available for a controlled change of the problem elements. Thus, it is interesting to consider the nature of modifications at one-more finer detail.

Victor (example 1) has posed problems of identical nature to the given one, just by varying the size of the net. Even though in his solutions we saw that he was aware of the constraint allowing an optimal solution, attending only to the modification of the grid suggests that he has not yet developed efficient mechanisms for changing more elements. Such situation is understandable if we take into account that Victor is a 4 grader, therefore his experience with different shapes and grid structures may be very limited. In contrast, Doina (example 2) seems to master such mechanisms, while keeping close to the problem type might be a personal preference. Somehow, Doina simplifies the starting problem because the pattern she has chosen for the "broken line" in each of her three proposals allows immediate identification of the grid-filling property. This simplification allows variations in the cognitive frame generated by the initial problem while keeping intact the analogy with the deep features of the starting problem. These variations in cognitive framing give an indication of her mathematical creativity.

Silviu (example 3), and Mircea, Andrei, and Nguyen (example 4) change many more elements of the starting problem. Furthermore, we found during the interviews that these students participated in intensive training programs (with their school teachers and with their parents). Their experience from such training might suggest that good problems are those with many data, which require breaking the problem into several pieces, and, in overall, ask for more fluid procedural work.

These cases reveal an essential fact: the extent of which the new proposal reflects an understanding of the hard core of the given problem drives the quality of the newly posed issues. We further analyze the students' posed problems from this perspective. Beyond the students' beliefs about problems and competitions, a dilemma still stands. On the one hand, we have more creative approaches but at the expense of mathematical quality, on the other hand, the newly posed problems that reflect in-depth understanding are apparently less creative.

Some of the students who suggested changes of an exogenous type placed in their texts new mathematical concepts and usually provided traps to solvers. Although they seem to be more creative – when judged on the novelty dimension – they depart from a deep understanding of the starting problem structure. The problems they posed have a low degree of generality, and their difficulty is given by the solving procedure (overcoming traps intentionally included in the text and performing step-by-step calculations). The problems arising in our sample in this way proved weaker in terms of the mathematics involved. We interpret this result as a (mathematical) failure in posing problems that preserve significant aspects of the deep structure of the original problem, yet confirming a distinction between being creative and being *mathematically* creative.

What are the underlying factors that ensure for a new posed problem to be mathematically consistent? We found that, among the students who used endogenous transformations, those who kept the global way of solving of the starting problem made mathematically qualitative new problems. But, as they identified the optimal way of solving, the resulted problem remained close to the initial one, therefore in this case the student proved a low level of cognitive novelty, and the changes in cognitive framing were minimal. Their creativity was driven by the solution space, and inevitably, it had low amplitude.

Concluding, the evidence we got from problem modification tasks in our sample show that high achieving children swing between low amplitude driven creativity and failure to pose consistent problems when it comes about understanding the deep structure of mathematical concepts and strategies. Are these the only alternatives? Further research is needed to find a more definite answer.

What can we learn from pre-service teachers' beliefs on and dealing with creativity stimulating activities?

Ilya Sinitsky

Gordon Pedagogical College, Haifa, Israel, sinitzsk@gordon.ac.il

This paper aims to highlight the different aspects of a discussion on creativity promotion from the point of view of an educator involved in professional development of pre-service teachers. Challenging the prospective teachers with open mathematical problems provides data on their beliefs and behaviour concerning creativity and creativity encouragement in the classroom. We emphasize a certain manner of revealing elements of relative creativity during students' activities. The final remarks suggest relevant agenda for further discussion and research.

Keywords: Mathematics creativity, teachers' education, problem solving, problem posing.

INTRODUCTION AND BACKGROUND

The promotion of creativity seems to be the central issue of mathematical education at all levels. As mathematics teacher educator, I believe in a crucial role of the teacher in promoting students' creativity, therefore, the development of creativity-inviting environment (Sinitsky, 2008) and analysis of students' activity in this environment are the issues of my primary attention.

During my long-term pedagogical practice, I have collected a vast amount of scattered empirical data on different approaches utilized by prospective and in-service teachers for treating open mathematical situations. The course called "Development of Mathematical Thinking" is a subject of my explicit interest, as its attendance consists of prospective elementary school teachers. This paper refers to various aspects of behaviour and the activities of future teachers themselves as the students of the course. With almost two hundred prospective elementary school mathematics teachers involved in different stages of a study, it may be regarded as fairly wide albeit not a very systematic one. Obviously, some aspects of the study have been related to creativity promotion, and provide an empirical basis for the discussion below.

Despite widespread declarations on cultivation of creativity as the core of mathematical education, there is no single accepted definition of creativity (Mann, 2006; Sriraman, Yaftian, & Lee, 2011). Since creativity is related to the process of problem solving, some research papers focus on in-depth investigations of several, mainly intermediate, stages of cognitive and mental processes - in the spirit of a four-component model of preparation, incubation, illumination and verification proposed by Wallas (Dodds, Ward, & Smith, 2003). Following this paradigm, researchers pay major attention to the structure of an 'Aha!' moment (Liljedahl, 2009; Prabhu & Czarnocha, 2014). At the same time, Leikin (2009) has enriched the model of creativity as a specific combination of fluency, flexibility and originality of Torrance, making it possible to measure various components of creativity. In the frame of this paper, we refer to this description of creativity that enables us to analyse the creative elements in mathematical behaviour of prospective mathematics teachers for elementary and secondary schools.

Recent researches on teachers' component of creativity have been carried out both on macro- (Leikin, Subotnik, Pitta-Pantazi, Singer, & Pelczer, 2013) and micro-levels (Pitta-Pantazi, Sophocleous, & Christou, 2013). Up to now, however, teachers' conceptions and practice in relation to creativity has not been studied systematically (Lev-Zamir & Leikin, 2013).

The aim of the paper is to propose additional issues for further research agenda in the field from the point of view of teachers' educator. The discussion refers to the empirical data concerning the following questions:

— What do prospective and in-service teachers think about the possibilities of promoting creativity through everyday learning of mathematics in elementary school?

— How would they deal with various creativity stimulating activities?

— Which features of creativity could be associated with the process of solving multi-step mathematical tasks by prospective mathematics teachers?

BELIEFS VS. DECLARATIONS: POSSIBLE REASONS OF THE GAP

Studying teachers' beliefs regarding the encouragement of students' creativity was not our primary goal. Yet, the issue has arisen when pre-service teachers were asked to list the reasons for the importance of the course "development of mathematical thinking". "We need to encourage creativity in framework of mathematics lesson in school; and the competence of mathematics teacher in aspect of creativity promotion is a key factor in this process," – they stated. This composite proposition has almost become an axiom in the last decade, and pre-service teachers are broadly familiar with both components of it. In the open-form questionnaire, almost 80% of them declared that teachers are required to develop mathematical thinking through learning mathematics rather than focusing solely on standard algorithms and procedures. Significant part of prospective teachers also delivered interesting thoughts on the necessity of involving all the students in the learning process by using suitable pedagogical tools. Nevertheless, it is known (Lev-Zamir & Leikin, 2013), that the likeness of declarative conceptions concerning creativity does not provide the similarity of pedagogical practice related to promoting creativity.

Let us examine the 'real value' of these claims. The same group of students discussed the well-known problem: divisibility of sum of consequent addends:

> Assignment 1. Construct different sums of three consequent addends. What is the common property of these sums concerning divisibility? Try to prove your assumption.
>
> Check the situation with another quantity of consequent addends. Try to generalize.

Following a multi-stage process of problem solving, discussing the results and summarizing the conclusions, students have been asked about possible ways of introducing this activity (partially or as a whole) in elementary school mathematics lessons. Only 20% of respondents have described more or less suitable arithmetic situations or problems.

The reasoning of the remaining 80% of students as to why they could not use such a task in a regular mathematics lesson in an elementary school classroom can be summarized as follows:

— This activity is a difficult one; it is suitable for advanced students only.

— I have no idea how to fit this activity to the needs and the abilities of elementary school students.

— The activity does not belong to any school curriculum.

We observed similar replies when a group of in-service teachers had been discussing analogous tasks during a professional training course. Moreover, many of them have added that "it seems to be a waste of time".

Let me put here two notes and to propose some related questions.

The first remark concerns the current elementary school curriculum. Is it possible that the extensive familiarity of teachers with textbooks and other teaching resources rules out the option of creativity-stimulating activities? In other words, *does the actual content of (elementary) school mathematics invite those activities and learning styles or at least provide a suitable environment for introducing them?* A survey by Sheffield (2013) contains some significant remarks on this topic, but the problem, indeed, requires a separate discussion concerning both evaluation standards and curricula issues.

Another comment is on the structure of pedagogical content knowledge (PCK). In terms of mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008), we can easily conclude that pre-service teachers do not have enough PCK in the field of creativity promotion. However, *which specific component of pedagogical knowledge can be associated with tools that a prospective (or current) teacher might use in a classroom to encourage creativity?* It certainly does not fit into the 'knowledge of content and teaching' and cannot be included into the 'knowledge of content and students' category that deals with strategies of learning about specific issues. Since the ability of problem solving is both a principal component of mathematical reasoning and its main measure (Borasi, 1994; Silver, 1997), non-routine activities that stimulate creativity have to appear throughout all the content of subject matter. It seems that awareness on components of creative thinking lies beyond the topics of school mathematics and needs to be built as a core and cross-subject pedagogical mathematical knowledge. By analogy with horizon knowledge (HK) of subject matter content knowledge, it can be determined as HK component of PCK.

Let us turn now to the practice. How do prospective teachers deal with mathematically challenging situations? It is accepted that pre-service teachers need to construct their pedagogical knowledge about encouraging creativity by using their own experience of 'mathematical challenge and discovery' accompanied by further practice in the elaboration of creativity-stimulating activities for students (Shriki, 2010).

"WHAT DO I NEED TO DO?"

For years, students have started the course "Development of mathematical thinking" by filling in a closed-type questionnaire on the nature of problem solving in elementary mathematics. I have observed throughout the years that about 70% of prospective teachers have accepted the following description of mathematics problems and the ways of solving them:

— Each problem belongs to a specific mathematical topic, and there are explicit tools that are suitable for solving the problem within given mathematic areas only;
— To solve the problem, one needs to execute a series of operations (in the right order), similar to a sample, typically known to a student.

These data correlate with the findings of Zazkis and Liljedahl (2002) on perceiving school mathematics as a collection of isolated propositions and the tendency of forthcoming teachers to focus on formulas and algorithmic procedures.

All students had enough knowledge in elementary mathematics to progress with proposed assignments through the research. Nevertheless, the title of a section is, not surprisingly, a citation of central theme and a leitmotif observed in students' replies once they had faced a mathematical situation without an immediate solution algorithm. The pre-service teachers were real newcomers to the field: only 2% of respondents have acknowledged having practice with non-standard mathematical situations and/or open problems.

During a six-month course students were typically challenged with 7–9 assignments of open type (Silver, 1997). Certain assignments were multiple-solution tasks (Leikin, 2009) while others included the search of multiple solutions as an essential stage of the overall inquiry. Each assignment was presented as a multi-stage problem with auxiliary questions acting as a natural way to generalize results derived from the earlier stages. The set of assignments was designed according to a criteria elaborated by author (Sinitsky, 2008). I present here two of these assignments alongside the analysis of students' solving strategies. The first activity and a subsequent extensive discussion on the nature of open-problems has in fact served as a 'pedagogical preparation' for the following assignments.

> Assignment 2. Student has solved the following task: "For a given chain of natural numbers 1, 2, 3, insert signs of arithmetic operations between numbers in order to obtain arithmetic expression which equals zero." He has produced the solution as follows: $1 + 2 - 3 = 0$.
>
> Try to solve the similar problem for longer chains of natural numbers that start with 1, i.e. find suitable arithmetic operation signs to obtain the equality for

> 1 2 3 4 = 0; 1 2 3 4 5 = 0; 1 2 3 4 5 6 = 0; … etc. For each chain, find as many solutions as you can.
>
> Try to find solutions with addition and subtraction only. What can you say about the number of those solutions?
>
> Come back to the same chains with a number 1 as a target result. Explore each of the previously solved chains (for instance, 1 2 3 4 = 1).

When dealing with the first part of Assignment 2, the students have used two principal strategies, i.e. 'balancing' of added and subtracted operands (as $1 - 2 - 3 + 4 = 0$), and multiplying by an arbitrary factor of an algebraic sum that equals to 0 (as $(1 + 2 - 3) \times (4 + 5) = 0$). Each strategy provides a significant amount of relevant solutions, thus we suppose that the fluency in this problem is a function of the number of proposed solutions of a given type and of time the student spent on finding them. After a couple of preliminary stages, many students have worked more or less in an algorithmic manner in compliance to the scheme mentioned by Ervynck (1991). Yet, some students have 'rediscovered' the leading principle for each solution without using any routine procedures.

In contrast to fluency, the flexibility of solutions in this assignment is associated with a shift to another type of solution (for example, switch from expression $1 - (2 + 3) + 4 = 0$ to $(1 + 2 - 3) \times 4 = 0$). We also regard the ability to adjust previously constructed solution to another situation as a feature of flexibility. Thus, we interpret the transition from 'balanced' equality $[(1 + 2) \times 3] - (4 + 5) = 0$ to the equality with unity as a quotient of two equal numbers, $[(1 + 2) \times 3] : (4 + 5) = 1$ as flexibility as well.

Typically, for different groups of students, about 80% of future teachers have shown several degrees of fluency and almost 40% revealed some flexibility in their solutions for Assignment 2. Additionally, small portions of students (about 8–10%) have constructed a handful of surprising and non-trivial solutions that will no doubt belong to unconventional solution space (Leikin, 2007). I would like to present two notable expressions as an example: $((1 + 2) : 3 + 4) : 5$ and $(1 - 2) \times (3 - 4)$. Remarkably, these solutions have served as a starting point for further fluency, as in $(1 + 2) : 3 = ((1 + 2) : 3 + 4) : 5 = (((1 + 2) : 3 + 4) : 5 + 6) : 7 = \dots$, and flexibility as in $(1 - 2) \times (3 - 4) = 1 \times (2 - 3) \times (4 - 5)$, with a relevant search for limits of possible generalization. In terms of Koestler (1964), progress in understanding provides the basis for the exercise of understanding, and can even lead on to the "next level" of understanding.

According to the accumulated data, Assignment 2 had served as a reasonable tool to evaluate the components of creativity through constructed solutions. This assignment also invites a discussion in classroom about introducing some creativity-related concepts to the reference group. After reaching such a promising conclusion let us turn to the next assignment and analyse the student's activities within the framework of the following example:

> Assignment 3. We assigned the label 'exceptional' to number 11 because it can be expressed as a difference of two square numbers: $11 = 6^2 - 5^2$. Is this the only 'exceptional' number? How can we find other 'exceptional' numbers? For a given natural number, is there a way to write it as a difference of two perfect squares? Can we state that each natural number is an 'exceptional' one?

At the first stage of the solution, pre-service teachers have demonstrated a very limited repertoire of tools and ideas. Almost half of them claimed they 'can do nothing' with a problem and the following dialogue was a typical stimulating tool to start some progress towards a solution:

> Tutor: Do you really believe that 11 is the only "exceptional" number?
> Student: No, I think it is not the only example.
> Tutor: How can you *calculate* an additional "exceptional" number?
> Student: Aha! I can take any pair of perfect squares and subtract one from another. For example, $10^2 - 9^2$, therefore 19 is also an "exceptional" number.

Despite the fact that various pairs of squares give numerous "exceptional" numbers, the ability to record a series of technical results hardly seems to be associated with a fluency of thinking. Alternatively or additionally, some students have shown a fluency in their search for solutions, constructing chains of differences with some regularity. For example, students have constructed a series of differences of squares of consequent numbers or a series of differences of squares with a constant difference between bases, but in all their suggestions students did not *use algebraic expressions*. As a result, those students have derived a distinctive series of desirable representations of natural numbers as "exceptional" ones.

Since representation of any odd number as a difference of two (adjacent) square numbers was the ultimate outcome of the above scheme, a number of students have changed the pattern to produce solutions of diverse types. Following this route, they have discovered "multi-exceptional" numbers – those that have more than one representation as a difference of square numbers. Flexibility may certainly be attributed to this step of the solution.

Can we find any elements of originality among the routines explored by the students? Which mathematical tool did they use in order to complete the solution? Notably, the factorization of squares' differences alone almost immediately leads both to a list of possible wanted decompositions and a discrimination of criterion as an opportunity of such a representation for each natural number. Since a suitable formula has been applied, one may continue with a simple routine. In this context, the breakthrough is connected to a switch towards simple algebra, and not a single prospective elementary school mathematics teacher succeeded in making this switch.

Discussing this disappointing result of the last assignment is especially interesting given the fact that the situation was fairly similar to other assignments, but it is not the scope of this paper. Instead, let us come back to the main goal of our case: assignments as a room to explore creativity. Did we really construct the set of assignments in order to identify gifted students (those with extraordinary creativity) in a population of pre-service teachers? Note that I did not present any numerical data on measuring fluency and flexibility of students' solutions, and I did that for a reason. We want prospective teachers to deal with creativity-promoting assignments in order to make them familiar with the field and to equip them with principal notions and components of 'everyday' creativity (Kaufman & Beghetto, 2009). It is a matter of fact, that through such an experience prospective teachers have meet "global" mathematical ideas and concepts (Safuanov, 2015).

On the other hand, pre-service teachers' own experience may serve, to some extent, as a reasonable model of mathematical behaviour of students faced with challenging activities. Analysing the collected data, we can suggest some specific features for the characteristics of creativity-connected activity of non-experienced students in non-standard mathematical situations.

Most of these students *need* certain *guiding hint or solution as a starting point* to go further and explore the problem. This hint may simply be a minor reformulation of a problem in the terms of possible answers (as one can see from the presented Assignments). In the absence of this 'push', students typically come back to the above-mentioned question "What do I need to do?" in full compliance with the statement of Sternberg (2009) on the role of a supportive environment as a condition for demonstrating creativity.

Furthermore, we can attribute a number of particular features to the dimensions of creativity that have been developed by pre-service elementary school mathematics teachers when exploring multi-step problems. As we have seen, *fluency* is associated with a series of solutions produced on the basis of a discovered sample or pattern. Contrary to this, *flexibility* reflects the ability to switch to a completely different pattern or to take the search to another direction. It seems that the discussion on originality is not relevant in this case, since some straightforward algorithmic solutions have to be accepted as "original" ones: they do not belong to the set of solutions produced by similar groups.

INTEGRATION OF PROBLEM POSING AND PROBLEM SOLVING

The multi-stage and open character of proposed assignments invited and stimulated the students to pose specific and general questions on mathematical situations and also on the results of the preceding steps of their inquiry.

Since problem posing is a central component of creative processes (Silver, 1997), we have constructed and researched the situation of 'pure' problem posing in the frame of above-mentioned course for prospective teachers. A group of 21 pre-service teachers learned the course "Development of mathematical thinking" in self-regulated learning (SRL) format. Following exemplification with several assignments, students were requested to construct *their own open-type mathematical problem* and to explore it. With accordance to 'pure' SRL approach (Goodwin, 2010), students have been asked to design their study, including the choice of a relevant mathematical situation itself as well as the tools and rate to explore it. In this approach of 'absolute free problem posing', the mission proved to be impossible to complete: only 30% of students were able to even formulate a task, and all the tasks submitted had a form of enrichment questions concerning curriculum items of different levels. This result is not a surprise: prospective teachers needed to 'work like real mathematicians' (Shriki, 2010) through generating and solving new problems. Nonetheless, after the tutor's intervention and intensive group discussions, 75% of respondents were able to construct open mathematical situations of different grades of complexity and relevance.

Another item concerning mathematical creativity awareness of teachers is their ability to construct challenging activities for students. As a pilot test, we asked four prospective teachers to adjust their successfully constructed assignments for students of an elementary school. One of the results is presented below.

> Assignment 4 (original version). I have a set of 40 items that look identical but have different weights. The weight is a whole number in kilograms, from 1 to 40. In order to find the weight of each item, I can use a scale in one of the two manners: to balance an item on one side with one or more weights on another side; to balance an item and weights (if necessary) with a set of weights on another side. For each manner, what is the number and the value of required weights?

> Assignment 4 (adapted version). Represent arbitrary natural number from 1 to 40 with numbers 1, 3, 9, 27 and using operations of addition and subtraction (each number may be not be used more than once).

Unfortunately, the result is somewhat of a profanation of the initial assignment, and a total loss of the creativity component can be observed. This means that even when prospective teachers try to adapt their own problems to a "real-world" classroom, they are expected to meet some crucial difficulties. Recent research that was focused on the ways teachers posed problems for their students (Pitta-Pantazi, Christou, Kattou, Sophocleous, & Pittalis, 2015) proves that we still need to consider a wide range of cognitive, psychological and social factors.

FINAL REMARKS

Let me emphasize below the major questions dealing with encouraging creativity that, in my opinion, require further clarification.

— Part of pre-service teachers believe that the content of elementary school mathematics is not suitable for activities that promote creativity. Does (and to what extent) the current curricula allow, invite and encourage mathematically challenging activities?

— Pedagogical content knowledge emphasizes the importance of issue-dependant ways of teaching and learning. What is the place of awareness on creative thinking and which are the ways to promote it in the structure of pedagogical mathematical knowledge?

— According to our findings, external support at the initial stage has a crucial role for launching the process of creative thinking. Additionally, the elements of *fluency*, *flexibility* and *originality* appear: utilizing patterns and samples are two examples of that. Do those peculiarities depend on reference groups and/or on the nature of the proposed assignments?

— Posing of mathematically challenging problems must be a part of teacher's repertoire. How does this ability relate to the experience of problem posing through prospective teachers' own handling open mathematical situations?

Mathematical problem-solving by high-achieving students: Interaction of mathematical abilities and the role of the mathematical memory

Attila Szabo

Stockholm University, Department of Mathematics and Science Education, Stockholm, Sweden, attila.szabo@stockholm.se

The present study deals with the interaction of mathematical abilities and the role of the mathematical memory in the problem-solving process. To examine those phenomena, the study investigates the behaviour of high-achieving students from secondary school when solving new and challenging problems. Although the mathematical memory accounts for a small part of the problem-solving process, it has a critical role in the choice of problem-solving methods. The study shows that if the initially selected methods do not lead to the desired outcome, the students find it very difficult to modify them. The study also shows that students who use algebraic problem-solving methods perform better than those who use numerical methods.

Keywords: High-achievers, mathematical memory, abilities, problem solving.

INTRODUCTION

Despite increasing emphasis on the education of gifted and high-achieving students, we still have limited empirical data about their mathematical abilities and use of memory functions during mathematical problem-solving. So far, much of the research on mathematical abilities has been conducted on low-achievers (e.g., Swanson & Jerman, 2006). Only a few studies are focusing the mathematical abilities of gifted and high-achieving students (e.g., Brandl, 2011; Vilkomir & O´Donoghue, 2009) or the connection between those students' memory functions and their mathematical performance (Leikin, Paz-Baruch, & Leikin, 2013; Raghubar, Barnes, & Hecht, 2010). Yet no study since Krutetskii (1976) has examined the role of the mathematical memory in the context of able students' problem-solving activities.

BACKGROUND

Mathematical abilities

We are not born with abilities that are explicitly mathematical, but an active contact with the subject may, under favourable circumstances, generate complex mathematical abilities (Krutetskii, 1976). When discussing the subject, we should remind ourselves that mathematics is not a topic defined by sufficient and necessary components and there is no uniform terminology for the abilities that we tend to define as mathematical (Csíkos & Dobi, 2001). Thus, it is not possible to define a structured system of mathematical thinking in which the units are satisfactory to understand the system. A historical review shows that Calkins (1894) concluded – based on replies from Harvard students – that mathematicians have concrete rather than verbal memories, that there are no differences in ease in memorising between mathematicians and other students and that, when doing mathematics, there is no significant difference between men and women. In the early 1900s, mainly because of the dominance of psychometric approaches, the research community's efforts to define mathematical abilities were unsatisfactory. Nevertheless, Binet, Piaget and Vygotsky made relevant contributions to the subject by replacing psychometric approaches with socio-cultural attitudes and thereby showing that abilities are nor static or innate, but qualities that can be assimilated and developed by the individual (Vilkomir & O´Donoghue, 2009).

An essential contribution to the subject was made by Krutetskii (1976) who observed around 200 pupils in a longitudinal study (1955–1966). Krutetskii's analysis of the pupils' problem-solving activities lead to a model of mathematical ability as a dynamic and complex phenomenon, consisting of: a) the ability to *obtain* and *formalize mathematical information* (e.g., formalized perception of mathematic material), b) the ability to *process mathematical information* (e.g., logical thought, flexibility in mental processes, striving for clarity and simplicity of solutions), c) the ability to *retain mathematical information* or *mathematical memory* (i.e., a generalized memory for mathematical relationships) and d) a *general synthetic component*, named a "mathematical cast of mind" (Krutetskii, 1976, pp. 350–351).

Although the above model is often used to identify mathematical giftedness – and studies (e.g., Brandl, 2011; Krutetskii, 1976; Öystein, 2011) show that high-achievers are not necessarily mathematically gifted – Krutetskii indicates that even students performing very well in the learning of the subject, e.g. high-achievers, manifest abilities that can be regarded as proper mathematical abilities (ibid, pp. 67–70).

Mathematical memory

Memory is thought to be critical to both learning and doing mathematics (e.g., Leikin et al., 2013; Raghubar et al., 2010). Research that deals with memory functions was conducted for more than 120 years, but during the first eight decades the topic was almost exclusively examined by quantitative measures (Byers & Erlwanger, 1985). However, in the 1940s, the research shifted focus toward more qualitative terms. Thus, Katona (1940) stated that information related to a method and based on understanding is easier to remember than arbitrary numbers. Later, Bruner (1962) noted that detailed knowledge can be recalled from memory with the use of simple interrelated representations. Although numbers are fundamental tools in mathematics, Krutetskii (1976) underlines that recalling numbers or multiplication tables cannot be equated with mathematical memory; highly able students memorise contextual information of a problem only during the problem-solving process and forget it mostly afterwards. Yet, they can still several months later recall the *general method* which solved the problem. In contrast, low-achievers often remember the context and exact figures related to a problem, but rarely the general problem-solving method. Thus, mathematical memory is a *generalized memory* for mathematical relationships, schemes of arguments and methods of problem-solving (ibid, p. 300).

Studies (e.g., Squire, 2004) show significant distinctions between different types of memory systems. Relating mathematical problem-solving to the cognitive model – by using a simplification – one can say that information is processed (e.g. the problem is solved) in the working memory and is stored (e.g. the problem-solving method) in the long term memory. Long term memory has two subcategories: *explicit* and *implicit* memory, depending on the type of information stored in the respective system. The implicit memory stores information about procedures, algorithms and patterns of movement that can be activated when certain events occur; in mathematical context, the *procedural* memory is a relevant part of this system (Olson et al., 2009; Squire, 2004). The explicit memory stores information about experiences and facts which can be consciously recalled and explained; thus, it is associated with the ability to create mental schemas for problem-solving (Davis, Hill, & Smith, 2000). Thus, we can assume that mathematical memory, as defined by Krutetskii, belongs to the explicit (hence not to the implicit) memory system.

Krutetskii (1976, p. 339) and Davis and colleagues (2000) suggest that proper manifestations of mathematical memory are not observable in the primary grades, because at that age able pupils usually remember relationships and concrete data equally well. Krutetskii indicates that mathematical memory is formed at later stages, most probably on the basis of the initial ability to generalize mathematical material (ibid, p. 341).

Accordingly, the present study (Szabo, 2013) examined the dynamics between mathematical abilities, as defined by Krutetskii, from the following perspectives:

1) The evidence and the interaction of mathematical abilities when high-achieving students are solving new and challenging mathematical problems.

2) The role of the mathematical memory in the process of solving new and challenging mathematical problems.

METHOD

Participants

According to Krutetskii: a) the mathematical memory cannot be observed properly in young pupils or in low-achievers and b) mathematical abilities are manifested by high-achievers. Consequently, the present study focused remarkably high-achieving, 16–17 years old students from Swedish secondary school. The participants attended an advanced mathematics programme and achieved the highest grade in mathematics. The participation was optional; after four months of classroom observations and consultations with their mathematics teacher, three boys and three girls were selected to attend the study.

Tasks

The analysis of a given problem, regardless of the mathematical field it belongs to, indicates the structure of the mathematical thinking needed to solve the problem (Halmos, 1980). Several studies confirm that the most effective way to discern mathematical abilities is to analyse the behaviour of individuals in the context of problem-solving activities (e.g., Gyarmathy, 2002; Krutetskii, 1976). Other results (e.g., Krutetskii, 1976; Öystein, 2011) indicate that individual experience influences students' ways of solving problems. The aim of the present study was to investigate the participants' mathematical abilities, not their knowledge of the subject; thus, to avoid as far as possible the influence of prior experiences, new problems were proposed that were not of a standard nature. After examining the participants' textbooks and consulting their math teacher, the following problems were selected:

Problem 1: In a semicircle we draw two additional semicircles, according to the figure. Is the length of the large semicircle longer, shorter or equal to the sum of the lengths of the two smaller semicircles? Justify your answer.

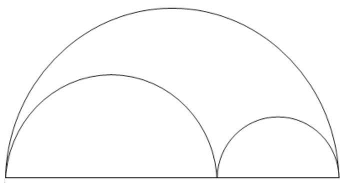

Figure 1

Problem 2: Mary and Peter want to buy a CD. At the store, they realise that Mary has 24 SEK less and Peter has 2 SEK less than the price of the CD. Even when they put their money together, they couldn't afford to buy the CD. What is the price of the CD and how much money has Mary and Peter respectively?

Observations and materials

Classroom interaction affects student's thought process and that interaction is not limited to verbal communication; even gestures or other minor events are affecting the process (Norris, 2002). Krutetskii also underlines that it is difficult to map individual mathematical abilities if pupils are observed in a classroom situation. To avoid these confounding factors, the students were observed individually and, in order to avoid stress, they had unlimited time for completing the tasks. They were asked to write down every step in the process and to "think out loud" whenever it was possible. If a student neither wrote, nor drew or spoke for a while, some of the following questions were posed: What is bothering you? Why do you do that? What do you want to do and why? What are you thinking about? All observations were carried out during a single day and recorded by using a technology which enables to digitalize handwritten notes and related verbal utterances (www.livescribe.com).

Pupils are not used to communicate their thoughts while solving problems (Krutetskii, 1976). To avoid the risk that significant parts of their cognitive actions would not be documented during the process, every problem-solving activity was followed by a contextual interview. The recordings of the interviews and problem-solving activities were transcribed verbatim. Although the unlimited time for solving the problems, no participant needed more than 14 minutes to solve a single problem and the average duration of the succeeding contextual interviews was four minutes.

Data analysis

The *general synthetic component* in Krutetskii's model, i.e., the "mathematical cast of mind", is difficult to observe during occasional problem-solving and is typical for mathematically gifted students (ibid, pp. 350–351). The participants were certainly high-achievers, but not tested for mathematical giftedness and besides that, only two tasks were proposed to them during the present study. Thus, the general synthetic component was not focused in the study. Conversely, the *ability to generalize* is frequently used when pupils establish mathematical memories (ibid, p. 341); thus, the study examined the presence of the ability to generalize mathematical information during the students' activities. A rigorous a-priori analysis of the proposed tasks led to an identification-model for the present study, which focused the following abilities from Krutetskii's framework: *obtaining* and *formalizing* mathematical information (O), *processing* mathematical information (P), *generalizing* mathematical relations and operations (G) and *mathematical memory* (M).

The digital recording of the problem-solving activities resulted in an exact linear reproduction of the pupils' written solutions, drawings and verbal utterances. This was very useful when performing *qualitative content analysis* of the empirical material, inspired by Graneheim and Lundman (2004) and van Leeuwen (2005). The students' solutions were analysed by identifying, coding and categorising the basic patterns in the empirical content. At first, the method highlighted those abilities that were directly expressed in the empirical material, i.e. the *manifest content*. After that, the *latent content* was analysed, by combining data from observations and contextual interviews. I exemplify this with data from Linda, who – when solving Problem 1 – looked at the task, drew some semicircles and whispered for herself:

Linda: Thus, eh... Oh, and here we are after all just using what radius they have and such. One would...

After this device, which occurred after 30 seconds from start, she solved the problem by not saying that much and it was not possible to decide if mathematical memory was present at the time or if she only used her ability to obtain and formalize mathematical information. Later, when analysing the latent content, the following sequence from the contextual interview referred to the above mentioned episode:

Linda: And then you express it simply as that, well, expressing their different diameters as something of each other.
Interviewer: Yes.
Linda: It is similar to another task that I like very much...
...
Linda: Like there, when solving that, the first thing to do... it is making formulas... How different triangles and squares... how the inside of it looks.
Interviewer: Yes... hum.
Linda: Just like there, if you express different sides through... and take one side minus the other, just like in that problem...

The statement "It is similar to another task that I like very much" and the following explanation, relating the actual problem to an apparently different task – with a context of triangles and squares – show the evidence of an (explicit) memory for a generalization, i.e. mathematical memory in the actual device. The combined analysis resulted in a matrix there every device which lasted at least one second during the observed activities, and the time period for its occurrence, was related to the mathematical abilities focused in the present study. The matrix displayed both the interaction between the focused abilities and the occurrence of the abilities, measured in seconds, during every particular problem-solving activity. The matrix also indicated that some devices were actually related to two interconnected abilities.

RESULTS

The interaction of the mathematical abilities

Every student confirmed that the problems were new and challenging, which was a key issue in the design of the study. The analysis displays that the students' problem-solving activities contain three main phases. All activities start with an *initial phase* which encloses both the ability to *obtain and formalize the mathematical information* and *mathematical memory*; these abilities are intimately connected and it is difficult to differentiate them. Directly after the initial phase, follows a phase where the ability to *process mathematical information* is prominent. Nevertheless, every activity ends with a different phase of *processing mathematical information*, where the students are checking their results. Beyond these three main phases, the observed mathematical abilities interact in irregular and unstructured configurations.

The analysis also shows that if the chosen method does not lead to a direct solution of the problem, students become stressful and discontinue processing the mathematical information; they return to the initial phase, which is once again followed by a phase of information processing. Some participants went through this shifting of phases three times. The stress was most evident at Problem 2, where three of those four students who used similar methods made the same error when solving the inequality $2x - 26 < x$. All three activities include the incorrect sequence "$2x - 26 < x$ gives $x - 13 < x$", before returning to the initial phase. All participants were familiar with inequalities; thus, one may naturally wonder why high-achievers make seemingly simple errors. The interviews reveal that the stress occurred when the formalization led to inequalities instead of the expected equations:

Earl: That´s I was a little surprised when it was... on the inequality you solved it.
Erin: It is always difficult to start thinking outside the box... It feels like your mind goes blank.
Linda: Because I get so... When I start with equations ... then I really want to solve it with equations.
Sebastian: This kind of tasks usually requires an equation.

Thus, it seems that the stress was due to the selected method, i.e. equation-solving, lacked those procedures that are necessary when solving inequalities.

The problem-solving methods used by the students

The problem-solving methods could be divided into two categories, as identified during the a-priori analysis of the proposed tasks: *algebraic* respectively *numerical* methods. Consequently, it was possible to distinguish 7 algebraic and 5 numerical methods among the 12 processes. All of the algebraic methods – despite different approaches – led to correct solutions. In contrast, when applying numerical methods, the problems were not solved in a proper way.

The general structure of the students' mathematical abilities

The analysis emerged in a matrix there every device in the problem-solving activities was related to at least one mathematical ability. On the other hand, the analysis revealed that at some devices there were two interrelated abilities present at the time – thus the methods of observation and analysis used in this study were not sufficient to differentiate those interrelated abilities. Accordingly, the ability to process mathematical information (P) is present at 52 % of the total time of the students' activities (see also Table 1). Obtaining and formalizing mathematical information (O) – solitary or in combination with other abilities – is present at 45 % and mathematical memory (M) at 17 % of the total time (Table 1).

According to the a-priori analysis of the tasks, the ability to generalize mathematical information (G) could be detected when numerical solutions were developed into general solutions. Consequently, when numerical solutions were presented by the students, they were asked if they were able to generalize the obtained results. The analysis shows that none of the participants has been able to generalize the obtained numerical solutions; thus, the ability to generalize mathematical information could not be observed in this study.

The role of the mathematical memory in the problem-solving process

The analysis demonstrates that the mathematical memory is present predominantly at the *initial phase* of the process, at a relatively small proportion. In isolated form – at 5 % of the process – the ability is present in the manifest content and it is mainly used for recalling mathematical relationships and problem-solving methods. In the latent content, the ability is present during 12 % of the process, mainly in combination with the ability to obtain and formalize mathematical information (O with M) (Table 1).

Despite of its minor proportion, the mathematical memory is essential to students' achievement in the problem-solving process, because: a) the students selected their methods in the initial phase of the process and b) the students found it very difficult to modify the selected methods. Although they started over the process by returning to the initial phase, none of them abandoned the initially selected method.

DISCUSSION

One of the study's main objectives was to map the interaction of high-achieving students' mathematical abilities during problem-solving. Three main phases of the problem-solving activities were identified: the *initial phase*, the *subsequent phase* of processing the

O	O with P	O with M	P	P with M	G	M
33 %	2 %	10 %	48 %	2 %	0 %	5 %

Note: O = the ability to obtain and formalize mathematical information; P = the ability to process information; G = the ability to generalize mathematical information; M = mathematical memory

Table 1: Average time for mathematical abilities, according to the total time of the problem-solving process

information and the *ending phase*, where results are checked by once again processing the information. Despite the limitations of the study, the chronological order of the mentioned phases emphasize to some extent Polya's (1957) model for problem-solving, which consist of four phases: a) *understanding* the problem, b) *devising a plan* in order to solve the problem, c) *carrying out the plan* and d) *looking back*. Thus, the study indicates that high-achievers solve new and challenging mathematical problems according to the ground stones in Polya's model.

According to the results, the role of the mathematical memory – despite its relatively small presence in the process – is critical, since the participants selected their methods at the start of the process and did not change them later, e.g. when the formalization led to inequalities instead of the expected equations, the participants returned to the initial phase but did not abandon the selected method. A selection of an improper method caused stress, time delay and errors during problem-solving. Thus, it seems that the participants experience a close and rigid interrelation between problem-solving methods and included procedures, i.e. they are not acting flexibly when solving new and challenging problems. By confirming the findings of other studies (e.g., Brandl, 2011) – where typical high-achievers are characterised by being dutiful, nonflexible and conformist – the results indicate that these participants were high-achievers but probably not mathematically gifted. In contrast, mathematically gifted students are described as flexible, high-level problem-solvers and out-of-the-box-thinkers (e.g., Brandl, 2011; Krutetskii, 1976; Leikin, 2014). Hence, the study confirms some qualitative differences in problem-solving between high-achievers who are not essentially mathematically gifted and mathematically gifted students.

However, the inflexibility of the participants can also be explained by two main functions of the cerebral cortex, where working memory operates. One function is to assemble all new information in relation to previous experiences (Olson et al., 2009). Thus, we can assume that at the initial phase, when obtaining and formalizing the information, the students are influenced by previous experiences (e.g. mathematical memory) and act as they are used to, e.g. by starting problem-solving with equations. Another main function of the cerebral cortex is to automate all knowledge (Olson et al., 2009). Yet, automated processes are rigid and extremely hard to modify during an on-going activity. Therefore, it seems that equation-solving is an automated process for typical high-achievers and that the interpretation of new information in the light of past experiences affects their possibility to think flexibly in unusual situations.

Finally, it has to be mentioned that the present study confirms Krutetskii's (1976) observation that during the initial phase it is extremely difficult to distinguish the ability to obtain mathematical information from the mathematical memory. Since information-units stored in the long term memory systems are retrieved at extremely high speed to the working memory (Olson et al., 2009), the methods used in this study were not sufficient to differentiate the information-units related to respective abilities. For a better understanding of the interaction of the mathematical abilities there is a need of further studies. One possible access is to design studies where the structure of the mathematical ability is examined with approaches from several research fields, e.g. by combining qualitative research methods with practices from cognitive neuroscience. In that way, we would possibly be able to answer the questions that were not possible to be answered in the present study.

Problem solving competency and the mathematical kangaroo

Elisabet Mellroth

Karlstad University, Karlstad, Sweden, elisabet.mellroth@karlstad.se

The goal of the study was to investigate differences in how two groups of students activated mathematical competencies in the mathematical kangaroo (MK). The two groups, group 1 and 2, were identified from a sample of 264 students (grade 7, age 13) through high achievement (top 20 %) in only one of the tests: the MK or a curriculum bounded test (CT). Analysis of mathematical competencies showed that the high achievers in the MK activated the problem solving competency to a greater extent than the high achievers in the CT, when doing the MK. The results indicate the importance of using non-traditional tests in the assessment process of students to be able to find students that might possess good mathematical competencies although they do not show it on curriculum bounded tests.

Keywords: Problem solving, mathematical competency, alternative assessment.

RESEARCH QUESTION

How can differences in students' strength in the problem solving competency be visualised through the mathematical kangaroo (MK)?

THEORETICAL BACKGROUND

Teachers in Sweden have observed that some students achieve highly in the international competition, the MK, although they have trouble with the national courses in mathematics. Some teachers suspect that those students are highly able in mathematics (Mattsson, 2013). To investigate if differences in achievement between groups of students on the MK can be explained by mathematical competencies, Mathematical Competencies: a Research Framework (MCRF) (Lithner et al., 2010) is used as framework. The framework describes six mathematical competencies: applying procedures, representation, connection, communication, reasoning and problem solving (Lithner et al., 2010).

METHOD

Empirical data is test results of same students' (n = 264) from the national test (CT) given in grade 6 and from the MK given in grade 7. Two groups of students were identified: *Group 1*, top 20 % achievers in the MK but not in the CT, i.e. among the bottom 80% in the CT. *Group2*, top 20% achievers in the CT but not in the MK. The two groups' activation of mathematical competencies on the MK was compared after eliminating the achievement factor. Competencies are therefore activated within an individual by showing the individuals' strengths and weaknesses. Each identified individual belonged to one of the two disjunctive groups, and differences between the groups were analysed.

RESULTS AND DISCUSSION

This study verifies teachers' observation, that there are students who achieve among the top in the MK but not in the CT. It is shown that on the MK, *Group 1* activates the problem solving competency to a greater extent than *Group 2*. Some tasks (6 out of 21), in the MK differ more than others in response rate between the two groups. Those tasks have in common that they all give opportunity to activate either the problem solving (n = 5) or the reasoning (n = 5) competencies. The reasoning competency is in the MCRF closely related to the problem solving competency, it is its juridical counterpart (Lithner et al., 2010). This study shows that the MK consists of a relatively high number of problem solving tasks, the MK also aims to offer interesting challenges. The use of challenging problems are important when working with mathematically highly able students (Nolte, 2012), The MK has inspired part of a model used to identify students highly able in mathematics (Pitta-Pantazi, Christou, Kontoyianni, & Kattou, 2011), maybe the students in *Group1* actually are mathematically highly able and given challenging mathematical problems makes them achieve. This study indicates that through the MK some students show good mathematical competencies that they not are able to show on the national test. It is therefore important to use both curriculum bounded test as well as non-curriculum bounded in assessment, so that students get more and varying possibilities to show their strength.

Exploratory learning in the mathematical classroom (open-ended approach)

Ildar Safuanov, Sergey Atanasyan and Irina Ovsyannikova

Moscow City Pedagogical University, Moscow, Russia, safuanov@yahoo.com

This paper explores the possibilities of the organisation of research projects by pupils in the Secondary school when the open-ended approach is utilized.

Keywords: Exploratory learning, open-ended approach.

RATIONALE AND BACKGROUND

Exploratory learning has been often used in the mathematics teaching practice in Russia, typically, using the form of project (Shatskiy, 1989). As a result of the preliminary research, our interest focused on the open-ended approach to mathematics teaching that appeared in Japan in the 1970-s and was developed in the next decades (see, e.g., Becker & Shimada, 1997; Nohda, 1991). Essentially, this method was based on the use of problems with multiple solutions. After studying the philosophy of this approach, as well as its didactic opportunities and similar Russian practices, we developed a methodical system of using open-ended problem approach for lessons of mathematics in the secondary school. The goal of this study is to check the effectiveness of the exploratory learning based on the open-ended approach in the mathematical classroom.

SETTING AND METHODOLOGY

We created a toolkit consisting of two blocks: a methodical manual for teachers and a booklet for pupils. The methodical manual contains practical guidelines for using open-ended tasks in classes, a set of tasks for pupils of different age, examples of assessment systems, and instructions for composing open-ended tasks. The booklet for pupils is intended to assist in developing their metacognitive awareness.

Some of the important stages in the lesson preparation coming from the experience of schools using exploratory learning approach in their practice should be mentioned:, 1) solving open-ended tasks cannot be used more often than once a week, 2) at the same time such an activity will not be of any use if research assignments are not used at least once a month.

Also, it is necessary to decide if the exploration is to be done by the entire class acting as one group or the class is to be divided into groups.

The experiment has been carried out during three years. The first phase of research included the design of the format of classroom work, and the identification of the indicators to be controlled, as well as the development of teaching materials. The second (main) phase of the experiment began in the fall of 2012 in a secondary school in Moscow, in three grade 5 (12 years old pupils) classes, and was continued in those classes up to grade 7. One class (N=28) formed an experimental group, and two others (N=45) a control group. The objectives of the research project were:

1) to clarify possibilities and ways for using open-ended approach;

2) to examine how pupils' problem solving ability develops in response to the changes of teaching methods;

3) to reduce pupils' mathematical anxiety.

Before the beginning and at the end of the experiment, teachers' and pupils' opinions about methods of teaching mathematics have been collected using questionnaires and interviews (that are presented on the poster). At the second stage of the experiment, about 20% of lessons in the experimental group (a lesson once a week) were devoted to open-ended tasks.

FINDINGS AND DISCUSSION.

Summarizing the results of the study, we observed the following changes indicated by the responses to the questionnaires before and after the main stage of the study:

- increase of students' engagement in the classroom;
- progress in acquiring the experience of applying mathematics to real life;
- stable positive dynamics of improvement of research competences;
- improvement of the psychological climate in a classroom;
- changes in the role of a teacher as a participant of the educational process in a classroom;
- acquisition of skills of team work.

Some important questions still require further research. In particular, our further research will focus on the development of detailed recommendations for teachers for using open-ended tasks in their practice, and for preparing worksheets with opened-ended tasks for pupils of different ages. Changes in teachers' beliefs and practices seem to be crucial.

Teaching prospective mathematics teachers to solve non-routine problems

Ildar Safuanov

Moscow City Pedagogical University, Moscow, Russia, safuanov@yahoo.com

This paper explores different ways of teaching pedagogical universities' students to solve various types of non-routine mathematical problems.

Keywords: Problem solving, teacher education.

RATIONALE AND BACKGROUND

The rationale of this paper is to describe a new experimental course in solving non-routine mathematical problems developed for prospective mathematics teachers. The course was based on the genetic approach combined with G. Polya's principle of consecutive phases and also with principles and rules developed by Soviet tradition of fostering problem-solving abilities. The creation of the course as well as the study of its results was guided by the following questions:

1) How new course will improve problem-solving skills of students?

2) How students' views of mathematical problem solving will change?

George Polya (1981, I, p. xii) emphasized that prospective mathematics teachers should be specially taught to solve mathematical problems. "...The solution of a non-routine mathematical problem is genuine creative work". Moreover, he indicated the importance of the discussing methods of solving problems in the classroom. However, as Abramovich & Brown (1996, p. 323) rightly mentioned, "traditional teacher training courses have offered little if any engagement in exploratory mathematics". Furthermore, non-routine mathematical problems now constitute the essential part of the Uniform State Examination in Mathematics for secondary school graduates (tasks C1-C6). The aim of this paper is to describe the experience of teaching prospective secondary mathematics teachers to solve non-routine mathematical problems including Olympiad problems and problems C1-C6 of the Unified State Examination in Mathematics. The new experimental course in solving non-routine mathematical problems for prospective mathematics teachers conducted with a group of 4-th year mathematics major students at the Moscow City Pedagogical University will be discussed.

SETTING AND METHODOLOGY

In our course, we used genetic approach (Safuanov, 2004). In particular, having solved a problem, we gradually establish its connection to some fundamental mathematical theories. For example, considering naturally arising problem of Konigsberg bridges, we arrive to the important mathematical theory of Eulerian graphs. G. Polya (1981, II, p. 133) wrote that "the genetic principle may suggest the principle of consecutive phases".

The principle of concentrated teaching (Safuanov, 1999) manifests itself in our course in several directions. Knowledge of some mathematical topics was deepened. Some simple problems serve for the anticipation of more complex problems and mathematical theories. Many problems serve not only for the raising of the interest to studies (due to their entertaining character) but also promote the acquisition of new theoretical knowledge because they are connected to modern mathematical theories – one can say that he combination of pedagogical functions was achieved. Finally, the "linkage" and "connections" were systematically used: one interesting problem led to other, in some way connected with the former; thus the chains of problems were considered. For example, we offer chains of problems on weighing coins, chains of problems on quad paper etc. It is important to tell student teachers about more general approaches, using the psychological characteristic of the process of problem solving. The new course was implemented within an undergraduate curriculum for a group (N=18) of 4-th year mathematics major students. Before the beginning and at the end of the course, students' skills of solving non-routine problems have been tested and their views of problem solving have been identified using questionnaires and interviews. The classroom work has been organized as a collective solving of some key problems and mostly as a work in small groups solving problems.

FINDINGS AND DISCUSSION

First outcomes of the implementation of our course demonstrated the positive changes in prospective mathematics teachers' skills in solving non-routine problems as well as in their beliefs about the problem solving.

Process-based analysis of mathematically gifted pupils in a regular class at primary school

Stefanie Winkler and Matthias Brandl

University of Passau, Faculty of Computer Science and Mathematics, Passau, Germany,
winkler-steffie@arcor.de, Matthias.Brandl@Uni-Passau.de

With heterogeneity at schools growing, individualisation of education has become more important than ever. For teachers it is vital to recognise their pupils' diverging abilities effectively in order to meet the pupils' respective learning requirements. The following project, which is based on a regular education setting at primary school (3rd/4th graders, German Primary School), aims at showing ways to identify and characterise mathematically gifted pupils during regular lessons.

Keywords: Mathematical giftedness, mathematical thinking, inquiry-based learning, process-based analysis.

MATHEMATICAL GIFTEDNESS IN PRIMARY SCHOOL

With respect to the development of mathematical skills and interests at primary school, two relevant projects have been influencing effective teaching at German Primary Schools: F.W. Käpnick, who picked out children according to their own motivation or teachers' reference and let them take part in extra mathematics lessons where their methods of working mathematically could be monitored (Käpnick, 1998, pp. 36–38). M. Nolte initiated extra meetings for inter-

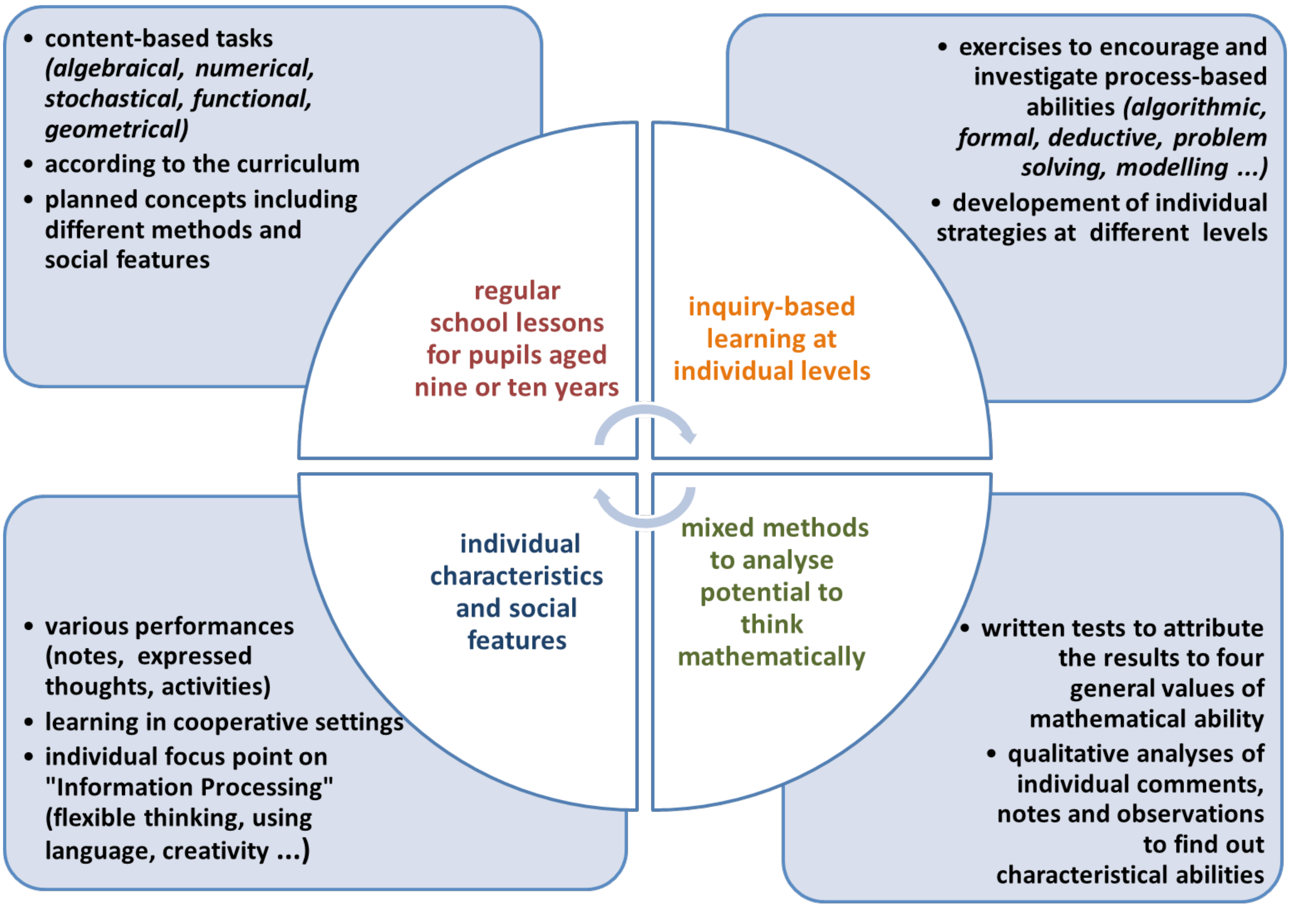

Figure 1: Empirical framework for a process-based analysis of mathematical gifted pupils in primary school

ested pupils, and implemented tests and challenging exercises (Nolte, 2004, pp. 17–20). Both stated that it is quite difficult to define or even categorise an exact level of mathematical giftedness, if pupils are chosen only according to teachers' references, parents' suggestion or their performance in standardised tests (Käpnick et al., 2005, pp. 18–28). We assume that "mathematical giftedness is the individual potential to think mathematically. (...) High mathematical giftedness is characterised by an above-average potential in several aspects of mathematically thinking." (Ulm, 2011, p. 7) Content-, process- and information-based thinking as well as environmental and individual features influence the pupils' ideas, results and performances (Ulm, 2011, pp. 6–9).

Empirical project and analysis

This project focusses on the research question whether there are significant differences between the mentioned ways of identifying mathematical giftedness, and what a simple identification tool for teachers' observation in everyday classroom situations must look like in order to allow for a successful identification of gifted pupils. With regard to research methodology, the development of different tasks which correlate with varying aspects of mathematical thinking builds the starting point when it comes to encouraging pupils during lesson to work on a topic independently and cooperatively (cf. upper half of Figure 1). In addition, various didactical settings and methods offer a detailed, qualitative view on the pupils' individual mathematical abilities (cf. Figure 1 below). Afterwards, observations are interpreted by a qualitative content analysis. The latter considers different aspects of mathematically thinking corresponding to four levels of mathematical ability. In a final step, the results are compared to the results of standardized tests.

Affect and mathematical thinking

Introduction to the papers of TWG08: Affect and mathematical thinking

Pietro Di Martino[1], Inés Ma Gómez-Chacón[2], Peter Liljedahl[3], Francesca Morselli[4], Marilena Pantziara[5] and Stanislaw Schukajlow[6]

1 University of Pisa, Pisa, Italy, dimartin@dm.unipi.it

INTRODUCTION

The quantitative data about the participation to TWG08 at CERME9 highlights the growing interest toward affective issues in the field of Mathematics Education. 40 manuscripts were submitted to the group, 34 were accepted for the discussion, and finally in these proceedings 29 papers and 4 posters are included.

Although we have seen a general upward trend in the number of countries represented within this TWG, CERME9 set a new record in this regard with 16 countries present, representing four different continents. This meant that we had more papers both submitted and presented than ever before. 40 manuscripts were submitted to the group, 34 were accepted for the discussion, and finally in these proceedings 29 papers and 4 posters are included.

Due to the high number of papers and in order to have adequate time for a deep discussion of all the contributions, we organized five of the seven working group sessions splitting the group in two subgroups, maintaining the whole group for the first and the last session. Moreover, in order to avoid the split of the group into two fixed subgroups A and B, we collected participants' interests before the conference and organized different subgroups for each split session. During the five sessions, each participant had the opportunity to attain either group A or group B according to their preferences and in this way to meet all participants of the TWG08.

All submitted documents (paper or poster) were discussed: presenters had 10 minutes (5 minutes for posters) to introduce the key-ideas of their papers, then an assigned reactor had 5 minutes to underline issues or pose questions to the whole audience and finally there were 15 minutes for discussion (5 minutes for posters). In this way, discussions were generally centred and engaging. The final versions of the papers and posters have benefited and developed from the inspiring and motivating discussions conducted during the Conference, that have also involved 5 researchers without submitted papers.

THE STATE OF THE ART

Boero and Szendrei (1998) stress the cumulative and universal characters of the research in mathematics education: this universal character appears to be particularly important in the field of affect, characterized by several constructs derived by other domains of research. For this reason and due to participation of many newcomers in the TWG08, we used part of the first session to report the results emerged in the TWG08 in previous CERMEs conferences.

Marilena Pantziara (who chaired the previous two TWG08) developed and presented a very interesting overview, significantly titled "CERME TWG08: The past-The present-The future".

Starting with the past, i.e. the first studies in mathematics education where *affect* emerges as a field of research (McLeod, 1992), Pantziara retraced the reasons that induced many researchers to go beyond the cognitive for better understanding the complex process of learning and teaching mathematics. Then Pantziara introduced the main affective constructs – from the more "classic" (emotions, beliefs, motivation and attitudes) to other constructs introduced in the more recent editions of CERME (identity, mathematical security, uncertainty orientation). The presentation included the evolution of definitions, methods and questions in our field, as emerged by discussions in previous Affect TWGs, and the model for the structure of the affective domain introduced by Hannula in CERME7 (2011).

In the description of the progress of the research in the field of affect (corresponding largely to the evolution of the papers presented in the overview of Affect TWG), the presentation stressed:

— the growing attention to the clarification of concepts (despite that, the problem of different meanings given to the same words is even now not overcome) and to the mutual relationship between concepts;

— the trend towards the use of mixed methods (quantitative and qualitative) in the research on affect, overcoming the initial preponderance of quantitative methods. The interesting aspect is that this trend is related to the shift from the description of a phenomenon to the interpretation of the same phenomenon;

— the growing attention to the interpretation of the collected data (this aspect is clearly linked to the previous one, and in particular to the shift on affect from a normative approach to an interpretivist one).

Within this frame, the presentation highlighted some important possible directions for future research on affect. Some of these directions were exactly discussed during the sessions of TWG08 in CERME9.

THE PAPERS PRESENTED IN TWG08 AT CERME9

The analysis of research questions of the papers discussed reflects the current diversity of interests and approaches inherent in the field of affect research. The only commonality across these diverse perspectives is that the papers all deal, for the most part, with disaffection. We are still, as a field, working towards precision in terminology and the papers reflect this effort. Finally, as in previous meetings, the papers continue to take into consideration the cultural contexts (language, traditions, and history) within which the research is set.

However, these similarities aside, CERME9 also saw a significant evolution from past affect TWG's.

In this CERME9, in continuation with a long tradition in the field of affect, a spread topic concerns the study of (pre-service or in-service) teachers' beliefs: Arslan and Bulut study middle grades mathematics teachers' teaching efficacy beliefs and their sources; Schmitz and Eichler investigate teachers' beliefs about the roles of visualization; Yurekli and Isiksal discuss the origin of pre-service teachers' self efficacy beliefs; Haser, Arlsan and Kübra explore primary pre-service mathematics teachers' beliefs about mathematics teachers through asking them about their metaphors for mathematics teachers; Bräunling and Eichler exhibit a case study to reconstruct the whole belief system of a single teacher about the teaching and learning of arithmetic; Skilling and Stylianides investigate secondary teacher beliefs and practice that the teachers report using to promote cognitive engagement in their classes. Charalampous deals with students' beliefs and particularly with the question: "does mathematics pre-exist and hence is discovered or is it invented and owes its being to humans?".

Two papers are related to the development of instruments to analyse students' beliefs: Kibrislioglu and Haser develop mathematıcs-related belıefs questionnaires while Andrà, Brunetto, Parolini and Verani propose a codifying system for inferring the students' "I can" and "you can" during a groupwork activity.

Another issue of interest concerns the role of motivation/engagement in mathematics learning and the way to improve perseverance in students' mathematical activities: Lewis studies and describes patterns of motivation in mathematics classrooms; Pantziara and Philippou discuss the role of multiple goal in students' motivation and achievement; Barnes discusses how to improve children's perseverance in mathematical reasoning; Kazima investigates students' reasons for preferences of contexts in learning mathematics; Beumann analyses the impact of mathematical activities on motivation and interest (these last two papers are not included in the proceedings).

Several papers deal with the issue of affect in problem solving – Viitala discusses a case study of a grade 9 girl; Antognazza, Di Martino, Pellandini and Sbaragli and Daher, Swidan and Shahbari study the intertwining of affective and cognitive factors in problem solving in two different school levels (respectively kindergarten and grade 7 students); Müller-Hill and Spies analyse the role of aesthetic experiences in problem solving processes; Tuohilampi, Näveri and Laine present a three-year intervention designed to improve primary school pupils' problem solving skills, and mathematics-related affect; Morselli and Sabena present a study about primary pre-service teachers' affective pathways in problem solving – and, more in general, with emotions. Helmane describes basic emotions of primary students during mathematics lessons; Martínez-Sierra describes students' emotional experiences in high school mathematics, Schukajlow analyses a connection between boredom and students' performance; Fyhn deals with the original theme of the consideration of affective aspects of knowing mathematics in oral examinations in Norway.

De Simone and Lake discuss in their papers the emotional experience of teaching mathematics at the secondary school level.

Regarding the posters, Grothérus describes a method for teaching, evaluation and assessment in mathematics finalized to reduce students' math anxiety; Hansson investigates how students explain their selected failure in mathematics; Andrà, Brunetto, Parolini and Verani study teachers' interpretations of students' mathematical competencies; García González and Farfán Márquez analyse students' attitudes towards mathematics.

As usual in our group, there are papers that examine in depth theoretical aspects: Liljedahl uses the theory by Leont'ev to interpret pre-service teachers' changes after an intensely negative emotional experience and introduces the idea of hierarchy of teachers' motives; Moscucci and Bibbò describe relationship in the affect domain using theory by neuroscience; Pieronkiewicz introduces the notion of affective transgression in order to interpret students' negative emotions towards mathematics; Branchetti & Morselli study the relation between identity and rational behavior.

The discussion of theoretical aspects was particularly stimulating because it highlighted new trends. In particular, in CERME9 for the first time we had papers looking at affect from the participationist (social) perspective overcoming a pure aquisitionist (individual) perspective. Moreover, the discussion about identity (a construct that has a growing attention in the field of affect) has underlined the possible contributions for the study of this construct from a socio-psychological and interactionist approach emphasizing the construction of identity processes and conceiving identities as strategies.

The importance of considering the dynamic dimension of culture has been also underlined. In particular, it has been highlighted the need to unpack "cultures", considering how they have been enculturated into a set of pedagogical assumptions (that is, beliefs and orientation).

Summarizing this brief panning shot at a more qualitative level, the papers presented are focused much more on teacher affect (as opposed to student affect) than we have seen in the past.

Trait and *state* (Hannula, 2011) research has long been presented in the papers at past CERMEs. However, unlike previous years, the research at CERME9 was much more focused on the *state* side of this dichotomy. CERME9 also saw an increase in the number of different affective frameworks being used to analyse phenomena and more qualitative papers. This stands in stark contrast to, for example, CERME5, where almost all of the papers were quantitative.

We also saw several papers dealing with emotions, which is a significant change from past CERMEs. Likewise, there was an increased presence of research into meta-affective aspects, the role of interests, creativity, and self-regulation – topics that had previously received little attention at CERME.

Finally, for the first time we had two papers looking at affect from the participationist perspective.

Despite all this evolution the participants felt that more changes are still needed. In particular, there was a call for further work in improving our definitions. In addition, there was a feeling that more work was needed on the emergent topics of emotions, and meta-affect.

Although we continue to consider cultural contexts it may also be time to consider micro-cultures, such as the classroom or student-teacher relationships. More longitudinal research is needed and, with the shift from quantitative to qualitative research methods, it is now time to consider mixed methods. The introduction of participationist perspectives signals a need to pay more attention to theorizing and networking of theories as well as more comparative and cross-domain research. And, of course, more work on the implications of research on the constructs for curriculum development, teacher education, assessment, and intervention is warranted.

‘I can – you can’: Cooperation in group activities

Chiara Andrà, Domenico Brunetto, Nicola Parolini and Marco Verani

Polytechnic of Milan, Department of Mathematics, MOX, Milan, Italy, chiara.andra@polimi.it

We stem from phenomenological stances that each thought originates from a perceived competence (“I can”), which has a strong affective nature. In groupwork activities the “you can”, namely the competence that a student recognizes in the classmates, is also important. We propose a codifying system for inferring the students’ “I can” and “you can” during a groupwork activity. The results are 2D-diagrams that capture the main moments of the activity and help us identifying the leader(s) of the activity and the different roles the students play.

Keywords: Group interaction, perceived competence, cooperation.

INTRODUCTION AND FRAMEWORK

Learning in mathematics occurs in and through interaction with others, the learner becomes conversant with new concepts emerging in the activity, as Sfard (2001) points out: “communication may be defined as a person’s attempt to make an interlocutor act, think or feel according to her intentions” (p.13). Activity allows the growth of mutual understanding and coordination between the individual and the rest of the community (Sfard, 2001). Cooperation is one of the main focuses. Different kinds of cooperation have been depicted (Gooding & Stacey, 1993), with respect to the objective of the activity. Also, conditions that foster cooperation have been highlighted: operational, computational requests of the activity enhance cooperation, whilst reflexive ones may impede it (Hertz-Lazarowitz, 1989). But, are there conditions that shape cooperation which can be traced back to the relationships among the students, rather than to the features of the task?

We stem from Merleau-Ponty (2002) claim that every thought originates from an “I can” rather than from an “I think of”. Di Martino and Zan (2011) have identified the students’ “I can” in the narrative accounts of their relationship with mathematics during the school years: they call it *perceived competence*. “I can” may prompt the student to intervene in a conversation, proposing a strategy, rephrasing another student’s utterance, adding a detail, fostering her thinking. “I can’t” may push a student to ask questions, seek for clarification, stay silent and listen to her mates (see Andrà & Liljedahl, 2014). Since each student may (or not) recognize a competence to each one of his classmates, there is another dimension that counts: “you can”. Andrà and Liljedahl (2014) have shown that, during a group activity, a student may care of a certain classmate’s attention and, at the same time, be annoyed by another student’s reaction to his proposal. “I can” and “you can” are seen as interior states, whilst utterances, postures, glances, gestures are the external expressions of such internal states that determine each student’s will to propose, to react, to stay silent.

METHOD OF ANALYSIS

We exploit an idea introduced by Sfard and Kieran (2001) to capture “two types of speaker’s meta-discursive intentions: the wish to react to a previous contribution of a partner or the wish to evoke a response in another interlocutor” (p.58): reactive and proactive utterances, respectively. Proactive and reactive statements are, in our view, indicators for inferring a sense of “I can”, a sense of likelihood of success that provides the basis for thought and communication. A sense of “I can’t”, conversely, can be inferred from a student’s silence, but also from his/her questioning the strategies/results proposed by his/her classmates. Postures, glances, tone of voice can sustain our inferences about a student’s sense of “I can” versus “I can’t”. A sense of “you can’t” is, as well, inferred from absence of reactions to other students’ utterances. A student who does not glance at a classmate, but looks at the paper, or elsewhere, may not recognize a competence to her (see also Andrà & Liljedahl, 2014). Conversely, a student who care about a classmate’s attention, a student who gives her way, who reacts to her, may feel a sense of “you can”.

We analyze two video excerpts. We codify the excerpts as follows. Each example is divided into *moves*, lasting few seconds each and being identified by the placement of the students into a 2D-diagram, representing the internal states: "I can" versus "I can't", "you can" versus "you can't". If a student change his/her placement in the 2D-diagram, a new move starts. Even if there can be various degrees of "I can" and "you can", in our first analysis we decided to depict only two possible, dichotomous states. The result of the analysis is a series of 2D-diagrams (4 possible "states") that capture the subsequent moves of the activity. We added arrows to denote changes (if any) for a student with respect to the previous move. The first episode has no arrows.

The diagrams are the result of: (i) extensive observation made by each author, (ii) intense discussion about possible interpretations of data. After hours of joint work in team, it is not possible to provide indices for inter-rater agreement within us, given that each interpretation is strictly intertwined with each other's one. This can be seen as a weakness of this work. Hence, in a poster (Andrà, Brunetto, Parolini, & Verani, 2015), we report on several secondary school teachers' comments, and we specifically seek for agreement/disagreement with respect to our interpretations.

DATA

We present two excerpts taken from a course in probability aimed at preventing gambling abuse. These excerpts come from 22 hours of video recording in 13 different schools of different types in Northern Italy. These two excerpts have been selected because they capture some interesting dynamics. True, the small sample is a limitation of this study. Another limitation is the focus only on the perceived competence: Di Martino and Zan (2011) identify another important dimension, 'I like'. Motivation is third dimension that plays a crucial role in framing students' interaction. As a first step, we decided to focus only on the 'I can'-'you can'.

The first excerpt comes from a group activity engaging 4 grade-12 (17 years old) students: Enrico (E), Federico (F), Giovanni (G), and Michele (M). They are attending a technical high school program and are asked to invent a fair game using two dices (possible outcomes are all the sums from 2 to 12). In a fair game, the expected winning equals the ticket price. They have computed the probability of each sum, reporting it on the paper (Figure 1A). They now have to assign the prize to each sum from 2 to 12: G wants to start from 7, and F from 12. The excerpt lasts almost 1 minute. Out-of-school knowledge emerge, as well as school mathematics.

The second excerpt comes from a group activity engaging 4 grade-10 (15 years old) students: Alice (A), Barbara (B), Carola (C), and Dora (D). They are attending a scientific high school program and are analyzing a slot machine, which has three rolls with 9 different symbols each. The number of different sequences is 9^3=729. There is only one winning symbol: the gold bar. The students have computed the probabilities of one, two and three gold bars, and reported them on the paper (Figure 1B). They now compute the expected

Sum	Probability	Prize
2	1/36	
3	2/36	
4	3/36	
5	4/36	
6	5/36	
7	6/36	
8	5/36	
9	4/36	
10	3/36	
11	2/36	
12	1/36	

(A)

Probability of 'gold bar-other-other': 64/729 → 9%

Probability of getting 1 gold bar: 192/729

Outcome	Prize	Probability
1 gold bar	1 euro	
2 gold bars	10 euros	
3 gold bars	100 euros	

(B)

Figure 1: Parts of tasks completed before the first (A) and second (B) excerpts begin

winning. To do so, they have to report the probabilities in the table, to multiply each of them by the corresponding prize, and to sum up the results (weighted prizes). The excerpt lasts 8 minutes.

DATA ANALYSIS

Excerpt 1—move 1. We now present the excerpts, inferring the students' "I can" and "you can" from their utterances, their postures, their gazes and the tone of their voice. Data analysis begins with the first 13 seconds of the first excerpt.

1 G: We should start with 7, which has the highest prize. ...No, the lowest prize.
2 F: No, let's do, let's bet 1 euro.
3 M: Easy.
4 F: If e.g. you bet on 12, it comes out, you win...
5 M: But bet 2 euros.
6 F: ...you win 36 euros. Let's do 36 to 1.

Both G and F make proactive statements. G looks at the paper but addresses F. F, in fact, reacts immediately to G ("No"), and makes a proactive statement ("let's do, let's bet 1 euro"), which involves everyone: in fact, M reacts to it in 3 ("Easy"), and in 5 ("bet 2 euros"), and E will react later, in 13 ("Else, bet 50 cents"). G opens the conversation, proposing to start with the prize to be assigned to 7. A proactive statement is an indicator for G to have a sense of "I can". We claim that such an "I can" is grounded on the intuition that 7 should be assigned the lowest prize, and this intuition comes from his experience with betting games: the higher the probability to win, the lower the prize. F makes three proactive statements, showing a clear sense of "I can": in 2, 4 and 6. In his proactive statement in 4 F proposes to start from the prize to assign to 12. At 6 he intuits that one should win 36 euros, and this intuition comes from his vivid experience with sport betting practice. The language he uses is the language of sport betters. In the first two proactive statements, F looks at the paper, in the last one he looks at G. To look at the paper is an indicator of "you can't", and in fact F speaks over his classmates both in 2 and 5. In 2 F contradicts G with a "No", without providing any justification to the group concerning why should them do differently from what G has proposed. In 5 M reacts to F, but F does not react to M. F discards M's proposal to bet 2 euros instead of 1.

In 1, indeed, G feels a sense of "you can", using the first plural person ("we"). He makes his proposal, but he remains silent to listen to the others, without trying to impose his standpoint. As well, also M shows a sense of both "I can" and "you can": the adjective "Easy" he uses at 3 to comment on F's proposal, clearly refers to his perceived competence, and his proposal in 5 to bet 2 euros is both involving and bearing a sense of competence with respect to the activity. E is silent in this move of the activity and we conjecture that E is listening ("you can"), but he is still making sense of the activity and hence his perceived competence is low ("I can't"). We infer this by looking also at his posture: from 1 to 5 he stares at F, but in 6 he takes the paper and brings it closer to him, starting reading the task silently.

Excerpt 1—move 2. Also this move starts with a statement from G, who reacts to F.

7 G: Wait: 7, how much is it? We should compute the average prize and...
8 F: It's enough to do this (points to 36, the denominator) divided by this (points to 6, the numerator of the probability to get a sum of 7). If you do 36 divided by 7, what do you get? (makes computations with the calculator) 5. If you bet 1 euro on 7, you win 5 euros.

In 7 G reacts to F, recalling his will to start with 7 and the mathematical activity on the mean prize during previous lessons at school. In this moment, G feels a sense of "I can't" and asks for F's help in computing such a mean. F reacts to G, showing a sense of "I can" and "you can't". The sense of "I can" can be inferred from his prompt, procedural reaction, and "you can't" can be inferred from his proposal that differs from the one recalled by G. In fact, F again refers back to sport betting practice rather than the mathematical activity. A conflict starts to emerge, the conflict between the experience at school (the average) personified by G, and the betting experience personified by F. Since E and M are silent, but they are listening to F and G, we conjecture that they feel a sense of "I can't" that hinders their will to speak, and a sense of "you can" since they give F and G their way. We further observe that F and G occupy two mirroring positions: F is the "I can"-"you can't" area, whilst G is in the "I can't"-"you can" area (Table 1, column 2). This area is occupied also by E and M and it seems that the group has reached a sort of frozen situation: there is F, who has a strong sense of "I can" and "you can't", whilst his mates feel that they "can't". How can the group sort this situation out? A possibility is that E, G or M start to question the sense of "you can" with respect to F. If also F "can't", the group activity can go on *as a group activity*. This is happening in *Excerpt 1—move 3*.

9 G: Hence, the minimum you can win is 5 euros.
10 E: (inaudible)
11 G: It's too much.
12 F: The highest prize is 36 euros.
13 E: Else, let's bet 50 cents.
14 F: It's the same, finally. If we bet 1 euro at least we have (inaudible)
15 M: (inaudible)

In 9 G reacts to F's result and tries to give sense to it. This confirms that, even if he has a low sense of perceived competence in the second move of the activity ("I can't"), he trusts F and he listens to him ("you can"). In 11 G adds: "it's too much". His emotions provide G with a sense of unlikelihood of success, a sense of both "I can't" (as in the previous phase of the group activity), and "you can't": F now can't solve the problem, the solution he is proposing is "too much". G looks at the paper, but E and F, conversely, look at him. F, specifically, recognizes his role ("you can"). Even if they are almost inaudible, also E and M contribute to the activity in its third move: their perceived competence has increased ("I can"), and—as we have already commented—we infer a sense of "you can" towards G and F.

In 12 F makes his fourth proactive statement to the whole group, and this is taken as an indicator of "I can". In 13 E reacts to F's proactive statement, and F in 14 makes his first (and only one) reactive statement, reacting to E. F looks at E, differently from his usual practice. Hence, F not only recognizes G's role ("you can"), but also sees E as an interlocutor (again, "you can").

G's move towards "you can't" is mirrored by F's move towards "you can": F has recognizes to G a role, F is recognizing G as an interlocutor (Table 1, column 3). Furthermore, E and M have moved from "I can't" to "I can", since they feel they can follow G's argument and contribute to the group activity. This is mirrored in the next move of the activity, where E nods at F and F stares at E. *Excerpt 1 – move 4*.

16 F: E.g. 12 is given ... like the SNAI[1] (all the students laugh)
17 F: 12 is given 36 to 1. If I bet 1 euro I win 36 euros.
18 E: (nods)
19 G: mmm it's too much, because, then, the 7...?

In 16–17 F makes another proactive statement: "12 is given 36 to 1. If I bet 1 euro, I win 36 euros". F looks at the paper in 16, and at E in 17. We read a sense of "I can" for F, but a sense of "you can't", since he looks at the paper and he does not involve his mates, he does not invite them to react to him. G reacts to F, and this reaction speaks to his sense of both "I can't" (in fact, he is asking again how to deal with the case of 7) and "you can't" (in fact, he feels that the result got by F "it's too much"). E has moved towards "I can", continuing to feel a sense of "you can" with respect to both F and G. Since M does not intervene, we infer that he moves again to "I can't".

We observe that the situation at this point is very balanced (Table 1, column 4). There is a leader, F, who feels a sense of "I can" as well as a sense of "you can't", but there is another student, E, who has been almost silent during the activity, who attracts F's gazes at this point, since he has a sense of "I can" and "you can". Also M feels a "you can", while G feels both an "I can't" and a "you can't". At this point, something really interesting happens (*Excerpt 1 – move 5*): F ignores G's doubt ("the 7?"), and he goes on with the prize to be assigned to 11. Then, he feels a sense of "I can't" saying

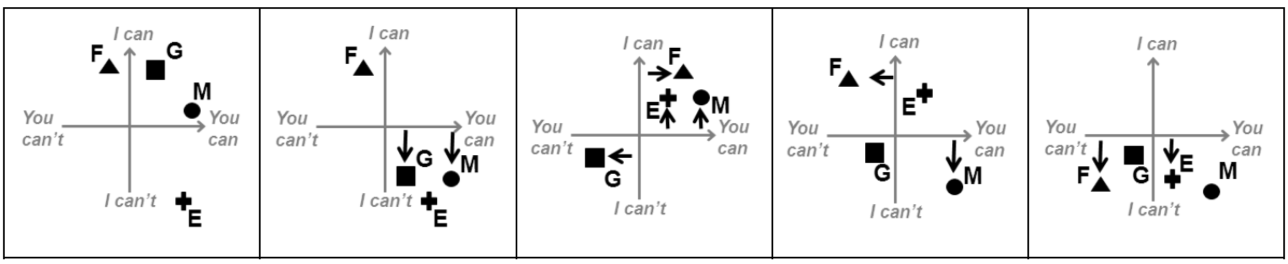

Table 1: The five subsequent moves of the activity involving E, F, G and M

"Eh, no, because…". His emotions provide F with a sense of unlikelihood of success, a sense of "I can't", which freezes him. Also M and E, despite their sense of "you can", feel a sense of "I can't". Table 1 summarizes the five subsequent moves that have been analyzed.

Excerpt 2 – move 1. In the first 15 seconds B reads the task, then

5 B: We should use combinatorial mathematics.
6 D: No, we have computed that the probability of finding one gold bar and two other symbols (she takes the sheet of paper to be able to read it) was…
7 B: …was it 192?
8 D: No. No. This one maybe (she points to the probability of getting the sequence 'gold bar–other–other')
9 B: (reads) 'probability of gold bar-other-other' (nods). 9%
10 D: 9%

The students look mostly at the paper, only B in 5 looks at D. B in 5 makes a proactive statement, but D reacts proposing to use the probabilities they have already computed. In 8 B reacts to D's proposal and she reads on the sheet of paper the correct answer: the probability of getting one gold bar is 192 (over 729), but D contradicts B and leads the group to use the probability of getting "gold bar–other–other", that is 9%. Both B and D feel a sense of "I can", whilst A and C––being silent—yields us thinking that they are feeling a sense of "I can't" and "you can", giving B and D their way. Also B feels a sense of "you can", but D feels a "you can't": in 6 and 8 she contradicts B ("no"), proposing something different from what B has proposed. There is a conflict that is emerging, a conflict between two strategies: B would like to resort to the formulas learned in previous lessons, while D would like to use the computations already made. The group follows D's proposal, as we will see in the next move, but both B and D are right: B (as well as the rest of the group) is not aware that they have already used combinatory. We add a local comment to this segment of data analysis: this lack of awareness is quite usual when the students deal with strategies and concepts that are "new" for them, since they are still not conversant with them. Learning is, in fact, a progressive becoming aware of mathematical meanings.

In the subsequent 2 minutes, the students make computations and report the results on the paper, then they ask the teacher if their work is correct, and the teacher confirms their doubt: it is wrong. *Excerpt 2 – move 2.* B recalls her first proposal:

42 B: That is why we should use combinatorial mathematics. Otherwise, they would not have given it to us.
43 C: Let's use our ingenuity!
44 B: For sure it's with combinatory, then let's invent something. Well, in combinatory one needs to multiply many numbers, so let's have a look…

D is silent, we infer that she is feeling a sense of "I can't", but C intervenes and say "let's use our ingenuity" looking at A, the classmate that has remained silent until now. We see a sense of "I can" in C, who looks at the student that has been silent like her, in a sense encouraging her to intervene. B is proactive ("I can"). A does not intervene for the present. The teacher provides a feedback about the mistake the group has made: the probability of getting one gold bar is not 9%. A takes the floor:

67 A: This one (she points to 192/729) is the probability to get one gold bar.
68 B: Hence, I have said it correctly at the beginning! It is 192 divided by 729.
69 C: (speaks over B) 192 divided by 729.
70 B: (addressing D, pleased) Ah! Ah!

B and D look at each other in this sequence, and B expresses a sense of revenge with respect to D: we read it in terms of "I can" and "you can't" on B's side. Moreover, the conflict between B and D is solved: D was right in having proposed to use their own computations, and B was right in using 192/729.

Excerpt 2 – move 3. The students copy the probabilities on the sheet, then they stop.

110 C: (looks at B) But what should we compute?
111 B: The total average prize. The… mm… namely…
112 D: All those prizes times the probability that you win them, namely that you win the prizes, divided by… all the cases?
113 C: Eh?

114 D: 729? Because there are many cases in which you win nothing.
115 A: Exactly. There are many cases where you get nothing, where you get 'other'.
116 B: Hence we should do the prize..? No, the cases in which you win, divided...
117 D: The cases in which you win, the total prize divided by all.
118 B: Why divided by all?

D makes two proactive statements in 112 and 117, and all her classmates look at her. A, B and C react to her proactive statements: C ("Eh?") at 113, A echoes D's comment at 114, and B at 116 makes sure she has understood, but at 118 asks for explanation. D feels a sense of "I can" and "you can": she is proactive, but she also reacts to her classmates. Also A intervenes, showing a sense of "I can" and "you can". B and C, instead, feel a sense of "you can" with respect to D, but they are not understanding D's proposal, and ask for clarifications: we infer a sense of "I can". *Excerpt 2 – move 4*. The group remains silent for a while, then A (the student that feels "I can"), tries to reformulate D's proposal:

119 A: You are saying: to sum all the average prizes. Is it what you're saying?
120 D: I do not know (smiles).
121 C: Eh, (echoing D) 'I don't know what I am doing'! (smiles)

We see a sense of "I can't" in D's utterance "I do not know", and of "you can't". *Excerpt 2 – move 5*. C, after having echoed D, addresses B and asks:

122 C: Wait. Is it asked (A pulls the paper close to her) the mean of the prizes?
123 B: But, but I would have done this: I would have multiplied the mean prizes for the probability, then summing the probabilities, divided for all the cases.
124 C: Like the last time!
125 B: Yes, it is the weighted average.

D remains silent and stares at the paper, but C in 122, even if she is addressing B, looks at D, and also B looks at D in 123. D's silence leads us inferring a feeling of "I can't" and "you can": she is listening to her mates. A shares the same state of D, being silent. B and C, indeed, share a sense of "you can", accompanied by a sense of "I can". They have found the correct strategy, and they are confirming it to each other trying to involve the rest of the group (looking at D, for example). They are recognizing the distinguishing features of a procedure they have already used, and their positive emotions provide them with a sense of likelihood of success. They are intuiting the analogy with respect to a procedure previously used, that can work.

DISCUSSION

Answering to the research question (are there conditions that shape cooperation which can be traced back to the relationships among the students?), we can see that: (a) proactive utterances and *vertical arrows* allow us to identify *the leader(s)*; (b) *horizontal arrows* allow us to identify *collaboration*. In excerpt 1, F provides the majority of proactive utterances, whilst G is proactive only at the beginning, then he reacts to F's proposals. In excerpt 2, B and D are proactive throughout the excerpt; B and D are the leaders, but also A and C make 2 and 3 proactive utterances, respectively. B and D are collaborative leaders.

E and M show only vertical movements: they occupy always the "you can" area, and they *oscillate* between the "I can" – "I can't" positions.

We may also notice that vertical arrows characterize the moves of students who are not leaders: E and M are clearly not leaders in excerpt 1, like A and C in excerpt 2. But, there are downward arrows also for F (Table 1, last move) and D (Table 2, move 2). These two downward arrows, indeed, depict two different situations. In F's case, it is F alone that stops speaking and starts to doubt about his strategy: his emotions

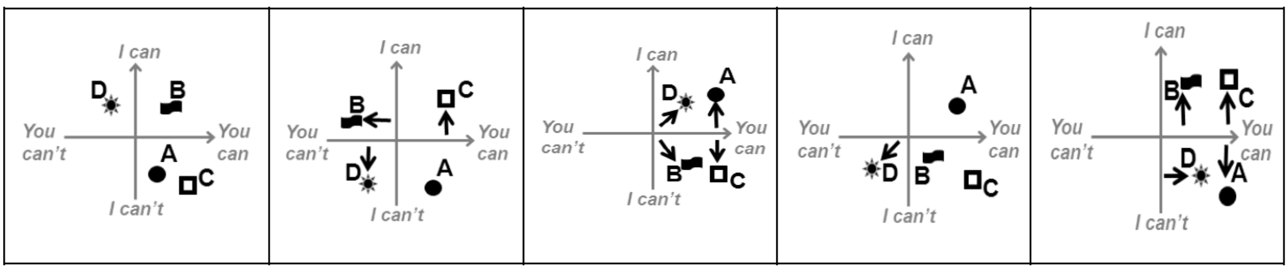

Table 2: The six subsequent moves of the activity involving A, B, C and D

provide him with a sense of unlikelihood of success. F, in fact, is a leader that is not collaborative. In D's case, D goes down because it is B that is leading in that move. Hence, the leaders' "I can" can be diminished either by his/her emotional sense of likelihood of success, or by the feedback of the classmates. This may open the possibility for the others to intervene (Andrà & Liljedahl, 2014). Negative feedback determine a decreasing of "I can". The other way around, to increase one's "I can" by providing positive feedbacks, does not work likewise: in excerpt 2, D receives the glances of her mates (that is to say "you can" to D), but her "I can" does not improve.

We have also seen that *conflicts* emerge: between G and F, between B and D. Conflicts can be read as contrasting views that can impede true dialogue between students. Each student's view of mathematics shape cooperation in groupwork activities, but cooperation is driven also by "you can", the competence recognized by the others. Horizontal arrows correspond to movements on the "you can"-"you can't" axis. In Table 1, we see that F shows only movements of this sort, and moreover he is quite stable in the "I can"-"you can't" position. F is a leader, which *does not recognize* an ability to his mates. In excerpt 2, also B and D occupy the "I can"-"you can't" area, but for few seconds. We sense that such a position is (or can be) necessary for the development of the activity, it is when a student occupies it *for the most of time* that cooperation between the students may be hindered.

One can question whether there are configurations, in the 2D-diagram, identifying situations where the group activity gets. We observe that each excerpt ends with either all the students in the "I can't" area (excerpt 1), or all of them in the "you can" one (excerpt 2). Interestingly, these two configurations are followed by an intervention from the teacher. This issue needs further reflection, however.

This paper reports a qualitative study aimed at defining a descriptive schema to analyze group activities, and the focus of this work is mainly methodological: stronger theoretical foundations are needed in future works.

The flow of emotions in primary school problem solving

Davide Antognazza[1], Pietro Di Martino[2], Aline Pellandini[1] and Silvia Sbaragli[1]

1 SUPSI, Department of Education and Learning, Locarno, Switzerland

2 University of Pisa, Department of Mathematics, Italy, dimartin@dm.unipi.it

Research into if, and how, students' emotions change during problem-solving, the factors behind the change, and the potential impact of a certain emotional change on mathematical activity, may provide significant indications regarding students' problem-solving difficulties, and regarding the link between affective and cognitive factors "in context". In this paper, we describe the results of a pilot study conducted at primary school level, while also emphasising the methodological choices made in relation to the young ages of the students involved.

Keywords: Emotions, problem solving, affect, primary school, mathematics.

INTRODUCTION AND THEORETICAL FRAMEWORK

The role played by the affective factors in the study of the mathematics teaching and learning process has been little explored for a long time. The success of behaviourism in psychology, the clear division between emotions and rational thinking, and the conviction that this latter sphere is particularly predominant in mathematics marginalised research into affective factors in mathematical education until the 1980s. As emphasized by Zan, Brown, Evans and Hannula (2006, p. 113): "affect has generally been seen as 'other' than mathematical thinking, as just not part of it."

In the 1980s, the gradual affirmation of the interpretative paradigm in the social sciences, related to a greater attention to aspects regarding the complexity of human behavior, has led researchers to abandon the attempt to explain behavior through measurements or general rules based on a cause-effect scheme, and to search instead for interpretative tools. Within this approach, the scientific community in M.E. has recognized the need to go beyond purely cognitive interpretations of failure in mathematics, in particular to interpret the failure of individuals apparently possessing the necessary cognitive resources in mathematical problem solving (Silver, 1985).

In 1989, the book *Affect and mathematical problem solving by McLeod and Adams* opened up a new era in research into emotions in mathematics education. As a matter of fact, the book includes several contributions that, following the theoretical model for the cognitive origin of emotions proposed by the psychologist George Mandler, underline the role of emotion in one of the most important mathematical activities (problem solving). According to Mandler (1989), complex emotions are the result of the cognitive evaluation of a visceral arousal provoked by a discrepancy between the individual's expectations and the demands of ongoing activity.

In the meantime, evidence of the strong interaction between cognitive and affective factors – in particular, of the influence of emotions on decision-making processes – also emerges from studies from other fields of research such as neuroscience (Damasio, 1996) and psychology (Salovey & Mayer, 1990). The study by Salovey and Mayer, introducing the concept of *emotional intelligence,* completely changed the way of looking at the affective component of human personality and its relationship with the cognitive field. Emotions are no longer regarded as a disturbance to correct thinking, but as a potential for effective thinking, particularly when our (and those of other people) affective experiences are recognised and managed appropriately.

On the other hand, according to Mandler (1989, p. 16): "Affectless learning is not a possible goal for a theory or for the praxis of instruction. Common sense tells us that emotions and affective reactions are with us now and forever."

This all leads to the conviction that it is important to teach emotion management in learning, a conviction that is also gaining ground in the mathematics education research field, which confirms how emotions on the one hand affect cognitive processing, biasing attention and memory and activating action tendencies, and on the other have a key role in human coping and adaptation (Evans, 2000; Hannula, 2002). In particular, Op 'T Eynde, De Corte and Verschaffel (2006, p. 194) claim: "from a socio-constructivist perspective, students' emotions and other affective processes are conceived as an integral part of problem solving and learning."

An important objective of mathematics education should therefore be that of teaching how to manage emotional involvement, particularly that which involves negative emotions (Op 'T Eynde, De Corte, & Verschaffel, 2006, p. 204).

Teaching students how to solve mathematical problems then implies that we have to teach them also how to cope effectively with feelings of frustration or sometimes anger. In other words, when teaching and learning mathematical problem solving, the allowing of space for negative emotions might be an educational goal from a cognitive, as well as motivational, point of view. Indeed, only when experiencing negative emotions will students have the opportunity of learning how to deal with them.

The very features of problem solving mean that the process is typified by frequent *interruptions to pre-established plans* and by local failures, which, according to Mandler's model, initiate the emotional experience process. In his overview of the research on emotions in problem solving, Hannula (2012) concludes: "The main lesson to learn from the research on emotions in problem solving is that emotions are an essential part of problem solving."

Mathematical problem solving is therefore often marked by a strong emotional component, which can very rapidly evolve from positive to negative, pleasant to unpleasant, or vice versa, and emotion management profoundly affects students' performances. So, as emphasised by Op'T Eynde and colleagues (ibidem, p. 204) it is very important to conduct further study into these emotions, in order to "become aware of dynamics underlying the succession of several emotions over a short period of time".

The aim of our research was to study these dynamics at primary school level, investigating students' emotions when faced with a mathematical problem, how these emotions change, and the factors that the students recognise as being responsible for the emotions and for the changes.

METHODOLOGY

Population

The study involved five primary school classes in Canton Ticino (Switzerland): one 3rd grade class (18 students), three 4th grade classes (53 students) and one mixed 3rd- 4th grade class (20 students), making a total of 91 students.

Rationale

It is very difficult to study emotions: all instruments are limited in capturing emotional reactions that are not conscious (Schlögmann, 2002) and, as Ortony, Clore and Collins claim (1988, p. 9): "There is as yet no known objective measures that can conclusively establish that a person is experiencing some particular emotion." These same authors emphasise how emotions are nevertheless not linguistic things, but the most readily available non-phenomenal access we have to them is through language and we are willing to treat people's reports of their emotions as valid.

In the context of mathematics education it has been shown that it is important to adopt a multiple approach to data collection in the research on emotions (Evans, 2004), and how: "mathematical activity should be studied in context, and that researchers should take an actor's perspective [emphasis in the original] *that allows the meaning structure underlying students' behaviours and emotions to become explicit.*" (Evans, 2006, p. 241)

In order to "take an actor's perspective", we believe that it is important to choose instruments that contemplate open answers, where the respondent is free to express his emotions using his own words; as Cohen and colleagues (2007) underline:

> It is open-ended responses that might contain the 'germs' of information that otherwise might not have been caught in the questionnaire (...) An open-ended question can catch the authenticity, richness, depth of response, honesty and candor which are the hallmarks of qualitative data.

On the other hand, the low number of mathematics education studies on the emotions of "young" students (primary school) is probably due to the difficulties experienced by the students in terms of possessing and managing the "language of emotions". This is precisely why an important item of our research was an emotional literacy course conducted by Antognazza and Sciaroni (2010) in the classes participating in the research project, aimed at the allowing students to acquire an understanding of their emotions, and also to learn a specific vocabulary for clearly expressing which emotions they are experiencing at a specific time.

Procedure

There were three phases to our study:

1) **A pre-test** conducted on some pilot classes in order to assess, on the one hand, if the mathematics problems tested were calibrated, and to what extent (i.e. the average level of difficulty for the students), and, on the other hand, to identify a codification protocol for analysing the open-answer questions.

The questionnaire used in the research, and the codification protocol, were defined at the end of this phase, and six problems were identified as appropriate to the research objectives. The texts of the problems were shown to the class teachers, who were asked to choose one that they considered to have the *correct* level of difficulty for their students: neither too easy nor too difficult. One example was: "Giulio and Andrea play together with their toy cars. They have a total of 48 cars to play with. At the end of the game, they each take back their own cars. Andrea has three time as many cars as Giulio. How many cars does Andrea have at the end of the game? How many cars does Giulio have at the end of the game?"

2) **An activity phase**. The students were asked to read the selected problem on their own, to answer the questionnaire tested in phase 1, and, subsequently, to try to solve the problem. No time limit was given. This phase was conducted individually in school workplaces in which the students felt comfortable (class, creative activity laboratory or support class).

The questionnaire given to the students consisted of three questions investigating three aspects:

a) assessment of the difficulty of the problem. Closed-answer question "*how do you evaluate the problem?*" with the following possible alternative answers: easy, quite easy, medium, quite difficult, difficult;

b) expression of the emotion perceived when having to solve the problem. Open-answer question: "*how do you feel about having to solve this problem?*";

c) identification of the reasons underlying the perception of the emotion expressed: Open-answer question: "*Why do you think you feel like this?*".

3) **Semi-structured individual interview** (transcribed), focussing on the emotional states experienced when solving the problem, any changes from the emotion initially expressed ("*On the paper you wrote that you were* [emotion written down]. *Did you feel any other emotions when you were solving the problem?*"), and the reasons for these changes ("*Why did your emotion change? What happened?*").

The students were observed while they were solving the problem, in order to analyse their behaviour and their facial expressions. This observation took place under conditions of experimenter blindness (the experimenter did not know how the students had answered the questionnaire), and was also useful in terms of allowing specific questions to emerge in the course of the individual interviews.

RESULTS AND DISCUSSION

A priori assessment of the difficulty of the problem

An analysis of the questionnaire showed how, after having read the text, most students effectively classified the set problem as "quite easy" or "medium" (see Table 1 below).

A priori assessment of the difficulty of the problem	Easy	Quite easy	Medium	Quite Hard	Hard
Percentage	12%	43%	31%	12%	2%

Table 1: A priori assessment of the difficulty of the problem

Emotion perceived from reading the text

Analysis of the answers to the second question – open-ended and fluid responses – is more complex. On the one hand the positive/negative emotion dichotomy must be defined, while on the other hand it is necessary to identify the "representatives" in order to categorise various labels that appear to take inspiration from similar emotions.

According to Ortony and colleagues (1988), emotions are considered as "valenced reactions" to consequences of events, action of agents, or aspects of objects, and then it is possible to classify the reactions to events as being pleased or displeased, the reactions to agents as approving or disapproving, and those to objects as liking or disliking. These dichotomies permitted a first classification of emotions into positive and negative.

In terms of identifying the representatives, the codification protocol developed following the pre-test phase was utilised, making it possible to identify 6 categories consisting of 3 dichotomous pairs: *confident*, *worried*, *nervous*, *calm*, *happy*, *sad*, to which, a posteriori, was added the category *bored,* not found in the answers obtained in the pre-test. We emphasise that the answer was open, without any kind of restriction and with the possibility for the students to specify more than one emotion.

Table 2 summarises the quantitative results obtained.

Some interesting observations: the emotions initially stated, and supported by the subsequent interviews, are essentially perfectly divided into "positive" and "negative", but although this equilibrium is also found in the specific nervous/calm dichotomy (22% vs 20%), "worried" appears to predominate over "confident" in terms of the possibility of solving the problem, and "happy" appears to predominate over "sad" in terms of having to tackle the problem.

Another significant aspect consists of the fact that the balance between positive and negative emotions obtained from the sample of the five classes is less strong when analysing the individual classes involved in the study. For example, the 3rd grade class is typified by positive emotions selected by 17 out of 18 students (10 students express happiness, and 7 students express calmness), while in other classes negative emotions predominate. For example, in one of the 4th grade classes, consisting of 17 students, the following emotions were expressed: worry (6 students), nervousness (3 students) and sadness (2 students). This may depend partly on cognitive aspects such as superior competence, but also on affective aspects, such as conviction in one's own understanding regarding the specific problem, and on other aspects (emotions, convictions, attitudes and values) depending on the specific social context of the class: "students' interpretation and appraisals processes that initiate the emotional process are grounded in a specific context" (Op 'T Eynde & et al., 2006, p. 196).

As a qualitative note to the analysis of the second question of the questionnaire, we emphasise that in three cases the students' answers testify contrasting emotions. In one of these cases, Enea states testifies between the fear of not knowing how to solve the problem ("*a little scared*") and his confidence in his own abilities, or, in any case, the desire to muster his courage ("*but I'm sure that I can do it*"). In the other two cases, the contrasting emotions are associated with various aspects: *intrinsic*, in the sense of being related to the specific problem, and, *extrinsic*, in the sense of being extraneous to the specific problem. Martina appears worried about having to solve the problem of the toy cars ("*I am in a little bit of difficulty because I can't find the calculation*"), but at the same time she notes that she feels fine as she always does in class ("*I feel good, like in class*"). On the other hand, Mattia feels nervous because, as he later explains in the interview, he always feels nervous when he has to solve problems, but he feels relatively calm about the toy cars problem.

Correlation between the perception of the difficulty of the problem and the emotion stated

Most of the students who state that they think that the problem is easy/quite easy feel calm or happy; on the other hand, those who think that the problem is quite difficult/difficult feel worried or nervous. Out

Emotion	Confident	Worried	Nervous	Calm	Happy	Sad	Bored	Other
Percentage	7%	18%	22%	20%	22%	2%	8%	1%

Table 2: Emotions associated with the problem

of 91 students, only 13 do not assign positive emotions to presumed ease, or negative emotions to presumed difficulty.

Analysing the answers to the third question (the reasons for the emotions), these 13 students are seen to divide into two "categories". The first category consists of those who, in a certain sense, show that they appreciate the "intellectual challenge" of the mathematics problem (usually good-achievers) and for whom the easy problem is boring (Chiara: "*I feel bored because it's boring when problems are easy*"), and the difficult problem a real challenge (Irene, who thinks that the problem is difficult, writes: "*The emotion that I feel is joy because the problem is nice*"). The second category consists of those who, like Mattia cited above, say that they feel nervous when they have to solve mathematics problems, and although they think that the toy cars problem is easy, are overcome by what we might call a worry consistently associated with having to tackle mathematics. This is a very interesting phenomenon, in terms of both research on affect in mathematics education, and in terms of didactics. In fact, it is precisely when aversion, worry and fear are experienced *regardless* of the intrinsic aspects that a negative attitude of fatalism toward mathematics can develop, an attitude which is very difficult to modify (Zan & Di Martino, 2009).

Causes of the declared emotions

More generally, when analysing the causes of the declared emotions (question 3 of the questionnaire), the aspect we found most interesting was that of distinguishing between reasons referring to the specific problem (*intrinsic*) and reasons not referring to the specific problem (*extrinsic*).

If we consider only the explicit references to intrinsic or extrinsic aspects – not classifying in either sense statements difficult to interpret, such as "*I feel nervous because I am afraid of making a mistake*": the fear of making a mistake might be associated with doing mathematics (extrinsic) and unrelated to the specific problem, or, on the other hand, it might be associated with the assessment of the level of difficulty of the problem to tackle (intrinsic) – what emerges from the positive/negative emotions dichotomy appears to be rather significant. In fact, the positive emotions are motivated mainly by intrinsic aspects (for example "*because it's easy*"): 56% of those who said they felt happy, 62% of those who said they felt calm, and as much as 86% of those who said that they felt confident. The negative emotions are motivated mainly by extrinsic aspects (for example "*because I don't like doing problems*", "*because I don't like mathematics*", "*because I don't like school*"): 58% of those who said that they felt worried, 67% of those who said that they felt nervous, and more than 86% of those who said that they felt bored.

It should also be noted that the 54% of the students who said that they felt nervous, and the 45% of those who said that they felt worried, highlight the fear of making a mistake or the desire to do everything correctly (for example: *"because I worry about making mistakes"; "I don't like them. And if I get them wrong, how will I manage when I'm big"; "because I don't know if I do it all correctly"; "I think that it's because I don't know if the problem is right or wrong")*. This phenomenon is particularly significant because fear of making errors often becomes fear of math, a phenomenon that has serious consequences on mathematics learning (Di Martino & Zan, 2013).

Change in emotions perceived while solving the problem

One particularly interesting feature from what has been observed until now emerges from the interviews: most of the sample (52%) reports emotional changes from the *initial state*. Those who say that they did not experience any emotional changes are mainly those who started with a positive emotion that was confirmed in the course of the problem-solving process, or else those who started with a negative emotion, associated with extrinsic aspects, an emotion that affected their perseverance in trying to solve the problem. This confirms the link between negative emotions associated with extrinsic aspects and poor perseverance (Hannula, 2012).

The following observations emerge from an analysis of the interviews conducted with those who stated that they experienced emotional changes:

i) **changes in 'intensity'** (8%, only one case with positive emotions and 6 starting from negative emotions), like that reported by Chiara, who initially said that she felt worried because after having read the problem she thought she would not manage to finish it, but who in the interview explained that at a certain point she stopped feeling worried and became "*almost desperate, because already I didn't manage to finish it, and then,* *seeing all these calculations …*", or like Martino, who said that he felt happy during the solving process "*because I realised that the calculation wasn't so difficult*";

ii) **changes in 'direction'**: from positive to negative emotion (25%) (like Samuele, who initially said that he felt happy, but who in the interview explained that he felt worried "*because I was trying to do the calculation but I didn't manage*"), and from negative to positive emotion (14%) (like Selene, who said that she felt worried because she felt alone, but who at the end said that she felt happy because she hoped to have solved it correctly and because "*I feel I did it correctly*"). Moreover, 5% of the students expressed a double change in "emotional direction" while solving the problem: for example, Sofia said at first that she felt calm, then nervous *"because I was afraid of making a mistake"*, then calm again because *"it seemed easy to do"*. Sofia's account demonstrates a repeated assessment of the situation and of any progress made, and, in particular, this testifies the fact that her emotions are (also) associated with intrinsic aspects.

In both cases (changes in intensity and in direction) it is seen how, except in very rare cases, when explaining the emotional change reference is virtually always made to intrinsic aspects, to the perception of making, or not making, progress in solving the problem. This confirms the close link between affective and cognitive aspects: in fact, a fundamental role is played by convictions about making (or not making) progress toward solving the problem, about having solved the problem correctly or not, convictions that are profoundly linked to the mathematical knowledge of the students. In relation to this, and as an important comment, it is interesting to observe how many of those who changed from a negative to a positive emotion because they were sure that they had solved the problem correctly, in fact handed in a wrong solution to this problem. It would be interesting to investigate the emotion triggered off by discovering that the solution handed in, and believed to be correct, was in fact wrong.

CONCLUSION

In the analysis of the results we have focussed particularly on what we feel is the most interesting aspect of our study, in terms of both research and didactic practice. That is, the distinction between positive or negative emotions perceived in a specific mathematics problem solving activity and deriving from an assessment of the difficulty of the activity proposed (intrinsic aspects), or from more general aspects (for example, the stance of those who think "I don't like mathematics, you are asking me to do maths and I therefore have a negative emotion").

What clearly emerges is that most of those who express a positive emotion on finding out that they have to solve the problem in fact refer to intrinsic aspects, and the issue is therefore one of problem assessment. Conversely, most of those who express a negative emotion refer to aspects unrelated to the problem, or, in other words, to extrinsic aspects (except for the fact that it is recognised as a mathematics problem).

On the one hand this confirms how, already at primary school level, there is a generalised type of "a-priori" hostility towards all things mathematical, hostility that is very often typical of an unquestionable negative attitude toward mathematics (Di Martino & Zan, 2011). On the other hand it suggests the importance of working with students so that any negative attitudes of this type do not compromise the a-priori cognitive assessment of the mathematical activities to be tackled, and the resulting performance. In fact, the negative effects of this kind of phenomenon are clear: negative emotions associated with any mathematics-related activities, deciding against investing the cognitive resources required in order to tackle the activity.

However, the results of our study tell us something more: emotional changes (intensity and direction) during the problem solving activity occur almost exclusively as a result of considerations related to intrinsic aspects. These emotional changes appear to be fundamental in problem solving activities: both those "in the positive direction" (they play an important role in problem-solving perseverance), and those "in the negative direction" (they have an important function in terms of cognitive control stimulation).

Further investigation into the link between emotional change during problem solving, and aspects as perseverance and the activation of cognitive controls would certainly constitute an interesting research direction. It definitely appears that it may be important to promote emotional literacy and emotional awareness, also in order to develop problem solving skills already at primary school level. Our research also shows how, at the same time, it is fundamental to develop the "proper mathematical understanding": in our experiment we have shown how many of the positive direction emotional changes were related to the erroneous conviction of having solved the problem correctly.

Turkish prospective middle grades mathematics teachers' teaching efficacy beliefs and sources of these beliefs

Okan Arslan and Aykut Bulut

Middle East Technical University, Faculty of Education, Ankara, Turkey, arokan@metu.edu.tr

In this study, 187 prospective mathematics teachers' teaching efficacy beliefs and sources of their beliefs were investigated through the administration of Teachers' Sense of Efficacy Scale (TSES) and The Sources of Self Efficacy Inventory (SOSI) scales. Furthermore, this study explored how well hypothesized sources (mastery experiences, vicarious experiences, verbal persuasions, physiological and affective states) predict participants' teaching efficacy beliefs. The calculated mean scores (out of 9) for dimensions of TSES were: 6,35 for Efficacy for Student Engagement, 6,57 for Efficacy for Instructional Strategies, 6,35 for Efficacy for Classroom Management. Multiple regression analysis results showed that combination of hypothesized sources significantly predicted overall teaching efficacy beliefs and all dimensions of TSES.

Keywords: Teaching efficacy beliefs and sources, prospective mathematics teachers.

INTRODUCTION

The term of self-efficacy was introduced first in Social Cognitive Theory and defined as one's personal judgments about doing a particular behavior and these beliefs have a great effect on the future behavior (Bandura, 1997). Its effect on the future behavior leads to an interest on this construct and there has been several research related with self-efficacy beliefs in the literature so far. It has also been an important topic in the field of education and much research has been done on the efficacy beliefs of students and teachers. In line with Bandura's definition of self-efficacy, Tschannen-Moran and Woolfolk Hoy (2001) introduced the term teaching efficacy as "…judgment of his or her capabilities to bring about desired outcomes of student engagement, and learning, even among those students who may be difficult or unmotivated" (p. 783).

Studies have revealed that teaching efficacy beliefs have effects on teachers' teaching related decisions and student learning outcomes (Işıksal & Çakıroğlu, 2006; Poulou, 2007). Teachers with high teaching efficacy beliefs keep their efforts in the classroom even if there are problems in the class (Tschannen-Moran & Woolfolk Hoy, 2001), behave more positively to students who fail in the class (Ashton & Webb, 1986), and have more effective teaching strategies when compared with the teachers who have a low teaching efficacy (Işıksal & Çakıroğlu, 2006). Such research may enable not only to predict prospective teachers' possible teaching behaviors but also to interpret the effectiveness of teacher education programs (Poulou, 2007). Therefore, the focus of the current study is to investigate prospective mathematics teachers' teaching efficacy beliefs.

The significance of teaching efficacy beliefs also lead to an interest on how these beliefs are constructed. Therefore, the sources of teaching efficacy beliefs began to take attention in the literature (Morris, 2010; Usher & Pajares, 2008). When the issue is the sources of teaching efficacy beliefs, the main interest in the literature is the sources of self-efficacy beliefs hypothesized by Bandura (1997) in Social Cognitive Theory. Bandura hypothesized four main sources of self-efficacy beliefs which are *mastery experience*, *vicarious experience*, *verbal persuasion*, *physiological and affective states*. *Mastery experiences* refer to the results of one's personal experiences in the past and based on these experiences, one knows in which conditions s/he would succeed or fail (Bandura, 1997). In other words, one feels more efficacious if s/he succeeded at doing that behavior before and feels less efficacious if s/he failed before. Bandura (1997) claimed that *mastery experiences* are the most powerful source of self-efficacy beliefs among the four sources. One not only gains self-efficacy beliefs through personal experiences, s/he also gains efficacy beliefs through observing the experiences of others, and this source is named as *vicarious experience* (Bandura, 1997). One might judge his/her capabilities on a particular behavior based on his/her model's accomplishment on that behavior, which functions as a standard for him/her (Tschannen-Moran & McMaster, 2009). Another source of self-efficacy beliefs is *verbal persuasions* received from others (Bandura, 1997). *Verbal persuasions* refer to judgments about one on his/her capability on doing a particular behavior and these judgments might come from different sources such as colleagues, parents, teachers or administrators (Tschannen-Moran & McMaster, 2009; Usher, 2009). As a last source, Bandura (1997) mentioned one's judgment of personal capabilities is affected from his/her physiological and affective states at that moment. For instance, one might feel less efficacious when s/he is under stress or anxiety (Tschannen-Moran & McMaster, 2009) or when s/he is exhausted (Usher, 2009).

When we consider these hypothesized sources in terms of teaching efficacy, theoretically it is possible to claim that prospective teachers' previous teaching experiences, their observations of peers' and previous teachers' practice, judgments about their own teaching performances, and their feelings such as excitement, tension, fear during teaching have an effect on the development of their teaching efficacy beliefs. However, the effect of these hypothesized sources on teaching efficacy beliefs are not consistent in all contexts and domains (Morris, 2010; Usher & Pajares, 2008). Therefore, investigating how the hypothesized sources contributed to teaching efficacy beliefs would provide insight on understanding the development of prospective teachers' teaching efficacy beliefs and teacher education programs might benefit from such studies.

In brief, the current study aims to investigate a group of Turkish prospective middle grades mathematics teachers' teaching efficacy beliefs and how well hypothesized sources predicts their teaching efficacy beliefs. In line with these purposes, the following research questions were sought in the current study:

1) How efficacious do Turkish prospective middle grades mathematics teachers feel themselves as a teacher? In which dimension(s) do they feel themselves mostly efficacious?

2) How well hypothesized sources of self-efficacy beliefs predict prospective middle grades mathematics teachers' teaching efficacy beliefs?

METHOD

Contexts and participants

The participants of the current study were conveniently selected 187 prospective middle grades mathematics teachers from two public universities in Ankara, Turkey. Middle grades Mathematics Education Programs are four-year programs designed to train prospective teachers for teaching middle grades (grades 5 to 8) mathematics in Turkish middle schools. The first two years of the program focus on mathematics courses and the last two years focus

Descriptive Information		Number of Prospective Teachers (N)	Percent (%)

Practice Teaching course	Yes	10	5
	No	177	95

Table 1: Information about participants

on pedagogical content knowledge and pedagogical knowledge courses. Two-semester methods (Methods 1 and Methods 2) of teaching mathematics courses are offered in the third year, and School Experience and Practice Teaching courses are offered in the fourth year of the program with very little actual teaching experience opportunities. Descriptive information about participants can be seen in Table 1.

Prospective teachers were also asked about their teaching experience. An important number of them (74%) indicated that they have a teaching experience mostly in the form of private tutoring. These teaching experiences are being a private tutor, being a math teacher in private teaching institutions, being a teacher in voluntary organizations/institutions or being an intern teacher in Practice Teaching course.

Data collection procedure and instruments

Data for the current study was collected in the final week of the fall semester of the 2013–2014 academic year. Prospective teachers were informed about the purpose of the study and only voluntary participants participated in the study. There were two data collection instruments called as "Teachers' Sense of Efficacy Scale" (TSES) and "The Sources of Self Efficacy Inventory" (SOSI). These two scales were widely used in the teaching efficacy related literature and both of the scales were translated into Turkish before and validated. Therefore, the cultural bias is eliminated.

The first scale was TSES which was developed by Tschanen-Moran and Woolfolk Hoy (2001) and adapted into Turkish by Çapa, Çakıroğlu and Sarıkaya (2005). The scale was in 9 point Likert format and consisted of three dimensions. Sample items for these dimensions are given in Table 2.

In order to get validity evidence for the obtained data through TSES, confirmatory factor analysis was applied. According to analysis results, Root Mean Square Error of Approximation (RMSEA) value was calculated as 0.080, Normed Fit Index (NFI) was found as 0.94, and Comparative Fit Index (CFI) was found as 0.97. Finding RMSEA value lower than 0.10, and CFI and NFI values close to 1 could be accepted as an indicator of good fit (Kelloway, 1998). Cronbach Alpha values were also calculated in order to interpret the reliability of the obtained data. For each TSES dimension and whole scale, it ranged from 0.74 to 0.93, which indicated satisfactory internal consistency (Pallant, 2007).

SOSI, which was developed in line with the sources of the self-efficacy in Social Cognitive Theory by Kieffer and Henson (2000), was used as the second data collection instrument. Therefore, these four hypothesized sources constituted the four dimensions of SOSI. This scale was adapted into Turkish by Çapa-Aydın, Uzuntiryaki-Kondakçı, Temli and Tarkın (2013). The scale is in 7 point Likert format and consisted of 27 items in four dimensions which are explained above. In order to have a better understanding of the scale, looking at the sample items from each dimension in Table 3 might be beneficial.

Confirmatory factor analysis was conducted in order to present a validity evidence for the data obtained through SOSI. Calculating RMSEA value lower than 0.10 (RMSEA = 0.085), NFI (0.86) and CFI (0.91) fit indices close to 1 was interpreted as satisfactory for the data fit (Kelloway, 1998). Furthermore, calculated Cronbach Alpha values for each SOSI dimension and whole scale ranged from 0.77 to 0.86, which indicated satisfactory reliability evidence (Pallant, 2007).

Data analysis procedure

In order to answer the first research question, data obtained through the administration of TSES were analyzed with descriptive statistics techniques and ANOVA. To investigate second research question, multiple regression analysis was conducted. Independent variables of the analysis were each dimension of SOSI. Dependent variable in multiple regression analysis

Dimension	Sample Item
Efficacy for Instructional Strategies	To what extent can you provide an alternative explanation or example when students are confused?
Efficacy for Classroom Management	How much can you do to control disruptive behavior in the classroom?
Efficacy for Student Engagement	How much can you do to get students to believe they can do well in school work?

Table 2: Sample of items of TSES

Dimension	Sample Item
Mastery Experiences	I became successful when trying to teach something to students.
Vicarious Experiences	I had chances to observe other teachers in class environment.
Verbal Persuasion	I often get feedback from experienced people about my teaching skills.
Physiological and Affective States	I get worried when I teach something wrong.

Table 3: Sample of items of SOSI

was all dimensions of TSES and overall teaching efficacy belief which was the total mean score obtained from TSES.

FINDINGS

Teaching efficacy beliefs

Descriptive analysis was conducted to explore the prospective mathematics teachers' teaching efficacy beliefs. Table 4 indicates mean values and standard deviations for participants' teaching efficacy beliefs scores for each dimension.

In TSES instrument, a rating of 7 out of 9 refers to the quite a bit efficiency on the given item, and 5 out of 9 refers to the some efficiency on the given item. Table 3 shows that mean values in the dimensions of teaching efficacy beliefs ranged from 6.3 to 6.6 out of 9. It might be inferred that participants felt efficacious themselves as a teacher. In order to understand whether there was a significant difference among dimensions of TSES, ANOVA was conducted. Before starting the analysis, all of the assumptions were checked and confirmed.

Findings of ANOVA indicated that there was a statistically significant difference among TSES dimensions (Wilks' Lambda = .88, F (2, 185) = 13.24, $p < .05$). As a follow up test, paired sample t tests were conducted and results were evaluated using Holm's Sequential Bonferroni Procedure.

According to Bonferroni Procedure, "Efficacy for Instructional Strategies" (M = 6.57, SD = .071) was significantly different from "Efficacy for Student Engagement" (M = 6.35, SD = .073) and "Efficacy for Classroom Management" (M = 6.35, SD = .074). The magnitude of the mean differences among dimensions were respectively .10 and .09, which indicated moderate effect size. It means that prospective mathematics teachers felt mostly efficacious in "Efficacy for Instructional Strategies" dimension.

Prediction of teaching efficacy beliefs by hypothesized sources

In order to explore the how well hypothesized sources of self-efficacy beliefs predict participants' teaching efficacy beliefs, multiple regression analysis was conducted. Before starting the analysis, eleven assumptions addressed by Tabachnick and Fidell (2007) had been checked, and one outlier was eliminated from the data since it highly exceeds the critical value of Mahalanobis Distance. After assuring the assumptions, the analysis was conducted with .05 alpha level and pairwise deletion method.

	Mean	SD	Skewness	Kurtosis
Efficacy for Student Engagement	6.35	.073	-.49	.61
Efficacy for Instructional Strategies	6.57	.071	-.23	-.04
Efficacy for Classroom Management	6.35	.074	-.47	.86

Table 4: Descriptive analysis for teaching efficacy beliefs dimensions

Pairs	t	df	Sig.
Student engagement – Instructional strategies	- 4.55	186	.00
Classroom management – Instructional strategies	- 4.40	186	.00
Student engagement – Classroom management	.05	186	.96

Table 5: Paired sample t-tests

	R	R Square	Std. Error of the Estimate	Durbin-Watson	F	Sig.
Student Eng.	.63	.395	.79	1.87	29.59	.00
Instructional Str.	.63	.392	.76	1.81	29.21	.00
Class. Management	.56	.318	.84	1.92	21.10	.00
Total TSES	.66	.433	.70	1.84	34.58	.00

Table 6: Regression analysis

The examination of multiple regression analysis values from Table 6 indicated that the combination of hypothesized sources of teaching efficacy beliefs significantly predicted all dimensions of TSES and overall teaching efficacy beliefs. Moreover, explained variance in dependent variables ranged from 31.8% to 43.3%.

As shown in Table 7, *mastery experiences* and *physiological and affective states* significantly predicted all dimensions of TSES and overall teaching efficacy beliefs. To consider the Beta scores, *mastery experiences* made the strongest contribution to explaining the overall teaching efficacy and TSES dimensions. In addition, *physiological and affective states* made more contribution than *verbal persuasion* and *vicarious experiences* to explaining them. On the other hand, *verbal persuasion* and *vicarious experiences* did not significantly predict teaching efficacy beliefs.

DISCUSSION

The present study aimed to examine one group of Turkish prospective middle grades mathematics teachers' teaching efficacy beliefs and how the hypothesized sources predict these teaching efficacy beliefs. The descriptive statistics results for TSES indicated that participants feel themselves efficacious in mathematics teaching. Relevant studies in the national context supported this finding. For instance, Işıksal and Çakıroğlu (2006) mentioned that prospective middle grade mathematics teachers' teaching efficacy level could be interpreted as high. In another study, Koç (2011) reported that prospective middle grades mathematics teachers had significantly higher teaching efficacy beliefs than prospective secondary mathematics teachers.

The current study also indicated that prospective mathematics teachers' teaching efficacy beliefs for instructional strategies were significantly higher than teaching efficacy for classroom management and student engagement. This might address that prospective mathematics teachers felt more competent and sophisticated in employing instructional strategies. Participants might have benefited from courses in teacher education program, especially from methods

		Student Eng.	Inst. Str.	Class. Management	Total TSES
Mastery Experiences (M = 5.09, SD = .78)	Beta	.60	.55	.47	.59
	T	6.53	6.04	4.80	6.62
	Sig.	.00	.00	.00	.00
Vicarious Experiences (M = 5.25, SD = .84)	Beta	.08	.08	.08	.09
	T	.77	.80	.79	.91
	Sig.	.44	.42	.43	.37
Verbal Persuasion (M = 5.39, SD = .94)	Beta	-.06	-.01	.03	-.02
	T	-.74	-.13	.31	-.21
	Sig.	.46	.89	.76	.84
Physiological and Affective States (M = 4.66, SD = 1.05)	Beta	-.14	-.18	-.16	-.17
	T	-2.42	-3.02	-2.54	-3.04
	Sig.	.02	.00	.01	.00

Table 7: Coefficients

of teaching mathematics courses, in which they learnt using different instructional strategies for teaching mathematics. On the other hand, mean scores of efficacy for classroom management and student engagement dimensions were relatively lower than efficacy for instructional strategies. It might be the case that the lack of participants' experience in real classroom environment resulted in relatively lower scores in these dimensions. Although a considerable part of participants (74%) had a teaching experience, most of these experiences were private tutoring in a one-to-one context, not in a classroom. Offering teaching experience courses not only in the last year, but also in the previous years might be beneficial for prospective teachers to improve their teaching efficacy for classroom management and student engagement.

Multiple regression analysis indicated that combination of hypothesized sources significantly predicted overall teaching efficacy belief and all dimensions of TSES. Therefore, it could be stated that the analysis results were in line with the theory. However, apart from the hypothesized sources, there might be other sources for teaching efficacy beliefs. To give an example, content knowledge (Can, 2015), invitations send and received by the individuals (Usher & Pajares, 2008), and personal characteristics and motivation for teaching (Poulou, 2007) might be additional sources which are mentioned in some of the related studies. Hypothesized sources might be supported with such additional sources in the further studies.

When the individual contribution of hypothesized sources are investigated, it was seen that mastery experiences and physiological and affective states significantly predicted teaching efficacy beliefs in all dimensions of TSES and in overall teaching efficacy beliefs. As hypothesized by Bandura (1997), mastery experiences are the most influential source for self-efficacy beliefs. Studies in the literature also consistently show that mastery experiences are the best predictor of teaching efficacy beliefs (Morris, 2010). Therefore, the results of the current study could be interpreted as in consistency with the theory and practical studies in the literature and highlights the importance of mastery experience for teaching efficacy beliefs. In line with this finding, it is possible to claim that there is a need to create environments which provide mastery experiences for prospective teachers during their training. The teaching experience courses can be enhanced for prospective teachers to include more actual teaching experience, and new courses in which they will have opportunities to improve their teaching experiences can be designed. However, when designing these courses, it should be beneficial to bear in mind that prospective teachers should be in a supportive environment during these experiences (Knoblauch & Woolfolk Hoy, 2008). When they do not have support from their mentors and instructors from the university, and when they do not have enough resources to improve their practices, mastery experiences do not become an improving source for prospective teachers' teaching efficacy beliefs as seen in Knoblauch and Woolfolk Hoy's study (2008).

Although mastery experiences consistently predict teaching efficacy beliefs in the related literature, there is not a consistent result for the other three hypothesized sources (Usher & Pajares, 2008). In the current study, it was seen that physiological and affective states significantly predicted teaching efficacy beliefs of prospective teachers unlike some findings in the related literature. For instance, in their study Mulholland and Wallace (2001) stated that physiological and affective states contributed to a novice teachers' efficacy beliefs less than the other three hypothesized sources. Similarly, Poulou (2007) mentioned that physiological and affective states are the least influential source among other sources. Such findings cause to neglect the possible contribution of physiological and affective states on teaching efficacy beliefs. However, such results might derive from the difficulty of measuring physiological and affective states source and some measurement errors rather than the nonsexist contribution of this source on teaching efficacy beliefs (Usher & Pajares, 2008). The findings of current study and the study of Morris (2010) support this claim and show that physiological and affective source should be taken into consideration while investigating teaching efficacy beliefs.

While investigating physiological and affective state source, feelings of anxiety and/or stress are generally interpreted as negative for the development of teaching efficacy beliefs. However, Bandura (1997) stated that some degree of such feelings might positively contribute to teaching efficacy beliefs. The study of Morris and Usher (2011) also supported this claim and showed that even award winning professors feel some anxiety and stress before their lessons, but they are able to overcome this feelings during lessons which in turn enhance their teaching efficacy beliefs. In this study, the calculated mean score for the physiological and affective state source indicates that participants occasionally feel anxiety, stress and tension while teaching. However, whether these feelings affected their teaching efficacy beliefs in a positive way or in a negative way remained unclear. Therefore, qualitative follow up studies might be beneficial while investigating how physiological and affective states affected teaching efficacy beliefs (Usher & Pajares, 2008).

According to multiple regression analysis results, vicarious experience and verbal persuasions did not significantly predict teaching efficacy beliefs of prospective teachers. However, Bandura (1997) stated that hypothesized sources are highly related with each other. In such situations, independent contribution of verbal persuasion and vicarious experiences in multiple regression might be over shaded by mastery experience (Usher & Pajares, 2008), which might be the case in the current study. Therefore, there is a need for the further study in order to clarify how the vicarious experiences and verbal persuasions are internalized by prospective teachers in terms of teaching efficacy.

Limited number of participants and non-random sampling method limits the generalizability of the observed results in the present study. Therefore, it is suggested to replicate the study with different samples in order to improve the generalizability. Furthermore, when the issue is how the hypothesized sources contributed to teaching efficacy beliefs, supporting quantitative analyses with qualitative analyses would be beneficial to undermine the limitations of quantitative measurement on hypothesized sources (Usher & Pajares, 2008). Therefore, mixed method studies are suggested as a further study. Future research studies may also focus on possible teacher education program experiences in which prospective teachers' teaching efficacy beliefs are likely to improve and how these beliefs and their sources change during the teacher education program.

Improving children's perseverance in mathematical reasoning: Creating conditions for productive interplay between cognition and affect

Alison Barnes

University of Brighton, Brighton, UK, a.barnes2@brighton.ac.uk

This paper reports on a small-scale intervention that explored perseverance in mathematical reasoning in children aged 10–11 in an English primary school. The intervention facilitated children's provisional use of representations during mathematical reasoning activities. The findings suggest improved perseverance because of the effect the intervention seemed to have on the bidirectional interplay between affect and cognition. This initially created affectively enabling conditions that impacted on cognition and then created cognitively enabling conditions that impacted on affect. A tentative framework describing this interaction is proposed.

Keywords: Perseverance, mathematical reasoning, affect, cognition, provisional.

INTRODUCTION AND THEORETICAL BACKGROUND

The development of mathematical reasoning is not straightforward; reasoning processes can trace a "zig-zag" route (Lakatos, 1976, p. 42) which necessitates perseverance to navigate cognitive and affective difficulties. The cognitive processes relating to mathematical reasoning have been well documented over the last seventy years (for example, Polya, 1945) and in more recent decades there have been significant theoretical developments in the interpretation of the affective domain in relation to learning mathematics (for example, Hannula, 2011). However, pedagogies to develop children's mathematical perseverance are not yet articulated in the literature. This study sought to develop a practical intervention to improve children's perseverance in mathematical reasoning. The significant interplay between cognitive and affective domains during mathematical learning has been noted at previous CERMEs (Di Martino & Zan, 2013; Hannula, 2011) and this interplay provided the framework for analysing and interpreting the findings in this study.

The importance of reasoning

The central importance of reasoning in mathematics education has been widely argued. For example, Yankelewitz and colleagues (2010) assert that reasoning is crucial in the formulation and justification of convincing mathematical argument. Ball and Bass (2003, p. 28) make a connection between reasoning and the development of mathematical understanding, arguing that in the absence of reasoning, "mathematical understanding is meaningless". They further argue that reasoning has a significant role in the recall of procedures and facts as it is the ability to reason, and not memory that enables a child to reconstruct knowledge when needed. The capacity to reason is therefore a significant factor in children's learning of mathematics and there is value in framing a study with reasoning as its focus.

Mathematical reasoning can be considered to include deductive approaches that lead to formal mathematical proofs and inductive approaches that facilitate the development of knowledge; Polya (1959) broadly interprets these two types of reasoning as demonstrative and plausible reasoning respectively. In this study, my interpretation of mathematical reasoning was based on Polya's (1959, p. 7–9) "plausible reasoning" and includes the use of processes detailed by Mason et al (2010) such as: random or systematic specialising by creating examples; noticing patterns to formulate and test conjectures; generalising and convincing.

Perseverance in reasoning

In this study, I have interpreted perseverance in accordance with common dictionary definitions to mean "persistence in [mathematical reasoning] despite difficulty or delay in achieving success" (OxfordDictionaries, 2014). Lee and Johnston-Wilder (2011, p. 1190) identify perseverance as one aspect of the construct mathematical resilience and argue that it is needed to overcome "mathematical difficulties". Such difficulties arise from the "zig-zag" route that mathematical reasoning typically traces (Lakatos, 1976, p. 42) and can be cognitive or affective in nature.

Overcoming cognitive difficulties necessitates the use of meta-cognitive self-regulatory approaches. For Mason, Burton and Stacey (2010), this is characterised by developing internal monitoring to facilitate deliberate reflection on reasoning processes and their outcomes. Such monitoring might result, for example, in changes in approach or use of representation, or rejection of ideas. This fosters a fallibilistic approach (Charalampous & Rowland, 2013; Lakatos, 1976) to engaging with mathematics and mathematical uncertainty. Mason, Burton and Stacey (2010) emphasise the value of considering three phases of work when engaged in activities involving mathematical reasoning: entry, attack and review. The entry phase, characterised by the making of random trials, and the back and forth movement between phases, exemplifies and facilitates a fallibilistic, self-regulatory approach to mathematical engagement.

Navigating Lakatos' (1976, p. 42) zig-zag path also has affective impact and this necessitates affective self-regulatory responses. Goldin (2000) proposes that affective pathways, comprising rapidly changing emotional states, arise during mathematical problem solving. Malmivuori (2006, p. 152) argues that these emotion responses "direct or disturb" mathematical thinking and activate either active or automatic self-regulatory processes. During active regulation of affective responses, an individual consciously monitors affective responses to inform cognitive decision making. By contrast, automatic affective regulation describes self-regulatory processes that act at a sub-conscious level in which negative emotions can act to impede the higher order cognition involved in reasoning.

Successful engagement with mathematical reasoning can be rewarding and impact on an individual's sense of self-worth. Debellis and Goldin (2006, p. 132) describe mathematical intimacy as an affective structure which portrays an individual's potential "deep emotional engagement" with mathematics. They argue that intimate mathematical experiences can give rise to emotions such as deep satisfaction that impact on self-worth. However, positive mathematical intimacy could be jeopardised by experiencing failure. Debellis and Goldin (2006, p. 138) reason that coping with swings in mathematical intimacy is a "meta-affective capability", the development of which characterises successful problem solvers; this is a further presentation of the perseverance needed to be able to reason mathematically.

THE STUDY

In this study, I sought to improve children's perseverance in mathematical reasoning by applying an intervention that provided children with opportunities to use mathematical representations in a provisional way.

The importance of representation in mathematics learning has been extensively documented and this study draws significantly on Bruner's (1966) modes of representation and Dienes' (1964) Dynamic Principle. However, the notion of provisionality is less widely interpreted within mathematics education.

Provisionality is an idea that is drawn on in information technology (IT) education (Leask & Meadows, 2000). The provisional nature of many software applications enables users to evaluate and refine a product as it is being created. Papert (1980) utilised the provisional nature of programming in designing the LOGO environment. LOGO enables a child to create instructions to move a turtle dynamically on the screen. It facilitates children to conjecture, make trials and use the resulting data to make improvements. Hence, this software enables children to construct understanding through a trial and improvement, conjectural approach to mathematics; the intervention in this study sought to impact on children's cognitive responses by applying a similarly provisional approach to children's use of mathematical representations.

Papert (1980) also notes how the provisional nature of programming impacts on the affective domain. It fosters an attitude that mathematical thinking is fallible (Charalampous & Rowland, 2013), that it concerns trial and improvement and conjecturing rather than the singular pursuit of right or wrong answers. Such an approach, he argues, makes children "less intimidated by a fear of being wrong" (Papert, 1980, p. 23). Hence, by constructing an intervention that enabled children to work provisionally, this study also sought to impact on children's affective responses.

This research took place in an English primary school using an action research approach. The study comprised one Baseline Lesson in which the intervention was not applied, and two Research Lessons in which the teacher applied the intervention to her teaching approach. The teacher selected four children to form the study group based on her assessment that their perseverance in mathematical reasoning was limited and would benefit from improvement. Prior to each of the lessons, the teacher and I selected a mathematical activity that presented opportunities for mathematical reasoning. For the Research Lessons, we discussed how the children could use representations in a provisional way and the teaching strategies that might facilitate this. The teacher then created the detailed plans and taught the lessons.

The fieldwork comprised collecting data from the three lessons, post-lesson interviews with children and an evaluation meeting with the teacher. During the Baseline and Research Lessons, I collected data on the four children relating to the cognitive and affective domains through non-participant observation and by taking photographs of the representations that they made. Audio recordings were made of the children's dialogue during the lessons and I used these to augment the observation notes post-hoc. During observations, I used an approach similar to that used by Schorr and Goldin (2008) in their analysis of filmed lessons to gather data relating to key affective events. For example, I noted the children's manner of engagement, their body position and the speed of their speech. I interviewed the study children immediately after each observation. The focus of the interview was threefold: to check my understanding of what I had observed; to gain the children's interpretation of what had happened and why, and to explore the extent of the children's mathematical reasoning.

This paper reports on the thick data arising from the second Research Lesson pertaining to two of the study group, Lucy and Emily.

FINDINGS AND DISCUSSION

Bidirectional interplay between cognition and affect (Di Martino & Zan, 2013) was evident during Lucy and Emily's mathematical engagement in Research Lesson 2. However, it seemed to operate in different directions at different stages of their thinking. Hence, I have used Mason, Burton and Stacey's (2010) entry and attack phases of problem solving as a temporal framework for the presentation and discussion of findings.

During Research Lesson 2, Lucy and Emily engaged as a pair with the problem:

> A square pond is surrounded by a path that is 1 unit wide. Explore what happens to the path length for different sizes of pond.
>
> Resources available: Cuisenaire rods, pencils, A3 plain paper.

The impact the intervention during the entry phase

During the entry phase (Mason, Burton, & Stacey, 2010), Lucy and Emily used Cuisenaire rods in a provisional way to get a feel for the problem; they explored how the criteria given in the activity could be represented and began to explore how the path size related

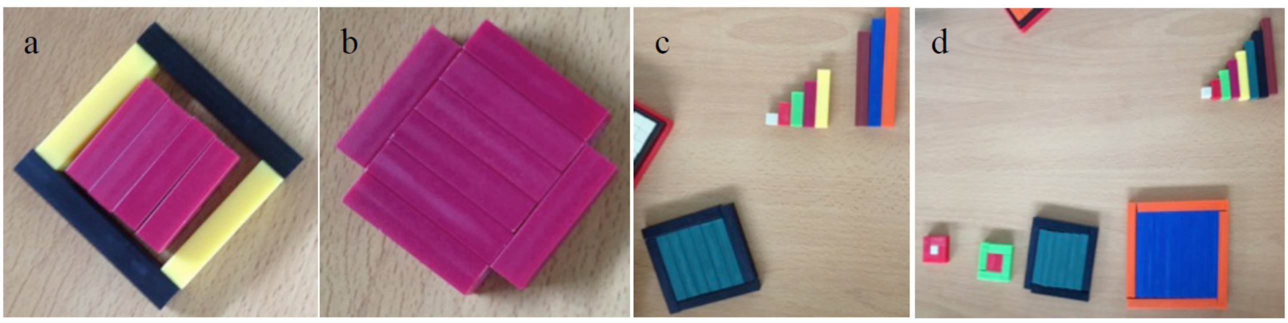

Figure 1: Entry phase trials

to the pond size. In their first three trials (Figure 1a-c) they focused on what it meant for the path to *surround* the pond. They used the information from the first two partially successful trials (Figure 1a-b) to inform their third trial (Figure 1c). This is similar way to in which Papert (1980) described children using the outcomes from their programming in LOGO to fix bugs in code.

The girls' provisional use of representation during the entry phase seemed to impact on their capacity to work with mathematical uncertainty and to adopt a fallibilist approach. Any trials that resulted in failure to meet the criteria set out in the activity, for example those depicted in Figure 1a and 1b did not appear to decrease their engagement or persistence with the activity. Their capacity to work with mathematical uncertainty facilitated their self-regulation and the application of their learning from apparently unsuccessful trials. Emily and Lucy showed no indications of fear, anxiety, bewilderment or reticence that can accompany the beginning of mathematical exploration, when least is known and understood about the problem. Conversely, they seemed highly engaged; they were leaning forwards, constantly exploring the parameters of the problem through their manipulation of the Cuisenaire rods and they alternated between quiet individual construction of examples and paired dialogue to share and develop thinking. The girls portrayed a relaxed appearance during the entry phase; their approach had a sense of playfulness and exploration that could be likened to the unstructured play that Dienes (1964) describes in his Dynamic Principle and this seemed to enable them to experience mathematical uncertainty in a positive way.

During the construction of their third trial, the pair created an ordered arrangement of all ten Cuisenaire rods to serve as a reference of relative lengths and support selection (top right of Figure 1c). In so doing, they noticed that they had selected consecutive rods to create the 6^2 pond and its path. This led them to form the conjecture that began to articulate the relationship between the two dependent variables:

Lucy: I think it will be if you use 1 [for the pond] then it will be 2 [for the path], if you use 2 then it's going to be 3, so it's [the path] going to be 1 higher than your square number

By the end of the entry phase they had constructed and ordered four examples (Figure 1d). They appeared to create each example by randomly selecting a Cuisenaire rod and using this as the basis to create one example; this use of random specialisation typifies the entry phase trials (Mason, Burton, & Stacey, 2010). This facilitated cognitive developments that enabled the girls to notice and formulate conjectures about the emerging patterns between the width of the pond and side length of path and to begin to articulate this relationship.

Hence, during the entry phase, the provisional way in which the girls used representations seemed to foster the emergence of affectively enabling responses and this enabled cognitive developments in mathematical reasoning. The impact of the girls' provisional use of representation during the entry phase is depicted in Figure 2.

The impact of the intervention in the attack phase

The transition to the attack phase was indicated by the girls' use of systematic specialisation (Mason, Burton, & Stacey, 2010). Having organised the data generated through random specialisation into an ordered sequence (Figure 1d), the girls then used the provisional nature of their representations to create gaps between the examples, apparently to identify and accommodate missing data. They then represented all the ponds in an ordered sequence from 1^2 to 9^2 using Cuisenaire rods (Figure 3).

The girls then switched to a more permanent representation in the form of a table (Figure 4). This representation does not simply illustrate total amounts relating to pond size and path lengths. Rather, it includes significant detail relating to the mathematical structures that underpin the relationship between the dependent variables of pond size and path length. Each example of the pond described its width squared, its total value and the odd/even property of this to-

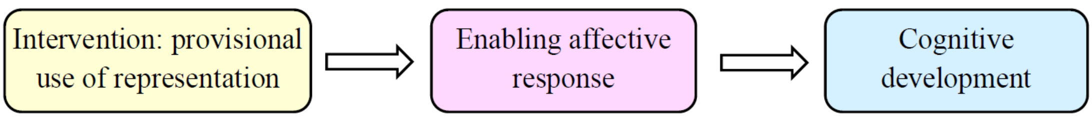

Figure 2: Impact of the intervention during the entry phase

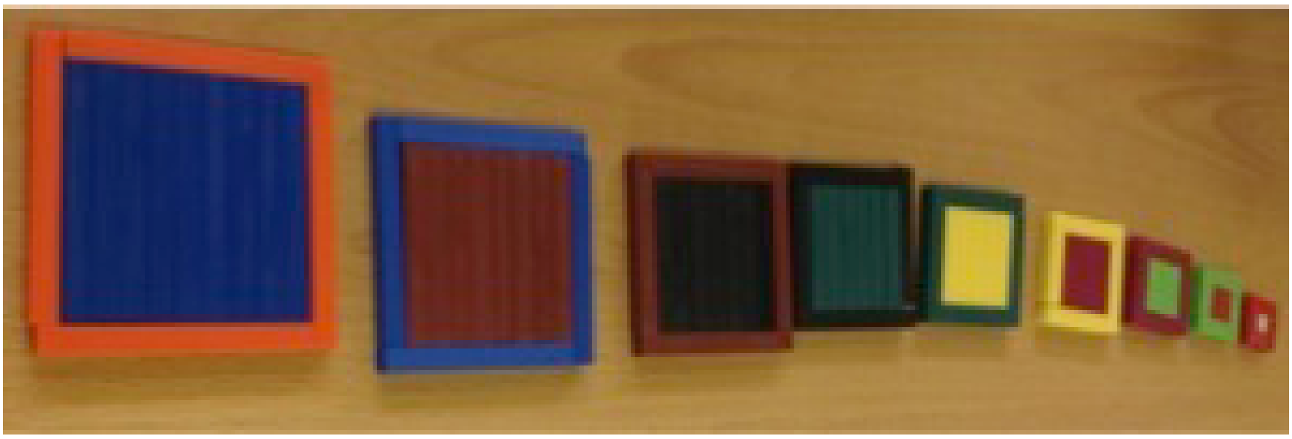

Figure 3: Systematic representation of ponds with widths 1–9

tal. Each example of the path is similarly described by side length multiplied by 4, the total value of the path length and the even nature of these totals. The girls also noted that each total was a multiple of 4. Interestingly, they realised that their recording had not been totally consistent in representing the x4 aspect of the path side length and this led them to underline the x4 component. Whilst there was no evidence in this lesson that the girls became overtly stuck, and hence no necessity to overcome this, they did persevere in formulating and articulating the reasoning for the patterns they observed. Emily's original response to the challenge of explaining the patterns they had identified resulted in a sentence that she was initially unable to complete:

Emily: All the paths are in the four times table. They have to be in the four times table because...

The girls persisted and utilised their understanding of the structures they had identified to formulate their reasoning for the observable patterns. This is captured on the right of Figure 4. In the post-lesson interview, the girls re-visited this:

13 Emily: We noticed about the path, because there's 4 sides to the path, we need 4 sides of the path, so you need to times it by whatever number the length of the path is. So then it's the 4 times table because there

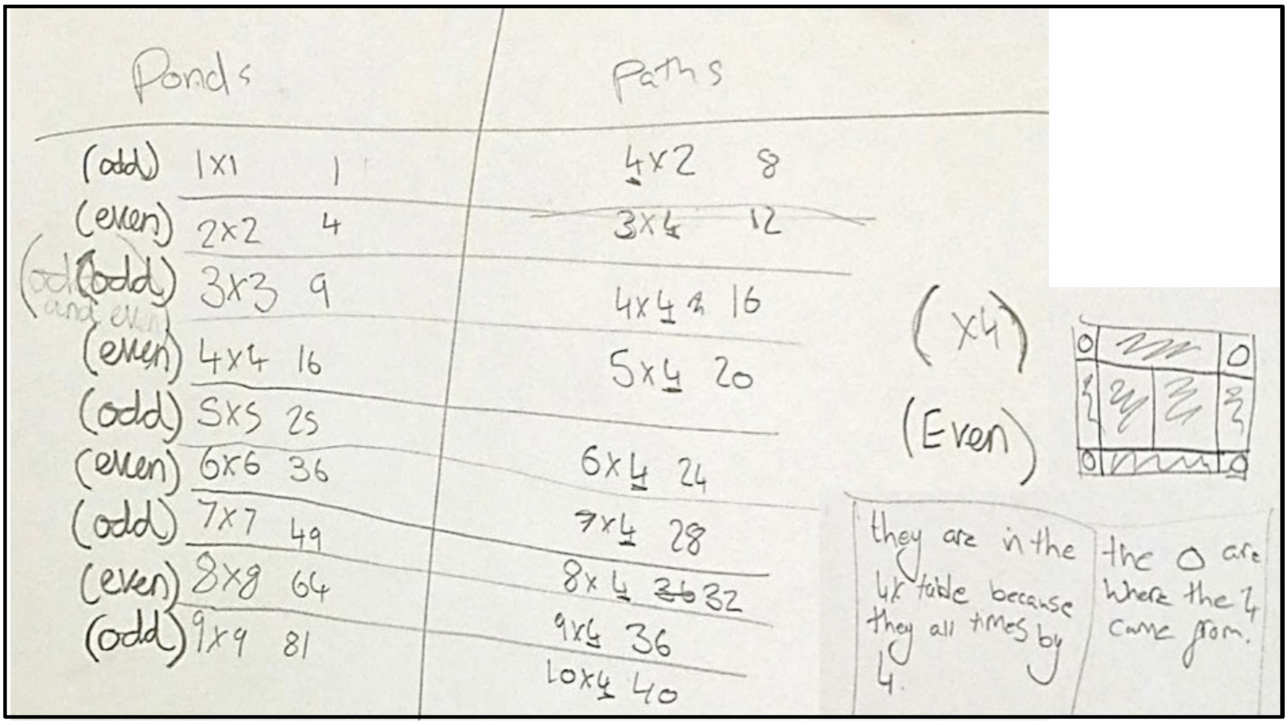

Figure 4: Lucy and Emily's table of findings

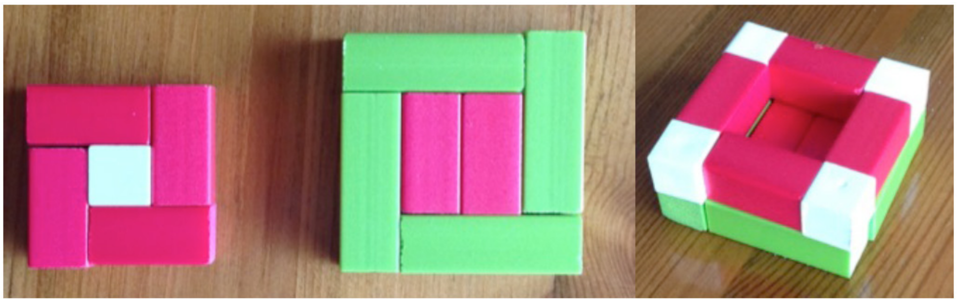

Figure 5: Representations created to support reasoning in line 69

are 4 sides and all of them, the numbers are even because they are all in the 4 times table

69 Lucy: Because it expands so you need to add 4 each time you go up

The diagram on the right of Figure 4 supports the reasoning expressed in line 69. In the interview, the girls re-created this image using Cuisenaire rods; Figure 5 shows how the path surrounding the 12 pond is positioned on top of the path surrounding the 22 pond with the gaps at each corner filled by four rods, each of length 1. There are similarities between the representations drawn in Figure 4 and constructed in Figure 5 and the girls' second trial (Figure 1b); the initial provisional explorations using the Cuisenaire rods, and in particular the example in Figure 1b seems to have helped the girls to understand the structures underpinning the growth of the path size. This understanding enabled Lucy to articulate the reasoning in line 69. The depth of understanding and the extent of the reasoning that the girls achieved resulted in positive affective responses. As in the entry phase, both girls remained highly engaged in the activity throughout the attack phase and took every opportunity presented to talk with the teacher about their findings and seemed eager to share the reasoning that they were constructing.

In the evaluation meeting following the Research Lesson, the teacher reported the impact of the girls' provisional use of representations during the attack phase on their cognitive and affective domains:

18 Teacher: I think [the provisional use of representation] helped them explain their reasoning more and therefore that helped them sustain their interest because they could explain more, because they had something to work from, to explain with. Their level of reasoning was amazing.

96 Teacher: [Lucy's] very proud of the work she's done [in the project]. I only have to mention it and a smile spreads across her face.

108 Teacher: I have seen some improvement in [Emily's] perseverance and resilience [...] in the past she would very much continue to follow a path even though it was wrong [...]. She's been able to stop mid way and realise it's wrong and have to go back to the beginning.

In line 18, the teacher exclaims about the level of the girls reasoning. In the baseline lesson, the girls were able to notice and articulate patterns, but not reason about why these occurred, hence there was a significant contrast with the extent and depth of their reasoning between the baseline lesson and the second research lesson.

The teacher also makes two connections in line 18. First, she makes a link between the girls' provisional use of representation and their articulation of mathematical reasoning. Second, she perceives that the positive cognitive developments contributed to the girls' sustained engagement and curiosity. The impact on Lucy's affective domain appeared to continue beyond the Research Lesson. Lucy's apparent sense of pride (line 96), suggests that she may have experienced developments in mathematical intimacy; that she was emotionally engaged and achieved a sense of satisfaction and self-worth through her cognitive mathematical activity (DeBellis & Goldin, 2006). Line 108 suggests that Emily may have increased her capacity to actively self-regulate (Malmivuori, 2006); this perhaps arises from developments in her capacity to work with mathematical uncertainty which may have arisen through working in a provisional way.

It appears that the provisional use of representations in the attack phase impacts first on the cognitive domain and second on the affective domain; a reversal

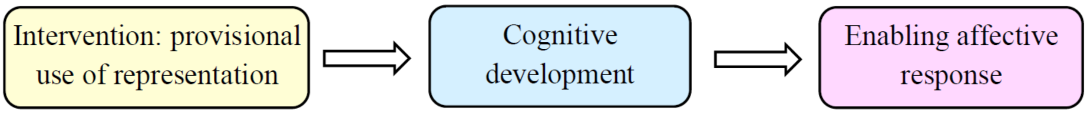

Figure 6: Impact of the intervention during the attack phase

of the processes emerging in the entry phase. This relationship is depicted in Figure 6.

CONCLUSION AND NEXT STEPS

This study sought to develop a practical intervention to improve children's perseverance in mathematical reasoning. The girls' provisional use of Cuisenaire rods appeared to have an enabling affective impact during the entry phase. This facilitated cognitive developments in reasoning as it supported them to behave in an exploratory way, to make and learn from trials, work with mathematical uncertainty and begin to formulate conjectures. In the attack phase, their provisional use of representation seemed to enable the girls to develop systematic approaches to their creation and organisation of trials. This led to their noticing patterns, understanding the underpinning mathematical structures, and using this to persevere in formulating reasoning. It seems that positive bidirectional interplay (Di Martino & Zan, 2013) between affect and cognition, facilitated by the intervention, resulted in improved perseverance in mathematical reasoning. A tentative analytic framework detailing these interactions and synthesising Figures 2 and 6, is depicted in Figure 7.

In the next phase of this research, I plan to work with two classes of children aged 10–11 in different schools to further test the impact of the intervention on children's perseverance in mathematical reasoning.

Analysing teachers' belief system referring to the teaching and learning of arithmetic

Katinka Bräunling[1] and Andreas Eichler[2]

1 University of education Freiburg, Freiburg, Germany, katinka.braeunling@ph-freiburg.de

2 University of Kassel, Kassel, Germany

In this paper, we want to discuss the structure of teachers' belief systems. Firstly, we discuss teachers' belief systems from a theoretical perspective including characteristics of beliefs systems like its cluster structure, the centrality of beliefs or the hierarchy of beliefs. Afterwards, we analyse the beliefs of one primary teacher emphasising particularly the structural aspects of this teacher's system of beliefs concerning the teaching and learning of arithmetic. Finally, we discuss potential benefits of investigating a belief system in detail. We conclude the paper with a brief summary and suggestions for further research.

Keywords: Arithmetic, belief system, central and peripheral, primary and derivative.

INTRODUCTION

Teachers individually define their way of teaching. Thus teachers decide what mathematical content they bring to the classroom and they decide how they teach a specific content. A teacher's individual reasoning why he/she selects specific content and why he/she prefers a specific teaching style could be understood as a notion of a teacher's system of beliefs (Eichler & Erens, 2015), in which beliefs represent the intersection of the cognitive and motivational aspects of a teacher's mathematics related affect (Hannula, 2012). Lerman (2015, p. viii) states that, "exploring teachers' beliefs and their development are important topics in themselves". However, the importance of gaining knowledge towards mathematics teachers' beliefs has also been emphasised by many researchers since teachers' beliefs about mathematics and the teaching and learning of mathematics potentially have a high impact on the teachers' classroom practice (Philipp, 2007).

As a prerequisite of analysing both, the development of teachers' beliefs and the enactment of teachers' beliefs, there is a demand to investigate the complex structure of teachers' beliefs in detail. For example, referring to the change of teachers' beliefs, Liljedahl, Rolka and Rösken (2007, p. 280) state that a "deeper analysis of beliefs in the context of mathematics teachers' professional growth is needed to penetrate the surface stories of the data and reveal the nuanced and situated belief structures that are often hidden". The mentioned belief structures are also understood to potentially unfold the relation between teachers' professed beliefs and the teachers' enacted beliefs; this relation is not completely explained yet (Furinghetti & Morselli 2011). For example, Wilson & Cooney (2002) suggested that only those professed beliefs would be enacted that are central for a teacher and, thus, they suggested that unfolding the structure of a teacher's belief system could explain inconsistencies. As an important aspect of an in-depth analysis of mathematics teachers' beliefs, research results imply to consider the discipline-specifity of teachers' beliefs (Franke et al., 2007). Consistently, our own research yield considerable differences of teachers' beliefs about different disciplines like e.g. arithmetic (Eichler & Erens, 2015).

Two aims of this project are to analyse the development of mathematics teachers' beliefs and the extent in which these beliefs are enacted in the teachers' classroom practice. For this reason, following the considerations outlined above, we firstly tried to "penetrate the surface stories" (Liljedahl, 2007, p. 280), i.e., to analyse the structure of the teachers' beliefs in depth. After outlining our theoretical framework, we discuss the method of analysing teachers' belief structures or rather teachers' belief systems in depth. This analysis is the main focus of our paper. We further outline the results of our analysis for one teacher. This teacher is part of a sample of 20 mathematics teachers of primary schools involved in our research project. We conclude this report summarising our findings and suggestions for further research.

THEORETICAL FRAMEWORK

Following Pajares (1992) the term beliefs represents an individual's personal conviction concerning a specific subject, which shapes an individual's way of both receiving information about a subject and acting in a specific situation. The specific subject in our research is the teaching and learning of arithmetic. We decided to focus on this specific subject due to two reasons: Firstly, arithmetic is the main subject for the primary teachers of our sample. Secondly, a focus on a specific mathematical discipline is in our research an important aspect for facilitating an in-depth analysis of mathematics teachers' beliefs. As a specific form of beliefs we regard the teachers' beliefs about content, beliefs about ways of teaching or beliefs that represent a teacher's teaching goals (c.f. Eichler & Erens, 2015).

The internal organisation of the mentioned beliefs is called a teacher's belief system (Green, 1971). A belief system is mainly characterised by three aspects:

1) "Beliefs can be either *central*, which means strongly held, or peripheral, which means less strongly held" (Philipp, 2007, p. 260).

2) A belief system could consist of different clusters that are connected in at least quasi-logical ways. This means that different clusters of beliefs could be isolated, but different clusters of beliefs could also be contradictory (ibid.). For example, central beliefs are not necessarily connected to peripheral beliefs. Further beliefs referring a mathematical discipline like arithmetic could be contradictory to beliefs referring another mathematical discipline (Eichler & Erens, 2015)

3) Beliefs systems could be organised hierarchically including primary beliefs and derivative beliefs (Green, 1971). If teaching goals are regarded (see above) a primary goal could be to prepare students to solve problems in their future life. A derivative goal could be to follow a cognitive guided instruction (Franke et al., 2007). A relation between primary and derivative goals must not be necessarily logical in an objective sense (quasi-logicalness, see above). Further, it is noteworthy that "primary beliefs might not necessarily be more central than the associated derivative beliefs" (Philipp, 2007, p. 260).

Research in mathematics education has reported specific clusters of beliefs that refer to different features of the perception of mathematics in general (Dionne, 1984). Based on these two reports Grigutsch, Raatz and Törner (1998) distinct four views that could describe teachers' beliefs about mathematics in general but also teachers' beliefs about the teaching and learning of arithmetic:

— A formalist view stresses that arithmetic is characterised by a logical and formal approach. Accuracy and precision are most important.

— A process-oriented view is represented by statements about arithmetic being experienced as a heuristic and creative activity that allows solving problems using different and individual ways.

— An instrumentalist view places emphasis on the "tool box"- aspect which means that arithmetic is seen as a collection of calculation rules and procedures to be memorized and applied according to the given situation.

— An application oriented view accentuates the utility of arithmetic for the real world and the attempts to include real-world problems into class.

Further we refer to a global distinction of two different ways of teaching mathematics or arithmetic, i.e., a "cognitive constructivist orientation", and a "direct transmission view" (Staub & Stern, 2002, p. 344). We assume that these two different orientations are two ends of a continuum with three points of orientation: constructivism, co-constructivism and transmission (Strohmer et al., 2012).

METHOD

The sample consists of 20 primary teachers. However, in this paper we restrict the discussion to one teacher, i.e. Mrs. A (a young teacher from south of Germany), and her beliefs referring the teaching and learning of arithmetic. This restriction is not based on specific characteristics of Mrs. A, but is based on the main aim of this paper, i.e. to discuss an in-depth analysis of the structure of teachers' belief systems.

We collected data in two different ways: Firstly, we used a semi-structured interview including clusters of questions referring to arithmetic content and goals of teaching arithmetic as well as goals of teaching mathematics, students' learning of arithmetic or materials used, e.g. textbooks. In addition, the interviews incorporated prompts to evaluate given arithmetic tasks or fictitious statements of teachers or students that represent one of the views mentioned above.

Secondly we used a questionnaire referring to teachers' views (Grigutsch, Raatz, & Törner, 1998). Participants were asked to rate every item (e.g., item 5: Everyone is able to invent mathematics or rather to re-invent mathematics) using a 4-point Likert-scale. We adapted this questionnaire by changing the focus to beliefs referring arithmetic (new item 5: Everyone is able to invent arithmetic or rather to re-invent arithmetic), but also used Likert scale. Finally, we used the existing scale of Strohmer and colleagues (2012) to measure the teachers' teaching orientation that we also adapted for teaching arithmetic. We conducted the following three steps for analysing the data.

First step of data analysis

We used a qualitative coding method (Kuckartz, 2012) that is close to grounded theory (Glaser & Strauss, 1967) to analyse the data of the verbatim transcribed interviews. We used deductive codes derived from a theoretical perspective like 'application oriented' belief and inductive codes for those beliefs we did not deduce from existing research (Kuckartz, 2012). We will describe different inductive codes later in the result section.

Second step of data analysis

We weighted the deductive codes with 1, 2, -1 or -2 due to the following rules:

- If a teacher mentions a goal without a precision we weighted the code with 1.
- If a teacher explains a belief more deeply we weighted the code with 2.
- If a teacher refused a belief without explanation, we weighted the code with -1.
- If a teacher refused a belief with explanation, we weighted the code with -2.

One aim of this step of the data analysis was to develop quantitative evidence for the results that we gained through interpretation of the interview transcripts. For example, if the weighted sum of codes referring to a specific view is much higher than for another view, this could serve as evidence for a different grade of centrality of these two views. Further the sum of the weighted codes facilitates the comparison of the analysis of the interview and the analysis of the questionnaires. The deductive codings as well as the inductive codings were conducted by at least two persons and we found the inter-rater reliability to show an appropriate value.

Third step of data analysis

The four subscales of the adapted questionnaire of Grigutsch, Raatz and Törner (1998) yielded four sums of ratings referring to the application oriented view, the process oriented view, the instrumentalism view and the formalism view. We compared the distribution of these four subscales to the sum of weighted codes referring the same views. To facilitate the comparison we used standardised distribution of the rating sums and the sums of the weighted codes. To compare both standardised distributions we used a correlation coefficient and other measures on association (e.g., Kendalls Tau-b) in an exploratory way and, further, used a U-test for proving differences between the two distributions.

RESULTS

As mentioned before, we restrict the focus to one teacher, Mrs. A, and her belief system to give a comprehensive picture of the structure of one belief system.

Process orientation as a central belief of Mrs. A

Mrs. A expressed coherently a process oriented view. For example, to the question of her favourite style of teaching arithmetic and her preferred methods she answered:

> "Truly, it is important that they are able to find the solutions on their own, that they can work individually (...) that they can solve problems, that they can work on open tasks, that they can find their own strategies."

Statements of pupils:

2 I like mathematics because there is a connection to real life problems.

1 I like mathematics because hard nuts must be cracked and difficult problems can be solved.

4 I like mathematics because many exercises can be solved by similar procedures/patterns.

3 I like mathematics because the logic is clear and it follows strict mathematical rules.

Figure 2: Prompt: What would you like for pupils to answer?

Later, nearly the same answer ensued when she was asked about pupils and their way of learning arithmetic:

> "It is always important for me, that it comes from the pupils themselves, that it includes a problem, I like giving pupils problem statements."

Again, being asked to the question, which goals she would like to reach with her arithmetic lesson, she answered:

> "And then there are strategies, i.e. to be flexible, to adapt oneself to something new. Therefore, you need the right attitude that you have the confidence to try something you don`t know and to put effort into it."

The three quoted episodes referring to different topics of teaching arithmetic, i.e. the teaching style, students' learning and teaching goals give evidence that beliefs representing the process oriented view are central in the belief system of Mrs. A.

Further, the prompts given during the interview contain a process orientation. For example, Mrs. A was asked to arrange eight given teaching goals into a hierarchy. Figure 1 shows her arrangement of these goals for arithmetic lessons, where Mrs. A valued problem solving and process orientation as the most important goals.

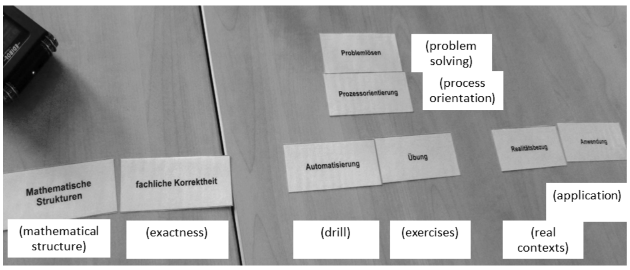

Figure 1: Arrangement of goals for arithmetic lessons by Mrs. A

In Figure 2 we show a further prompt consisting of students' statements representing the four views towards mathematics. The teachers were asked to arrange the statements from most desired (1) to least desired (4) if the statements represent arithmetic. Mrs. A preferred the second statement representing the process orientation.

Just as the professed beliefs the responds to the prompts referring teaching arithmetic give strong evidence that process orientation is central for Mrs. A.

The results of the second and third step of analysis (sum of weighted codes; questionnaire) are shown in Figure 3 where both distributions are standardised.

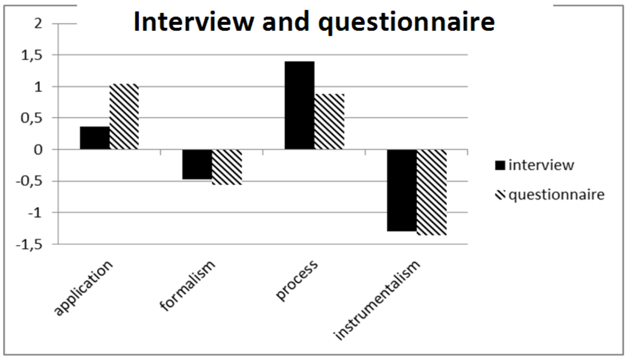

Figure 3: Weighted sum of codes and questionnaire scores

Looking at the figure it is obvious that application and process are more accepted than the other two orientations. The interview results as well as the questionnaire results imply this assertion. In conclusion application and process are central in Mrs. A's belief system. The high degree of coherence in different parts of the interview, the sum of weighted codes and, finally the questionnaire underline that the different instruments all measure the same.

Application as a derivative belief

Although application oriented beliefs are central for Mrs. A, however, her answers concerning the application oriented view gave evidence that application oriented beliefs are derivative beliefs. Thus they seem to be subordinated to process oriented beliefs. That means that application is in some sense a central teaching goal but rather a means to an end for another primary belief:

> "The relation to reality is important too, as I said before referring to money and time, but it doesn´t has to be highlighted all the time. Today, for example, I just gave them a mathematical problem..."

Application oriented goals seem not to be derived from process oriented goals in a logical way. However, both (clusters of) beliefs are central and application oriented beliefs are subordinated to process oriented beliefs.

Formalism and instrumentalism as peripheral beliefs

Although formalism is mentioned in some parts of the interview, it just has a peripheral meaning in the belief system of Mrs A. She names the importance of mathematical correctness once. Further, she emphasises that students should understand what they do in mathematics and why they do things. However, formalism seems to be a peripheral belief of Mrs. A and in some sense a desirable but peripheral result of process orientation as the following quotation illustrates:

> "Apart from that the process oriented training is more useful, because there is a little bit more reflection and control, so you can see what you are doing and why you are doing it!"

While Mrs. A talks positive about process, application and formalism when she regards her teaching of arithmetic, she often refuses instrumentalism. It is mentioned and it is denoted as important, but instrumentalism often receives a negative connotation, e.g. when Mrs. A talks about "mindless practicing" or when she says "you just have to do it this way":

> "I realize this drill is just mindless practicing, but in some ways it makes sense, for example when you want to establish an algorithm, yes, then you just have to do it this way."

The critical comments referring the instrumetalism view of Mrs. A show that this aspect is peripheral in her belief system. Referring to instrumentalism, we did not find evidence for a clear relation to another view.

Concluding the analysis of the belief system of Mrs. A the process orientation is central. Also application orientation is central in her belief system but, however, subordinated. Thus, application oriented goals could be understood as a means to an end to reach process orientation. Formalism is a positive connoted peripheral belief that represents a desired but peripheral result of process-orientation. Instrumentalism is also a peripheral but isolated belief with a negative connotation (Figure 4).

The belief cluster of process orientation

Mrs. A's central belief, i.e. process orientation, is closely connected to a set of further beliefs and, thus, could be understood as a belief cluster consisting of several defining beliefs. These defining beliefs are a result of inductive codes which were formed during the analysis of the interview transcript. We illustrate only two beliefs that constitute the belief cluster of process orientation. The first belief concerns *comprehension* that Mrs. A explains the benefit of open word problems - so called Fermi tasks - that are based on individual models:

> "Comprehension must stand on the top and you can reach it while giving tasks with a problem solving context. This has not to be a big Fermi task but also you can just confront the pupils with something and then see what they do.

The second quotation represents the belief *flexibility*. Here, the word strategies illustrate the closeness to process orientation:

> "...they [the children] should not be afraid of numbers. They should be flexible and fit in their head. And this brings us back to the strategies, they can learn with the help of the "half-written" calculation."

As well as process orientation also application, formalism and instrumentalism are belief clusters. In Figure 4 we show some of the beliefs that for Mrs. A define the four belief clusters.

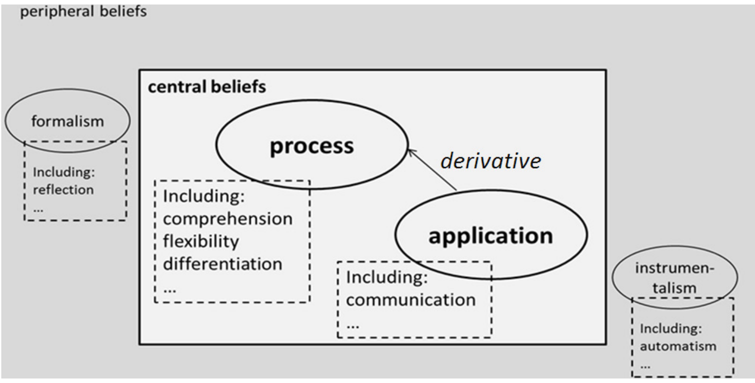

Figure 4: The belief system of Mrs. A

Statement of the pupil	Wish of the teacher (1 is best, 3 is worst)
„I can learn best, when I can choose my work completely on my own and when I am allowed to work independently on it!"	1
„I can learn best, when my teacher tells me what to do and when he helps me immediately when I have any questions!"	3
„I can learn best, when I can choose from different offers and when my teacher supports me when I need help!"	2

Figure 5: Prompt "wish of teacher"

(Co-)Constructivism as a central belief

In the same way as it was shown above, we investigated beliefs that concern more general the process of teaching and learning. Referring these beliefs, a (co-)constructivist orientation is central for Mrs. A:

> "Well, it should be oriented on the pupils, the teacher should abstain himself, so that there exists a high amount of work the pupils do, it should not only be training but also the teacher should give them credit so that they can work independently..."

The centrality of this orientation is also shown in the following prompt referring to learning arithmetic. Here Mrs. A should rate three different statements of pupils. The figure illustrates that it is important for her that the pupils work independently.

As discussed to the results referring the arithmetic related beliefs, the qualitative interpretation, the sum of weigthed codes and, finally, the results of the questionnaire yield very similar results also referring to the different ways of teaching (Figure 6).

Direct transmission view as a peripheral belief

As Figure 6 illustrates for Mrs. A, a direct transmission view only appears peripheral. This is also shown in her statements to her experience in sitting in on classes:

> "... and I have seen this in secondary school, [...] but it is so different and boring. The older teacher stand in front of the class, they lead the way and the pupils replicate and practise. And we learned quiet different things, for example at the university – much more pupil activity, much more problem solving and open lessons."

Most of the time Mrs. A emphasises that she wants the pupils to make their own experiences and that she does not want to stand in front of the class and tell the pupils how things work. Still there exist a few episodes where she talks about the relevance of teacher-centred teaching:

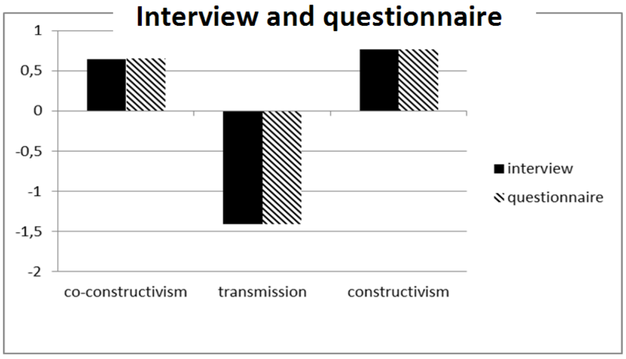

Figure 6: Weighted sum of codes and questionnaire scores

"...so teaching should be effectively and therefore it also is important to teach the pupils sometimes in teacher-centred teaching."

These examples show that a direct transmission view is not rejected but peripheral in the belief system of Mrs. A.

DISCUSSION

Looking at the results we can approve some of the aspects which characterise a belief system referring to Green (1971). Thus the structure of a mathematics teacher's belief system referring to the mathematical subdomain arithmetic contains beliefs with different centrality. The beliefs can be central (here: application and process orientation) or peripheral (here: instrumentalism and formalism). Further, the beliefs are hierarchically arranged as primary beliefs and derivative beliefs. In the case of Mrs. A the application orientation is a means to an end to facilitate process orientation. Finally, we identified different belief clusters, e.g. the cluster process orientation which contains for example comprehension or flexibility (cf. Figure 4). The theoretical statement that central beliefs are not necessarily connected to peripheral beliefs (Philipp, 2007) was pointed out in the connection between the central and peripheral beliefs of Mrs. A. Formalism could be understood as a peripheral result of process orientation, instrumentalism however has no connection to this belief.

Our results can be used to compare teachers from different type of schools and with different background concerning their professional career. However, the main reason of the in-depth analysis of a teachers' belief system that we discussed in this paper is to provide a basis that facilitate further research, i.e. investigating both the relation between professed beliefs and enacted beliefs and the development of teachers' beliefs.

Identity and rationality in group discussion: An exploratory study

Laura Branchetti[1] and Francesca Morselli[2]

1 University of Palermo, Palermo, Italy, branchetti.laura@gmail.com
2 University of Torino, Torino, Italy, francesca.morselli@unito.it

In this contribution we study group work in mathematics adopting a socio-cultural perspective and combining two theoretical lenses: the construct of identity and that of rational behavior. More specifically, we show how individual identity and dimensions of rationality in interaction may influence conceptual change. Data analysis is performed on excerpts from a group work (age of the students: 12) on negative numbers.

Keywords: Group work, identity, rationality.

INTRODUCTION

Group work as a methodology is often advocated in mathematics education, and its value is often taken as obvious by researchers and also teachers. Nevertheless, working in group does not immediately turn into a search for a common solution. What happens to the students when they see the others doing something different from them? Does every student care about the agreement with classmates? Research may help figuring out the possible causes of failure of group activities. Conversely, research may also show to those teachers, who ask their students to provide a common solution for group activities, how difficult is for students to reach on their own an agreement and how far is a solution from being "common" and accepted by all the members of the group. In this contribution we study group discussion adopting a socio-cultural perspective and combining two theoretical lenses: the construct of identity and that of rational behavior. By means of a networked analysis, we aim at better understanding what happens during group interaction, in particular what makes a group interaction efficient or not for students involved in a task-based activity designed with the aim of stimulating a conceptual change.

LITERATURE REVIEW AND THEORETICAL FRAMEWORK

Group work and sociocultural perspective

The pioneering analysis carried out but Vygotskij (1978) concerning the crucial role of social activities mediated by signs and language in the development of mathematical thinking traced a path in which a whole thread of researchers placed their roots. The effects of students' interactions in classroom activities have been studied, described and interpreted in mathematics education since its origins, see Radford (2011) for an overview. We rely on a sociocultural perspective, according to which the learning of mathematics takes place in a social context through interactions and is deeply affected by culture (Radford, 2006; 2011). Radford (2006, p. 58) affirms:

> Certainly, the students were actively engaged in what has been termed a "negotiation of meaning". But this term can be terribly misleading in that it may lead us to believe that the attainment of the concept is a mere consensual question of classroom interaction. [...] meaning also has a cultural-historical dimension [...]. It is in fact this cultural object that shapes and explains the teacher's intervention [...] classroom interaction and the students' subjective meaning are pushed towards specific directions of conceptual development. Cultural conceptual objects are like lighthouses that orient navigators' sailing boats. They impress classroom interaction with a specific teleology.

Students are involved in a double-faced problem: they meet at the same time the culture and the others and have to find a place in both the cultural and the classroom discourses, that are related but not necessarily equal. In particular we will focus on the classroom discourse side. Even if the attainment of a concept is not a mere consensual question, the agreement between students is very important in mathematics group activities, as we will show. We refer to Radford's interpretation of cultural-historical activity theory (Roth, Radford, & Lacroix, 2012). This theory is rooted in Leont'ev and Vygotskij's dialectical psychological theories. The keyword *activity* is defined as a common place in which cognition and consciousness arise; through activity individuals relate not only to the world of objects but also to other individuals. Learning is the result of a shared common practice that involves students' subjectivities and in which subjectivities moves towards others and culture to find and transform themselves. In Radford (2008) it is pointed out that students' interaction in a small group is a complex process in which students are involved at many levels, not only at the cognitive one. The processes of objectification (students align their thoughts with culture) and subjectification (a *thinking and becoming* process of being-with-others mediated by alterity) that take place in the teamwork are mediated by culture.

Conceptual change

In our perspective, learning is a *thinking and becoming* process in which students are involved not only at the cognitive level, and a continuous negotiation of meanings between one individual and another mediated by culture (Radford, 2008). We conjecture that conceptual change, as part of mathematics learning, cannot be seen just as "change of concept" at cognitive level: it is a social act deeply related to the subjectivities of students involved in group activity. Drawing from the definition of concept as an emergent object that condenses or generalizes the previous practices (Sfard, 1991), we speak of *group concept* as an object emerging from the individual or shared activities, whose validity is recognized and accepted by all the students.

Identifying and subjectifying

In the thread of Leont'ev and Vygotskij's dialectical psychological theories presented before, we analyze group activity by means of one analytical tool that was introduced by Heyd-Metzuyanim (2009). The author presents a useful tool to distinguish the different ways of interacting of each student in terms of individuality, in particular in a mathematics group work. The tool "allows to point out how identity and emotional processes influence the effectiveness of learning. Subjectifying may help in mathematizing or obstruct it" (Heyd-Metzuyanim, 2009, p. 2). The subjectification process is linked both theoretically and operationally to the identity construction process and to the mathematizing activity in group work. The starting point is the definition of identity (Sfard & Prusak, 2005, p. 1): "Identity is a set of reifying, significant, endorsable stories about a person." This definition is deeply related to the *commognitive perspective* (Sfard, 2008), whose cores are the notion of thinking and communicating. Since thinking is a form of human doing, it can only develop as a collective patterned activity: "Thinking is an individualized version of (interpersonal) communicating." (Sfard, 2008, p. 81). Heyd-Metzuyanim frames mathematizing and subjectifying in the commognitive perspective: mathematizing is communicating about mathematical objects, subjectifying is communicating about participants of the discourse. In this perspective the construction of identity takes place as an internalization of collective discourses that make stories about the self arising. These stories can talk about the way in which a person relates to the mathematics and so can influence the participation in the teamwork, the engagement, and definitively, success or failure in mathematics activities. In her work, Heyd-Metzuyanim (2009) looks at verbal and non-verbal acts of subjectification, distinguishing participation and membership. She operationalizes the notion of *resistance to participation*, seen as a type of subjectifying action always interpreted according to context, especially to the reactions of other participants, especially the teacher. Then she analyzes these acts, deciding if they are identifying processes or not. Identifying utterances (verbal or non-verbal) are "those that signal that the identifier considers a given feature of the identified person as permanent and significant." (Heyd-Metzuyanim, 2009, p. 2). The prototypical cases of different aspects of the relation between subjectifying, mathematizing and identifying are exemplified in Table 1.

Rationality

The construct of rationality was presented by Habermas (1998) in reference to discoursive practice and later adapted to mathematical activity (see Morselli & Boero, 2009 for the special case of mathematical proving). According to Habermas, rational behaviour may be seen as three interrelated dimensions: epistemic dimension (related to the control of the propositions and their chaining), teleological dimension (related to the conscious choice of tools to achieve the goal of the activity) and communicative one (related to the conscious choice of suitable means of communication within a given community).

Identity, rationality and conceptual change

We hypothesize that the conceptual change is a social act and that acceptance of this change may depend on a group-coherence, i.e., a sort of agreement reached using cultural tools provided by the teachers or personal tools. Subjectification and participation can be considered at the same time stimulus for engaging in a group conceptual change process and an obstacle in the individual conceptual change process. In order to describe individual contributions within the group work, we add the construct of rational behavior. Since we will deal with peer interaction, the communicative dimension will have a relevant role. Moreover the epistemic rationality, encompassing the possibility of changing opinion, seems to be linked to group work and conceptual change:

Someone is irrational if she puts forward her beliefs dogmatically, clinging to them although she sees that she cannot justify them. In order to qualify a belief as rational, it is sufficient that it can be held to be true on the basis of good reasons in the relevant context of justification - that is, that it can be accepted rationally. The rationality of a judgment does not imply its truth but merely its justified acceptability in a given context. (Habermas, 1998, p. 310)

RESEARCH QUESTIONS

We wonder whether identity and rationality may have a role in influencing (positively or negatively) the conceptual change that may occur during group problem solving activity. The initial research focus on group work can be turned into the following research questions: 1) Is it possible to describe group interactions in terms of identity and subjectification? 2) Are there cases of resistance to participation? 3) Is group conceptual change an act of social agreement, and this necessity of agreement influence the individual conceptual change? 4) What is added by the analytical tool of rationality?

METHODOLOGY

The task

We present and analyze data from a teaching experiment carried out in grade 6 (age of the students: 12). The teaching experiment concerned the concept of negative numbers. At first, students were asked to answer individually these questions: *1) What is a number? 2) What is it possible to do with numbers?* Afterwards, they worked in group on a task to be solved on the Cartesian axes. The negative part of the axes was used by the students and such a solution was after institutionalized by the teacher. Finally, the students were asked to answer in group to the following questions: *3) You said that numbers are [reference to their former individual answers]... and with numbers you can do [reference to their former individual answers]... Do you confirm your opinions now? 4) Negative numbers are numbers in the sense you intended before?*

The aim is to analyze the conceptual change that occurs when moving from natural numbers to negative numbers to whole numbers, that is to say a wider set that contains both positive and negative numbers. Here we confine to one episode referring to the group work on questions 3 and 4.

Using the analytical tools

We perform a networked analysis, combining different theoretical tools with the aim of reaching a fuller understanding of the episode at issue. The lens of conceptual change allows to characterize the acts of mathematizing analyzed in our research. The first analysis aims at detecting verbal and non-verbal acts that are signal of participation or resistance to participation, membership or non-membership, mathematizing, identifying. The lens of rationality can provide information about the rationality dimension of these sentences. The joint analysis addresses the topic of relating mathematizing and subjectifying acts to rationality.

At first we analyze the episode in terms of identity, subjectification and conceptual change, as derived from Heyd-Metzuyanim's paper (2009). Some sentences from the transcript are interpreted following the criteria proposed by the author in Table 1 and labeled with the codes: identity (I), subjectification (S) and conceptual change (C). Also the specific codes for subjectification used by Heyd-Metzuyanim will be used. Afterwards, we add the analytical tool of rational behavior. We refer to the epistemic dimension when one sentence is linked to a mathematical fact, and we speak of lack at epistemic level if some assumption is taken per se, without the need for a justification. For instance, in the very first part of the working group one student says that negative numbers are to be considered numbers ("*Because she (the teacher) spoke us of negative and positive*"): she is just relying on the authority of the teacher, without paying any effort towards a real understanding. We may say that her statement lacks in terms of epistemic rationality. We refer to the teleological dimension when the action is clearly linked to a goal (and we report a lack in teleological rationality when the reference to the final goal is missing). We refer to communicative rationality when a special care is paid to the organization of the discourse, so as to make the listener to understand. For instance, one student's wide use of drawings and diagrams may be linked to her effort in making her positions understandable to others, thus to a communicative dimension.

DATA ANALYSIS

At the beginning of the group work, students discuss to decide whether it is possible to deal with negative number as numbers. The selected episode refers to a connected crucial issue: whether it is possible to perform operations with negative numbers.

Analysis in terms of identity (I), subjectification (S) and conceptual change (C)

In the subsequent part, we present an example of analysis of one episode in terms of identity (I), subjectification (S) and conceptual change (C), with more specific codes used by Heyd-Metzuyanim (2009). Some labels are assigned even if in the transcript the utterances are not recurrent, because they are repeated many times in the whole transcript.

Other isolated episodes allow to characterize students' behaviors in terms of identifying and subjectifying acts and to link students' way to attend the group work and conceptual development. *Nor* always works on her own, never speaks, even if the teacher asks to do it. Every non-verbal act performed by *Nor* may be read in terms of *resistance to participation*. 6 on 8 students look for agreement but with different aims: some of them to convince the classmates, some to make the work of others coherent to their personal discourse, other to be accepted from the classmates rather than thinking at mathematical contents (as student *Ari*). From the analysis we grasp different ways to participate in the group, that affect personal concept development: *Mar* and *Nor*, working on their own, develop personal concepts; *Ari* and *Luc* abandon their conceptual change to find an agreement; *Bea* and *Er* follow the group conceptual development and only ask for clarifications; *Giu* imposes her point of view on all the group affirming her personal opposition to conceptual change. She identifies clearly herself as good in math and influences the whole process, even when she's not right. The agreement is not reached and the group conceptual change doesn't occur. This failure drives all the students but *Giu* to abandon

	Type			Example	Identifying?
Mathematizing	Mth				No
Subjectifying	Pe: participation evaluating	Sp: related to a specific performance		Saying "I don't understand"	No
		Ge: generalizing		Saying "I hate doing this"	If consistent with other data
	Me: membership evaluating	Vb: verbal	Di: direct	Saying "I am a math person"	Yes
			Id: indirect	Changing the subject of discourse, which can be interpreted as "I don't want to talk about this"	Depends on the nature and frequency of the utterance
		Nv: non verbal	Di: direct	Raising one's hand, which may interpreted as "I wish to speak about this"	Only if recurrent
			Id: indirect	Groaning at a given task, which may be interpreted as "I don't' like this"	Only if recurrent

Table 1: Prototypical cases and labels (Heyd-Metzuyanim, 2009)

11 *Giu*: it must be for all the operations, and then -3 times -2 is equal to?	*Giu* is mathematizing but also identifying as good in math. (I) [Me Nv Di] *Giu* provokes a change in the discourse generality: "If it's true, it has to be always true, for every kind of operation" (C)
12 *Ari*: just a minute, I wrote: This means that it is negative number, but anyway you can do -2+-3 [in column] you get -5.	
13 *Teacher*: and how do you get it?	
14 *Ari*: the sign means that it is a negative number, then I can do... that sign does not mean anything! It just means that it is a negative number, so...	*Ari* is mathematizing and suggesting a path for a conceptual change from numbers as natural to numbers as positive and negative (C).
15 *Giu*: no, A, what you are saying is meaningless.	*Giu* introduces the question of the sense of the operations with negative numbers. This change the status of the following statements (C). She also talks about *Ari* (S) [Pe Sp] and confirms *Ari*'s identity as person not good in math, as she did for the whole discussion saying that as usually she doesn't understand (Is) [Me V Di]
16 *Ari*: yes.	
17 *Giu*: -16:-4? [laughing]	*Giu* laughs when she doesn't agree with *Ari*'s proposals, showing self-confidence in math (I) [Me Nv Di]
18 *Ari*: -16? You must do 16 -4 [after, she adds the minus before the numbers, in column].	
19 *Giu*: try and do the division. The division.	*Giu* is mathematizing but also identifying as good in math and saying to *Ari* what she has to do (I). [Me Nv Di]
20 *Ari*: ok.	*Ari* interrupts her activity accepting *Giu's* request (S). [Pe Nv Sp]
21 *Luc*: wait a minute! [she takes the pen].	*Luc* wants to find a place in the discussion (S) [Me Nv Di]
22 *Giu*: let me speak!	*Giu* wants to participate (S) [Me Nv Di]
23 *Luc* [she does -4 divided by -2, and she writes -2]. Here you are! -4 divided by -2 is -2.	*Luc* tries to answer to *Giu*'s provoking question but doesn't satisfy *Giu*'s request (C).
24 [*Ari* does again 16:4].	

Table 2: Transcript and analysis

their personal path to conceptual change because of group disagreement. So neither the group conceptual change nor the individuals occur and the first event seems to be cause of the second.

ANALYSIS IN TERMS OF RATIONALITY

The theoretical lens of rationality is used to gain understanding of interactions. Here we confine our analysis of *Giu* and *Luc's* excerpts, with a special focus on the part of discussion on the possibility of performing operations with negative numbers. A first result is the crucial role of teleological rationality. *Giu's* initial position is that negative numbers are not numbers as positive ones and she does not want to modify her position. According to this goal (*teleological rationality*), she challenges the propositions of her groupmates. Her interventions are mainly on the *epistemic* level: she suggests that, in order to have negative numbers a numbers, it must be possible to perform operations, and she asks for justification and meaning for such operations (interventions 15, 19). *Giu's* requests to the groupmates are at epistemic level, she pretends justification and meaning. *Luc's* initial position is that negative numbers are not numbers like positive ones (she sees the number and the minus as separate objects). Nevertheless, she is keen to change her opinion: her priority is to gain a group solution. According to this aim (*teleological rationality*) she puts great effort in sharing her ideas with the mates, for instance using diagrams (*communicative rationality*) (intervention 26). When challenged by *Giu*, she is ready to find solutions (e.g. how to perform operations; see intervention 23) and she is rapidly satisfied. She does not put much effort in justifying or giving meaning to the methods. In her exchanges with *Giu* the communicative dimension is prevailing; she does not move to the epistemic level, then she does not come to an agreement with *Giu*.

DISCUSSION AND PRELIMINARY CONCLUSIONS

The first part of the analysis shows that the students participate in the group work in different ways. There are even two cases of *resistance to participation*. We argue that different participation sometimes affects personal concept development and, of course, hinders conceptual change as a group. At the end of the session, there is not a general agreement. We wonder why it was not possible, in spite of individual good ideas, to reach an agreement and why some students abandon their attempt if groupmates don't agree. We turn then to the theoretical lens of rationality. The analysis in terms of rationality shows that teleological rationality may refer to different goals and that some interventions are clearly on communicative or epistemic level. Combining the two analysis, we can state that individual *participation or resistance to participation* and also *membership or non-membership* may be described in terms of *dimensions of rationality*: if individual interventions are on different levels (epistemic vs communicative), it seems very difficult to reach an agreement. If a dimension prevails, some students can avoid to participate. Moreover, individuals may have different aims and act accordingly (teleological rationality), may consider the epistemic dimension or not, and this may affect individual/collective conceptual change. We hypothesize that group work, in order to be efficient, should take into account the three dimensions (in particular, the epistemic dimension can not be neglected); moreover, group interactions are not fruitful if the groupmates focus on different dimensions.

The preliminary results of this study suggest further research. From one side, we plan to analyze other data (including long-term observations of the students), in order to test our working hypothesis concerning the link between identity, conceptual change and rationality. Moreover, we see other issues that need further exploration:

1) The link between identity and teleological rationality brings to the fore the relationship between identity and goals. This could also be linked to the work of Gómez-Chacón (2011), who draws from Camilleri and colleagues (1990) the idea of identity strategies as "processes or procedures set into action (consciously or unconsciously) by an agent (individual or group) to reach one or more goals (explicitly stated or situated at an unconscious level); procedures elaborated in function of the interaction situation, that is in function of the different determinations (socio-historical, cultural, psychological) of this situation" (p. 24).

2) The role of the teacher is crucial in helping students to interact at the same level; furthermore, we hypothesize that other kind of tasks, for instance aimed at comparing individual solutions rather than providing immediately a group solution, could be more efficient.

3) Finally, we wonder whether there is a link between identity and rationality: more specifically, we wonder whether the resistance to participation depends on the dimension of rationality that most characterizes the identity.

Invented or discovered?

Eleni Charalampous

University of Cambridge, Faculty of education, Cambridge, UK, ec455@cam.ac.uk

Does mathematics pre-exist and hence is discovered or is it invented and owes its being to humans? What do students believe and how does this interact with their beliefs about the production and the meaningfulness of mathematical knowledge? This paper presents results based on 18 Greek students' interviews about their relationship with mathematics through an epistemological lens. The findings diverge from what the literature suggests especially with respect to whether mathematics is perceived as a meaningful human activity and to what extent it produces certain and fixed conclusions. Ideally educators could foster beliefs which promote students' engagement and understanding of mathematics.

Keywords: Mathematics ontology, epistemology, existence.

INTRODUCTION

The ontology of mathematics is a hot debate in the philosophy of mathematics. The key question is whether mathematics pre-exists or comes into existence through human activity. Does mathematics transcend humans or is it simply yet another sector of human knowledge. The question is complicated with respect to mathematics because it is entangled with its epistemology. Although mathematical concepts may not appear to be materially substantiated – at least not in the same sense that a table is – mathematical conclusions have long been endowed with a certainty that would be strange to assume for any creation of the human mind (Hersh, 1999).

Moreover, it seems that mathematicians and mathematics educators do not share the same views on this issue. Most mathematicians tend to embrace the belief that mathematics is independent of the human mind. On the contrary, most educators advocate the belief that mathematics is constructed by humans (Sfard, 1998). Research has generally associated the belief that mathematics pre-exists with traditional teaching practices. Teachers who view mathematics as an independent entity would present mathematical knowledge as fixed. Consequently, their role is to transmit it to the students while the latter's role is to passively absorb it. Educators, of course, opt for an active engagement of the students (Lerman, 2002). However, there have been great mathematicians (e.g., Hardy, Gödel) who have been actively engaged with mathematics and who have done wonders holding the belief that educators dread.

Consequently it is contestable what we would like students to believe about mathematics' ontology. Should they follow the steps of great mathematicians or will this render them passive learners? Nevertheless, before aiming at such a question, we need to know more about students' beliefs on this issue and how they affect the student's relationship with mathematics? Although there has been abundant research in students' beliefs about mathematics (e.g., Schoenfeld, 1992) the issue of ontology seems to have been neglected. This paper focuses on it, investigating the second of the above mentioned questions in the traditional teaching context of Greece.

THEORETICAL FRAMEWORK

The distinction between finding something that already exists and something that is novel is captured by the verbs 'discover' and 'invent'. We discover something that already exists the same way that Columbus discovered America. To the contrary when we invent something it owes its existence to this very process of invention[1].

The predominant opinion in the history of the philosophy of mathematics speaks of discovery. This tradition may be traced back to Plato and has been called Platonism[2] after the philosopher. Platonism is nicely captured in the words of the mathematician G. H. Hardy who maintains that

> mathematical reality lies outside us, that our function is to discover or observe it and that the theorems which we prove ... are simply our notes of our observations. (1967, pp. 123–124).

This is an ontological assertion related to the 'mode of existence' of mathematics. However, it has been this ontological assertion that underlain the predominant epistemological conviction about the certainty of mathematical knowledge. Mathematical truth is absolute and objective since the truth of any mathematical statement is judged against an extra-human mathematical reality.

Nevertheless, many modern philosophers reject Platonism as an absurd idea; we can see and touch the physical reality, but where is this purported mathematical reality (Hersh, 1999)? If Platonism is rejected, then mathematics can no longer be discovered. Mathematics is now claimed to be invented, and again an ontological conviction is coupled with an epistemological claim. Mathematics does not exist and mathematical knowledge becomes fallible. Lakatos (1976) argues that no proof guarantees the truth of the theorem it proves; there is always the possibility of a hitherto unknown counterexample which will refute the theorem's generality. Moreover, Paul Ernest (1991) presents mathematics as a socially constructed field of knowledge; there is no longer a need to assume an external mathematical reality and no longer a need for this craving for certainty.

Paul Ernest also relates this to mathematics education. If mathematics is invented it acquires a human face. It is not a timeless, unerring entity which imposes itself on students. It is only a human creation and students can re-invent it through the process of learning. Consequently, mathematics could become meaningful for students as a product of a human activity. Nevertheless, mathematics seems to retain this potential even if it is discovered. According to Galileo 'the book of nature is written in the language of mathematics' and understanding the world around us has always been meaningful to humans.

In any case, philosophy of mathematics suggests that it is hard to disentangle ontological from epistemological beliefs about mathematics. Therefore, in the following I also discuss epistemological beliefs of the students, but only in relation to the main question of ontology.

METHODS

This article reports some preliminary results of a study investigating epistemic beliefs of Greek students at the last grade of upper secondary school (17–18 years old). The study follows a qualitative interpretivist paradigm. Twenty eight students were interviewed twice. The interviews investigated their relationship with mathematics through an epistemological lens touching upon subjects such as truth, certainty, logic, rules and usefulness and comparing mathematics to other courses or to life in general.

Before the second interview was conducted, the first one was transcribed and used as a stimulus for a further and more detailed discussion. Effectively, generating questions for the second interview with a particular student was influenced both from that student's first interview and earlier first interviews; while later first interviews were also affected by this process. The duration between the two interviews varied between 10 days to one month and on average each interview lasted 70 minutes.

All students come from the same middle-class school of Athens. Practical reasons limited the research to this school where access was easily granted. However, the interviews revealed such a variety of beliefs that including other schools in the sample was not judged necessary.

The analysis is still in progress. All interviews have been transcribed and the two interviews of each student have been paired. The second interview is regarded as a continuation of the first one and each pair is analysed as a whole. So far I have worked with the paired interviews of 18 students in a chronological order. As a first step each of them was read as a story trying to identify the main factor or factors which marked the student's relationship with mathematics. This initial reading revealed that the main points of each interview could be organised as a cohesive narrative around these factors. The factors were very diverse (e.g. doubt, theory, mistakes, fiction). However there were broad themes which appeared repeatedly in most of the narratives. The factors may be seen as different ways to colour such themes.

One of the themes is the ontological status of mathematics. This paper focuses on it in connection to epistemological issues of mathematical truth and certainty, and to meaningfulness of mathematics for the students. The results that follow are organised around the concepts of discovery and invention. They are based on the interviews of eighteen students, who here have been given pseudonyms.

FINDINGS

Discovery

Some students maintained that mathematics exists. For example, Platonas, maintained

> When in the past, they tried to interpret a phenomenon … they needed mathematics, in a sense they, not created it, in a sense mathematics was there, but they, that is, they discovered it, yes.

Of course, most students had a difficulty explaining how mathematics exists. Nonetheless, their belief was usually not shaken and even when it was, they still found it hard to coordinate this with their experience.

> Yes, mathematics isn't something ordinary that you can say you discover, it is a way of reasoning. . . . It's invented, now that you mention it, but it isn't that we came up with mathematics, now you'll ask me who did? (Aspasia)

A dubious concept was imaginary numbers. However, although most of them admitted that they are invented, they retained their Platonistic beliefs.

> Yes, imaginary numbers are called imaginary exactly because we invented them. However, in general mathematics is discovered. (Xenofontas)

> But mathematics hasn't been created. It's been discovered in the sense that, okay apart from some things which we have made in order to help us, in general mathematics is something that exists. (Foivos)

Mathematics was perceived to exist around us. It started from observing objects around us and it ends in explaining phenomena around us.

> It's just that based on . . . numbers, humans defined that a certain object, this is the 1, this is the 2, and so slowly they discovered that around them there are groups of identical objects. So then they started doing operations, and this led after many years in the invention[3] of theorems in order to justify phenomena that occurred around them. (Filia)

The paradox is that although discovery implies that mathematics is independent of human beings it also brings mathematics close to human beings. If mathematics is out there in the physical world then it is something quite intimate and not just some weird figment of imagination.

> I know that it isn't impersonal and that everything is based on it. . . I've thought about it. In order to construct something the mathematics which made it is needed . . . so I'm grateful to mathematics. (Foivos)

None of the Platonists doubted that mathematics has applications in our lives.

> the exercises, for example, they have applications on things that we want to find. . . for example, we have an, an equation and we want to know the result … for something that will help in our daily lives. (Filia)

Mathematics was important exactly because it explains our world and otherwise it wouldn't have been so developed.

> No, [mathematics] would exist, but … we wouldn't have discovered it to the extent that we have discovered it now. (Ermis)

In all, mathematics was meaningful. Moreover, human agency was not absent with respect to mathematical discovery. After all, it is people, mathematicians, who produce mathematics. This could justify why students, who generally endorsed Platonism, sometimes utilised phrases which would hint at invention while describing mathematics as a human activity. Further justification is provided by the fact that invention succeeds anyway in penetrating mathematical activity. At least we did not find symbols in the world; we only agreed to use them in order to denote what we did find in the world.

> As you go backwards you'll eventually reach the basis, an axiom of the kind 1+1=2. . . This is so because *you have defined it so*. (Foivos)

> I believe that it was *an initiative and an inspiration* of those who started all this. (Patonas)

Other common beliefs were that mathematics may change, but the change is incremental. Essentially, change is better perceived as development, an enlargement of mathematics when new data are discovered.

> Yes I believe that if some needs lead to an extension of mathematics, then new rules will be discovered . . . on the basis of the old ones, of course. (Platonas)

> No, this is a development . . . and complex numbers, which they didn't know, they discovered them. And it emerged through, now I remember. . . I think through physics, the issue of light. (Ermis)

New propositions complement the old ones. All of them believed that mathematics essentially comprises one system.

> I don't know [if we could have defined things differently] because whatever we have defined we have defined it based on our universe, based on some things that we observe. (Foivos).

> No, [it can't be different]. Mathematics is in a way the explanation of what we see. It's something natural, that is, you have one apple and another apple, so you have two apples, it can't be something else. (Xenofontas)

Different sub-systems may exist but they do not cancel each other; they co-exist as different models of the same reality. The old models suffice for certain cases, while the new ones explain new data which cannot fit the old model.

> No, [Euclid] wasn't wrong. It's just that when they examined it deeper and with more cases . . . they suggested that other things may also happen. (Platonas)

The belief in one system and incremental change of mathematics is also reflected in their belief that there is a unique absolute truth which we may not be able to find, but which we slowly approach. Mathematical conclusions are part of this truth.

> Truth is one-sided. . . I believe that new things are continually discovered. That is, soon we'll have learned much more; now we're still in the darkness. (Aspasia)

> [The proof] is essentially the tangible evidence that a proposition that you have assumed is true. (Platonas)

Interestingly though, Platonism did not exclude verification of mathematics through fallible social processes.

> Somebody says an idea, 500 people agree, 600 disagree and in the end one of the 600 finds something else or they simply agree because one of the 500 proves that it holds for additional reasons which the first one had not found. (Foivos)

This is reminiscent of Lakatos' *Proofs and Refutations* rather than Plato. However, it is not in opposition with Platonism per se. If mathematics is external to humans it can remain infallible even though their attempts to discover it are not. So, Platonism allows for certainty in mathematics even if people are not entirely certain about it.

> When I think about mathematics and somebody shows me something, that this must be done, [then] I'll think why it mustn't, I will examine it. . . Therefore, so far: yes, I'll accept the results of mathematics, but always having also in mind the doubt that something else may hold. (Ermis)

Invention

Most students suggested that mathematics is invented.

> [Mathematical conclusions] are unshakable because they are stable, that is, they don't change. You'll tell me that some of them change, but they have been checked, as I mentioned before. It has been supported that they are unchangeable, that is, their value is permanent. (Platonas)

> Generally, I don't believe that mathematics exists as a material idea, that is, you can't touch it. (Diomidis)

> In mathematics there is 'if this holds then it's done so'. That's all there is. Or 'let', 'let this be'. . . Assumptions of the mind. (Evyenia).

> It's a human creation. . . I think that when you prove something, you essentially make the rule. (Pelopidas)

The paradox in this case is that although invention implies that mathematics is part of the human intellect it may also create a gap between mathematics and the individual. This depends on whether the invention of mathematics is meaningful to the student. There were students for whom mathematics was deeply meaningful, students for whom mathematics had some worthwhile meaning and students who struggled to find any meaning in mathematics.

> Yes [mathematics] is standardised . . . but this has another beauty. (Loukianos)

> Yes, I belong to the couples who though separated I still love [mathematics]. (Litha)

> Mathematics is completely theoretical, that is, the logic that it has, it won't produce . . . something crazy, that is, it won't be something that I can use in my everyday life, that's why I don't hold mathematics in great estimation. (Kosmas)

In the first case students had at least a feeble idea of axioms and perceived mathematics as something that humans have invented based on initial assumptions in order to suit their needs.

> It doesn't mean that they hold necessarily, we just have created things so that they . . . improve our everyday life. (Lysimahos)

> the world of mathematics is as we define it, that's why there are different geometries . . . And geometries, all that exist, they were created with the intention of solving some problems. (Kleomenis)

In the second case mathematical invention was perceived as some sort of experimentation. Mathematics was invented as applications corroborated some assumptions.

> basically everything has an experiment. Because in order to find something new, for example, you must try it out. This is called experiment. (Lida)

> I think that they solved many times an exercise or type of exercise . . . that they were reaching at the same conclusion repeatedly, so . . . then they said to make it a rule . . . Not that they deliberately tried to make a rule, I believe that it just appeared. (Diomidis)

Finally, in the third case invention appeared to be the result of the lack of meaning.

> I'd say pre-existed, pre-existed? It didn't pre-exist, it's all human investigation, I believe. (Kosmas)

> That is, someone would have imagined all these, to someone all these came; it can't be just like this. (Evyenia)

Some students in the third group seemed to perceive mathematics as some people's personal views. These were students who held a highly relativistic view about life.

> They should ask Pythagoras. . . [Me having an opinion on his theorem], essentially it's like me going and saying something with respect to a view of Socrates. (Klio)

> Okay now, it would be somehow [strange], if we said for each [person] that they don't think correctly (Evyenia)

In all, only two students who chose invention believed in a unique truth, and even these did not believe that we had access to it. Moreover, they were both students who did not find mathematics meaningful.

> we are just people, each of us is just a unit, If we could see the world from above then we would be able to judge that this is a definite truth, this is a definite lie. (Kosmas)

Certainty was much more moderate among students who maintained that mathematics is invented. However, it was present especially in the cases when mathematics was also meaningful – even moderately – to them. Some of them found certainty in the exact process of invention, but almost all of them grounded it on social reasons too. Nevertheless, the process of invention itself was excluded from certainty.

> Because it's theory . . . basically there's no chance. . . in life, something may hold or may not hold . . . Well, no [it isn't strange that you don't find this in

> mathematics] because mathematics is theoretical. (Kleomenis)

> [We accept the first assumptions] because we get used to them . . . I think that there haven't been attempts to change . . . the foundations. . . So since they have results and validity in everyday life [we] continue using them. (Lysimahos)

> [What's proven] usually doesn't change . . . all the mathematicians have seen them, and they have been considered. . . but I think that within the university context . . . I think that there is more room to doubt them and to be demolished by someone. (Diomidis)

Certainty was absent only in cases when mathematics was not meaningful to the students. This could simply be due to under-confidence, but sometimes was inherent of a subjective view of mathematics. If certainty persists in this group then it is genuinely social.

> I wouldn't say that something said by mathematics is always true. . . you take cases and you assume, essentially, as we said before, 'let this be' or 'if that'. (Evyenia)

> I haven't seen anything different, only what I have been taught . . . they haven't shown to me something else in order to believe that it may not be this way. (Pelopidas)

What is special about social certainty is that it can remain intact even in the face of change because each time it includes exactly these truths which are believed to be certain.

> So until someone demolishes it, it's right, it's true. If it's demolished, then it's wrong. . . because it's truth, we accept the truth, but truth may many times be reversed with the presentation of new evidence. (Kosmas)

Nevertheless, certainty was not absolute, but the result of the scarcity of change or of the lack for necessity of change. Moreover, although past content was generally viewed as stable, it was not entirely safeguard against invention.

> Okay, there is a chance of mistakes, but I believe that most of them won't change. (Diomidis)

> If it changes then all the rest should change too . . . I'm not absolute about this not happening. I just don't think that it's possible to happen. (Danai)

Therefore, change is not necessarily incremental. Nevertheless, mathematics remained a unified system apart from the cases of utter subjectivity and of one student whose knowledge of axioms was more developed. Otherwise the system was one: what they have been taught in school.

> The most typical example is geometry. Euclid organised it anyway, but afterwards Riemann? Who was it? He didn't like it; he wanted to use, to show other things, and so he changed it. (Kleomenis)

> [Definitions may] not have the exact same words, they simply have the same sense. . . It can't be [that they don't have the same sense]. (Diomidis)

CONCLUSION

Although the students had learned mathematics within a traditional setting, most of them believed that mathematics was invented. However, it was within the context of invention that mathematics could appear meaningless to students. Contrary to what would be expected according to the literature (e.g. Simon et al., 2000), students who believed that mathematics is discovered also viewed it as a human activity. Their account of the discovery was given in social terms and echoed *Proofs and Refutations* (1976). Most importantly, the fact that mathematics existed was coupled with mathematics' ability to explain the natural world and it made mathematics meaningful. On the other hand, some of the students who saw mathematics as a human invention failed to find meaning in it. Moreover, it seemed that this failure almost forced the idea of mathematics as an invention; it was just somebody else's invention and they could not see themselves in it.

Furthermore, Platonism is also associated with the belief that mathematics is a static body of knowledge (Charalambous et al., 2009). Nevertheless, all students regarded mathematics as something that evolves. A static element appeared indeed among Platonists, but referred to past knowledge and it did not prevent new data amending this knowledge. Additionally, this belief was not restricted to students who believed in discovery of mathematics. It was generally endorsed by most students though it was socially tinged when mathematics was seen as an invention. Mathematics brings results so there is no reason to change it; old claims have been already checked by myriads of mathematicians and so on. Doubt, when present, seemed to be a general trait of the student's personality and the greatest doubter among my sample was a Platonist.

This picture of discovery or invention of mathematics as painted of the students of this study is quite different from the one usually forwarded by mathematics education. However, what seems more important is not what students believe about the being of mathematics, but whether they find meaning in it. If they do, then they will be willing to engage with it. It seems that Platonism may help towards this goal. It would also be interesting though to find the reasons which lie behind the divergent views of invention of mathematics. Some students do not find the invention meaningful. However, invention appeared to allow for a clearer view of the organisation of mathematical knowledge into axiomatic systems and thus a better understanding of mathematical epistemology.

ENDNOTES

1. Invention and discovery do not represent a strict dichotomy neither in the literature (e.g. Livio, 2011) nor in my interviews. However, for issues of space I will focus on the two extremes and on the predominant view in each student's interview.

2. I use 'Platonism' as an umbrella term for all theories which postulate that mathematics somehow exists.

3. Filia used invention meaning 'we were aware of it, that we wanted to find something'.

Discursive positionings and emotions in a small group's learning of geometric definitions

Wajeeh Daher[1,2], Osama Swidan[3] and Juhaina Shahbari[1,4]

3 Kaye Academic College of Education, Beersheba, Israel
4 Sakhnin College of Education, Sakhnin, Israel

This research examines the discursive positionings and emotions related to them of a group of three seventh class students. We videoed the group of students' discussions regarding the definition of terms associated with the circle topic and interviewed them regarding their emotions during the process of defining the geometric terms. We used the discursive analysis of Evans, Morgan and Tsatsaroni to analyze the participants' positionings and emotions. The research results indicate that the learning atmosphere in the group was positive due to type of leadership that prevailed, as well as to the collaborative working with a technological tool. This atmosphere resulted in the students having positive emotions about their learning.

Keywords: Discursive affect, positionings, emotions, geometry, small group.

INTRODUCTION

Students' emotions have become a growing research area in educational psychology (Knollmann & Wild, 2007). Ingleton (1999) describes emotions as a powerful factor which encourages or inhibits effective learning. Furthermore, the affective aspect of students' mathematical learning (including beliefs, attitudes, and emotions) has a mutual relationship with the cognitive aspect of this learning (Sriraman, 2003). This puts studying the affective aspect of students' learning on the agenda of mathematics education research. Here we study students' positionings and emotions when learning geometry. To do that, we use the discursive positionings and emotions framework (Evans, Morgan, & Tsatsaroni, 2006; Morgan, Evans, & Tsatsaroni, 2002). The use of this framework enables us to analyse two aspects of students' learning that affect other aspects of this learning, namely the social and the emotions aspects. Moreover, using the framework, we can examine how emotions are related to positionings, an issue that has not been attended to widely. More specifically, the social aspect is studied through looking at students' positionings and their expressions in language, as the use of pronouns, which indicates whether the group member feels insider or outsider to the learning taking place. This feeling could also affect the member's emotions. For example, the insider probably feels content and satisfied by the learning taking place.

The discursive positionings and emotions framework draws on social semiotics, pedagogic discourse theory and psychoanalysis, and studies emotion as discursive positioning. The analysis of learners' mathematical positioning and emotions, according to this framework, takes into consideration positionings available to the mathematics learners through their learning practices, where those positionings enable and constrain the learners' emotions, and where emotions are considered as shaped by power relations. Few studies used this framework that takes care of two primary aspects of students' mathematical learning (the social and the emotional) to analyze students' positioning and emotions in geometric situations. We will attempt to do that, specifically, when a group of seventh grade students works with Geogebra to discuss geometric terms associated with the circle's topic. The discursive analysis, its basis and its phases are described in more detail below.

A discourse is a system of signs that provides resources for participants to construct social meanings and identities, experience emotions, and account for actions. Evans (2006) names the following functions of discourse: First, it defines how certain things are represented, thought about, and practiced; second, it provides resources for constructing meanings, and accounting for actions; and third, it helps construct identities and subjectivities that include affective characteristics and processes.

The discursive analysis of students' emotions and positioning has two phases: the structural and the textual. In the structural phase, learners' positionings are analyzed. Evans (2006) defines positioning as a process where a participant takes up and/or is put into one of the positionings made available by the discourse(s) at a specific context. This explains the mutual influence of the social and the individual, where the social setting makes available specific practices and thus positionings, and individuals retain a degree of agency that enables them to position themselves in available or created positionings. According to this framework, a person's identity, which includes more durable components of affect such as attitudes and beliefs, comes from repetitions of positionings, as well as their related emotional experiences that occur in the history of the participant (Evans, ibid). Evans, Morgan and Tsatsaroni, in their writings about discursive analysis describe the positionings taken care of in the structural analysis: Helper and seeker of help (helper positioned more powerfully), collaborator and solitary worker, director of activity and follower of directions (the latter less powerful), evaluator and evaluated, insider and outsider.

There is more than one available positioning for a participant, if in one discourse or in several discourses. Moreover, positioning is not permanent, not completely determined, nor freely chosen, where participants are constrained and enabled by their personal histories and the discursive resources available to them (ibid). Furthermore, in the 'progressive classroom', the positionings of the collaborator and insider are encouraged because they help advance students' learning of mathematics.

The second phase of discursive analysis (the textual analysis) has two functions (Evans, 2006): (a) showing how positionings in social interactions are actually taken up by the participants, and (b) providing indicators of emotional experience. Furthermore, in the textual analysis, indicators of interpersonal relationship and emotional experience are considered (Tsatsaroni, Evans, & Morgan, 2007). This analysis has two stages. In the first stage, the focus is to identify the interpersonal aspects of the text that establish the positions of the participants. Indicators at this stage include reference to self and others, reference to valued statuses (e.g. claiming understanding or correctness), modality (indicating degrees of un/certainty), hidden agency (e.g., passive voice) or repetition. The second stage of the textual analysis attends to (a) indicators of emotional experience generally understood/used within the (sub) culture: direct verbal expression (e.g., 'I feel anxious'), use of particular metaphors (e.g. claiming to be 'coasting'), emphasis by words, gesture, intonation, or repetition (indicating strong feelings), body language (e.g., facial expression or blushing); (b) indicators suggested by psychoanalytic theory, as indicators of defenses against strong emotions like anxiety, or conflicts between positionings (as 'Freudian slips'), surprising error in problem solving, behaving strangely (as laughing nervously), denial (e.g., of anxiety).

Using the two phases of the discursive framework, we analyzed the positionings taken by seventh grade students and their related emotions when developing collaboratively, with the help of GeoGebra, the definition of geometric terms associated with the circle topic.

Research questions

1) How are positionings taken up by middle school students, working in a group to define geometric concepts in the presence of technology?

2) How are students' emotions associated with the positionings that they take up when they define geometric concepts with technology?

3) How does technology affect students' positionings and related emotions?

METHODOLOGY

Research setting and participants

We analysed in the present research the affective aspect of the learning of a group of three grade 7 students. Following is a description of this group, where the description is based on the evaluation of the students' mathematics teacher.

The group consisted of Haya (A high achieving student in mathematics with strong personality), Janan (A high achieving student in mathematics with a sociable and friendly personality), and Rana (A middle achieving student in mathematics, who encountered learning difficulties due to family circumstances).

The three participating students did not work with GeoGebra before, and they were introduced to it in two hours' time. Furthermore, the students had learned the topic of the circle in the sixth grade, but they learned it then without GeoGebra.

Our analysis of one group's learning of geometric definitions attempts to shed light at students' positionings and related emotions, when they learn geometry with a technological tool. This analysis of just one group learning is consistent with previous studies that analysed different aspects of students learning (See for example Yerushalmy & Swidan, 2012). Nevertheless, we are aware that further research is needed to verify the results we arrive at.

Data collecting and analysing tools

We collected our data using observations of the group learning and interviews with its members. The group's learning was videoed and at the end of each lesson, the three students were interviewed individually regarding their positionings and emotions during learning. We analysed the two types of collected data using the discursive analysis framework presented above. Moreover, we combined the analyses of the data collected by the two tools.

Learning material

The group of seventh grade students worked with different activities, where they discussed the definitions of geometric concepts associated with the circle's topic. It was expected that performing the activities, the participants would deepen their knowledge regarding the concept of circle and its related concepts: circle's center, chord, radius, diameter, circle tangent, circle circumference and area. The activities were written keeping the explorative and discursive learning in mind. Below is an example on a question in the unit.

(a) We want to draw a circle using Geogebra.

(b) We want to draw a diameter in the circle.

(c) Manipulating the diameter, how can we define it?

(d) How many diameters are there in a circle?

(e) What is the relation of the diameter and the chord?

FINDINGS AND ANALYSIS

We describe here the different learning events of the geometric concepts associated with the circle topic, together with students' positionings and related emotions that prevailed in these learning events. We start from the learning events as we consider students' positionings and emotions associated with these events.

Difficulty in defining the circle's center in spite of the group members being collaborators

The first requirement of the activity was to define the circle's center. Haya initiated the exploration of the group (1), by telling the group's members (she and two other members) that they should follow the directions of the activity (1 and 5), and by using GeoGebra to drag the circle. Then she addressed Janan and Rana (the other two members of the group), and started to discuss the circle's center, but soon the conversation turned to be about the chord (6–11), the diameter (6–11), the secant (12–17) and the tangent (12–17).

Note: When describing the learning events, silence for m moments will be denoted by [..m..].

1 Haya: The circle's center is ....
2 Janan: it is the point lying in the middle of the circle.
3 Haya: the middle ...
4 Janan: It is the center.
5 Haya (again): The circle's center is ....
6 Janan: every chord that passes through it becomes a diameter.
7 Haya: a diameter? [..15..] What is a diameter?
8 Janan: it is this that passes through the circle.
9 Haya: it is this that passes through the center and the circle.
10 Janan: it is a line that passes through any part of the circle.
11 Haya: if it passes through the center it becomes a diameter [Haya uses the mouse to drag the circle and watch how the diameter and radius change] ... the secant is like ... it intersects the circle in two points.

12 Rana: the tangent surrounds the entire circle [Rana and Janan were looking at GeoGebra interface).
13 Janan (vehemently): Yeh [Haya dragged the tangent again and again].
14 Rana: the tangent is this that touches the circle.
15 Janan (again vehemently): it does not intersect the circle. It touches the outer line. [Haya continues to drag the tangent].
16 Janan (looking at GeoGebra interface with interest): when the secant touches the circle it becomes a tangent.
17 Haya: the secant is like … it intersects the circle in two points.

Haya played the role of the group director, though the whole conversation and actions seemed to be of collaborators more than of a director and two followers of directions. The collaboration occurred through asking questions and answering them, and through frequent attempts to agree on the definitions of the circle's center and other concepts associated with the circle. Haya seemed to be directing the activity, by two means: her persistence to ask questions and her use of GeoGebra to get new examples of the circle and its components. Haya's questions and actions led the group to improve their definitions of the concepts associated with the circle.

The facial expressions of the group members showed that they were enjoying their learning with GeoGebra as a group. This learning enabled them to improve, as a group (collaboratively) and on their own account (independently), their knowledge of the circle topic, which was represented in better statements about the diameter, the secant ant the tangent [interview]. Furthermore, the improvement in the group knowledge empowered them, which made them content and happy [interview].

The group turned again to discuss the concept of the circle center, as the following learning event shows.

The group's director effort to come back to the original activity

Haya continued acting as the group leader. She declared they need to write the answer of the first question (18). She repeated the center's definition given earlier by Janan (19), and advanced the discussion further by asking another question to make that definition clearer (20). As a response to the question, Janan once again tried to describe the center (21). Haya tried to overcome the group difficulty in defining the center by investigating further the issue through dragging the center of the circle using GeoGebra (22). She announced again the mission of the group. So, Janan added another property to her definition of the center (23). Rana, contributed to the discussion by repeating Janan's first description of the center (24).

18 Haya: We have not answered the first question yet. What is the circle center?
19 Rana: a point. [..15..] [Haya wrote: a point lying in the middle of the circle].
20 Haya: how can we assign a point in the middle of the circle?
21 Janan: what? [..15..] before the radius.
22 [Haya dragged the circle center and the group described what happened to the circle and its components] Haya: We want to define the center of the circle.
23 Janan: it is the base of the circle.
24 Rana: It is a point lying in the middle.

Janan's behavior indicates her interim positioning as a follower of directions (21, 23).The silence indicates the group difficulty in defining the circle's center. In the interview, the group members said that their silence hid their frustration and uncomfortability due to feeling powerless because of their difficulty, as a group, in defining the center of the circle. Haya's work with the applet emphasizes her leadership. Her use of the pronoun 'we' (18, 20, 22), indicates she was an insider, and Janan's immediate answer (21, 23) indicates that she too was such. Rana's participation (24) also indicates her interim positioning as a collaborator. It seems that Rana, being not a strong student in mathematics, lessened her collaboration in the group discussion and mathematical work, which made her at the beginning less of an insider than the other two girls. This also made her feel neither content nor comfortable [interview]. Nevertheless, this did not prevent her from interfering and correcting the other members of the group when needed, as the following learning event shows.

Trying to be an insider and get involved in discussing the circle's radius

Once again Haya moved the mathematical talk away from its focus - the circle center (25), this time to answer the next question in the activity about the radius of the circle. Probably she did that to change the negative mood of the group, becoming uncomfortable and frustrated because of their feeling powerless due to their difficulty to arrive at an accepted definition of the circle center. Janan tried, as before, to participate in the group's discussion (26, 29, 31), indicating she continued to look at herself as an insider.

25 Haya: How can we set the radius of the circle?
26 Janan: we extend a line from the center.
27 Rana: No, the radius.
28 Haya: the radius. How can we set the radius?
29 Janan: we extend a line from the center to the line of the circle.
30 Haya (pointing at the circumference in GeoGebra interface): to the circumference.
31 Janan: to the circumference, Yeh.
32 Rana: according to the diameter length. [The facial expressions of the group members showed frustration]
33 Haya: what is the radius of the circle?

Rana seems here trying to get power in the group, correcting Janan (27), and participating in the answering of the question about the setting of the radius (27, 32). Rana's contribution was not evaluated highly by the director of the group who again asked about the radius (33). This little acceptance of Rana's answer by the director of the group made her frustrated of her positioning in the group [interview]. Nevertheless, she tried to contribute again to the discussion, as can be seen from the following event.

Collaborating to define the diameter and discuss its relation with the chord: The power of knowledge

Haya tried to define the radius (34). She stated her definition hesitantly, as if not confident of it. In spite of her hesitation, the two other members accepted her claim by repeating it (35–36). Haya then turned to read the next question in the activity (37). The three girls collaborated to define the diameter and describe its relation with the chord (38–43).

34 Haya (pointing at the circle in GeoGebra interface and saying in a hesitant voice): we write like this: "the radius is a line that starts at the center and extends to the circumference".
35 Janan: the radius is a line that goes from the center to the circumference.
36 Rana repeats: From the center to the circumference.
37 Haya read the next question: what is the diameter of the circle? [The group members looked at the diameter that they drew].
38 Janan: It is a straight line that passes through the circle's center.
39 Haya read the next question: what is the relation between the chord and the diameter? She answered: the diameter is in origin a chord passing through the circle's center.
40 Janan: If it does not pass through the center it will be a chord, but if it passes through the center it will be a diameter.
41 Haya: the diameter is a straight line that starts at the circle's circumference and passes through the circle's center.
42 Rana: it ends at the second side of the circle.
43 Haya wrote: the diameter is a straight line that starts at the circle's circumference, passes through the center and continues to the other side of the circle.

Again we see that the three students worked as collaborators, which led to their agreement on one of the definitions of the circle's diameter. Here, Haya maintained her firstness through reading the question and writing its answer. The two other students also contributed to the common knowledge of the group, which gave them more power. This power resulted in the two girls' satisfaction, as their facial expressions showed, which encouraged them to keep participating in the group discussions.

DISCUSSION AND CONCLUSIONS

In this paper, we analysed the positionings and related emotions of a group of students when defining geometric concepts associated with the circle's topic. Doing so, we used the discursive emotions framework suggested by Evans, Morgan and Tsatsaroni. This framework is a promising one since it is appropriate for complex context. This is so though it is difficult to incorporate some important constructs in it like previous students' experience and current learning beliefs.

The research results indicate that the director of the group's learning claimed her positioning by means of different behaviors: initiating the exploration work of the group, telling the group members what should be done to answer the activity questions, demonstrating persistence in asking questions that investigate the geometric topic, and in manipulating the geometric objects in GeoGebra. At the same time, the director of the group claimed her positioning by regulating the group members' emotions to avoid their negative emotions associated with their difficulties to define geometric concepts and to facilitate their engagement with their learning (Fried, 2011). As a result of this emotion regulation strategy of the group director, the interpersonal functioning of the group improved (Gross & John, 2003). It can be said that the actions of the group director, in the frame of her positioning as such, are related not only to the emotional aspect, but also to the different aspects of the group learning: the cognitive (asking questions related to the circle topic), the meta-cognitive (regulating the group's advancement through changing the discussed topic), the social (advancing the discussion of the group), the behavioral (manipulating GeoGebra), and the meta-affective (regulating the group's emotions) aspects. So, the group director claimed her positioning by means of administrative means more than by means of knowledge, though she asked and answered questions, and tried her most to contribute to the group process of defining the circle concepts. Thus discursive power could be claimed by administrative means, in addition to other means described in (Evans, Morgan, & Tsatsaroni, 2006), as knowledge and giving help.

To direct the group learning, the group director generally used the pronoun 'we' to initiate a journey with the group (Dafouz, 2007) regarding the learning of one of the concepts associated with the circle topic. This use of the plural personal pronoun indicates that the group director was an insider (Evans, Morgan, & Tsatsaroni, 2006) who took the lead in making the group succeeds in investigating the geometric topic.

Overall, the group members worked as collaborators. The collaboration of the group was facilitated by the group conversation, so it could be said that the leadership in this group was conversational leadership, where this conversation was seen by the group members, especially the director of the group, as a core process for effecting positive change (Hurley & Brown, 2010), in our case learning change.

Being collaborators, the group members worked with GeoGebra to further their study, were curious to move forward with their geometric investigations and were content and satisfied due to the power they acquired as a result of their collaborative knowledge advancement with the help of GeoGebra. Thus the technological tool facilitated their collaborative investigations of geometric concepts, empowering them as mathematics learners, and, as a result, causing them to have positive emotions about their learning of geometry. Moreover, in spite of these positive emotions, the group members had negative emotions when they had hard time defining the geometric concepts associated with the circle. These negative emotions were caused due to their feeling powerless not able to agree on the definition of the geometric concepts. The group members overcame their negative emotions by manipulating the geometric objects in GeoGebra and thus arriving at agreed definitions of the geometric concepts. Thus the technological tool empowered the group members, changing their negative emotions to positive ones. Furthermore, the technological tool not only empowered the group as a whole, but also empowered members who controlled the work with it, like Haya.

The group members' level in mathematics influenced the acceptance of the member to be an insider or outsider. Thus the two relatively strong members in mathematics accepted being insiders, while the middle achieving member did not accept at the beginning of the activity to be an insider regarding the learning happenings of the group, which made her frustrated from her positioning in the group. This situation changed as she tried to participate in the group's discussions and contributed to the knowledge development of the group about concepts related to the circle's topic. This change in her involvement with the group's work could be related to the group's perceived atmosphere, for the "members of a group will tend to behave according to the way they perceive the prevailing atmosphere" (Douglas, 1978; as in Gunn, 2007). This perceived atmosphere was characterized by being a positive learning atmosphere maintained by the group director. Moreover, this positive atmosphere gave power and freedom to the group members, enabling them to express themselves freely, and, as a result, causing them to have positive emotions: content, satisfaction and being happy.

The mathematics teacher: An emotional rational being

Marina De Simone

Università di Torino, Dipartimento di Matematica "G. Peano", Torino, Italy, marina.desimone@unito.it

Starting from the "theory of rational behaviour", introduced by Habermas in 1998, I attempt to demonstrate how affective factors are entwined with those of rationality in in the decision-making processes of the mathematics teacher. This type of analysis has been carried out by developing an adaptation of the concept of "emotional orientation", offered by Brown and Reid in 2006. In particular, I will present the case of one teacher with her grade 9 class, involved in the explanation of linear equations.

Key-words: Rationality, emotional orientation, expectation, mathematics teaching, beliefs.

INTRODUCTION

In this paper, I focus the attention on the discursive activity of the teacher when she is introducing linear equations. At the end of the twentieth century, the philosopher Habermas developed the "theory of rational behaviour", where he discusses how people discursive activities show their rational behaviour. In the last years, this philosophical and sociological framework has been re-elaborated and adjusted to mathematics education by a working group constituted by many researchers from Italian, French and Spanish universities. This collaboration has produced two different research forums, presented during the PME Conferences in 2010 (Boero, Douek, Morselli, & Pedemonte, 2010) and in 2014 (Boero & Planas, 2014). This paper is an expansion of the research presented within the last RF by F. Ferrara and myself and that I developed for my PhD dissertation.

Many of the educational studies about rationality according to the Habermas framework, were centred on the students in the mathematics classroom (e.g., Morselli & Boero, 2011). However, if, from the one side, this theoretical framework seems to be suitable to examine decision-making processes of a 'rational being', from the other side, also the study of the discursive activity of the teacher seems to be crucial examining the interactions which happen in the classroom. It is important to consider the decision-making of the teacher, because one peculiarity of the teacher is making decisions within the classroom. Several authors have recognized an essential role to the decision-making of the mathematics teacher. For example, Bishop considers it as the activity "... at the heart of the teaching process" (Bishop, 1976, p.42).

THEORETICAL FRAMEWORK

Habermas defines a rational being as a human being who "can give account for his orientation toward validity claims" (Habermas, 1998, p. 310). He speaks about the concept of discursive rationality of the subject, explaining that it is not only referred to the discourse – as it could seem from the term at a first glance – but it has three different roots: the knowledge, the action and the speech, or, said in a different way: knowing, acting and speaking. Then, starting from the Habermas' assumption that for a rational being the discourse and the reflection on it (not necessarily explicit) are entwined, "the three rationality components - knowing, acting, and speaking - combine, that is, form a syndrome" (Habermas, 1998, p. 311) at a holistic level where reflection and discourse live together. Knowledge, action and speech constitute what he calls the epistemic, the teleological and the communicative components of rationality. They are inseparable, since a rational being acts in a specific manner to achieve a goal, on the basis of a specific knowledge, communicating in a precise way with the aim of being understood by the community. Hence, within the discursive activity, they are always present at the same time. According to Habermas, the epistemic rationality is connected to the justification of the knowledge at play: "We know facts and have a knowledge of them at our disposal only when we simultaneously know why the corresponding judgments are true" (Habermas, 1998, p. 312). Concerning the teleological rationality, Habermas states that "all action is intentional", that is, every action is originated from an intention of the subject with the aim of the realization of a result. He speaks of teleological rationality when "the actor has achieved this result on the basis of the deliberately selected and implemented means" (Habermas, 1998, p. 313). Finally, Habermas states that the communicative rationality "is expressed in the unifying force of speech oriented toward reaching understanding" (Habermas, 1998, p. 315).

In his speculation about rational behaviour, Habermas seems to lack any reference to emotion or passion. He seems to avoid any emotion by claiming that the force of a good argument should be free of emotional tags. Several philosophers and social theorists complained that, in the development of his theory, Habermas doesn't take in account the emotional side of human beings. For example, Rienstra and Hook, quoting the philosopher Heller, posed the question that "Habermas leaves no room for "sensuous experiences of hope and despair, of venture and humiliation", accusing him of completely avoiding the "creature-like" aspects of human beings" (Rienstra & Hook, 2006, p. 13). Therefore, basing on the assumption that rationality is deeply linked with the emotional sphere, I looked for researches that confirmed this hypothesis in particular in mathematics education and human neuropsychology.

In the last years, research in mathematics education has progressively perceived the existence of a mutual interaction between the affective sphere and cognition in mathematics learning (Zan, Brown, Evans, & Hannula, 2006). As highlighted by Hannula (2012), many research studies, focused on mathematics-related affect, have been dated from the eighties. An important grow in the theory on mathematics-related affect was due to McLeod (McLeod, 1992), whose main goal was to build "an overall framework of mathematics-related affect that would be consistent with research that is cognitively oriented" (Hannula, 2012, p. 138). In McLeod's framework (McLeod, 1992), which is considered a cornerstone for the literature on mathematics-related affect, emotions occupy a fundamental place, because of their unstable or less stable nature than that of beliefs and attitudes. Unfortunately, the aim of constructing a general theoretical framework that embrace all the research on mathematics-related affect has not yet been achieved. The most relevant problem is related to the terminology used in this field, because it is not universal. For example, as Di Martino and Zan discussed deeply (Di Martino & Zan, 2010), "some define attitude as positive or negative degree of affect, others identify emotions and beliefs as two components of attitude, while yet others define attitude as consisting of cognitive (beliefs), affective (emotions), and conative (behaviour) dimensions" (Hannula, 2012, p. 140). The recent research in mathematics-related affect has considered different affective concepts from those of the McLeod's (1992) framework such as values, identity, motivation, and norms. Zan and colleagues (Zan, Brown, Evans, & Hannula, 2006) have recognised the limited use of emotion in mathematics education research, even if it should be one the essential concept. They pointed out "how repeated experience of emotion may be seen as the basis for more 'stable' attitudes and beliefs" (Zan, Brown, Evans, & Hannula, 2006, p. 116). For Schoenfeld, emotional aspects are included in the wider category of beliefs, while goals is a motivational concept (Schoenfeld, 2010).

Human neuropsychology is another important field of research that studies the relationship between the affective and the rational sphere from a neurological point of view (Damasio, 1994, 1999). Specifically, Immordino-Yang and Damasio have shown the connection among emotion, social functioning and decision-making as a turning point for understanding the role of emotion in decision-making, the relationship between learning and emotion, and how culture shapes learning (Immordino-Yang & Damasio, 2007). While educational research often considered decision-making, reasoning and processes related to reading, language and mathematics as detached from emotion and body, these authors have shown that "learning, in the complex sense in which it happens in schools or the real world, is not a rational or disembodied process; neither is it a lonely one" (Immordino-Yang & Damasio, 2007, p. 4). For them, emotion is "a basic form of decision making, a repertoire of know-how and actions that allows people to respond appropriately in different situations" (Immordino-Yang & Damasio, 2007, p. 7).

This neurological research is becoming applicable also in the field of mathematics education. For example, Brown and Reid have developed and adapted the hypothesis of somatic markers (Damasio in 1994) for studying the decision-making processes (Brown & Reid, 2006).

EMOTIONAL ORIENTATION

Brown and Reid (Brown & Reid, 2006) analysing the processes of teachers and students' decision-making, have considered the notion of "emotional orientation" (Maturana, 1988). In particular, they have focussed on the "decision-making that happens before conscious awareness of the decision to be made occurs." (Brown & Reid, 2006, p. 179). Maturana (1988a, 1988b) referred the notion of "emotional orientation" to the criteria for acceptance of an explanation by members of a community, and considered emotions as being the foundation of such criteria. Reid adapted the concept of emotional orientation to the mathematics field, defining the "mathematical emotional orientation". The criteria for accepting an explanation in the particular case of the mathematical emotional orientation involve "the use of deductive reasoning, a basis in agreed upon premises, and a formal style of presentation" (Reid, 1999, p. 1). Moreover, there are many shared experiences and assumptions in mathematics, like the language used to talk about it. In the end, there are also many "actions" when someone does mathematics, like "drawing diagrams, generalizing statements, making conjectures" (Reid, 1999, p. 1). Emotions are still at the basis of these criteria. The concept of "emotional orientation" allows me to speak of the interconnection between rationality and emotion. In fact, as the words themselves suggest, the "orientation" of a subject oriented towards validity claims is "emotional", that is, affected by the emotions in a certain way. But there is still a methodological problem of how, practically, this entanglement can be analysed. Hence, I sketchily present an adaptation of the theoretical framework of the emotional orientation in order to speak practically about these two sides of the same coin. I define the "emotional orientation" of a subject (e.g. a teacher) in terms of "the set of her expectations": the term "expectation" is connected to her "emotions of being right" when she uses specific criteria for accepting an explanation by a community (e.g. a class) rather than other ones (Ferrara & De Simone, 2014). The most difficulty encountered in studying emotions is their "visibility" and, then, their "certain" identification. In this context, when I speak of emotion of the teacher I will refer to her *emotionality*, namely the set of "behaviours that are observable and theoretically linked to the (hypothetical) underlying emotion" (Reber & Reber, 2001).

METHODOLOGY

The study presented in this paper is part of the research for my PhD thesis whose focus is on aspects related to rationality of the teacher in the teaching of linear equations at secondary school. The participants were 3 teachers and their grade 9 classes, in a scientifically oriented secondary school in Western Italy. The teachers were selected assuming that rationality and emotions are proper of human beings and with the purpose of having different emotional orientations. Each teacher was first interviewed and asked about her personal beliefs on the topic of linear equations, on algebra in general and on how she uses the didactical materials. Each interview lasted roughly twenty minutes and was videotaped with one camera facing the interviewer and the subject. Then, the whole class activities conducted by the teacher and the students' working group activities were also videotaped. All voice and bodily movement during the interviews and the classroom activities were recorded. The videos were transcribed for data analysis. For the identification of the emotional orientation of the teachers I paid attention also to some indicators that allow me to say something about the emotions of the teacher. In particular, I considered as indicators the tone of voice, the words, the repetitions, the emphasis and the body language (facial expressions, gazes, gestures…). So, I identified the expectations of the teacher – that constitute her emotional orientation – starting from what she explicitly declared in an *a-priori* interview. Then, I tried to find them again, reflected in the class activities, through the indicators I listed above. At last, I analysed the transcriptions from both the emotional and the rational point of view, at the same time, because they are naturally entwined. Due to space constraints, I present the case of one of the three teachers involved in the whole research, whom I call Lorenza.

AN EXAMPLE: THE EMOTIONAL ORIENTATION OF LORENZA

I identified different expectations that constitute the emotional orientation of Lorenza, but for the limited space, I show just one of them. From the interview, I identified her *expectation about the validity of the previous knowledge of the students that can be used for* *constructing the new one*. With "previous knowledge", I mean what students have learnt both in the middle school and with her. In order to highlight this expectation, I collected the moments of her interview from which this expectation could be detected. Lorenza explicitly declared: "Usually, I begin to treat linear equations starting from their previous knowledge *in order to see whether it is valid, or whether the students have misinterpreted the various procedures that they have been taught in the previous years. Anyway, I begin a new topic starting from the knowledge that the students already have*". During the interview, I asked Lorenza when she introduces for the first time the letters in algebra. She answered that she usually uses letters for the first time in physics, but she commented: "*they are already able a little bit to manage it*" and, then, she repeated the same concept: "*even if when we speak of sets, the letter represents already something for them or also in the logic language the logic variable, then there is already a formalization from this point of view, we say*". In another passage, it was asked to Lorenza when she speaks for the first time of equations and if she links the concept of linear equation with that of function. She stated that she makes this link for the first time in physics: "*in physics we have already said something about the equations, but just basics because I wanted to put them to work on inverse formula, then I said: "What do you know?" they know already something and they know to deduce or, in theory, they should be able to deduce an inverse formula given a formula*". An interesting thing is that, during the interview, she explicitly made just the same question that she asks to her students, perhaps, because she is used to make it to her students for testing what is their knowledge and if it's valid. Lorenza added that students have already known something about equation, but "*in a very naïve way*", so they have to go in depth with her become aware of the link between the equations and the straight line.

From these pieces of the interview, it becomes quite clear that Lorenza believes that it is important to recall the previous knowledge of the students during all the lessons, not just when a new mathematical topic is introduced.

After detecting Lorenza's expectations, I analysed the transcriptions of her lessons in which they are actually reflected. I will show how her "orientation" towards validity claims is "emotional", that is affected by emotions. Using a metaphor, rationality and emotions of the teacher can be seen as the weave and the warp of the fabric. As the weave and warp entwined constitute the fabric, the rationality and the emotions entwined shape the teacher as she actually is.

The first example I propose is taken from the first lesson after Easter holidays, during which the teacher was recalling the concept of identity – explained in the last lesson before Easter – with the aim of introducing, formally, the concept of equation.

1 T: before holidays, I hope that someone remembers just something, we have spoken about [pronouncing] identities, then, is there anyone who wants to give, for now, [tone of voice of a statement not of a question] the definition of identity and to do only an example of identity? Don't be shy! [smiling] (Figure 1) [lifting up her chin and biting her lips] (Figure 2). Please [she addresses to S1 who is raising up his hand]

Figure 1

Figure 2

2 S1: it is an equality that is verified for each value that it is replaced to the letter

3 T: fine, it is an equality between two expressions, that contain letters, that is verified for each value we go to ascribe to

the unknown. One example, we have done an example within the classical ones [smiling]

4 S1: (a+b)2=a2+b2+2ab

5 T: for example, the development of a special product is an equality between two expressions that contain letters and then it can be considered an identity and each value we go to give to the unknown a or to the unknown b, the result on the left and on the right of the equality sign must be the same and, conversely, what can be considered as an equation, do you remember? [speeding up] you have already seen them in the middle school, partly, no? yes [she is answering herself], we have already reviewed in physics since at the beginning of the year they serve us for working with formula etcetera, so we have already given indications. In the light of this path that we have done, any of you would like to hazard a definition of equation [tone of voice proper of a statement not of a question and, then, she lifts up her chin]? Try to hazard, Andrea!

The action of Lorenza of asking something that students already know (the definition of identity and an example of it) is aimed at constructing the concept of equation (# 5). This action comes along with a particular tone of voice not proper of a question, but rather of a statement (# 1). The affirmative tone of voice of the question and that facial expression (# 1: she lifts up her chin after speaking) could show her expectation that someone remembers the concept of identity and will answer to her, because the class has already seen it a short time before. Waiting an answer, she laughs (Figure 1) and she bites her lips (Figure 2), probably, because she wants a feedback from the class. The action of asking something that the students should know is full of emotional hues linked to her expectation about the validity of the previous knowledge. This passage of the transcript highlights an *emotional teleological rationality* of Lorenza. It is not just a matter of what she is doing, but rather of *how* and *why* she is acting in that way. From the beginning, her speech seems to be charged by emotions (#1: "I hope", "just something", "Don't be shy!"). These emotions are related to her expectation ("I hope") that students remember the concept of identity, even "just something" (she can be easily satisfied, as long as, they are able to say something). She seems quite confident about their knowledge, thinking that her students don't answer because they are shy, indeed, she incites them into doing, using the imperative phrase "Don't be shy!". This "emotion-soaked" speech highlights an *emotional communicative rationality* related to her expectation about classroom culture. There is not only what she is communicating, but also *how* and *why* she is doing it that way. Requiring again the example of an identity (#3), after the answer of S1, could be interpret as a way of involving more students in the discussion and to evoke the classroom culture as much as possible (#3: "One example, we have done an example within the classical ones"). Another time the teacher's speech comes along with an emotional element (she smiles), because she seems to feel that students need to be comfortable for answering, even if they already should know the example.

Lorenza recalls just the term of identity to shift easily to that of equation: the former is an equality true for every value of the unknown, while the latter is an equality that may not be satisfied or, in the case it is satisfied, it can be undetermined or determined. This epistemic shifting comes along with an insistence of Lorenza on the fact that they already learn first degree equations both in the lower secondary school (grade 8) and with her in grade 9 (#5: "you have already seen them in the middle school, partly, no?", "yes [she is answering herself], we have already reviewed in physics since at the beginning of the year they serve us for working with formula etcetera, so we have already given indications", "In the light of this path that we have done any of you would like to hazard a definition of equation"). In addition, she asked her students "to hazard" a definition of equation, but with the tone of voice proper of a statement and not of a question (#5), probably because she is expecting that students construct new knowledge starting from the previous one. The insistence in the speech, the facial expression, the tone of voice linked to the knowledge into play could inform us about an *emotional epistemic rationality*.

Then, the discussion goes on as follows:

6 S2: it is an equality between two literal expressions in which the value of x is replaced by a unique value to make it true

7 T: we say that it is satisfied just f(or)

8 S2: for a single value of x

9 T: always?! (Figure 3), do we always find it?!for you this value or (Figure 4), let's try to think a little bit

Figure 3

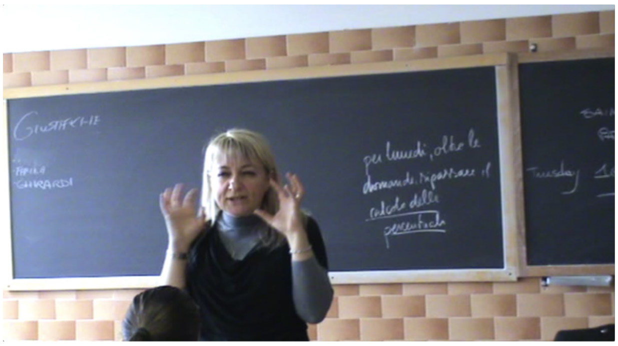

Figure 4

10 S2:		sometimes it's impossible
11 T:		It could be, right.

After the answer of S2 (#6), Lorenza clarified his definition of an equation. This action is aimed at a first introduction of the different types of equation (determined, undetermined, impossible), which she will develop in the next lesson. The rhetorical questions (#9: "always?!", "do we always find it?!"), the facial expressions in Figure 3 and Figure 4 and the general involvement in the discussion (#9: "let's try to think a little bit") accompany the actions she made on the basis of a certain knowledge into play, communicating in a specific manner. Particularly, in Figure 4, she seems to "catch" with her hands what they are in mind about the concept of equation. This frame brings out an *emotional teleological, epistemic and communicative rationality* of Lorenza.

DISCUSSION

I presented an emblematic example of the coexistence of the emotional rational aspects in mathematics teaching. In particular, I showed how this merger outlines the decision-making processes of the teacher. As I highlighted in the analysis of the example, all the teachers' decisions – about knowing, acting and speaking – are "visible" in language, but, mostly, in her emotional aspects. This doesn't mean that emotions explain the decisions, but, rather, that decisions are very often "visible" through emotions. I tried to study this complexity through an adaptation of the concept of "emotional orientation", used by Brown and Reid in 2006, drawing on the work of Maturana (1988).

Referring to the transcript, from one side, the emotions of Lorenza are linked to her expectation about the class culture she developed from her own beliefs. These emotions can become clear from her tone of voice, her way of speaking, her body language. From the other side, the choices of Lorenza (starting from the identities to introduce equations, recalling explicitly with insistence the previous knowledge of the students...) are connected to this expectation of constructing new knowledge, basing on the validity of the previous one. Then, the emotions are strictly related to the choices and this gives the meaning of how the "orientation" of Lorenza can be "emotional".

Hence, the analysis of the discursive activity of the teacher has naturally led to propose an enlargement of the Habermas components of rationality. As shown in the analysis of the excerpt, I tried to highlight the *emotional epistemic rationality*, the *emotional teleological rationality* and the *emotional communicative rationality* of Lorenza. In this context, I consider the *emotional epistemic rationality* as related to *why* the teacher uses that specific justification of the knowledge at play; the *emotional teleological rationality* as related to *why* the teacher makes that actions to achieve a goal and the *emotional communicative rationality* as related to *why* the teacher uses that speech oriented towards validity claims. These three adapted components of rationality are always present in the discursive activity of the teacher. Obviously, as testified by the example, during specific moments of the classroom activity, one component could emerge more than the others.

The role of the *a-priori* interview results particularly significant for this kind of analysis since it enabled to scrutinize the teacher's beliefs and orientations for the teaching of the concept at stake.

How a local oral examination considers affective aspects of knowing mathematics

Anne Birgitte Fyhn

UiT – The Arctic University of Norway, Tromsø, Norway, anne.fyhn@uit.no

To measure whether and to what extent pupils know mathematics is complicated. The test situation will influence the pupils' work and in addition there are aspects of knowing mathematics that are difficult for a written test to assess. Since the early 1990s, Norwegian pupils undergo a local oral examination at the end of the ten-year compulsory school. Rules and guidelines for this examination has developed over time in accordance with curriculum changes. According to the 1992 national guidelines, the examination has to be based on the pupils' project work or similar. In addition, pupils' creativity and imagination is highlighted. The 2014 national rules are different, the only thing here that a written test cannot reveal, is skills in mental calculation.

Keywords: Assessment, motivation, attitudes, beliefs, creativity.

INTRODUCTION

"Different groups of people can have very different views of what "counts", or should count, in mathematics" (Schoenfeld, 2007a, p. 3), so what it means to know mathematics is far from a simple question. The question of how to assess what pupils know, is even more complicated. Tests or examinations constitute one form of assessment; other forms are for example feedback on daily work. One aim of an examination is to assess what the pupils know; another aim is to assess whether the teaching is successful. Morgan (1999) identified two main strands in research related to assessment in mathematics education. One strand focuses on the design of the tests. The other focuses on critiquing traditional forms of assessment, and often proposes new forms of assessment that are better aligned with the curriculum aims. Norway introduced a local oral examination in 1990 (Ministry of Education, Research and Church Affairs, 1992). This examination highlighted local curricula and pupils' project work; this was a new form of assessment aligned with curriculum aims. The national guidelines for the local oral examination have evolved since the first written guidelines appeared in 1992. The research question is: How do the 1992 national guidelines and 2014 national rules for the local oral mathematics examination consider affective aspects of knowing mathematics?

Because the rules and guidelines reflect the curriculum, an analysis of the curriculum development is presented as an introduction to the further analysis. This paper focuses on the rules and guidelines for the local oral examinations from two perspectives: a) how to facilitate opportunities for the pupils to show what they know, and b) what is assessed. A common problem with tests and surveys is that there are aspects of knowing mathematics that are difficult to reveal in a written test. Affective aspects are among these. The paper first discusses motivation, attitudes, beliefs, and creativity, elements that reflect affective aspects of knowing mathematics and which are found in central documents for Norwegian mathematics education. The following section reveals how Norwegian curricula consider affective aspects of knowing mathematics. Then assessment in mathematics is presented, before the analysis of the 1992 national guidelines (Ministry of Education, Research and Church Affairs, 1992) and the 2014 national rules (Norwegian Directorate for Education and Training, 2014) for the local oral examination.

ATTITUDES, BELIEFS, CREATIVITY AND MOTIVATION

The Ministry of Education, Research and Church Affairs carried out a large project, Quality in Mathematics Education (Brekke, 2002/1995), between 1995 and 2002. The aims were to develop test materials, conduct a survey of pupils' attitudes and beliefs towards mathematics and mathematics teaching, and describe the spectrum of pupils' performances in different subject areas. During the 1990s, pupils' attitudes and beliefs were accordingly considered important in Norway.

When individuals are doing mathematics, the affective system is not just supporting cognition, but it is playing a central role. Affect as a representational system is intertwined with cognitive representation (Goldin, 2002). Goldin divides affective representations into four sub-domains: a) *emotions*: rapidly changing and usually local or connected to context; b) *attitudes*: moderately stable predispositions towards certain sets of classes of situations; c) *beliefs*: often highly stable, involving the attribution of some sort of external truth or validity; and d) *values*, including ethics and morals, and which refers to deep "personal truths". This paper pays less attention to emotions and values because the Quality in Mathematics Education project highlights pupils' attitudes and beliefs.

Sriraman (2009/2004) identifies creativity as part of mathematicians' work. He points out that creating original mathematics requires a very high level of motivation, persistence and reflection, all of which are considered indicators of creativity. For example, one could be in an environment that is non-supportive of creative efforts, but a high level of motivation may possibly overcome this and pursue creative endeavours. According to Sternberg and Lubart (1999), creativity may not only require motivation, but also generate it. Thus, given the chance to be creative, pupils who might otherwise lose interest in school instruction might find that it instead captures their interest. According to Liljedahl (2013), creativity has more affective aspects than just motivation, because illumination is important in the creativity process. Illumination occurs in the context of trying to work something out.

Self-determination theory proposes that all human beings have fundamental psychological needs for being *competent*, *autonomous* and *related* to others. People are assumed to proactively initiate engagement with their environments. The basis for this activity is intrinsic motivation (Deci & Ryan, 2012). The foundations of self-determination theory reside in a dialectical view, which concerns the interaction between an active, integrating human nature, and social contexts that either nurture or impede the organism's active nature. *Relatedness* concerns the psychological sense of being with others in a secure communion or unity. *Autonomy* refers to being the perceived origin or source of one's own behaviour; it concerns acting from interest and integrated values. Autonomy enables individuals to deal with novelty and generate creative products (Diezmann & Watters, 2000), so autonomy is part of creativity. According to Hannula (2006), motivation is observable only as it manifests itself in affect, cognition and behaviour, for example as beliefs, values and emotional reactions. Pupil-centred classrooms with much teamwork going on may rely on pupils' exhibiting their autonomy and social interactions. According to DeBellis and Goldin (2006), each person constructs complex networks of affective pathways and competencies. These networks have more or less mathematical problem-solving power and their meanings are context-dependent for the individual.

THE THREE LATEST MATHEMATICS CURRICULA IN NORWAY

Three different curricula have been in effect in the Norwegian School during the period from 1990 to 2015. These curricula provide different perspectives on pupils' affect. The 1987 curriculum (Ministry of Church and Education, 1987) focuses on pupils' project work and the schools' development of local curricula. This is interpreted to mean that the curriculum highlights the pupils' autonomy and relatedness, so it is in line with Deci and Ryan (2012). The overarching aims for the subject mathematics in this curriculum, claim that the teaching shall take care of and develop the pupils' logical thought, responsible decisions, imagination and creative enthusiasm. In addition, problem solving is introduced as a separate domain. The curriculum is thus in line with DeBellis and Goldin's (2006, p. 133) point: "The meanings of our emotional feelings are highly context dependent; far more, even, than the meaning of words and phrases." The focus on imagination and creative enthusiasm, shows that the curriculum considers affective aspects of creativity.

The 1997 mathematics curriculum (Ministry of Education, Research and Church Affairs, 1996a) introduces *mathematics in everyday life* as a separate domain. This is interpreted as an explicit focus on context and autonomy. The curriculum points out six main aims for the subject mathematics. One aim is that pupils should develop positive relations with mathematics, experience the subject as meaningful, build self-respect and have self-confidence. This is in line with self-determination theory (Deci & Ryan, 2012). Another aim is that pupils are stimulated to use their imagination, resources and knowledge to find solution methods and alternatives through investigative and problem-solving activities, as well as conscious choices of tools and instruments. This is interpreted as meaning that the curriculum focuses on the pupils' autonomy, creativity and motivation.

The Danish project Competencies and Learning of Mathematics, (Niss & Højgaard Jensen, 2002) constitutes the basis for the interpretation of mathematical competence in the recent mathematics curriculum (Norwegian Centre for Mathematics Education, 2014). *Competence* is someone's insightful readiness to act in response to the challenges of a given situation. The Danish project describes a set of eight delimited dimensions that together generate mathematical competence: Mathematical-thinking competence, problem-tackling competence, modelling competence, reasoning competence, aids-and-tools competence, communicating competence, symbol-and-formalism competence, and representing competence. No affective aspects of competence are explicitly listed, but Niss and Højgaard Jensen (2002) point out that mathematics-teaching competence includes the ability to motivate and inspire pupils. The overarching aims of the 2006 mathematics curriculum (Norwegian Directorate for Education and Training, 2013) emphasize that both girls and boys must get opportunities to gain experiences that create positive attitudes towards the subject.

Table 1 shows how the perspective on affect has developed according to the overarching aims of the latest three mathematics curricula. The 1997 curriculum's (Ministry of Education, Research and Church Affairs, 1996a) aims, explicitly include the pupils' attitudes and their affective aspects of creativity. "Meaningfulness" is left out in the 2006 curriculum. This is interpreted as suggesting that the pupils' autonomy and self-determination are less important. The greatest difference between the three curricula is that while the two previous curricula present a pupil-centred perspective on the teaching, the 2006 curriculum presents a teacher-centred perspective; the 2006 curriculum has no teaching aim regarding the pupils' affects.

The Core Curriculum (Ministry of Education, Research and Church Affairs, 1996b) states the overarching aims for the education. This part of the curriculum elaborates on the preamble to the Education Act, and it is continued in the 2006 curriculum. The Core Curriculum focuses on creativity, autonomy and relatedness. However, the word "motivation" occurs only once, successful learning depends on the teacher as well as on the pupil. The Core Curriculum highlights the pupils' attitudes by claiming that knowledge, skills and attitudes develop in the interplay between old notions and new impressions. The 1997 mathematics curriculum is in line with the Core Curriculum's perspectives on creativity, autonomy and relatedness, while the 2006 mathematics curriculum is not.

ASSESSMENT

Schoenfeld (2007a) claims that assessments can serve useful purposes for the pupils, but the challenge is to make them do so. According to Wiliam (2007), the use of assessment should support learning in any assessment regime; classroom assessment must first be designed to support learning. Schoenfeld (2007b) discusses how to assess mathematical proficiency: what a pupil knows, can do, and is disposed to do mathematically. He describes four aspects of mathematical proficiency: *Knowledge base* (what does it mean to know a content), *strategies* (ability to formulate, represent, and solve mathematical problems), *metacog-*

	1987 curriculum	1997 curriculum	2006 curriculum
Aims for the pupils	Experience mathematics as meaningful	Develop positive relations with mathematics Experience mathematics as meaningful	Get opportunities to gain experiences that create positive attitudes towards mathematics
Aims for the teaching	Take care of and develop pupils' imagination and creative enthusiasm	Contribute to the pupils' building of self confidence Make the pupils experience belonging	Include playful and creative activities

Table 1: How pupils' affects are considered in the curricula's overarching aims

nition (using what you know effectively), *beliefs and dispositions*. Pupils who experience skill-based instruction tend to succeed on tests of skills, but they do not succeed well when tested in problem solving and conceptual understanding. On the other hand, "[s]tudents who study more broad-based curricula tend to do reasonably well on tests of skills" (p. 63), while on tests of conceptual understanding and problem solving, these pupils succeed much better than those who just exercise on skills. *Beliefs* are important, because if you believe that mathematics is not supposed to make sense, your work will reflect this. The pupils pick up their beliefs about the nature of mathematics from their experiences in the mathematics classroom. That mathematical problems have one and only one answer and that mathematics is done by individuals in isolation are typical pupil beliefs.

Boesen, Lithner and Palm (2010) investigated relations between task characteristics and the mathematical reasoning pupils use when solving tasks in a test situation. Their results show that when solving tasks similar to those in their textbooks, the pupils were mostly trying to recall facts or algorithms. The pupils did not have to construct new reasoning or consider any intrinsic mathematical properties. By contrast, the tasks that were not similar to those encountered in the textbook were mostly approached with creative mathematical reasoning.

THE LOCAL ORAL MATHEMATIC EXAMINATION

As a result of the 1987 curriculum's (Ministry of Church and Education, 1987) focus on local curricula, project work and problem solving, Norway introduced a local oral examination that encompassed these three fields. Pupils may hence undergo two different examinations in mathematics at the end of the compulsory school: A national written mathematics examination and a local oral mathematics examination. Only some pupils undergo each examination.

According to the national guidelines, the 1992 oral mathematics examination aimed to: "... assess aspects of the teaching aims, which may be difficult to show in a written test" (Ministry of Education, Research and Church Affairs, 1992, p. 14, author's translation). The examiner (most commonly the mathematics teacher) leads the talk/discussion with the pupil, while the external examiner determines the grade afterwards. The Ministry designed and published booklets with guidelines and guiding materials for teachers. These guidelines are difficult to access, so they are listed here:

— The test has to include tasks from at least three of the ten main subject areas in the syllabus.

— The test has to give room for use of different methods, creativity and imagination.

— The test has to include tasks where the pupil may explain procedures and rules that she/he uses in solving the tasks. It might be satisfactory that the pupil just sketch how she/he will solve the task.

— The test has to include tasks involving mental calculation and approximation.

— The test might include tasks where the pupils are free to use technical artefacts such as calculators and computers.

— If there is information about project work or similar, then the test has to include questions related to this work (p. 14, author's translation).

In 2014, the responsibility for the local (oral) examination guidelines belongs to the school owners. The Education Act (Lovdata, 2013) regulates the oral examination, and the Norwegian Directorate for Education and Training (2014) has elaborated regulations for the national rules. There is a 24-hour mandatory preparation time, which starts with one day at school with all kinds of aids permitted. In the beginning of the preparation time, the pupil gets a theme or a problem. What goes on in the preparation time is not included in the assessment. Each pupil has a right to pedagogical aid during the preparation day at school. The pupils present their theme or problem during the examination. The examiners then use this presentation as a basis for a mathematical discussion, for which the teacher has prepared questions for the pupil. The examiners cannot ask questions just from a narrow part of the subject. The discussion has to cover at least 2/3 of the examination time. The examination has to be organized so that the pupil can show to what extent the competence aims in the curriculum have been reached. The mathematics curriculum clarifies the meaning of "oral skills":

> Oral skills in mathematics involve creating meaning by ... participating in discussions, communicating ideas and elaborating on problems, solutions and strategies with other pupils ... this development starts with a basic mathematics vocabulary that leads to precise professional terminology ... (Norwegian Directorate for Education and Training, 2013, pp. 4–5)

The schools can make local guidelines for how to carry out this examination. Two examiners assess the pupil, and one of them needs to be a teacher from another school.

ANALYSIS OF NATIONAL GUIDELINES AND RULES

Schoenfeld (2007a) points out that there is more to mathematical proficiency than being able to reproduce standard content on demand. He warns against what he calls "the illusion of competence" by asking: "Have you learned the underlying ideas, or are you only competent at things that are precisely like the ones you've practiced on?" The local oral examination has developed from 1990–1992 and into the 2014 examination form. In order to investigate how the rules and guidelines for these examinations consider affective aspects of knowing mathematics, a framework is built on theories from Deci and Ryan (2012), Hannula (2006), Sriraman (2009/2004), Liljedahl (2013), DeBellis and Goldin (2006) and Goldin (2002). This generates four affective aspects of knowing mathematics: motivation, creativity, attitudes and beliefs. The data in this study consist of the 1992 national guidelines for the local oral examination (Ministry of Education, Research and Church Affairs, 1992) and the 2014 national rules for the local oral examination (Norwegian Directorate for Education and Training, 2014).

The framework leads to three points in the 1992 guidelines: the conversation form, the use of creativity and imagination, and the inclusion of local curricula and pupils' project work. The guidelines explicitly emphasize that the examination shall aim at having a conversational format. This opens up for the teacher to focus on each of the framework's four categories. The use of creativity and imagination directly points at creativity and indirectly points at motivation. The inclusion of pupils' project work is an important aspect of the oral examination; according to the national guidelines (Ministry of Education, Research and Church Affairs, 1992), project work is based on the pupil's interests, ideas or experiences with social practice. Interests are part of the pupil's intrinsic motivation (Deci & Ryan, 2012). Our emotional feelings are highly context-dependent (DeBellis & Goldin, 2006) and thus related to social practice. According to the 2014 national rules (Norwegian Directorate for Education and Training, 2014), the most main point is that the pupils can show their competencies. The examination conversation may consider all the framework categories, but it is explicitly stated that the teacher and the external examiner choose the context for the examination. So the pupil's autonomy is not considered important. The examination aims to assess how the pupils have achieved the competence aims for grade ten in the national mathematics curriculum (Norwegian Directorate for Education and Training, 2013). It turns out to be one single competence aim that a written test cannot assess: to develop, use and elaborate on methods for mental calculations. Based on the competence aims, the teacher can provide each pupil with problems so that the four categories in the framework are covered, but the national rules leave it to the schools to make this choice. Creativity and the pupils' project work are not explicit issues for assessment in the 2014 examination. The teacher may hence provide the pupils with problems that concern the pupils' attitudes, beliefs, motivation and creativity, but the 2014 national rules have no explicit requirement for this, unlike the 1992 National guidelines.

CLOSING WORDS

The overarching aims in the mathematics curriculum have changed since the local oral curriculum for all was introduced. The overarching aims in the mathematics curricula from 1987 (Ministry of Church and Education, 1987) and 1997 (Ministry of Education, Research and Church Affairs, 1996a) present a pupil-oriented perspective, which highlights that the teaching shall provide the pupils with opportunities to show what they know. The overarching aims in the 2006 mathematics curriculum present a teacher-centred perspective with no teaching aims concerning the pupils' affects.

The 1992 national guidelines for the local oral examination (Ministry of Education, Research and Church Affairs, 1992) emphasize that the test has to assess aspects of the subject that are difficult to reveal in a written test. The 2014 national rules (Norwegian

Directorate for Education and Training, 2014) have no similar requirement. In 1992, the pupils' project work was the basis for the examination; in addition, the pupils' creativity and imagination were highlighted. This means that affective aspects of knowing mathematics were considered important. The guidelines point out that the test has to provide the pupils with opportunities to show what they know. In 2014, the teacher provides the pupils a problem or a task, and they get one school day to prepare a presentation of this task. At the examination the pupils discuss this presentation with the teacher and the external examiner. The pupils' social practice is hence not highlighted the way it was in 1992. The 1992 national guidelines explicitly points out that the test has to provide opportunities for the pupils to use creativity, and "to show creativity" was one requirement for achieving the highest grade. The 2014 national rules do not consider creativity; nor do they focus explicitly on affective aspects of knowing mathematics. However, the main point in these rules, is that the pupils can show their competencies. Further research is necessary to provide a more thorough analysis of this issue.

Students' emotional experiences in high school mathematics classroom

Gustavo Martínez-Sierra

Autonomous University of Guerrero, Research Centre of Mathematics Education, Chilpancingo de los Bravo, Mexico, gmartinezsierra@gmail.com

The aim of this qualitative research is to identify Mexican high school students' emotional experiences in the mathematics classroom. In order to obtain data, focus group interviews were carried out with 53 students. Data analysis is based on the theory of cognitive structure of emotions (Ortony, Clore, & Collins, 1988), which specifies eliciting conditions for each type of emotion and the variables that affect intensity. The participants' emotional experiences are: satisfaction, disappointment, hope, fear, joy, distress, boredom, interest, pride, reproach, self-reproach, like and dislike with different eliciting conditions. These results show that all students' emotional experiences are based on their appraisal in terms of a goal structure present in the mathematics classroom and in the school setting.

Keywords: Emotions in mathematics education, students' emotions, emotions in mathematics classroom, appraisal structures, theory of cognitive structure of emotions.

INTRODUCTION

In the field of mathematics education, most of the research on students' emotions focuses on their role in mathematical problem-solving (e.g., Goldin, 2000; Op' T Eynde, De Corte, & Verschaffel, 2007). Among other results, these studies have confirmed that people tend to experience similar emotions in the process of problem-solving. By example Op' T Eynde and colleagues (2007) found that students experience different emotions while solving a problem. They can be *annoyed*, *frustrated*, *angry*, *worried*, *anxious*, *relieved*, *happy* or *nervous*. First, for instance, a student can be *worried* during the process of finding a strategy to solve a problem (this is evidenced by students' use of descriptions such as "brow lowering" and "not feeling well"). The student becomes *frustrated* if the solution to the problem does not seem to appear after 10 seconds ("I don't want to use the calculator", "it does not help me", "but I still want to reach the goal"). Later, *panic* appears and finally *anger* ("come on, what is this all about").

Research on emotions in mathematics education highlights the necessity to move beyond the view of distinguishing between positive and negative emotions. It is also suggested to go beyond analysing emotions in problem solving and investigating emotions routine activity (Hannula, Pantziara, Wæge, & Schlöglmann, 2010). So we have assumed the task to identify emotional experiences in routine activities in mathematics classes. In order to go beyond a consideration of positive and negative emotions we use the cognitive structure of emotions theory (Ortony et al., 1988). This is the main reason to focus on the following research question: *What are the students' emotional experiences in high school mathematics classroom?*

We are aware that the analysis of narratives of emotional experiences is quite different from the direct analysis of emotions but, like Ortony and colleagues (1988, p. 8), we are willing "to treat people's reports of their emotions as valid, also because emotions are not themselves linguistic things, but the most readily available non-phenomenal access we have to them is through language".

THE THEORY OF THE COGNITIVE STRUCTURE OF EMOTIONS

We have chosen the *theory of the cognitive structure of emotions* (by the initials of the surnames of the authors OCC theory from now) to identify the students' emotional experiences. For Ortony and colleagues (1988) emotions arise as a result of interpretations of situations by those who experienced them: "[Emotions can be taken as] valenced reactions to events, agents or objects, with their particular nature being determined by the way in which the eliciting situations is construed" (Ortony et al., 1988, p. 13). Thus a particular emotion experienced by a person on a specific occasion is determined by his interpretation of the changes in the world: "When one focuses on events one does so because one is interested in their consequences, when one focuses on agents, one does so because of their actions, and when one focuses on objects, one is interested in certain aspects or imputed properties of them *qua* objects" (Ortony et al., 1988, p. 18).

Different types of situations that elicit emotions are labeled in classes according to a word or phrase corresponding to a relatively neutral example that fits the type of emotion (Ortony et al., 1988). For example, to refer to the emotion type "pleased about the confirmation of the prospect of a desirable event" they choose the emotion word *satisfaction* because it represents an emotion of relatively neutral valence among all those that express that you are happy about the confirmation of something expected.

The characterizations of emotions in the OCC theory are independent of the words that refer to emotions, as it is a theory about the things that concern denotative words of emotions and not a theory of the words themselves. From the distinction between reactions to events, agents, and objects, we have that there are three basic classes of emotions: "Being *pleased* vs. *displeased* (reaction to events), *approving* vs. *disapproving* (reactions to agents) and *liking* vs. *disliking* (reactions to objects)" (Ortony et al., 1988, p. 33).

Reactions to events breaks into three groups: one, the Fortunes-of-others group, focuses on the consequences for oneself of events that affect other people. The other two, the Prospect-based and Well-being groups, focus only on the consequences for oneself. Reactions to agents are differentiated into four emotions comprising the Attribution group. Reactions to objects lead to an undifferentiated group called the Attraction group. There is also a compound group of emotions, the Well-being/Attribution compounds, involving reactions to both the event and the agent simultaneously. It seems to be a general progression that operates the different groups of emotions in order: first reactions to events, then to agents, and finally to objects. From the previous considerations, the OCC theory specifies 3 classes, 5 groups and 22 emotion types. To illustrate in Table 1, we present the corresponding emotions to the Prospect-based group.

To interpret emotional experiences in mathematics classes we have added two types of emotions in the Well-being group of emotions to the OCC theory (Martínez-Sierra & García González, 2014). We call them *boredom* and *interest*. These emotional experiences are elicited by the appraisal that the students made of their own cognitive state: 1) states of *alertness* and *concentration* that produce understanding and learning in the case of *interest*, and 2) states of *distraction* and *deconcentration* that prevent understanding and learning in the case of *boredom*. Thus, we consider *boredom* emotions like "Displeased about an undesirable cognitive state of distraction" and *interest* like "Pleased about a desirable cognitive state of attention".

Class	Group	Types (sample name)
Reactions to events	PROSPECT-BASED	Pleased about the prospect of a desirable event (hope) Pleased about the confirmation of the prospected of a desirable event (satisfaction) Pleased about the disconfirmation of the prospect of an undesirable event (relief) Displeased about the disconfirmation of the prospect of a desirable event (disappointment) Displeased about the prospect of an undesirable event (fear) Displeased about the confirmation of the prospect of an undesirable event (fears-confirmed)

Table 1: Emotion types according to the OCC theory (an extract)

OCC theory specifies three global variables that affect the intensity of different emotions types, three central variables and nine local variables. They are briefly laid out in Table 2.

OCC theory defines *goals* as what one wants to achieve. There are three kinds of goals: active-pursuit goals (A-goals), interest goals (I-goals), and replenishment goals (R-goals). A-goals represent the kinds of things one wants to get done, like passing a course or finishing university. I-goals are more routine goals and are necessary to achieve A-goals or support them, like passing a test. R-goals are those that should be satisfied from time to time in a cyclical nature, like attending a class. Furthermore, it is important to distinguish between all-or-nothing goals, like passing a test, and partially attainable goals, like solving a problem. These distinctions allow oneself to determine the intensity of the different experienced emotions.

METHODOLOGY

Context

The high school where the study was carried out lies to the west of Mexico City. Most of the students live in municipalities bordering the metropolitan area of Mexico City located in the State of Mexico, they come from low economic extraction and most of their parents did not attend college-level. Most students' mothers are housewives. Due to the inflexibility of the curriculum, all students have the same mathematics schooling path composed of six courses (one per semester) with five hours each class per week: 1) Algebra, 2) Geometry and Trigonometry, 3) Analytical Geometry, 4) Differential Calculus, 5) Integral Calculus and 6) Probability and Statistics. Generally, there is a traditional process of teaching and learning mathematics because mathematics classes focus primarily on the teacher's explanation and the subsequent resolution of exercises by the students.

Participants

We selected 53 regular students for the study (aged between 16 and 18 years, 29 men and 24 women). They were in their fourth semester. Participation was voluntary. We chose this type of participants because given his age we believe they would be able to verbalize their emotional experiences. And since they have completed more than one year in high school, they would be able to inform us their experiences in math class in high school.The participants were officially registered in their fourth semester in the Differential Calculus course, which focuses on developing algebraic skills to study elementary Differential Calculus. The topics of this course are: (1) functions, limits and continuity, (2) algebraic functions derivatives and (3) transcendental functions derivatives.

Data gathering procedure

Methodologically, we decided to access to the students' emotions from their reports of experienced emotions because the focus of the research is on the students' subjective experiences of emotions. Thus, we carried out nine focus group interviews of approximately one and a half hours during the mathematics classes in a regular classroom. We decided to use it because

<table>

</table>

Table 2: Variables affecting the intensity of emotions according to the OCC

we observed during previous research at the same school that students feel confident and comfortable to express their thoughts, feelings and emotions about various topics in focus group interview.

For some researchers, individual interviews are more appropriate because emotions are personal. For others, focus group interviews are better because the interaction with others, who potentially feel the same, allows more free expression (Krueger, 1994). In this regard Krueger (1994, p. 20) mentions that "the focus group presents a more natural environment than that of an individual interview because participants are influencing and influenced by others just as they are in real life". Thus we consider that, in our research, the conducted focus group interviews are the correct choice. This is because our research goal is to identify whole participants' emotional experiences; it is not our goal to identify the emotional experiences separately for each of the participants.

The questions asked in the focus groups were: 1) What feelings or emotions do you experience about mathematics? Why do you feel this? 2) What feelings or emotions do you experience in the mathematics classroom? Why do you feel this? 3) What feelings or emotions do you experience just before a mathematics class? And later? Why do you feel this? 4) What feelings or emotions do you experience when you learn mathematics? And when do you do not learn? Why do you feel this? 5) What feelings or emotions do you experience when you solve a mathematical problem? And when you cannot? Why do you feel this? 6) What feelings or emotions do you experience in a good mathematics class? And in a bad class? Why do you feel this? 7) What feelings or emotions do you experience when a mathematics teacher is explaining? Why do you feel this, 8) What feelings or emotions do you experience for a good mathematics teacher? And for a teacher that is not good? 9) What feelings or emotions do you experience in a mathematics assessment? Why do you feel this? 10) What feelings or emotions do you experience in a mathematics test? Why do you feel this?

Two collaborators of the author conducted interviews. One is a PhD student in the field of mathematics education with experience in data analysis using the OCC theory (she is coauthor of the research of Martínez-Sierra & García González (2014)). The other interviewer is a research assistant with experience in conducting individual interviews and focus group interviews. Both interviewers are outside the everyday context of students. The analysis was conducted by the author and discussed with the PhD student. Considering that triangulation the author wrote this version of the analysis.

Data analysis

The videotaped interviews were fully transcribed. In the transcript, students were identified as M*n*-G*k* or F*n*-G*k*: M and F indicate that the participant is male or female; *n* (1 to 5 or 6) is the participant identification number; G*k* (1 to 9) indicates the focus group number. We included explanations in square brackets in order to clarify some of the students' expressions. According to OCC theory to identify a type of emotion we consider three specifications:

1) **Concise phrases** that express all the eliciting conditions of the emotional experiences. We highlight with italic bold letters the concise phrases that shows the eliciting conditions of an emotion in the evidence.

2) **Emotion words** that express emotional experience. We highlight with italic letters the concise phrases that show the emotions in the evidence.

3) **Variables** that affect the intensity of emotions. We underlined phrases that express intensity of the variables in the evidence.

RESULTS

Table 3 shows the students' emotional experiences in the mathematics classroom.

To illustrate in the following we show in detail the evidence related disappointment emotions.

DISAPPOINTMENT EMOTIONS

Not being able to solve problems

Disappointment emotions are triggered when the interest goal of solving problems is not attained.

> **M4-G8:** *I get angry, stress and with a headache* ***if I am not able to solve a problem, because I cannot reach a solution.***

There are two local variables that affect intensity of disappointment emotions: effort and probability.

The effort variable reflects the number of resources that the student uses to solve a problem. These resources depend on the kind of problem; for example, the student can ask their teacher or classmates for help during classwork, but this is not possible in a test.

> **F2-G8:** ***When I am not able to solve a problem*** then I ask myself *what to do because I didn´t* understand anything, <u>so I ask for help from my teacher or a classmate</u>.

A student can choose whether or not to solve a problem in a test. The student who chooses to solve it spends more time on it in order to reach a solution. This effort is linked to the interest goal of passing the test. If this goal is attained then it could trigger future active goal attainments like passing the course.

> **M1-G8:** ***If the problem is in a test,*** <u>then I will go to the extraordinary test.</u>

The probability variable reflects the degree of a student's belief that they will pass a test due to the solution of a problem. Disappointment emotions are more intense when the student believes that not passing the test is a consequence of not being able to solve a problem.

> **M1-G4:** *I feel bad* ***when I cannot solve a problem in a test,*** and I am constantly thinking of it until I get my grade. *I get angry and depressed.*

DISCUSION AND CONCLUSIONS

We found statements about 12 of the 24 types of emotions in our extended OCC theory. Except for *fears confirmed* emotions, we confirmed the presence of all emotions in the prospect-based group (*satisfaction, relief, disappointment* and *fear),* well-being group *(joy, distress, boredom* and *interest),* attribution (*pride, self-reproach* and *reproach*) and attraction group (*liking* and *disliking*).

There are three variables that intensify the prospect-based emotions triggered by the confirmation (satisfaction) or refutation of prospective situations (displeasure, hope and

Group	Type of emotion	Triggering situations	Variables that affect intensity
PROSPECT-BASED	Satisfaction	Being able to solve a problem	
	Hope	Not being able to solve a problem	
	Fear	Not understanding Fearing mathematics class Not passing a test	Desirability
	Joy	End of class Being able to solve a problem at the blackboard	Desirability
WELL-BEING	Distress	Not being able to solve a problem in class Not being able to solve a problem in a test Going to the blackboard	Desirability
	Boring	Not understanding the teacher's explanation Being in a non-dynamic class	
	Interest	Being able to understand teachers' explanations Having a positive attitude towards the teacher Being motivated to pay attention	Desirability
	Pride	Passing a course Being able to solve a problem	
ATTRIBUTION	Reproach	Reproaching the teacher	
	Self-reproach	Not being able to solve a problem	Expectation-deviation
	Liking	Understanding mathematics Being able to solve a problem	
ATTRACTION	Disliking	Not being able to solve a problem	

Table 3: Students' emotional experiences in a mathematics classroom

fear): (1) the desirability of a situation based on the attachment of a goal (such as solving problems), (2) the degree of belief that a prospective situation will actually occur (such as passing a test) and (3) the number of resources used to obtain or avoid a prospective situation (such as solving a problem in a test).

Well-being emotions are intensified by the desirability of the achievement of goals. Each goal is valued according to the goal structure of the student. The degree of this desirability is related to the degree to which the person expects positive consequences from the event. So, intensity of joy and interest emotions increases with desirability. On the other hand, intensity of distress and boredom emotions increases as desirability decreases.

In attribution emotions, pride is intensified in the event that the student follows the rules in their context. For example, a student will feel proud for the effort put into solving a problem or passing a course if this effort is worthy by itself. Intensity of reproach and self-reproach emotions increases depending on the deviation of the expected roles of students and teachers, as in the case of failing a course due to the teacher's actions.

Attraction emotions are intensified by the amount of time students have been attending mathematics courses. The number of courses attended affects students' emotional response: some of them consider mathematics to be a difficult but nice course and others simply don´t like it. This is not a transitory appraisal; it is the consequence of their academic life, which is still in formation and which influences their beliefs about mathematics.

We only found three types of goals that trigger all students' emotions in this context, even when OCC theory states different appraisal structures for each type of emotion. These goals are: active-pursuit goals (A-goals), interest goals (I-goals), and replenishment goals (R-goals). Their final structure is shown in Diagram 1. So, each situation has an implicit or explicit goal that triggers an emotion. This emotion will be positive or negative depending on whether the goal is achieved or not.

In Diagram 1 we express the different relationships between goals with arrows. An arrow from one goal to another means that the first goal may directly affect the achievement of the second goal. For example, passing a test is a goal that affects both passing a course and finishing high school. The diagram also expresses different ways to achieve a goal. For example, understanding teacher's explanations, paying attention in class or attending classes can help with the achievement of solving problems. Furthermore, the letter N above an arrow denotes that the first goal is necessary to achieve the second goal; the letter F denotes that the first goal facilitates the achievement of the second goal. For example, passing high school is a necessary goal to study at university and it facilitates getting a job.

Altogether the goal structure is an inherent part of the students' high school tradition. Goals can be explicit or implicit. The goal structure can be taken as part of the "didactic contract" (understood as "the set of specific behaviours of the teacher which are expected by the student and the set of behaviours of the students which are expected", Brousseau, 1997, p. 31), because it influences, along with the emotional reactions, the

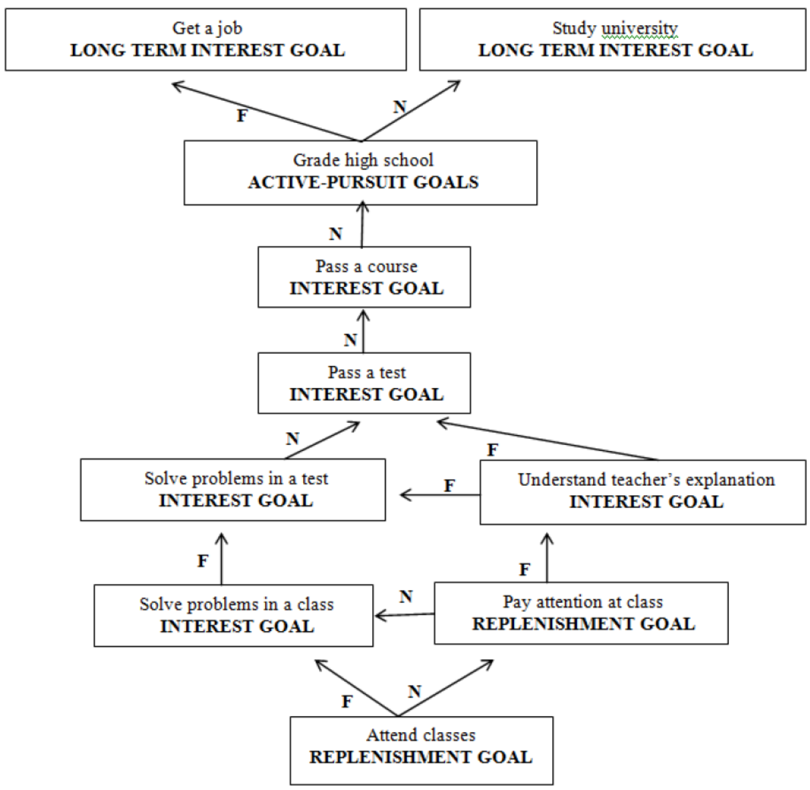

Diagram 1: Students' structure of goals

expected behavior of students and teachers in class. So, students direct their emotions in order to stimulate and guide their conduct to achieve goals that are implicitly or explicitly established in the mathematics class. This is consistent with the perspectives that highlight the complementary relationship between emotion and motivation in learning and performance (e.g., Kim & Hodges, 2011).

Finally, we consider that it is necessary to keep investigating students' emotions (and teachers') in different academic settings and at different school levels. Appraisal theories could help to identify the specific appraisal structure for each academic setting and school level. In this sense, we consider that people experience the same emotions but with quite different appraisal structures even if each individual values an event depending on their own appraisal structure.

Mathematics teachers in preservice teachers' metaphors

Çiğdem Haser[1], Okan Arslan[1] and Kübra Çelikdemir[2]

1 Middle East Technical University, Ankara, Turkey, chaser@metu.edu.tr

2 Gazi University, Ankara, Turkey

This study explored preservice mathematics teachers' beliefs about mathematics teachers through asking them about their metaphors for mathematics teachers. Preservice teachers' (N=249) metaphors and explanations for mathematics teacher were analysed considering the categorizations developed for the NorBa-TM project based on the extended framework of Beijaard and colleagues (2000). Most of the preservice teachers described mathematics teachers as didactics expert and through their personalities. The findings are discussed and implications for field of mathematics teacher education are presented.

Keywords: Preservice teachers, metaphors, beliefs.

INTRODUCTION

Teachers' beliefs can provide us an insight on how and/or why they teach in a certain way (Cross, 2009). Beliefs about the mathematics teacher are likely to provide information about the roles teachers might assume in the mathematics classroom and how they might enact these roles. Despite the constructivist reform in mathematics education in Turkey since 2005, many teachers continued to conduct more traditional teaching (Avcu, 2014) and many preservice teachers come to teacher education programs with beliefs developed in these classrooms. However, teacher education programs focus on more constructivist roles for preservice teachers and try to initiate related beliefs (Haser & Doğan, 2012). Understanding the image of teacher in preservice teachers' minds might provide clues about the effectiveness of teacher education programs in helping preservice teachers develop beliefs which will help them in their future career.

One way to understand preservice teachers' beliefs about mathematics teachers is to analyse their metaphors for mathematics teachers. The word "metaphor" derives from Greek term "metapherein" which means "to carry over" (Green, 1971). Basically, when describing something with a metaphor we somehow transfer the characteristics and experiences of one thing to another by considering the similarities between these two things (Lakoff & Johnson, 1980). Metaphors could be interpreted as blueprints of people's thought (Martinez, Sauleda & Huber, 2001) and they work as creative instruments to deeply understand a complex phenomenon when it is rather difficult to describe it (Oksanen & Hannula, 2013). Therefore, metaphors are used by researchers in order to investigate preservice and in-service teachers' beliefs about teaching and teaching environments which could be interpreted as complex constructs (Massengil-Shaw & Mahlios, 2008). Teacher identity frameworks could be helpful in analysing metaphors for teachers.

Beijaard, Verloop and Vermunt (2000) identified three distinct knowledge bases of teacher knowledge reflecting teacher's professional identity. Accordingly, teacher identity could be expressed in terms of teacher as *a subject matter expert*, *a didactic expert*, and *a pedagogical expert*. *Teachers as subject matter experts* have deep knowledge in their discipline and transmit information to their students. *Teachers as didactic experts* have knowledge on planning, implementation, and evaluation of teaching and learning process to facilitate understanding for students. *Teachers as pedagogical experts* focus on caring and nurturing students' holistic development (Beijaard et al., 2000). These three aspects of the model are connected with Shulman's (1986) ideas of teacher's content knowledge, pedagogical content knowledge and pedagogical knowledge respectively. However, teacher identity is beyond what teachers should know; rather it focuses on what teachers consider as important in their professional work (Beijaard, Meijer, & Verloop, 2004).

Löfström, Anspal, Hannula and Poom-Valickis (2010) have investigated and categorised preservice teachers' metaphors for teachers by using this model of teacher identity. They further added *self-referential metaphors* to address teachers' personality and suggested that metaphors could be labelled as *contextual* when they described characteristics of the environment teachers worked in. Metaphors including more than one characterisation in equal emphasis were considered as *hybrid*.

The above categorizations were investigated in preservice and inservice teachers' metaphors in Finland. Findings suggested that the most frequent metaphor category referred by inservice mathematics teachers was *didactics experts* (Oksanen & Hannula, 2013; Oksanen, Portaankorva-Koivisto, & Hannula, 2014), whereas preservice teachers mostly preferred *self-referential* metaphors (Oksanen et al., 2014). This difference might be due to the way participants were asked about their metaphors; inservice teachers were asked to complete "teacher is like..." statement and preservice teachers were asked to complete "as a mathematics teacher I am.... " (Oksanen et al., 2014).

The purpose of this study was to explore preservice mathematics teachers' beliefs about mathematics teachers by asking them about their metaphors of mathematics teachers. Another aim of the study was to pilot categorization of teachers' metaphors suggested by Löfström and colleagues (2010) based on Beijaard and colleagues' (2000) model.

METHODOLOGY

Context and participants

The study was conducted at Elementary Mathematics Education (EME) Programs at four Universities in Ankara, Turkey. These four-year programs train teachers for teaching middle school mathematics (grades 5 to 8) and courses are determined by the Higher Education Council (YÖK), the governing body of all universities in Turkey. Although the courses are distributed differently in programs, two-semester methods of teaching mathematics courses are offered in the third year and practice teaching courses are offered in the fourth year of the program across the universities (YÖK, 2007).

A total of 249 preservice teachers were accessed at the end of the spring 2014 and 226 of them (33 male, 193 female) were the participants of this study. Participants were 3rd year (123) and 4th year (103) preservice teachers because they were the participant group relatively close to the mathematics teaching profession. Differences in metaphors due to year level in the programs were not the focus of the study.

Data collection and instruments

The study was a part of a more comprehensive international comparative study NorBaTM (New Open Research: Beliefs about Teaching Mathematics, formerly known as NorBa) conducted in over 15 countries in order to investigate mathematics teachers' beliefs. The questionnaire used for the present study was elaborated from the more comprehensive scale used in NorBaTM study.

The metaphor questionnaire was composed of three parts. In the first part, participants' age, gender, and year level in the EME programs were asked. Then, a brief description of the word "metaphor" was provided as a way of describing a concept by using similarities to another concept. This description was given because the participants might not be familiar with the term "metaphor" or what it actually meant. A similar word used in Turkish language was also reminded. In the second and third parts, participants were asked to describe mathematics teacher and mathematics teaching respectively through metaphors and explain their metaphors. In this paper, their responses to the following statement are reported: "Mathematics teacher is like .... Because, ..."

Researchers contacted the EME Programs at participating Universities, after necessary ethics permissions were granted. They were allowed to collect data towards the end of classes. Pre-service teachers who were at the provided place of data collection (classes) at the time of data collection were surveyed by the questionnaire. They were informed about the study by the researchers and given 20 minutes to complete the questionnaire.

Data analysis was performed by employing the categorization explained below through a manual developed for the NorBa project (Löfström, Poom-Valickis, & Hannula, 2011). First, all three researchers carefully read and discussed about the metaphor categorization. Then, a randomly selected 20% sample of data was coded by the researchers individually. Researchers compared their codes and discussed about the minor differences in coding. This process helped the researchers to make more sense of the categorization and the possible examples in data for these categories. This pilot coding was completed with almost 100% agreement. Then, all data were coded by the researchers individually through the specified categorization. Three researchers compared their coding of data case-by-case. A total of 23 cases including 5 no-response, 9 invalid (cases which researchers could not code), and 9 undecided (cases which researchers could not agree on the final categories) cases were removed from the data. Remaining 226 cases were considered as the data of the study. The disagreements that appeared during the comparison of researchers' coding were discussed to avoid over-interpretation of the explanations.

RESULTS

Distribution of metaphors used by preservice mathematics teachers is presented in Figure 1 below. While the didactics (29.6%) and self-referential (26.5%) categories were seen as the highest categories, only a small portion of the participants preferred to use contextual metaphors (2.2%).

Teacher as didactics expert (29.6%)

Teacher as didactics expert was the most frequent metaphor in the current study. Preservice teachers in this group mostly described mathematics teacher as a guide who assisted students to discover and understand the world of mathematics, and helped students when they had difficulty in mathematics, with metaphors such as guide (3 times), light (2 times), candle, star, and map. Participants also mentioned that mathematics teacher used different ways and methods to facilitate mathematical learning of students. For instance, one participant considered a mathematics teacher like an enzyme:

> Mathematics teacher supports students to discover mathematical ideas through questioning, making inferences and evaluations. Like an enzyme in chemical reactions, a good mathematics teacher can facilitate the mathematical learning of students, whereas a bad mathematics teacher might cause to slow down this learning process.

Some of the preservice teachers who emphasized the importance of using different methods also described mathematics teacher as a creative artist who performed different roles in a mathematics lesson in order to gain attention of students and implement non-routine mathematics instruction.

Another common characteristic for mathematics teachers was providing a basis for students' mathematical knowledge. Preservice teachers who stressed this issue generally associated mathematics teaching with constructing a building:

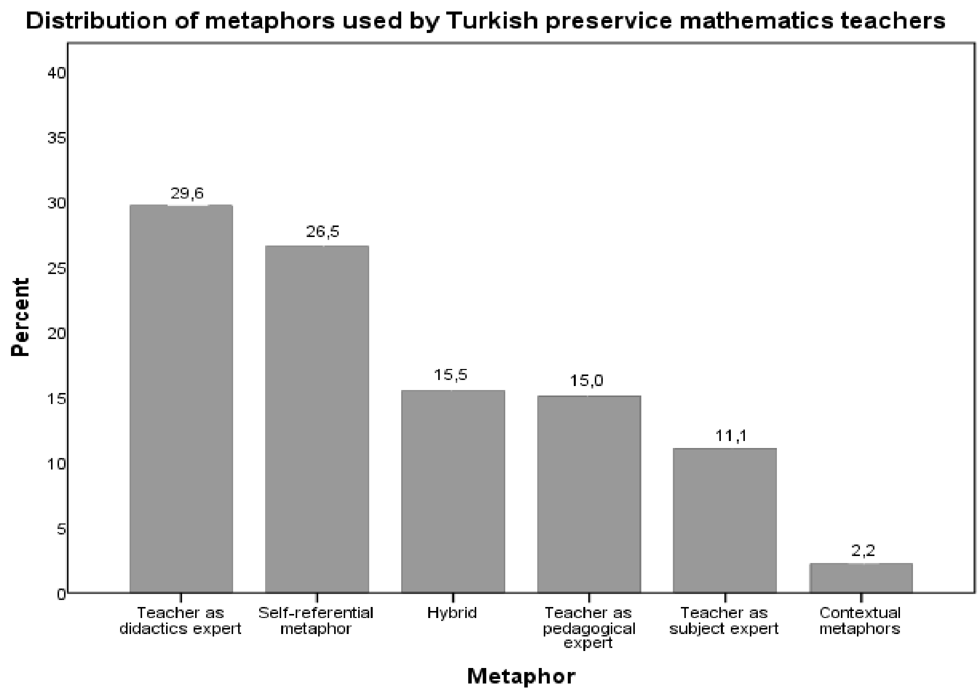

Figure 1: Distribution of metaphors used by the preservice mathematics teachers

> Mathematics teacher is like a contractor. If a contractor uses high quality material and properly constructs the base, the building becomes strong. Similarly, if a teacher teaches the topics by enabling meaningful learning instead of rote learning, students' mathematical knowledge becomes strong.

Self-referential metaphors (26.5%)

In self-referential metaphors, there was an emphasis on mathematics teachers' characteristics which were not related with teaching or mathematics teaching profession. Some of these metaphors were used to appreciate mathematics teachers, whereas some to criticize them. Common positive characteristics of mathematics teachers were stated as being smart, hardworking and practical. Some metaphors describing these positive characteristics were an ant (often used to describe hard working people in Turkish culture), small house appliances, and human brain. Participants appreciated mathematics teachers by stating that mathematics was difficult and only smart people could do mathematics.

Surprisingly, some preservice teachers mentioned mathematics teachers' negative characteristics by portraying them as insensitive machines such as robots or computers. Often, they were not friendly with students:

> Mathematics teacher is like a gravestone. They get tough with the class and do not ever smile.

Some other negative characteristics attributed to mathematics teachers were being arrogant and scary. These negative characteristics were rather stated as how mathematics and mathematics teachers were perceived by students:

> Mathematics teacher is like a doctor. A child who is afraid of getting a shot does not like the doctor. [Similarly,] when a student does not like mathematics, s/he does not like mathematics teacher. When s/he is afraid of mathematics, s/he is also afraid of mathematics teacher.

Participants also frequently stressed that mathematics teacher should be patient while teaching mathematics, which was a difficult job. Patience stone (a phrase used to describe a very patient person in Turkish culture, 3 times) and gardener (2 times) metaphors were used to emphasize this characteristic.

Hybrids (15.5 %)

Hybrids were metaphors including more than one category. The most common category in hybrids was didactical expert (27 times). Didactical expert category was generally expressed together with subject expert (11 times), pedagogical expert (10 times) and self-referential (9 times) categories. The following metaphor included both didactics and subject expert aspects:

> Mathematics teacher is like a chess player. For a chess player, it is not enough to know how each chessman moves. The player also needs to know how to develop tactics to win the game. Similarly, mathematics teacher needs to know all of the details of the topics and apply this knowledge to the lesson considering the students' needs and backgrounds.

Another observable issue about hybrids was that the number of hybrids including contextual elements (7/35) was more than the uniformed contextual metaphors (5/191). It seemed that preservice teachers preferred to use contextual elements by considering other characteristics of a teacher.

Teacher as pedagogical expert (15%)

Preservice teachers who stated metaphors in this category generally mentioned the guiding mission of mathematics teachers in students' lives. Mathematics teachers should support the development of students as human beings and thus, they should enlighten students' lives such as the sun (3 times), light, lighthouse, and pole star. For instance, one participant portrayed the mathematics teacher as the sun and the moon:

> Mathematics teacher enlightens his/her students. S/he tries to guide them and helps students to realize the things around them. Then, s/he observes what they can do by themselves. This is the time when mathematics teacher is like a moon. S/he does not leave them alone, s/he supports them like how moon looks after the night.

Another common issue was the caring and nurturing characteristics of mathematics teachers where they were described as merciful and helpful. Metaphors for the caring characteristics were mother (3 times) and father.

Teacher as the subject matter expert (11.1%)

Preservice teachers who described mathematics teachers as subject matter experts generally focused on two characteristics of mathematics teachers: (i) being knowledgeable and (ii) performing operations without making mistakes.

In the first group, there was a clear emphasis on the knowledge of mathematics teachers as indicated by metaphors such as book, journal, and encyclopaedia. In these metaphors, mathematics teachers were characterized as having accurate knowledge of mathematics similar to a book. Some participants indicated that a mathematics teacher was not only knowledgeable in mathematics, but also knowledgeable in the other content.

In the second group of metaphors, there was an emphasis on the calculation skills of mathematics teachers. Mathematics teachers could successfully perform operations and solve problems in a short time without making mistakes. Metaphors such as smart phone, calculator, and computer were stated:

> Mathematics teacher is like a calculator. A mathematics teacher should perform operations very efficiently otherwise, s/he might be interpreted as weak. S/he is expected to answer questions immediately.

Contextual metaphors (2.2%)

In the current study, only five preservice teachers uniformly mentioned the contextual factors while describing mathematics teachers with metaphors. Two of these preservice teachers focused on what it meant to be a mathematics teacher in Turkey. They indicated that it was difficult to be a teacher and a mathematics teacher in Turkey, and it was not appreciated enough:

> Mathematics teacher is like a slave. Because, a teacher has no value in this country. Furthermore, it is not a well-paid profession and thus, I just consider him/her as a slave.

Another stressed issue was related with how mathematics was seen in the society. Negative bias and fear of mathematics were the main foci:

> Mathematics teacher is like a bogy. In our country, teachers shout and get mad at students. According to my observations, students are especially scared of the mathematics teacher.

DISCUSSION AND CONCLUSIONS

What do these metaphors tell us? They seem to address that preservice middle school mathematics teachers prioritize didactics knowledge and skills when they consider a mathematics teacher as evidenced in their *didactics expert* and *hybrid* metaphors. For the Turkish context, the frequent reference to *didactics expert* might be a reflection of the courses on mathematics teaching and learning offered in the 3rd and 4th year where the guiding characteristic of mathematics teachers for students' learning was emphasized. EME programs had a major change in 2006 and the number of pedagogical content knowledge courses were increased without decreasing the number of mathematics content knowledge courses. A study conducted in the previous version of the EME program with less number of pedagogical content knowledge revealed that preservice teachers mostly believed that a mathematics teacher should have mathematics content knowledge, then pedagogical content knowledge, and then pedagogical knowledge (Haser & Doğan, 2012) in Shulman's (1986) terms. This corresponds to being *subject expert*, then *didactics expert*, and then *pedagogical expert* in the current study. Considering these findings, we cautiously speculate that the emphasis on pedagogical content knowledge courses in the last two years of the EME programs might affect preservice mathematics teachers' metaphors towards *didactics expert*. However, since we did not collect data from 1st and 2nd year students, we do not have information about preservice teachers' metaphors in the first two years of the program and this interpretation is very limited. On the other hand, Finnish preservice teachers described teachers mostly by their personality (*self-referential* metaphors) when they were asked in a rather personalized or subjective way (Oksanen et al., 2014), which could be the case in Turkish context if we had asked in a personalized way.

Preservice mathematics teachers who described a *subject matter expert* mostly emphasized procedural knowledge of mathematics rather than conceptual knowledge. Preservice mathematics teachers in EME programs have been reported to have both constructivist and traditional beliefs about the nature of mathematics (Kayan, Haser, & Işıksal, 2013). It seems that metaphors provided a different window for us to gain more knowledge about beliefs that preservice teachers might have carried from their precollege education.

Self-referential metaphors were stated mostly in relation to mathematics. Being a mathematics teacher was valued by emphasizing that teaching mathematics required being hardworking, smart, and patient. Surprisingly, some participants criticized mathematics teachers for being rather unfriendly and scary. It was not clear whether participants described the mathematics teachers in the eyes of the students or society, or what a mathematics teacher meant for them in their explanations. Therefore, what these metaphors communicated in terms of preservice teachers' beliefs about mathematics teachers remained inconclusive.

Oksanen and colleagues (2014) state that *hybrid* metaphors might reflect the complexity of the teaching profession. *Hybrid* metaphors might provide information about how different sides of the mathematics teaching profession are internalized and integrated. We argue that the effectiveness of teacher education programs might be traced by the *hybrid* metaphors that preservice teachers could develop. If preservice teachers would be able to explain their metaphors by referring to different types of teacher characteristics, could this be a reflection that they have developed a more comprehensive image of a mathematics teacher in their minds? This might be an issue for a further discussion and research in which preservice teachers' metaphors could be investigated through their studies in the teacher education programs and also based on the nature of the programs.

Contextual metaphors were the least mentioned metaphors in this study. This could be a reflection of the insufficient school experience in teacher education programs. Preservice middle school mathematics teachers spend 4 hours per week in the first semester and 6 hours in the second in their senior year in the program. This experience focuses on observing and generally includes 1 or 2 hours of teaching for the whole year. Therefore, they might not be experiencing the contextual elements about being a teacher as inservice teachers do. However, Finnish inservice teachers also did not state *contextual* metaphors much (Oksanen & Hannula, 2013). Yet, it might be the case that crowded classrooms and lack of sufficient instructional materials in Turkish schools (OECD, 2009) could result in more *contextual* metaphors if the study had been conducted with inservice teachers, compared to the Finnish case.

Using metaphors to gain insight about preservice teachers' certain beliefs also revealed evidences about other beliefs. Preservice teachers stated beliefs about the nature of mathematics in their explanations. Many explanations referred to society's views about the nature of, teaching, and learning mathematics. It seemed that asking metaphors might offer more or other than what was intended in the beginning. Asking specific experiences, significant person, or events that have caused to state their metaphors could provide more windows into participants' mathematics related beliefs.

The metaphor framework based on Beijard and colleagues (2000) model was effective in analysing Turkish metaphor data in this study. The eliminated data were difficult to conclude on a category due to the content they included. It should be noted that Turkish data for metaphors do not reveal participants' gender preferences (unless asked) in referring to a teacher because Turkish language does not have gender difference in referring to a person.

Certain limitations should be considered in making sense of the findings of this study. First, written data might not be as detailed as verbal data. Interviews conducted on these metaphors could have provided more insight into preservice teachers' beliefs about mathematics teacher. Participants might have written more about their explanations if they had been given more time.

Basic emotions of primary school pupils in mathematics lessons

Ineta Helmane

Riga Teacher Training and Educational Management Academy, Faculty of Education, Riga, Latvia, ineta.helmane@gmail.com

The article describes and analyses theoretical and empirical materials the experienced emotions by pupils when learning mathematics in primary school and highlight the factors arousing emotions in learning mathematics in primary school. The article analyses the data obtained in empirical research on the emotions experienced by pupils during mathematics lessons in primary school. In questionnaires and semi-structured interviews pupils reveal what gave them positive emotions in mathematics lessons, as well as what made them experience negative emotions. According to the analysis of empirical data we highlighted the factors of learning mathematics in primary school which caused positive emotions.

Keywords: Basic emotions, pupils, mathematics, primary school.

INTRODUCTION

The great pace of life in the contemporary society demands emotionally powerful people, able to maintain a positive attitude towards life, overcome the fast increasing tension and stress, sustaining appropriate self-esteem, healthy self-confidence (Helmane, 2010). One of the meaningful components creating a harmonious individual is emotions. Emotions mobilize each individual's psychic and physical strength for the further activity to reach the goal, or prevent and hinder the individual's activities, participation in the diverse life- activity processes (Izard, 1991; Thompson & Meyer, 2007). Therefore, it is necessary to be aware of the factors which evoked positive emotions in pupils when learning mathematics at school. The aim of the research is to investigate the experienced basic emotions by pupils when learning mathematics in primary school and highlight the factors arousing emotions in learning mathematics in primary school.

MATERIALS AND METHODS

The essence of basic emotions

Basic emotions appear already in the first years of life through all cultures and with slight or without variations (Izard, 1991; Miezitis, 1992), they are based on the demonstration of a person's movements and expressions (Carlson, 1990). All basic emotions possess the following characteristic features: they attract a clear, strong feeling which a person is aware of; they develop as a result of evolution - biological processes; they have an organizing and motivating affect on the person, serve for his adaptation (Izard, 1991) and manifest themselves in expressive and specific configuration of the movements of facial muscles - mimics (Izard, 1991; LeDoux, 1998).

The physiological base of such positive basic emotions as joy, interest, surprise (Kagan & Havermann, 1980; Ekman, 1984; Carlson, 1990; Izard, 1991; Miezitis, 1992) is mainly excitation process. Positive emotions tone up the body's activities and activate the person, generate strength and energy as well as enhance the person's capability of mental work, increase energy, promote heuristic or creative processing (Carlson, 1990; Ambady & Gray, 2002; Fredrickson, 2004). However, negative basic emotions: anger, hatred, disgust, fear, shame, fault, sorrow (Kagan & Havermann, 1980; Ekman, 1984; Carlson, 1990; Izard, 1991) are based on retention process. Negative emotions usually depress, even paralyse a person as well as decrease a person's activity and also reduce energetic resources (Carlson, 1990; Selighran, 1995). Negative emotions are associate with reduced accuracy on tasks that tap memory, intelligence, and executive functioning (Hartlage et al., 1993; Veiel, 1997). Therefore, emotions may have a positive or negative affect on a person's life processes, becoming a determining force of a person's action in crucial moments of life.

Emotions in teaching-learning process

Emotions are involved in almost every aspect of the teaching and learning process (Schutz & Lanehart, 2002). Pupils' emotions are formed at the interface of personal, contextual, and social aspects of learning (Volet & Järvelä, 2001; Ainley & Hidi, 2002; Schutz & Pekrun, 2007). The teaching/learning process based on positive emotions proceeds more successfully. If we do something with pleasure, we will try to do the same in future (Frenzel, Perkun, & Goetz, 2007). Within positive emotions a more profound approach to the acquisition of various skills and knowledge develops which facilitates openness to new things, creativity and energy to be productive (Olsonm & Torrance, 1996; Gorman, 2001). The positive emotions become a strong motivating, suggestive factor for future actions (LeDoux, 1998; Linnenbrink & Pintrich, 2000; Fredrickson, 2001). If successful, emotions positively motivate and reinforce several extremely successful activities, guesses and ideas which came up during the completion of tasks.

However, negative emotions direct attention and cognitive processing in a negative way (Power & Dalgleish, 1997; Linnenbrink & Pintrich, 2004), reduce the effectiveness of learning, the working memory, the ability to acquire various types of knowledge, skills as well as creativity (Olsonm & Torrance, 1996; Linnenbrink & Pintrich, 2000). If pupil is doing something with negative emotions, he/she will try to stop doing it in all possible ways in future (Frenzel, Perkun, & Goetz, 2007). Also monotonous, boring learning process and failures cause negative emotions (Selighran, 1995).

Learning mathematics is connected with the pupil's individual experience in mathematics and applying it in everyday life, the perspective of his individual learning where emotional factors are as significant and important as cognitive factors in learning process (Tosse, Falkencrone, Puurula, & Bergstedt, 1998). Emotions also include and sustain pupils interest in learning material (Ainley, Corrigan, & Richardson, 2005; Krapp, 2005), in teaching/learning content. Paris and Ayers (1994) underline the value of emotions in learning process - nobody can develop mathematics or intellectual values without emotions, especially in mathematics. The positive learning experience can help to change negative thoughts and feelings and raise pupils' motivation in learning process (Paris & Ayers, 1994). Pupils who experience more positive emotions may generate more ideas and strategies. In addition, emotions can have an impact on different cognitive, regulatory and thinking strategies (Pekrun, 1992), affect categorising, thinking and problem solving (Sutton & Wheatley, 2003). In contrast negative emotions may trigger the use of more rigid strategies, such as simple rehearsal and reliance on algorithmic procedures, thus leading to reduced attention and more superficial processing of information (Pekrun et al., 2002). If a pupil feels sad, she/he may be preoccupied with thoughts about negative emotions and unable to refocus her/his attention on educational information. This would have implications for children's academic performance (Davis & Levine, 2013). Negative emotions also commonly disrupt mathematics learning. Some children have a condition termed math anxiety that is characterised by fear of mathematics (Ashcraft, 2002; Hinton & Miyamoto, 2008). This emotional state disrupts cognitive strategies and working memory (Ashcraft & Kirk, 2001).

Research of pupils' basic emotions in mathematics lessons

The research of emotions experienced by pupils in mathematics lessons in primary school was carried out in Grade 3 in four Riga schools, total of 107 pupils (age 8–9). The selection of the schools involved into the research was done by intentional assessing of the school environment descriptions, based on the similarities of the following qualities: school social economic environment, ethnic environment, school's physical environment, time-table, the number of pupils in the school, as well as the length of the teachers' pedagogical experience. The selection of the classes involved into the research was done by intentional assessing of the mathematics lessons descriptions, based on the similarities of the following qualities: National Basic Education Standard (2006), mathematics text books according to List of Confirmed and Published text books (2009), 4 mathematics lessons per week. The research was done within the academic year over the period from 2012 to 2013 in which pupils self-evaluate experienced basic emotions while learning mathematics in primary school were explored.

The data were obtained applying such empiric research methods as questionnaires with open questions, semi-structured interviews and test as Dembo's methodology for self-assessment of basic emotions (Helmane, 2010). The aim of empirical research methods was to select and to specify the experienced basic emotions by pupils in mathematics lessons in primary school and the factors evoking emotions in general learning mathematics situations in primary school.

The pupils were asked to fill in a questionnaire about the experienced basic emotions while learning mathematics. The pupils of Form 3 involved in the research marked individually on Likert-type scale positive emotions (joy, interest, surprise) and negative emotions (anger, disgust, fear, shame, fault, sorrow) experienced while learning mathematics in primary school. When marking every basic emotion, the pupils took into consideration Likert- type scale where 1 point corresponds to the answer – never experienced the given emotion, 3 points correspond to the answer – the emotion has often been experienced, but 5 points meant that the emotion has always been experienced.

During the further survey the pupils individually reflected and pointed out at least 3 factors, stimuli, situations which evoked positive basic emotions at school as well as pointed out at least 3 factors, stimuli, situations when they felt negative basic emotions. The data obtained from questionnaires were specified in semi-structured interview where the pupils supplemented the answers to the questions about the factors evoking basic emotions. The peculiarity of this semi-structured interview was that the questions previously were not formulated precisely, and also their succession was not strictly determined, however, during the interview it was clarified to what extent, on what conditions, in which situations the pupils experienced positive or negative emotions while learning mathematics in primary school as well as specified the factors evoking these emotions, their exposure according to the criteria set out for the research. Each individual interview was about 15 minutes long, it was recorded, transcribed and coded.

RESULTS

The data obtained according to Likert-type scale as a result of questionnaires by 107 pupils testify that during school time pupils' experienced positive and negative basic emotions at similar intensity. The situations when the pupils experienced or not experienced distinct positive emotions during learning mathematics are not in majority. In contrast, when evaluating basic negative emotions, the pupils indicate that they did not feel disgust or were ashamed in math lessons (see Picture 1).

It is characteristic that the pupils often experienced such positive basic emotions as joy and interest in mathematics lessons. In most cases, the pupils' interest and joy were aroused by the opportunity to use visual aids, play didactic games and the teacher's positive attitude in mathematics lessons. However, a positive evaluation of the given tasks and activities in mathematics has been a precondition which aroused joy, interest and surprise in pupils. In most cases, the pupils experienced such negative basic emotions as fear, shame and sorrow in mathematics lessons. These negative emotions caused the situations related to a pupil's incompetence, failure in doing a certain mathematics task as well as the cases when pupils encountered with a negative assessment of their work and the comparison of their work with that of the other pupils.

The majority of pupils (86%) confirmed in semi-structured interview and questionnaires that in mathematics lessons, it was interesting to work with small countable material. Joy, interest and surprise in pupils were aroused by the opportunity to do mathematics tasks with the help of sticks, fingers, coins and banknotes. As a result of manipulation, the experi-

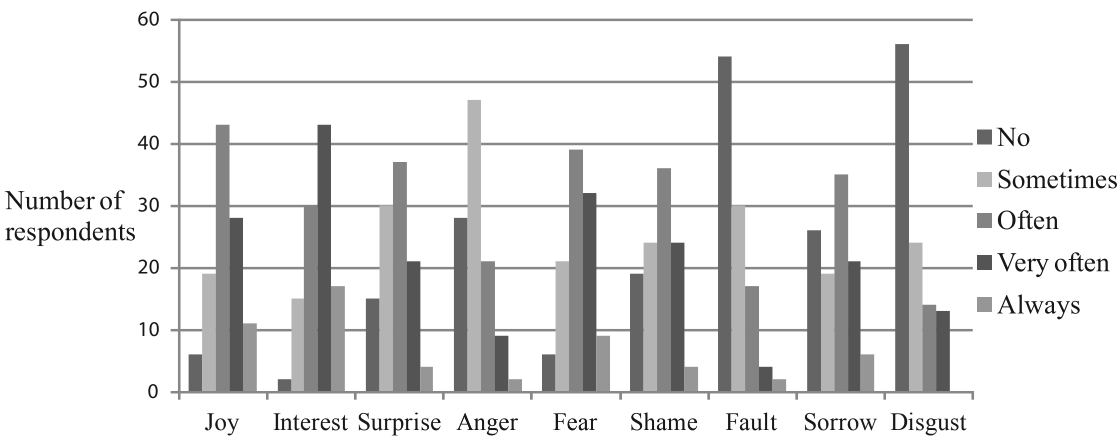

Figure 1: Pupils experienced basic emotions in mathematics lessons

enced positive emotions by pupils are related to the opportunity to get acquainted with mathematics skills more successfully, solve problems. Frequently, pupils mention varied didactic games with small countable material as a factor which generates positive emotions. It is testified by pupils' comments on the same question:

Interviewer: What is interesting in maths lessons?
Pupil: For me... to count with sticks and money banknotes.
Interviewer: What surprises you in mathematics?
Pupil: The teacher allowed me to count with fingers.
Interviewer: Count with fingers?
Pupil: Yes, it is cool, I can count everything... but mum does not allow to do it at home...

According to pupils' (92%) answers a factor evoking positive basic emotions is drawings, pictures in mathematics textbooks which attract pupils' attention, as well as facilitate the perception of the essence and conditions of the task. Pupils are happy about the objects seen in the pictures of the tasks, their reinforcing function in perception of the conditions and essence of the mathematics task. The pupils have interest in the tasks which are visualized in textbooks with the help of pictures and drawings, for example:

Interviewer: What surprises you in maths lessons?
Pupil: I have a colourful and beautiful maths textbook.
Interviewer: What is colourful and beautiful in it?
Pupil: A lot of pictures, I like that.
Interviewer: What do you do with pictures?
Pupil: I look at them, then I understand and... do correctly.

The teacher's personality as a factor evoking emotions can initiate both basic positive and negative emotions. The majority of pupils (44%) comment that positive basic emotions have been evoked by a sensitive, creative teacher, who has a positive attitude towards the pupil, interest in mathematics as a subject. The pupils experienced positive basic emotions in such mathematics lessons which were exciting, interesting, not boring. In these lessons, the pupils had joy about varied organizational forms of the teaching process (group work, games, research, manipulative activities), when the pupils were provided with the opportunity to be active participants of the study process. The interest in pupils was aroused by the explanation of theoretical concepts and the essence of mathematics skills with the help of real objects, thus the study content to be obtained was explained visually, for instance:

Interviewer: What is interesting in your maths lessons?
Pupil: I have the best teacher; it is so cool to learn together with her, she shows everything.
Interviewer: How does she show everything?
Pupil: With money notes, drawings...we also play games...and she smiles all the time, she does not yell.

In the cases, when pupils (36%) experienced negative basic emotions during school years, the teacher of mathematics had not listened to pupils' thoughts, had not allowed them to be active participants of the study process, sometimes the teacher's working style had been authoritarian. Pupils experienced fear of the teacher's reaction about the incorrectly solved problem, anger about the teacher's intolerant attitude to the pupil's incompetence and failure in mathematics lessons. Negative emotions anger and disgust in pupils were also initiated by monotonous, uniform mathematics lessons where pupils were passive performers of the teacher's instructions. For instance:

Pupil: I hate to go to the lesson, where it is boring and not interesting.
Interviewer: How is it – boring?
Pupil: Every day the same – sit and do tasks.

Very often in questionnaires pupils (88%) mention their personal achievements and success in mathematics lessons as a prerequisite initiating positive emotions when each success allowed to experience positive emotions. Also, the recognition of the achieved (69%) has often evoked positive emotions. Pupils experienced joy and surprise if they could solve a mathematics task correctly and received a positive assessment for their work according to each pupil's individual contribution and growth. Joy was also aroused by such situations where pupils were able to solve different problems of higher difficulty level. Failures in most of the cases caused negative emotions in pupils (74%). The pupil's mistakes were not perceived as an opportunity to develop correct mistakes and master the skill. In mathematics lessons, pupils felt angry about the inability to do a task or could not successfully solve the problems given to them in mathematics test. Fear and shame are evoked in pupils in such situations when they are made to demonstrate their inability in front of other pupils, for instance, when solving a problem unsuccessfully at the blackboard. Pupils feel ashamed when they do not understand a mathematics task, if it is compared to the positive achievement of other pupils in mathematics. For instance:

Interviewer: What are you afraid of in maths lessons?
Pupil: I am afraid to solve problems because I can solve them incorrectly.
Interviewer: Do you need to be afraid of that?
Pupil: If there is a mistake, it will be bad... others will get to know.

When characterizing mathematics content, pupils in most of the cases mention the acquisition of word problem (78%) and multiplication within the table (72%) as a factor which evoked negative emotions while learning mathematics. In a questionnaires and semi-structured interview pupils clarify the experienced negative emotions as incomprehension about the necessary activities for doing the task, an insufficient skill to read a word problem. Most of the pupils emphasize that negative emotions anger, sorrow and fear while solving word problems were experienced also because the word problems did not arouse their interest and did not have connection with real life and the surrounding processes. When mastering multiplication within the table, pupils name the main reason for having negative emotions shame and fault i.e. learning multiplication table by heart without the comprehension about relationships in the multiplication table:

Interviewer: What do you feel ashamed of?
Pupil: That I have to memorize multiplication table.
Interviewer: Is it difficult to memorize?
Pupil: I cannot remember so much by heart... I cannot count as fast as it is necessary, I want to think a little...Multiplication is terrible, why must I memorize it?

Pupils (73%) experienced positive emotions most often while mastering addition and subtraction skills at school. Pupils point out that they willingly did arithmetic operations, it was easy and understandable. The joy experienced by pupils is mainly characterized as a qualitative application of mathematics skills during the solution of mathematics problems, for instance:

Interviewer: What are you most of all pleased in mathematics?
Pupil: About numbers and their addition. It is terrific because I have to add numbers and I can make it because I can do it easily.

Partly experienced negative emotions sorrow, anger are in the acquisition of the following mathematics content: mastering fractions (64%), mathematical variables and measures (57%), pupils consider boring such tasks where they mechanically have to perform mathematical transformations and express relationships between variables and measures, and it is not shown in which life situations and how these acquirable skills could be applied.

CONCLUSION

The mathematics learning process needed to include and use that sort of positive emotion-causing stimuli: the manipulation activities with objects, based on the practical independent activity with diverse visual aids, rational work modes acquiring by manipulation with objects; the purposeful system of exercising, where the pupils clearly recognize the exercise aim, understand the execution of the exercise, the exercises are arranged in a well-considered system, disseminated in time, the exercises also include the revision of the mathematical skill and they are miscellaneous; the use of the skills in diverse life-activity situations where the diverse work forms, methods and approaches are applied, integration possibility into other subjects, miscellaneous exercises according to their contents, forms (Helmane, 2010).

As a result of the research, it is possible to select the factors facilitating positive emotions while teaching mathematics in primary school: curriculum which is easy for a pupil to understand and perceive, which is encouraging, in good arrangement, intensity and appropriate difficulty level; efficient techniques of work and visual aids are used in the acquisition of skills; also the pupils' activities are practical and independent; diverse forms of work, methods, especially the method of play are used in the acquisition of skills which encourage a pupil's active participation and mobilization of potential in order to achieve the desired objective; communication with peers and the teacher; evaluation of a pupil's progress and achievements by the teacher, peers, also self-esteem.

Development of mathematics-related beliefs scale for the 5th grade students in Turkey

Nermin Kıbrıslıoğlu[1] and Çiğdem Haser[2]

1 Hacettepe University, Faculty of Education, Ankara, Turkey, nkibrislioglu@hacettepe.edu.tr

2 Middle East Technical University, Ankara, Turkey

The aim of this study was to develop a valid and reliable scale for 5th grade students in Turkey to investigate their mathematics-related beliefs. For this purpose, a mathematics-related belief scale was constructed by the researchers based on Op't Eynde, De Corte and Verschaffel (2003) framework and piloted by 390 5th grade students from 2 middle schools in Ankara, Turkey. Data were analysed by descriptive and inferential statistics. Factor analysis revealed three factors: beliefs about mathematics and mathematics learning, self-efficacy beliefs, and beliefs about the role of the teacher. The overall reliability of the scale was .77, indicating a good reliability. The mathematics-related belief scale will be used in a future study where 5th grade students' mathematics related beliefs will be identified.

Keywords: Scale development, mathematics-related beliefs, 5th grade students.

INTRODUCTION

Beliefs are important components of mathematics teaching and learning process (Kloosterman, 1996; Philipp, 2007). Students' beliefs about mathematics influence the effort they will spend for the tasks, their interest in mathematics, and enjoyment with the task (Kloosterman, 2003), and they have the potential to determine how students connect real life activities and school mathematics (Lester Jr., 2002). Their beliefs about achievement have a considerable influence on their success at school (Wittrock, 1986). Students' learning experiences affect their beliefs and their beliefs about learning influence their approach to the new learning experiences (Spangler, 1992). Therefore, there seems to be a reciprocal relationship between mathematics learning and mathematics related beliefs (Schommer-Aikins, Duell, & Hutter, 2005).

Beliefs are formed by students' direct or indirect experiences (Lester Jr., 2003), which makes their classroom experiences important. However, in order to help students form beliefs which will enhance their mathematics learning, it is substantial to identify their existing beliefs. Identifying younger students' beliefs is specifically important because they are more open to be influenced by classroom experiences.

As a result of the recent change in school system in Turkey 5th grade is included in middle schools with some revision in mathematics curriculum. This revision did not change the emphasis on problem solving and building relationships in middle school mathematics and teachers' facilitating and guiding role for students' learning (MEB, 2013) that the previous curriculum stated. However, to what extent these emphases have influenced students' beliefs at this level has not been investigated yet. Investigating 5th grade students' beliefs when they start middle school will enable us to (i) understand the effectiveness of the elementary school mathematics instruction on students' mathematics related beliefs and (ii) determine the possible mathematical experiences in middle school grades which will help them learn meaningful mathematics. Therefore, the current study aimed to construct a valid and reliable instrument to investigate 5th grade students' mathematics-related beliefs.

There are several scales addressing students' mathematics-related beliefs. However, the psychometric properties of these scales, including some popular scales, are problematic (Walker-Wheeler, 2007) and their Turkish versions either lack validity evidences or target older students' beliefs. Therefore, there is a need to for a valid and reliable scale addressing younger students' mathematics related beliefs.

LITERATURE REVIEW

Several researchers have defined beliefs. For example, Fishbern and Ajzen (1975) define beliefs as information that a person has about an object or idea. According to Richardson (1996), beliefs are "psychologically held understandings, premises, or propositions about the world that are felt to be true" (p. 2). Kloosterman, Raymond and Emenaker (1996, p. 39) refer beliefs as "the personal assumptions from which individuals make decisions about the actions they will undertake." Schoenfeld (1998) indicates that "beliefs are mental constructs that represents the codification of people's experiences and understandings" (p. 21). These definitions address that we have beliefs about the world around us and we also use these beliefs to make sense of the world.

As beliefs are subject specific (Philipp, 2007), there is also a need to define mathematics-related beliefs. There are several definitions of mathematics-related beliefs and there hasn't been an agreement on a common definition (Furinghetti & Pehkonen, 2002). This study employed the definition proposed by Op't Eynde, De Corte and Verschaffel (2003) which addresses mathematics-related beliefs as "the implicitly or explicitly held subjective conceptions students hold to be true, that influence their mathematical learning and problem solving" (p. 28) because it focuses more on students' mathematical learning and problem solving.

Theoretical framework

Different approaches to mathematics-related beliefs have been discussed in the field and several researchers have introduced different categorizations, with common and distinct aspects (Philipp, 2007). A comprehensive framework given by Op't Eynde and colleagues(2003) is mainly based on Schoenfeld's (1983) view that cognitive actions are determined by the nature of the task, social environment, and the perception of the individual. Hence, beliefs reflect the effects of self, belief object and the context (Schoenfeld, 1983). Op't Eynde and colleagues (2003) proposed that mathematics-related beliefs were determined by the context, personal needs, and mathematics education. Their framework had three main categories of beliefs about: (i) mathematics education, (ii) the self, and (iii) social context. This framework was employed for the current study.

Beliefs about mathematics consisted categories of beliefs about mathematics as a subject, mathematics learning and problem solving, and mathematics teaching. Beliefs about mathematics were about the answer of the question "What is mathematics?" in students' minds. Beliefs about self included students' motivational beliefs such as self-efficacy, control, task value, and goal orientation beliefs. Beliefs about social context consisted of beliefs about social norms in students' classrooms including role and the functioning of the teacher and student; and beliefs about socio-mathematical norms such as beliefs about what is accepted as mathematical justification in the class (Cobb & Yackel, 2014). Table 1 summarizes the framework.

This framework is more comprehensive and it contains other classifications which provide a wider perspective for investigating students' beliefs. Therefore, it was employed as the theoretical framework in this study. However, its comprehensive nature makes it difficult to investigate these beliefs a single study with 5th grade students. Therefore, beliefs about nature of mathematics, learning mathematics, role of the teacher, and self-efficacy beliefs were investigated in this study.

SCALE DEVELOPMENT PROCESS

The scale was developed in three main steps. First, the related literature was reviewed in detail and items

Beliefs about mathematics education	Beliefs about self	Beliefs about the social context
-Beliefs about mathematics as a subjects -Beliefs about mathematical learning and problem solving -Beliefs about mathematics teaching in general	-Self-efficacy beliefs -Control beliefs -Task value beliefs -Goal-orientation beliefs	-Beliefs about social norms in their own class The role and functioning of the teacher The role and functioning of the students -Beliefs about socio-mathematical norms in their own class

Table 1: The framework of students' mathematic related beliefs

were written. Then, experts' opinions were gathered and items were revised. Last, five students were interviewed in order to ensure the clarity of the items for the students.

Literature review

An extensive literature review of belief frameworks in the literature were conducted and a comprehensive belief structure framework suggested by Op't Eynde and colleagues (2003) was employed for the study. A detailed examination of this framework, previous studies, and the characteristics of the age group resulted in four sub-domains (factors) to be considered for the study: beliefs about mathematics as subject, beliefs about learning and problem solving, mathematics self-efficacy beliefs, and beliefs about teacher role and functioning. Then, an extensive literature review was conducted for each factor. In general, these factors were studied individually in many studies through several scales in order to understand the types of items which explained the specific belief domain. An examination of these items showed that there were both common and different aspects, and these aspects were taken into consideration to get a more comprehensive instrument. After these studies, the first version of the instrument was developed with 68 items.

Experts' opinion

The first version of the scale was shared by two researchers working on beliefs in the field of mathematics education to examine the content and comprehensibility of the items. They were asked whether the items and factors were coherent, statements were clear, and expressions were appropriate for the 5th grade students. After they reviewed and suggested changes in the items, revised items were shared by two specialists in the field of educational measurement to ensure the properness of the scale in terms of measurement principles. Then, two middle school mathematics teachers reviewed the items with respect to clarity for students as they had more interaction with the students and they suggested certain changes about wording of the items. At the end of the experts' revision, scale consisted of 32 items.

Student interviews

After the revision of the scale, five 5th grade students from a public school in Ankara were interviewed about clarity of the statements. They were asked about what they understood of each item and whether there were any words that they did not know about their meanings. Students had difficulties in three items. It appeared that they considered "lecturing" and "guiding" the same. Therefore, the item "Our teachers guide us when we are learning" was deleted. Students also struggled with the item related to the relationship construction between old and new knowledge. While some students were able to understand the meaning of building relationship, others couldn't understand the item and preferred to respond as undecided. This item was revised as "I remember previous knowledge when I am learning new things" in order to make the statement clear.

In order to ensure that one class hour will be sufficient to complete the scale for students, the time students spent in answering items was observed. Students finished responding 32 items in approximately 20 minutes during the interviews. After the items were reviewed once more with respect to the interview results, the fourth version of the questionnaire was constructed which consisted of 34 items with 3 point Likert scale as agree (3 points), undecided (2 points), and disagree (1 points). Negative items were scored reverse. The maximum score one can get from the scale was 102 and the minimum score was 34. Three-point scale was preferred because 4^{th} and 5^{th} grade students might have difficulty in understanding "partially agree" or "partially disagree" phrases.

DATA COLLECTION AND ANALYSIS

Data for this pilot study were collected from two conveniently selected public middle schools in Ankara. Although there are different suggestions about the sample size for getting proper factor analysis results, it is indicated that larger sample sizes produce more proper results. Tabachnick and Fidell (2007) argue that sample size should be 10 times of the item number or at least 300 for proper factor analysis. These suggestions were taken into consideration and data were collected from 390 students (201 male, 182 female) from fifteen 5^{th} grade (ages 9–10) classrooms.

The implementation was conducted by the first researcher. Before distributing the scale, she explained students that there were no correct answers for the items and their thoughts were important for the research. Students were also informed that no information would be shared with their teachers, their answers would not affect their grades, and there was no need for writing their names. Data were collected in courses other than mathematics in order to reduce the teacher effect.

Principal Component Analysis (PCA) was conducted in order to determine subscales and validity of the scale. As the sample size was ensured during the data collection, other preparations were performed before conducting PCA. First, negative items were scored reverse. Second, Bartlett Sphericity Test and Kaiser-Meyer-Olkin (KMO) were checked to ensure that data set was factorable which means that some correlations should exist (Tabachnick & Fidell, 2007). In order data set to be appropriate for factor analysis, Bartlett Sphericity Test should be significant, which means p value smaller than 0.05 and KMO value should be at least 0.6 (Tabachnick & Fidell, 2007). The analysis indicated that data set was appropriate for factor analysis ($F=0.80$, $p < 0.05$).

Certain principles suggested by Tabachnick and Fidell (2007) guided the PCA: Items should have factor loadings 0.3 or above to fit the factor structure in the selection process. If items which are loaded in more than one factor have difference between factor loadings smaller than 0.1, then it is better to exclude them from the scale. When deciding the number of factors, the factors with eigenvalues more than 1 are initially taken into consideration. However, only eigenvalues may not be sufficient for the final decision. Another estimate can be made by interpreting scree plot but there is still need for more operations for proper factor solution. Based on these criteria, the factor analysis was repeated until reaching a proper factor solution.

RESULTS

The results of the first analysis showed that there were 11 factors whose eigenvalues were more than 1. However, the scree plot seemed very complicated to reduce the factors and factor loadings were not appropriate. In order to get a more appropriate factor solution, items with communalities less than 0.2 were removed because small communalities indicated that the variable was not related to the other variables in the data set (Tabachnick & Fidell, 2007). Therefore, 11 items were removed from the analysis. In order to reach the best factor solution, the Promax rotation method, an oblique rotation, was employed because gives better results in identifying the correlating and noncorrelating factors (Tabachnick & Fidell, 2007). After this reduction, the analysis was conducted once more and the most appropriate factor solution appeared as 3 factors solution. The scree plot in Figure 1 also supported 3 factors solution. Then, items which were loaded on unrelated factor, items whose factor loadings were smaller than 0.3, and items which were loaded almost equally to more than one factor were removed from the scale.

After deciding the factor structure, 5 items which were indicated as important in the literature were added one by one as they didn't conflict with the factor structure. Two items whose factor loadings were smaller than 0.3 were also added to the scale with the same reason. Wordings of two items were changed

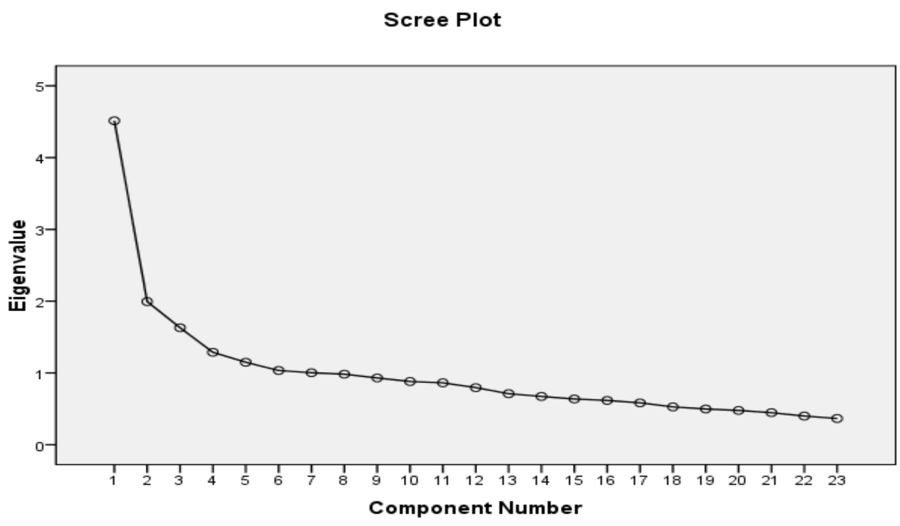

Figure 1: Scree plots of eigenvalues of pilot version of the scale

because they might be confusing for the 5th grade students.

According to the results of the analysis, 6 items were loaded under the first component (*beliefs about teacher's role*), 7 were loaded under the second component (*self-efficacy beliefs*), and 10 were loaded under the third component (*beliefs about mathematics and learning mathematics*). This structure explained the 35% of the total variance in the dependent variable, the total score gained from the scale. The mean and standard deviation of each item are given in Table 2.

Cronbach Alfa coefficient, was computed for the reliability measure and the pilot study of the scale resulted in 0.77 Cronbach Alpha reliability coefficient, which indicated a satisfactory reliable measure (Tabachnick & Fidell, 2007). The Cronbach Alpha value for components of *teacher's role* was 0.48, *self-efficacy* was 0.73, and *mathematics and mathematics learning* was 0.6. Students' mathematics-related beliefs were examined for each component and item by item.

The mean score for *beliefs about teacher's role* component was 14.3 (out of 18). This factor was about how students perceived the role of their mathematics teacher in the class. They rather portrayed their mathematics teachers as the authority for knowledge in the class showing them how to solve problems step-by-step and transferring knowledge to them. On the other hand, they believed that their teachers listened to them carefully and made mathematics lessons fun. Their teachers also seemed somewhat to encourage them to discuss mathematics problems.

Students' mean score in *self-efficacy* component was somewhere between undecided and agree (x=16.7 out of 21). They seemed to believe that they had ability in mathematics. They felt confident while studying mathematics and mathematics was not a difficult

Items	Mean	SD

subject for them. However, students were undecided about whether they could understand a concept which they couldn't understand in the first time later and that they would panic when they see a mathematics problem for the first time.

Students' mean score in *mathematics and mathematics learning* component was 27.3 (out of 33). Students agreed that knowing mathematics will ease their life and school mathematics could be used in real life. Their responses indicated that they considered mathematical concepts as related to each other, rather than unrelated facts. They agreed that there might be more than one solution for a mathematics problem and it was important to develop these solutions, but they were undecided for whether problems could be solved only by their teachers' method. Students believed that studying mathematics and working on homework enhanced their mathematics learning but they were undecided about the role of making mistakes in their learning.

DISCUSSION

The main purpose of this study was to develop a valid and reliable scale. The results showed that although the scale was constructed in four sub-domains, the items related to beliefs about nature of mathematics and beliefs about mathematics learning were loaded under the same factor. It might be the case that students' beliefs about learning mathematics are closely related to what they believe mathematics is about. *Self-efficacy* items and items related to *teacher role* appeared in separate factors as designed. The overall reliability of the scale was high, but *teacher's role* factor had lower reliability measure. The reason might be related to the number of items. Cronbach's Alpha value is very sensitive to number of items and when it is fewer than ten, it may take lower values (Tabachnick & Fidell, 2007).

Students' responses indicated that they agreed with rather authoritarian teacher roles in the classroom, but their classroom experiences seemed to help them develop beliefs about the connected nature of mathematical knowledge and existence of multiple solutions for mathematical problems. They also believed in the usefulness of mathematics, a belief that elementary school students tended to develop as they progressed towards higher grades (Kloosterman, Raymond, & Emenaker, 1996). Students' responses indicated that their teachers might be supporting discussion in the mathematics classroom, although the nature of the discussion was unknown. When students believed that they could learn mathematics through discussion, they engaged in discussion in the mathematics class (Jansen, 2008). These findings addressed that guiding mathematics teachers for effective discussion in the classroom could be considered in order to help students develop beliefs about and practice effective discussion in the middle school mathematics classrooms.

Students seemed to believe that spending effort in mathematics resulted in learning. Fifth grade students might not have developed beliefs about quick learning which relates learning quickly to ability rather than hard work. This might have resulted in their beliefs about the usefulness of mathematics, as observed in 7th and 8th grades students in other contexts (Schommer-Aikins, Duell, & Hutter, 2005).

Fifth grade students in this study had considerably higher self-efficacy beliefs and mathematics was not a difficult subject for them. These findings addressed that there might be a promising cumulative influence of elementary school and 5th grade experiences the mathematics class on students' beliefs. Understanding the nature of these experiences could provide middle and high school mathematics teachers with ideas for their practices resulting in higher efficacy beliefs in students.

'Two things I like, maths and chocolate': Exploring ethical hedonism in secondary mathematics teaching

Elizabeth Lake

University of East Anglia, Norwich, UK, e.lake@uea.ac.uk

What motivates mathematics teachers to remain in the profession when disengagement from mathematics is common? I would suggest one of the reasons is deriving pleasure from engaging in teaching mathematics. As part of research into how teachers communicate their enjoyment of mathematics, eight experienced teachers were interviewed, observed during teaching and then engaged in discussion of lesson extracts. This paper takes interview samples to illustrate intellectual pleasures, with a thematic analysis of the narrative generated from the interviews. The analysis suggests that the deeper pleasures experienced by mathematics teachers derive from experiences of dependability, deviation or success, whilst underlying pleasures in teaching mathematics is a living of self, motivated by service to others.

Keywords: Affect, pleasure, ethical hedonism, teachers, mathematics.

INTRODUCTION

Any interaction inevitably has an affective dimension. In this paper, affect is defined from a social perspective as a stable trait as opposed to a more transitory emotional state (Hannula, 2012). In the teaching of secondary school mathematics, emotions play a central role in forming an affective orientation (Drodge & Reid, 2000). If an experienced mathematics teacher has a strong positive affective orientation towards mathematics, then this orientation guides their practice, satisfies desires, and gives pleasure. Frenzel and colleagues (2009) suggest that not only is affect important within the learning of mathematics but that enjoyment supports effective student engagement.

This paper is part of a larger study exploring affective responses to mathematics for experienced teachers of mathematics and how these responses are communicated to students in the classroom. Currently there is little research on how experienced mathematics teachers communicate in mathematics teaching. This paper uses *ethical hedonism* (Onfray, 2007) as a frame to focus on what makes the teaching of mathematics pleasurable for a teacher. The assumption is that, to teach effectively, teachers must gain some affective reward from their teaching.

After defining pleasure in the mathematics classroom context, I review some relevant literature that provides insight into the pleasures of teaching mathematics. Acknowledging the inaccessibility of subjective experiences is important, so the data is teacher stories, and the analysis uses examples of teachers expressing pleasure. Conjectures are constructed from the literature and compared with selected data, enabling a presentation of espoused pleasures via themes with illustrative examples. I summarise, framing with the components of ethical hedonism, the elements that give teachers the greatest pleasure in their teaching of mathematics. The paper concludes with a brief discussion of implications of these interpretations of teacher pleasure.

PLEASURE AND ETHICAL HEDONISM

Pleasure is often defined as a feeling of satisfaction and enjoyment. Yet pleasure is also a subjective mental state experienced as enjoyable or worth seeking, a state that is satisfying more than basic needs or biological drives; on the contrary, experiencing pleasure is a psychological feedback mechanism that forms a potentially addictive feeling of positive anticipation. Pleasure generates a desire to recreate an experience found to be entertaining or aesthetically pleasing, which then impels seeking of similar sensations (Damasio, 2006). This process may then, by repetition, lead to fixed beliefs since even apparently unemotional everyday logic is conditioned by underlying impressions left by formerly intense affects (Schlöglmann, 2006).

In this paper, and this research, the term pleasure is used in an aesthetic and ethical sense, unlike, say, the French term ‘jouissance’ that has stronger physical connotations. Damasio (2006) discusses the interlinking of pain and pleasure, suggesting two parts: a bodily experience and the attached emotional experience. Both parts inform subsequent reaction and or action, subconsciously and consciously. Litman (2005) suggests pleasure links mathematics with an appetite for food or sex, where satiation or reward comes from positive feeding of social identity and community recognition. This social reward is associated with recognition and service.

Onfray (2007) defined ethical hedonism as an introspective attitude to life based on taking pleasure yourself and pleasing others, without harming yourself or anyone else. In other words, ethical hedonism is a joyful utilitarianism that gives moral pleasure. This perspective may be useful in exploring pleasure as it divides pleasure into self, others and an ethical yet purposeful context, where stronger, memorable pleasure is experienced when all three elements are addressed. Yet there is a temporal element to pleasure, unlike happiness which is more stable. Whilst one can again experience pleasure on recall, a person cannot always be in this state. Yet this very temporality may effectively aid the re-creation desire and compensate for any associated unpleasantness. Similarly to Utilitarianism, the ‘greatest good’ of ethical hedonism engages cognitively and viscerally whilst aligning one’s own pleasure with that of others. The pleasure then has personal and social value as the greatest good, is relatively damage free and hence is ethically acceptable. This is this multi-levelled view that accords to pleasure the dimensions of self, others and ethical.

To summarise, pleasure is taken as having emotional, psychological, physiological and social dimensions. Exploring whether there is evidence for ethical hedonism within the teacher narratives, whilst identifying what the teachers suggest as giving them pleasure in their roles, is also necessary. The next section locates pleasures for teachers within relevant research, and seeks themes to support data analysis.

STRUCTURING PLEASURES FOR MATHEMATICS TEACHERS

Research into affect specifically for experienced secondary mathematics teachers is limited, although there has been more mathematics student orientated research (McLeod, 1992). Given the interactive nature of teaching, this research is relevant to teachers as well. Smith (2010) examines pleasure in the form of happiness in learning mathematics, including the role of success and the dependability of mathematics within social and mathematical identities for students. Research on the role of the teacher, power relationships in the classroom (Walkerdine, 1988) and pleasures from deviation (Drodge & Reid, 2000) can also inform understanding of pleasure.

One of the more stable traits associated with pleasure is happiness. Smith (2010) found for mathematics students that happiness, especially subject pleasure, came from the dependability of mathematics. This pleasure from dependability may also prove to apply to teachers. Happiness as an affective trait requires constant high self-efficacy which combines confident knowing, doing and feeling. Smith (2010) suggests that, by choosing mathematics, people express something about themselves which is viewed as positive. By using and reproducing a mathematical identity they derive pleasure and hence happiness. Smith’s research explores finding pleasure in your own work, pleasure which includes working for and with other people. Smith suggests that pleasure is often equated with success and that work and happiness can coexist in contemporary society where happiness is the sole purpose of life, and society promises to provide conditions for you to obtain this happiness. This balance of work and happiness can exist for teachers too, but with additional complexity from the role of a mathematics teacher in regards to vulnerability and risk.

Between freedom and compliance, within the autonomy of a mathematics classroom, lie experiences of deviations from ‘norms’ that can give pleasure. Vulnerability, in the context of teaching (Davies, 2006), derives from conflict of mastery and submission. In this model, the risk or vulnerability comes from, for example, exposure to judgement, whilst pleasure derives from a sense of connectedness. The degree of emotion a teacher is comfortable showing may come from balancing these two limits. This perspective is important, as it may be that the exercise of freedom, self-regulated within constraints, is what gives pleasure. Yet simultaneously, social recognition from being seen as compliant can also give pleasure.

If a teacher’s own learning was empowering, and pleasure derives from successful teacher and student interactions, then revisiting an environment, such as a classroom where success was experienced may trigger re-creation desires. If pleasure deriving from repeated experiences of success is significant, then it is reasonable to expect that teacher interviews would have frequent examples of positive educational experiences. We can also assume that teachers of mathematics would be good at mathematics and hence experienced more pleasure than pain in transition from learner to teacher. This positive imbalance may have led to investment because of feeling pleasure, with subsequent development of trust in the dependability mathematics.

Mathematicians also obtain a sense of pleasure from mathematical discovery which may also apply to a teaching context. Similarly, ‘ah-ha’ moments, for example when a method or solution becomes suddenly clear, are known to be pleasurable for learners and bring power along with the experience (Liljedahl, 2005). The same pleasure for teachers could be the revelation of a student misconception, or through being a witness to student pleasure from their ‘ah-ha’ moments. If pleasure is associated with deviations from the norm, either a discrepancy (Drodge & Reid, 2000) or ‘ah-ha’ moments, then deviations can elicit emotional reactions and hence are likely to be recalled in interview, but also may elicit strong identifying statements that are directed at the deviator, for example a student. Robert and Wilbanks (2012) suggest that “we experience pleasure if the sudden resolution involves an unexpected connection. Making that connection has been likened to cognitive ‘play’ and to the feeling associated with solving a puzzle” (p. 1073). An enticement to engage in more similarly rewarding activities. Deviation may appear come in many forms; difference from routine, deviation from ‘normal’ behaviour, as in the unexpected, or from the pleasure of making unexpected mathematical or social connections.

To summarise, the data will be considered through the lenses of the themes of pleasure in success, pleasure arising from deviations and from dependability of mathematics as described above. The social context is important, as is the role and experiences of the teacher, especially pleasures which help form positive emotional disposition or attitude (Di Martino, 2011) associated with a mathematics teacher.

DATA COLLECTION AND ANALYSIS METHOD

The data used in this paper is from two audio-recorded unstructured interviews with eight UK secondary teachers (A-H, Adam to Helen) who have been teaching in school from three to nearly thirty years. There are equal numbers of male and female teachers, all but two trained at the same university at different times. Six teach in rural schools and two are from a larger urban school. In the first interview the teacher relates their life history, talking about their mathematics and their teaching. The second interview, closely following observation of the teacher in action, is a stimulated recall of an extract from the lesson using video extracts from their teaching. The extract selection is guided by the use of a galvanic skin response (GSR) sensor worn by the teacher in observed lessons. The sensor measures visceral response to intense emotions such as excitement or anxiety. In the stimulated recall the teacher evaluates and explains their thinking and how they felt during the observed lesson. Both interviews are audio-recorded and the transcripts analysed for examples of pleasure. The research design has been approved by an ethics committee and the participants have consented for the data to be recorded and used for research.

This paper draws on the articulated pleasures for each teacher. Analysis of the interview data is influenced by the first two parts of ethical hedonism, a division of self and others (social interaction).

These divisions provide structure for examining teacher pleasures. These categories (Table 1), for the teacher comments that relate to pleasure, are then subdivided into two further categories. The teacher comments are themed by pleasure for self; as their re-

Pleasure for self	Relationship with mathematics	Self-identifying stories
Social interaction	Role of a teacher as professional	Significant others

Table 1: Analysis categories for examples of pleasure

lationship with mathematics, and secondly self-identifying stories. The ‘others’ category, (social interaction), is divided into the role of a teacher as the professional self and then significant others. These are selected as all the teachers speak about these four categories. Once classified, each category is illustrated and interpreted before being discussed in the final section. The intention in the next section is to reveal through examples any similarities or differences within the pleasures of these mathematics teachers and to further explore their sensory and intellectual pleasures.

EXAMPLES AND INTERPRETATION OF TEACHER PLEASURES

The analysis presented here explores what gives pleasure to teachers of high school mathematics structured by the categories in Table 1, but discussed in *deviation*, *success* and *dependability* terms, followed a discussion of other pleasure examples.

In all the interviews, teachers talk about their relationship with mathematics, for example, ‘….my relationship with the subject, it’s stronger than ever’ (Edward). The relationship is presented as positive, and comments relate to personal *success* in the subject, ‘…just absolute joy. Nobody ever told me maths was hard…maths was just like breathing… I thought maths wasn’t important because it was easy’ (Gus), but also the *dependability* and certainty that mathematics represents for them, ‘I realised that I quite like maths, cos it’s nice, you can have a… there’s always a right answer, or most of the time…I really liked that…’ (Debbie) or ‘maths was something that was really important to me, and I enjoyed it’ (Freddie).

From these examples, I would suggest teaching mathematics is perceived as safe and *dependable*, the participants experiencing personal *success* in mathematics as their identities were forming. The intensity and frequency of the comments, as illustrated above reflects the importance of subject within the teacher’s identity. Re-living such an experience within a mathematics classroom allows constant recall of a positive experience. The pleasure in teaching a subject where they have experienced personal *success*, which effectively pleases the self, combined with actively sharing such pleasure with others in a morally good way, meets the criteria of ethical hedonism.

Similarly, all participants tell self-identifying stories of their self as student, ‘I have just always excelled at maths I could always do everything in maths lessons and I found other lessons quite hard’ (Adam). These comments show how important and pleasurable mathematics was to each teacher, ‘Maths has always been my favourite subject when I was at school, and I enjoyed it, and was fairly good at it, and found it interesting and I kind of…I liked being able to solve problems and I don’t know really, I enjoyed algebra’(Helen). But many stories report change during higher education, with examples showing critical points where their pleasure in the *dependability* of mathematics was shaken, ‘…by the end I kind of like lost the love a bit for maths…’ (Adam). ‘I enjoy my maths but I didn’t enjoy my degree’ (Carol). ‘…started and just, just hated it’ [laughs] (Edward). Yet, all of these participants are now teachers and have a professionally *successful* outcome.

It is common for the teachers to speak about their positive and *successful* school experiences in terms of mathematics. They talk about themselves as individual students, or embed subject comments in the social of school experience. All mention transition, especially negatives associated with transition into university, mainly assigning the difficulty of mathematics as the reason. All but one, who took a combined teaching and mathematics university course, speak very positively about this experience. One difference is illustrated by Debbie. She was ill during school and talks of mathematics as reliably accessible during her illness, unlike other subjects; her ‘horrid’ transition occurred earlier than university. However, all comments suggest that these teachers experienced positive emotions through *success* in school mathematics. Carol used mixed tenses in the interview, often bringing the past comments into links to her present role, suggesting reflection, but also that her wider identity aligns with her current role. The comment on mathematics and chocolate in the title comes from Carol whilst discussing a significant event in her school life, providing an example of aligning sensory and intellectual pleasures. The pleasure that social recognition can give is strong in the stories of this teacher, suggesting that for her, teaching offers a continuation of pleasure as socially recognised *success*.

Pleasure from the role of a teacher as professional, combined with the social dimension of teaching, is mentioned in association with *deviation*. Pleasure seems to come from changes to daily practice, 'Maths can become incredibly boring... bore you to death by making you practice it forever, and that's not what I do. Cos maths has got to be exciting, it's got to have something in it other than sheer boredom' (Gus). Or pleasure from surprises, or being creative and making change or challenges, a motivator for several of the teachers. '...they couldn't do it... I sort of then showed them, and they clapped me...I didn't expect it... it was just sort of "Oh well done miss"...' (Carol). or, similarly to a famous line in the film Forrest Gump's, 'Life was like a box of chocolates, you never know what you are going to get,' Debbie comments that '...teaching is different every day, it's a challenge, different challenges every single day...never dull, its lots of things but it is never boring...'

But *deviation* through challenge seems to be important, as without it boredom emerges, and excitement is lost,

> '...I was saying on Friday to my husband that I didn't really feel excited about maths, we were talking about the emotion of it... and perhaps I'm not conveying it because a lot of it is the day to day of it, I've done it 20 times, 50 times, 100 times...' (Carol).

However pleasure from deviation through challenge or creativity can be viewed as a lure into mathematics for students,

> '... I go with the philosophy of fun. If I'm not having fun in the lesson, if I'm not enjoying myself, then the kids aren't either...there's no hook...so it's trying to make it fun, trying to let my personality come through a bit, have a bit of a laugh with them...' (Debbie).

In general, the teachers use many terms to describe their teaching, from interesting, pleasurable (including social pleasure), creative or transformative, through to labour, challenge, routine, or a part of life. The descriptions illustrate the complexity of pleasure within a teaching context, and that pleasure is individual and social. Yet their comments do not necessarily distinguish between sensory and intellectual pleasures. Often there is a strong experiential aspect to what gives the teachers pleasure. I would suggest that pleasure emerges from aligning a socially located identity with their individual view on the purpose of being a mathematics teacher.

Yet simply identifying with the mathematics teaching role can give pleasure, '...other stuff that kind of takes you away from teaching...teaching's the fun bit...' (Adam), or personal pleasure in mathematics, '...and I sort of enjoy that freedom to explore my subject... and take students along with that...' (Edward), or in comparison with other life pleasures, '... I was playing teaching... I was teaching and it was more fun than playing rugby and therefore I didn't need the rugby anymore...' (Gus).

All the teachers mentioned one or more significant others, such as a teacher, 'My maths teacher for my GCSE, O level years was brilliant'(Bertha), 'I got on very well with him... someone I am still in contact with...' (Carol), 'I just really clicked with him and that style suited me and could just practice, practice' (Adam) '...and I had this wonderful nun who was my mentor and tutor, and she was magic' (Gus). A friend or a family member as a significant other, '...my dad... used maths a lot... I can remember him sitting down and helping me with maths....' (Carol). A stronger degree of pleasure from engagement with others as well as self is evident here. Especially as, in addition to all the teachers mentioning at least one significant other, all positively mention their mathematics teachers in high school.

Pleasure for others appears in interviews as indirect pleasure in the *success* of students, suggesting that pleasing others is perhaps a stronger driver for these teachers rather than balanced by pleasure for self. One of the strongest examples of pleasure combines sensual and intellectual pleasure, '...at the end of primary school there was a competition...we [dad and I] won a bar of chocolate [laughs], two things I like, maths and chocolate' [laughs] (Carol). Not only is eating chocolate a sensual pleasure, Carol uses chocolate to recall a story that illustrates the reward of early social recognition as someone who could do mathematics, an intellectual pleasure. Significantly, the story also relates *success* in relation to a significant other. I would suggest this pleasurably recalled experience supports establishment of her belief that mathematics gives pleasure; as does chocolate. The combination has all the characteristics of ethical hedonism, harmless pleasure for self, others, as well as social recognition and acceptance. The importance of the social within pleasure is emphasised by several of the teachers, such as the pleasure of helping others,

> ‘I remember somebody saying to me in the first lesson, where is the fraction key on the calculator. I think that was a bit of a “oh, maybe I do know a bit more than you, I can help you. That’s good.”’ (Helen).

And Carol reports ‘[I was] more comfortable talking to that group...cos they are weaker, so I feel I can help them more. They engage better’. There are examples of social pleasure from a common love of mathematics, ‘...there’s a little group and they’re like, yeh, I really like maths [laughs]...students I teach get that enthusiasm from me, and they like the subject... they like me as well’(Adam). Or social pleasure from interaction with a class, ‘But actually, that’s how I teach. Complete, complete enjoyment. And that class is an absolute joy to teach’ (Gus). Social pleasure by proxy appears in a number of interviews, including teachers articulating as if they were students. Such as ‘...I teach quite a lot of lower sets and somebody in the class might say, “oh right yeah I get that now”, and actually properly get it, and that will change... change their lives...’ (Bertha). Bertha is also describing her experiences of student ‘ah-ha’ moments by proxy as discussed above.

Overall, the stronger of the articulated pleasures appear when pleasure is experienced by teacher, students and further, is associated with satisfaction in fulfilling the role of a mathematics teacher. There is an individual, social and moral dimension to pleasure from fulfilling a role. For example,

> ‘...you can get the kind of challenge from that as well. I like the way that you can sort of relate it to real life. I like the fact that kids value it’ (Helen).
> ‘That’s me, the more you laugh the more you learn’ (Gus).

To summarise the selected data examples and interpretation, examples from teachers illustrate how pleasure is located within *success*, *dependability* and *deviation*. The categories of self and others enable the importance of social as a thread to emerge in different forms, such as indirect *success*, and how *deviation* appears to change between the role of student and teacher.

DISCUSSION AND CONCLUSIONS

In this section the categories are briefly discussed in terms of the themes of dependability, success and deviation in context, before considering intensity of pleasures in relation to ethical hedonism. Teachers find pleasure within their roles, something evident when talking about their professional lives, sharing their emotional relationship with mathematics, invariably in an open, cheerful manner. This paper focusses on the pleasurable aspects of teaching, although there are few negative examples. Just talking about their professional lives appears to be a pleasurable experience, and I was honoured to hear and engage, albeit briefly, in their stories.

As Smith (2010) found for mathematics students, subject pleasure and happiness, often in the context of success, comes from the dependability of mathematics. The data here suggests the same for teachers, where mathematics is, for example, ‘analogous to breathing’ (Gus). But most of the teachers report that their trust in the dependability of mathematics was shaken in their transition through university mathematics and the evidence from these teachers infers that dependability is less important when discussing teaching roles. I would suggest that deviation is especially associated with pleasure through power, that a teacher can decide to deviate from norms of their classroom, to be creative, accept the associated risk and use deviation as a teaching strategy; one which draws and engages their students and hence gives reward, a form of pleasure in teaching through intellectual play, as suggested by Robert and Wilbanks (2012). This idea of play or fun is used by Adam, Edward and Gus when talking about gaining pleasure from their teaching role.

Experiences of joint completion of hard work or overcoming difficulties may conjoin success, deviation and dependability, all in a pleasurable memorable experience for the teacher. The interview excerpts highlight the importance of the social aspects of teaching mathematics, including pleasing significant others. The ‘brilliant’ or ‘magic’ person described by these teachers. Research suggests significant others is important in a professional career (Zeldin & Pajares, 2000). Pleasing others as well as self is important, but the intense, memorable pleasures align different forms of pleasure and combine self, others and some form of value as in ethical hedonism. Yet additionally, pleasure can be by proxy, recall or from social interaction in a purposeful context. Pleasure in teaching derives through mastery shared (where learning occurs), and where mirroring or synchronisation of values occurs, and reciprocity of pleasure in the subject induces stronger pleasure. This reciprocity is particularly evident for Carol, telling her story of the pleasure of maths and chocolate.

Defined as pleasure at a deeper level, meta-satisfaction occurs at a personal, social and ethical level, a resolution through ethical practice (Hobbs, 2012), that shapes future action. This shaping develops the emotional orientation of a teacher, and the degree of investment, or risk they are able to take in a classroom, acting as a limit for positive emotional exchanges. Pleasure comes in many forms, especially from interaction that revisits an arena where the teachers themselves, as learners, were successful. Teachers would, from experience, anticipate and plan for such reward pleasure by proxy. Teachers seek and recognise revisiting as something that will give emotional reward. Gratification comes when repetition continues to give pleasure, strengthening their emotional relationship to mathematics in a teaching context.

Knowing more about contextual pleasures in mathematics, for teachers as well as students, may support countering any circumstances of displeasure within a mathematics classroom. Although this paper is focussed on what teachers say, the fuller research also explores observed classroom practices, especially how observed pleasure links to the pleasures identified in this paper. One intention is to explore how teachers share their emotional relationship with mathematics in a classroom and what limits positive emotional exchanges. This may have implications for teacher training.

ACKNOWLEDGEMENT

I would like to thank the teachers for their cooperation, and my supervisors, Professor Elena Nardi and Dr Paola Iannone, and UEA for PhD studentship funding.

Patterns of motivation and emotion in mathematics classrooms

Gareth Lewis

University of Leicester, Leicester, UK, gl116@leicester.ac.uk

A case is made that the study of state, as opposed to trait, is necessary to give a more rounded picture of affective aspects of students' experience of learning mathematics. This paper is based on a study of disaffection with school mathematics. The study was a primarily qualitative study conducted from a constructivist and interpretivist perspective, using Reversal Theory as the main design and interpretive framework. The paper reports findings of some patterns in the students' experience of motivation and emotion in mathematics classrooms. Sequences of motivation and emotion are described, and the notion of dominant narrative is introduced. Two common motivational pathways are described: 'mastery for a reason versus what's the point', and 'engagement and pleasure through interest versus I can't be bothered.'

Keywords: Motivational state, emotion, motivational pathways.

INTRODUCTION

Research in affect in mathematics education has been dominated by attention to stable and semi-stable constructs such as attitude, and as such these are often treated as trait. Twenty years ago McLeod (1994) pointed out that the predominant paradigm in mathematics education research is taken from psychometrics. He pointed out further, that:

> complicated statistical analyses of questionable questionnaire data were not necessarily reflecting accurately what students were thinking and feeling. (McLeod, 1994, p. 640)

Students' experience of learning mathematics involves a dynamic shifting of motivation, emotion and other affective constructs. Nonetheless, emotion has not been studied in great depth in mathematics education, as has been pointed out by Evans (2000) and others. Hannula and colleagues (2009) talk about 'a need to move beyond simplistic positive/negative view of emotions and distinguish different types of negative emotions.'

The equivalent importance of state, as opposed to trait has been pointed out by Hannula (2012). In that paper Hannula sets out a metatheoretic structure of affect, and one of his three key dimensions, seen as important, is the distinction between state and trait. He notes the long history of attention to this distinction, and traces important sources of research into issues of state. Goldin and colleagues (e.g., Goldin, et al. 2011) make a similar distinction to state and trait between what they term local and global affect, and point out the importance of research into local affect. What is important for the present paper is Hannula's statement:

> There is a clear imbalance in favour of studies that focus on traits over studies that focus on states… (Hannula, 2012)

He goes on to say:

> In particular, studies that focus on the dynamics of emotional or motivational states in a classroom or other learning community are still rare. (ibid)

This is not to claim, of course, that no such studies exist, and indeed, Hannula, in his paper, cites a number of examples, including his own work with Peter Op't Eynde. Goldin and colleagues have developed the notion of engagement structures, which are constructs related to state (Goldin, 2011), and more recently, colleagues have studied and reported on the dynamic of the movement of experience through the lens of such structures (Sanchez-Leal, 2014).

The study reported here focusses on the state rather than trait aspects of experience, and, further, emphasises aspects of experience related to motivation and emotion.

THE STUDY

The data reported here derives from a study of disaffection with school mathematics which seeks to understand more deeply the subjective experience of disaffection beyond the notion of positive or negative attitude and other trait-like constructs. The study centres the focus on motivation and emotion, and was conducted from a constructivist and interpretative perspective of the learning of mathematics. In this way, it was primarily qualitative. Reversal Theory (Apter, 2001) was used as the main design and interpretive framework. The theory is a comprehensive account of personality, motivation and emotion and as such affords a basis for understanding affect centred on the subjective experience of the individual.

The theory proposes that there are eight such motivational states, organised into four oppositional pairs, which each represent quite different ways of experiencing the world. The eight states are:

- Serious (telic) versus playful (paratelic)
- Conforming versus rebellious (negativistic)
- Mastery versus sympathy
- Self versus other-oriented

Reversal Theory also gives an account of 16 primary emotions, that are related to motivational states and our experience of the world. The theory further proposes that we are in one of each pair of states at any one moment, but that one (or sometimes a combination of two) states is focal in our phenomenal field, in that it (they) dominate our experience at that moment. The theory also introduces a new construct to psychology – that of reversal itself. This says that we switch or reverse between states frequently.

The primary method for data collection in the study was the individual interview, although a number of instruments and procedures were adopted in and around the interviews to aid the elicitation of data. One instrument, called TESI-ME, adapted from the Tension and Effort Scale (Svebak, 1993), was used to survey 150 pupils and students on their experience of negative emotions. Individual responses were available for discussion at interview. The methods and instruments, together with some preliminary results, are described in more detail in Lewis (2013a). Forty nine young people (aged 14 to 18 years) were interviewed from two further education colleges and one school in the UK. The data from 15 of these young people has been analysed and presented as a series of case studies and also as an aggregate analysis.

Among the findings of the larger study were:

- The volatility of young people's relationship with school mathematics – affect is not trait
- It also shows the complexity and ambiguities within students relationship to school mathematics – balancing positive with negative aspects
- Evidence of the whole range of motivations and emotions being operative in mathematics classroom
- Disaffection ≠ unmotivated. Helen, for instance, is clearly disaffected, but she is highly motivated – a paradox explored very little in current literature
- However, negative affect does disable or de-limit learning
- Unexpected but significant evidence of self-regulatory and metacognitive skills in disaffected low achievers

PATTERNS OF MOTIVATION AND EMOTION

As indicated above, the results of the main study have been reported elsewhere, including to the working group at CERME 8. Here, and below, I will draw attention to a number of theoretically-based and empirically grounded notions and propositions that have emerged from the research, which can be collectively thought of as patterns of motivation and emotion. Focussing on state, as this study does, demonstrates that students' subjective experience of learning mathematics is highly volatile (at all levels of temporal granularity), dynamic and complex. However, like all complex systems, evidence of pattern does emerge, and it is the intention here to indicate a number of aspects of those emerging patterns.

Evidence of sequences and shifts in motivational state, including reversals, are found throughout the accounts, and these come with the associated and expected shifts in emotion. And although there is extensive evidence of all 16 primary emotions being active in the experience of these young people, including evidence of positive emotions such as pride, excitement, the evidence from the TESI-ME suggest that the negative emotions of anxiety, boredom and anger are more prevalent than any other emotions. This is interesting in that, whilst anxiety has been widely studied, boredom and anger have not.

Shifts in motivational state and emotion are in evidence in all of the accounts in this study, and these sequences can be quite individual. A 'typical' sequence (although there are many such sequences, and variations on them), often starts with the need to succeed at a task, coupled with a strong need to understand the context or correct procedure. A subsequent lack of progress can lead to frustration, which in turn leads to anger brought about by a reversal from the conforming to rebellious state. Typically, the performative and the affective aspects operate in parallel in this way.

Dominant narrative

The flavour of such sequences can be illustrated by the case of Liam, who is a disaffected year 9 pupil.

> *I panic quite a lot when I don't get it.*

By his own account, the sequence sometimes also ends in anger.

> *L - if I don't get it...if people are getting ahead...I'm always behind....and it gets quite annoying...I just wanna..be where everyone else is*
>
> *Gl – why is it annoying?*
>
> *L – cos everyone else can get on and I just don't understand...but some people get quite annoyed as well*

Perceiving oneself to be behind the others is a strong source of negative affect. In Liam's case it leads to anger. There is a sense that 'this is not right – it's not the way it's supposed to be.'

In motivational terms, his desire to be 'keeping up with the others' is an expression of competitive self-mastery. To serve this need he has to be able to perform the tasks set as well (and as quickly) as the others, and so he approaches tasks in a serious-conforming frame of mind. When the goal is threatened, because he doesn't understand or can't do it, the arousal increases and he feels anxiety or panic. Not being able to 'do it' disrupts his sense of conformity, and he reverses into rebelliousness, and this switches the emotion from anxiety to anger. Sometimes he asks for help, but being able to 'do it' appears to result in little pleasure in itself. The benefit appears to be that he is able to keep up with the others. At one stage he says "I'm always behind (the others)." Even if it is not literally true, it reveals how he often feels about the situation in his mathematics classes.

Liam's guiding motivational statement is:

> *I just wanna be where everyone else is.*

Since the notion of 'keeping up with the others' recurs time and again in Liam's account, it can be considered as a *dominant narrative*. The dominant narrative itself is located within the motivation-emotion nexus of the experience of the individual. In Liam's case the notion of 'keeping up with the others' is based on the motivational state combination of competitive self-mastery, and in the 'losing' mode, the associated emotion is anger leading to humiliation.

A number of subjects have demonstrated strong recourse to such a recurrent theme, which represents something of a behavioural attractor to which they return again and again in their narrative, which suggests that this theme has some strong significance in their subjective experience of school mathematics. Examples would include Anna's apparently ever-present need to redefine herself from a 'D' to a 'B' (see Lewis, 2013b) ; Scott's inescapable characterisation of his relationship to mathematics as 'struggle' (a word he mentions 17 times in a half-hour interview), and so on. Such dominant narratives seem to touch every aspect of affect, from emotion to attitudes, beliefs and even their identity as mathematical learners, thus demonstrating the complex and intimate relationships between affective constructs within their subjective experience.

Not all of the sequences in the data relate to performative-focussed states and emotions such as anxiety and anger. Helping others is seen by many students as a motivationally rich activity, which often provides some of the rare positive experiences for disaffected students.

For instance, here is Anna:

> 'it makes you feel good...because you get it and someone else doesn't...so you feel a bit proud...but if you're helping them...you feel a bit nice about it...does that make sense?'

When asked about the possible contradiction about feeling good when someone else is struggling, she replies:

> 'It's not like I can do it and they can't.....it's like I *can* (my emphasis) do it...and they can't...it's not like they're bad...not like ohmigod I got better than her.'

From her account, the progression of states appears to be:

— Self-mastery – competitiveness, and an attempt to do better than the others, leading to a sense of pride (if successful)

— She then notices the lack of progress in others (other-sympathy), which may trigger a sense of guilt

— This causes her to help her classmates (other-mastery), which in turn results in her feeling 'nice' (self-sympathy).

In this way, helping others can be seen to be a motivationally rich activity for Anna, since it satisfies a range of motivational needs – even though some of them are contradictory.

MOTIVATIONAL PATHWAYS

Motivational states, or combinations of states represent qualitatively different ways of experiencing and engaging with activities in a mathematics classroom. There appear to be a number of identifiable motivational pathways which, whilst they play out in highly individual ways, have some features in common.

A number of contexts have emerged that seem to characterise much activity and learning in mathematics classrooms, and each of these involves a typical or predominant *motivational pathway*. I describe two of these here in more detail.

The serious-conforming pathway

The first of these can be described as the serious-conforming pathway. It is characterised in the Table 1 below.

Nature of activity	Mathematical context	Motivational state	Motivational requirements	Positive affective correlates – if successful	Negative affective correlates – if unsuccessful
Procedural tasks	Procedure to be learnt and performed correctly. Speed and right answers rewarded	Telic Conforming Self- Mastery	Telic – that meaning, purpose or utility are established. Conforming – sense of duty. 'Correct' procedure to be followed Mastery – I understand, so I can do	Need to apply effort to overcome negative feeling in order to learn. Performing correctly results in a sense of relaxation/relief. A sense of achievement (if it is perceived to be important, or if it took effort to learn). A sense of pride at overcoming and winning	Anxiety, fear or panic when faced with challenge. Possible switch to anger if effort is unsuccessful. Sense of detachment or being excluded in case of failure, resulting in mastery-losing and sense of humiliation

Table 1: Mastery for a reason versus 'what's the point?'

Since this pathway is dominated by the serious (telic) state, it is the outcome, and not the doing of the task itself that is the source of satisfaction, and as such successful engagement and performance is maintained by metacognitive skills such as effort and persistence. Students engage in this mode because they perceive the outcome to be valuable and worthwhile as well as achievable. Developing a narrative of significance will enhance motivation in this mode.

This mode of engagement is by far the most usual mode referenced in classes in this study, and reported by subjects. For some, it appears there seems to be little variation. Where it becomes institutionalised, it can become the dull 'textbook and worksheet diet' of drill and exercises described so vividly by many of the subjects of this study.

It is also worth pointing out that any possible pleasure and satisfaction here is deferred. In the serious (telic) state, this is only likely to be available on successful completion of a task. The satisfaction (e.g. relaxation/relief) is a low arousal emotion, and thus is unlikely to be experienced intensely.

The playful-rebellious pathway

The second pathway or mode is the playful-rebellious route.

The notions of fun and excitement appear often in many of these young peoples' accounts, it seems clear that it is an important motivational need that can provide a source of motivational satisfaction. The evidence here is that it is not trivial, and not an add-on to make difficult tasks more palatable. Yet the mathematical education community has rarely had the language or the theoretical frameworks to discuss its importance. It has thus been trivialised and so relegated in importance. In many classrooms described in this study, it is shut off as a motivational opportunity. At the same time, there is substantial evidence in the data that students will often be in the playful state.

Here is Adnan:

> when I'm not just listening to a teacher going on and on... I'd rather have a teacher involved in some sort of humour... or not just doing maths but for example using maths in everyday life.... so it would make you think... do you know... the next time I come across the situation I can do it like this... and that's where excitement comes in and curiosity... like it's a real life situation and they're making it exciting by giving you this real life situation... (Adnan)

The mention of humour, excitement and curiosity are all characteristic of the experience of the playful state. In fact, humour can trigger the playful state, and it is interesting to note that real contexts can create the excitement that is so enjoyable in this state.

Nature of activity	Mathematical context	Motivational state	Motivational requirements	Positive affective correlates – if successful	Negative affective correlates – if unsuccessful
Open-ended task or problem to solve or investigate	Mathematical thinking and heuristic skills required. No necessary single right answer. Methods are undetermined and in control of student. Possibility of group working. Making connections, reasoning and understanding are privileged.	Paratelic Rebellious Mastery	Curiosity, real-world interest, challenge, game, unfamiliarity or novelty. Activation of exploration and discovery. Need to share within the group	Fun, excitement, enjoyment and immersion in the task at hand. Sympathetic satisfaction from working in a group.	Boredom if the challenge is too easy. If too hard, a reversal to telic could induce anxiety, or shift of focus to mastery-losing resulting in humiliation

Table 2: Engagement and pleasure through interest versus 'I can't be bothered'

Here are other examples that emphasise the point:

> 'at some point I felt a bit of curiosity because... I wanted to know... because there was so much important stuff...like dealing with money obviously... and then... I knew that would help me at some point in my life... I knew... I'd get a job... or if I'd get in a career like dealing with maths or... so I did get curious... and some of the lessons were interesting as well.....depending on the teacher in the classroom (Nadia)

> Miss B... she taught it as a game... for different people she put it in different contexts... like for me it was always football... like angles... and stuff... she used football to help me understand it... but for different people it was different things... she knew a lot about us... what interested us... some people who liked to have questions... then work it out... but other people want to do it a different way... she taught us all a different way... how we liked (Harry)

When people are in the playful (paratelic) state, goals and outcomes are not in the phenomenal frame. People engage in activity for the momentary pleasure it affords them, and thus they are more likely to be creative and spontaneous, and to be unmindful of risk. This is a highly desirable state in which to engage with mathematical contexts. There needs to be pedagogically sound and justified ways of incorporating this into the life of the classroom.

It enables creativity and pattern-spotting, particularly in a problem solving context. It is precisely where the 'rich learning' described in ACME (2012) comes from. Indeed it is possible to go further and to say that to be paratelically engaged with mathematics is a sign of affection for mathematics, since our interest and curiosity will enable us to engage without fear. The inability to do so is a litmus test of disaffection. Further, the poverty of mathematics curricula and pedagogy reported by these young people means that paratelic activity and engagement is not encouraged and enabled in so many mathematics classrooms.

That there is more evidence in this study of boredom than of any other negative feeling or emotion related to school mathematics, suggests that these young people spend a lot of time in the playful state, but are unable often to find legitimate outlet or expression of it in the context of the activities of the mathematics classrooms. It seems that many teachers don't appear to understand that they could harness this playfulness into productive activity by introducing elements of curiosity, gaming, unfamiliarity, something out of the ordinary, to increase the arousal in a positive way, thus prompting the interest and engagement of the students.

In the context of teaching practice, it is interesting to note that there is a paradox at the heart of the experience of playfulness. As Apter puts it:

> in order to experience excitement, then, we need both the possibility of danger and something we believe will protect us from it. (Apter, 2007, p. 31)

This sense of danger or threat is psychological and can be brought about by uncertainty and ambiguity. The sense of safety, which Apter labels the 'Protective Frame', can be created by a classroom climate which reduces the focus on right answers, and a humane and supportive environment, among other means.

SUMMARY

The study shows that a deep account of the experience of learning (or not learning) mathematics can be provided by focussing on motivational state, and the associated emotions. Although the data is qualitative, and although stability as used in the notion of trait has been disregarded here, it is still possible to discern pattern in the accounts of these young people. In this paper, I have focussed on three theoretically-based but empirically grounded notions. Dominant narrative is exhibited by a number (but not all) of the participants in this study. It is an interesting phenomenon which deserves further study, and which may have implications beyond mathematics education. The two motivational pathways described here can be thought of as qualitatively different modes of engagement with learning mathematics. The serious-conforming pathway describes an emphasis on the development of competence (mastery), and outcome-focussed disposition which is consistent with much current research. On the other hand, the distinctive playful-rebellious pathway not only represents a qualitatively different mode of engagement, but at the same time is much less recognised or studied. This is not to claim that it is new. It is possible to recognise the ideas of Dienes in the notion[1], and, more recently, Goldin and colleagues (2011) have described a phenomenon with some similar characteristics in his engagement structure 'I'm really into this'. It would be interesting to examine further the presence and efficacy of this pathway in learning mathematics.

Emotions as an orienting experience

Peter Liljedahl

Simon Fraser University, Burnaby, Canada, liljedahl@sfu.ca

In this article, I first introduce data collected from 38 prospective elementary teachers after an intensely negative emotional experience preparing to play a game called Around the World. From these data emerges a picture of these prospective teachers being deeply affected by this experience. To try to understand these changes I present a theory by Leont'ev. This theory, based on Vygotsky's cultural historical theory, looks at the relationship between motives, activity, and emotions. Using this theory, I argue both theoretically and empirically that what has actually changed for these prospective teachers are their motives. More specifically, the hierarchy of their motives. The results contribute to work in mathematics education that anchors emotions in a theoretical framework and links them to other constructs in the affective domain.

Keywords: Emotions, participationist, motives.

INTRODUCTION

In the spring of 2010, Kim Beswick visited my EDUC 475 class for a day. EDUC 475 is the mathematics method course for prospective elementary school teachers. Each section of the course usually has 30–35 students, 90%-95% of whom are female. On the particular day that Kim visited we were discussing basic operations on single digit numbers – addition, subtraction, multiplication, and division. The goal of the lesson was to get the students to experience methods of teaching these operations other than memorization and rapid recall, which is the only method familiar to many of them.

Although the lesson has this goal, this only defined the general direction I wanted to go in. During the actual lesson I draw on a large repertoire of activities and discussion points that tumble out in a, more or less, improvised order. This allows me to more effectively respond to my perceived needs of the specific group of students at that specific time.

As it was, many of prospective teachers I was teaching the day Kim visited, although seeing the merit to the many alternative methods I was modelling, were still not ready to abandon the 'drill' method of teaching fluency of the basic facts. Many had mentioned at the beginning of this lesson, as well as in the previous lesson, that they had regularly used *The Mad Minute* during their practicum. This was problematic to me. The *Mad Minute* is a test, usually given once a week, where students are challenged to answer 30 questions in on minute. Their scores on these tests are often recorded in some public fashion and the top achieving students are rewarded for their achievements. The possible negative consequences of this method are many, yet it continues to be practiced for its efficiency, simplicity, and tradition ... and parents like it.

To emphasize the potentially negative consequences of this method I did something I had never done before. After the pre-service teachers returned from a break I gathered them around me. I told them that we were going to do a basic facts activity. The way this activity would work is that I would point at one of them and ask them a basic multiplication question (3 × 4, 6 × 8, etc.) and they would have two seconds to respond. If they responded correctly in that time they would be allowed to sit down. If they failed to give response, or their response was incorrect, they would remain standing and I would come back to them after I had gone all the way around the class. This would continue until all the students were sitting.

This game, as it is referred to by practicing teachers, is called *Around the World*, and is often used, in conjunction with *The Mad Minute*, as a way for students to practice their basic facts. Unfortunately, it has the same sort of public shaming qualities that the *Mad Minute* does.

The pre-service teachers gathered around me were, as a group, visibly uneasy. There were a few who seemed excited at the prospect of playing a 'game' and the thrill of competition. But the vast majority were horrified at what was about to happen. When the tension had built to a crescendo I pointed at the first prospective teacher and, instead of asking a basic multiplication question, asked, “How are you feeling right now?” And then, to the whole group, “How are all of you feeling right now?”

The relief in the room was tremendous, and the ensuing conversation was beyond anything I had expected. The experience of almost having to play *Around the World* was transformative for these soon-to-be teachers who talked about how they NOW understood how negative this game—and *The Mad Minute*—could be. For over an hour they talked about their past experiences, sharing the negative impact these types of ‘games’ had on them as learners. A few of them shared their positive experiences with these types of activates, but even then quickly acknowledged that their enjoyment was not worth the price of misery that the rest of the students had to pay. We discussed why parents liked these ‘games’ and ways, as future teachers, to deal with that. In the end they vowed, individually and as a group, that they would never do this to their future students.

After the class, in debriefing the activity with Kim, we both concluded the obvious – the prospective teachers had had a powerful emotional experience and that that experience had caused wide sweeping changes in their intended practice (Liljedahl, 2008). But, we also concluded that we currently had no theoretical framework to make sense of this experience.

In mathematics education research in general, and in affective research in particular, emotions remain a largely unresearched and not-well-understood construct. The little research that exists are “sidelights rather than highlights of the studies” (McLeod, 1992, p. 582).

As such, we decided that we needed to recreate the phenomenon and to gather data on it.

METHODOLOGY

So, in the spring of 2012, working with a new group of 38 (35 female and 3 male) EDUC 475 students, I recreated the *Around the World* activity. As mentioned, EDUC 475 is an elementary mathematics methods of teaching course. It runs for 13 weeks and is comprised of 13 lessons – one each week. Each lesson is four hours long and is typically designed around a number of activities and resultant discussions. Between lessons, students are assigned readings and prompts to be responded to in a reflective journal. As with the previous class, many of the prospective teachers in the current class had acknowledged that they had used *The Mad Minute* or the *Around the World* activities during their practicum, either on their own initiative or at the urging of their sponsor teacher.

As such, in the fourth week of classes I once again ran the *Around the World* activity. This time, however, instead of immediately going into a discussion I did something different. As the tension built to a crescendo I pointed at a student and asked her how she felt, and then I immediately asked her, and all her classmates, to sit down and write in their journal how they felt at that moment. The students wrote for 10–15 minutes. We then had a whole class discussion much as I had led for the class two years prior.

At the end of the class they were assigned a further journal prompt:

> Discuss your experience in today’s class around the issue of multiplication. What did you feel when I sprung the “stand up and get ready to answer multiplication facts” activity? What sort of self-reflection did you go through? How do you feel now after we debriefed it?

Towards the end of the course, the students were given a further writing prompt potentially related to the *Around the World* activity and discussion.

> Now that this course is almost over what is something that you will NEVER do in the teaching of mathematics? Why? What is something that you will ALWAYS do? Why?

Taken together, data consists of the relevant entries from the written journals of these 38 prospective teachers. These data were analysed using a constant comparative method (Glaser and Strauss, 1967) to emerge themes pertaining to their emotions and the effect of those emotions, both short term and long term.

RESULTS

For the most part, the game of *Around the World* created a very negative emotional experience for these prospective teachers.

Fear

Fear, in one of its many forms, was one of the most commonly expressed emotions immediately after the activity.

Misha — Terrified! I can't do mental math very quickly and I don't like being the centre of attention when under scrutiny. The only thing I could think was "I'm going to be the last one standing". I don't want to look slow in front of my peers and teacher. Through my education career I sit in my seat praying not to be called on.

Allison — Mortified. I don't like to be wrong or feel embarrassed in front of my peers. It can be extremely difficult to get the answer right as I'm too busy thinking about me, or what they are saying to care about the problem. Eventually I feel I'd just guess to get it over with.

Anxiety

The other emotion frequently expressed is anxiety.

Beth — Heart racing anxiety! The thought of being picked on and not knowing gives me the heebie jeebies, especially in a subject that is probably my weakest. Being that it is multiplication and is something that I probably would get right doesn't really help shake the feeling you get when you know that there is pressure to perform. [..] If I feel like this at 23 how would a kid feel?

Jocelyn — I am feeling really anxious and nervous. I am worried about being embarrassed about not being able to answer the multiplication question in front of the class and I am also really worried about being the last person standing.

Nervousness

Nalah — I felt nervous because I might not know the answer to the multiplication question he might ask. [..] While we were standing there waiting for Peter to ask, I was thinking back to grade two and three and how we played the game *Around the World*, and how nerve racking it was.

Defeated

Anne — It also reminded me of a time when my grade three teacher called me to the front of the class to answer a question. She knew I wouldn't know it, but I had to do the walk of shame to the board only to admit to the whole class that I didn't know the answer. I dreaded going to class. I just remember being in class and feeling defeated by math.

TEACHER CHANGE

These very negative emotions were not fleeting. Despite the fact that during the course we engaged in over 50 activities and discussions, and read over 400 pages mathematics education literature, six weeks after the *Around the World* activity, 24 of the 38 prospective teachers in the course chose to discuss this specific activity, and the emotions it triggered, when responding to the prompt about something they would never do in their teaching.

Misha — Something that I will NEVER do in the teaching of mathematics is put students on the spot and force them to answer questions. Like many other people, I have experienced embarrassment from being put on the spot and answering incorrectly. I understand how low it can make; a student feel and I don't want to be the one to make my class feel that way.

Sofia — In teaching math I will never use the Mad Minute to drill students on their multiplication tables. The costs to many students outweigh any benefits to a minority of students.

Jocelyn — Now that the course is over, I have discovered that I will never make my students do any sort of drill or mad minute that may deflate their confidence and cause them to want to avoid mathematics. I realize what effect 'mad minute' exercises had on me as a math student and when Peter simulated a mad minute situation, I felt terrified and extremely anxious. I would never want my students to feel that kind of panic and fear. As a teacher, I hope to foster a love for learning mathematics and want to create an environment whereby my students feel confident and safe.

Even those who were originally excited by the game talked about the negative emotions they say their classmates experience.

Alison To be honest, I was excited to play the game. But I can see how an activity like this could bring high levels of anxiety for students in a class that are insecure about their amount of knowledge or skills with respect to what is being quizzed on the spot. I did not feel panicked because I am confident that my multiplication skills are fine. [..]Something I will NEVER do when I teach math will be multiplication drills. It traumatizes children that are not finding this activity successful, and it could give them a bad taste for math for the rest of their life.

Of the 14 who did not speak of the *Around the World* activity explicitly in their response, 12 made commitments that were tangential to some of the ides that cascaded from subsequent discussions on the learning of basic facts in general, and assessment in particular.

Anne I will NEVER use assessment as a way to rank students.

Khaly I'm not afraid of mathematics any more, to learn or to teach. I also think that mathematics can actually be fun. I am excited to teach my new students (when I get my first class). Show them that math is not as scary as it seems.

Taken together, 36 out of the 38 prospective teachers, despite many having used it in their practicum, vowed to never use *Around the World* (or the *Mad Minute*) in their future practice as teachers. For them, their own experience with this activity had triggered very negative emotions, sometimes reminding them of similar activities and emotions from when they, themselves, were children. These emotions were not only enduring, but also instrumental in changing things in the prospective teachers' practice.

But what exactly is it that has changed for these teachers? This is my research question. Given that they don't actually have a classroom in which to enact these changes we cannot say that it is their practice that has changed. Perhaps it is their intended practice that has changed? But what is backstopping this intention? Intentionality is a reification of deeper constructs. The question is, what is the construct that grounds these intentions, that was deeply affected by the emotional experience that these teachers had when being placed in a position of having to play *Around the World*? To answer these questions we need to look more closely at emotions.

EMOTIONS

Emotions, as theoretical construct in mathematics education, are seen as the fleeting and unstable cousins of beliefs and attitudes (McLeod, 1992). They are either a reaction to an experience (McLeod, 1992) or a reaction to an interpretation of an experience (Mandler, 1984). Regardless, emotions are acknowledged to affect learning in general (Zan, Brown, Evans, & Hannula, 2006) and cognitive processing in particular (Hannula, 2002). Over time, negative emotions can reify into more stable and disassociated manifestations of fear, phobia, and hatred (DiMartino & Zan, 2012; Tobias, 2009), each of which will have an effect on actions (Hannula, 2002; Tobias, 2009).

That emotions exist, and that they simultaneously emerge from, and shape experience, is clear. That these emotions then regulate future actions is also clear. What is not clear, however, is how this happens. What psychological mechanisms link emotions to actions? The answer to this lies not in the abstract.

> The variety of emotional phenomena and the complexity of their inter-relations and sources is well enough understood subjectively. However,

> as soon as psychology leaves the plane of phenomenology, then it seems that it is allowed to investigate only the most obvious states. (Leont'ev, 2009, p. 168)

That is, emotions must always be considered in the context of the phenomena in which it occurred.

EMOTIONS AND ACTIVITY

Consider a wolf in the wild. This wolf has a vital need to eat, and this need to eat drives him to hunt. These hunts result in him catching mice, rats, and rabbits. This then shifts the abstract need to eat into a concrete need to eat mice, rats, and rabbits. Then one day, he catches, for the first time, a duck. This, in turn, changes his need to include ducks in his menu of things he eats. And so on. Each time the wolf, through his hunt, encounters a new animal that he can eat, his needs change.

For Leont'ev (2009), such is the relationship between needs and activity. As humans, our vital needs, abstract and unrefined, drive our activity to satisfy these needs. These activities, grounded in phenomena, in turn gives an object to the needs.

> The fact is that in the subject's needy condition, the object that is capable of satisfying the need is not sharply delineated. Up to the time of its first satisfaction the need "does not know" its object; it must still be disclosed. (Leont'ev, 2009, p. 161)

This recursive relationship between needs and activity, each driving the other, expands and refines both the object of need, and the need itself, forming what Leont'ev (2009) refers to as *concrete-objective needs*. This, in turn, changes the subsequent action.

> [..] it is understood that changing the concrete-objective contents of needs leads to a change in methods of their satisfaction as well. (Leont'ev, 2009, p. 162)

Sometimes, however, this recursive cycle shifts the need from the object to the activity itself, forming what Leont'ev (2009) calls an *objective-functional need*. These needs, such as the need to work, to be productive, or to be creative, for example, do not displace the original needs that spawned them, but come alongside them as additional new needs. It is important to note, however, that not all objective-functional needs come from a newly acquired focus on activity. Likewise, not all vital needs are based on objects. In a cultural historical framework, action oriented needs can be part of the milieu. For example, the need to be subservient, to strive for physical perfection, or to always clean, can be *a priori* embedded needs within a person's specific cultural upbringing. Regardless, activity and "the satisfaction of the need" helps to delineate it.

For Leont'ev (2009), these delineated concrete-objective and objective-functional needs, in their ideal and reflected forms, are what he calls *motives*. And despite the fact that the language on needs and activity are shot through with willfulness and implied consciousness, our motives are not always known to us. Further, our activities are multi-motivational.

> Such breaking down is the result of the fact that activity necessarily becomes multi-motivational, that is, it responds simultaneously to two or more motives. (Leont'ev, 2009, p. 169)

They organize themselves in hierarchies, and these hierarchies define, to a great extent, an individual's personality.

> A division of the function of sense formation and simple stimulation between motives of one and the same activity makes it possible to under-stand [sic] the principal relationships characterizing the motivational sphere of personality: the relationships of the hierarchy of motives. This hierarchy is not in the least constructed on a scale of their proximity to the vital (biological) needs in a way similar to that which Maslow, for example, imagines: The necessity for maintaining physiological homeostasis is the basis for the hierarchy; the motives for self-preservation are higher, next, confidence and prestige; finally, at the top of the hierarchy, motives of cognition and aesthetics. (Leont'ev, 2009, p. 170)

Finally, for Leont'ev (2009), *emotions* act as an internal signal within this relationship between our motives and the actions that work satisfy them. That is, despite the fact that motives could be unknown to an individual, when they are realized there is an emotional response that signals that success has been achieved.

> Here we are speaking not about the reflection of those relationships but about a direct sensory reflection of them, about experiencing. Thus they appear as a result of actualization of a motive (need), and before a rational evaluation by the subject of his activity. (Leont'ev, 2009, p. 166–167)

These emotions have the potential, then, to reorganize the hierarchical order of these motives.

For example, a businessman has a goal to earn more than $100,000 in his job as a sales manager. One day, his boss calls him into his office and tells him that he is receiving a raise and will now be earning $110,000 per year. The man is elated. Later on that same day he overhears that his colleague has also been given a raise and will now be earning $120,000. Suddenly, a feeling of dread comes over him. Reflecting on this negative emotional response the man comes to see that what he really wanted was to be the best sales manager in the company. Earning over $100,000 a year was not the primary goal. The primary goal was to be the best sales manager in the company. But that goal was hidden from the man.

In this example, the man's surprising emotional reaction to hearing that his colleague was making more than him left him with an "emotional residue" (Leont'ev, 2009, p. 172) that moved him to engage with his hierarchical structure of motives, and to try to figure out what it is that is really driving him. In so doing, a motive that he was not previously aware of revealed itself. This results in a re-orientation of motives, which is tantamount to a re-orientation of his personality – all of which is triggered by his emotional response to an experience.

As such, in Leont'ev's (2009) framework, emotions serve as the orienting mediator between action and motives, and between motives and personality. In short, an emotional response to a specific experience draws the attention of the individual to their motives and allows them to begin the cognitive process of re-orienting their motives hierarchy.

EMOTIONS AROUND THE WORLD

Leont'ev's theory of emotions, motives, and personality, situated within the cultural-historical paradigm of individualized activity theory allowed me to look anew at the data from the prospective teachers playing *Around the World*.

All of these teachers wanted to be good teachers. This was one of their many motives. But they also wanted to please parents, have their students be good at basic multiplication facts, and to not make their students anxious or fearful, to name a few. These many goals were organized into hierarchies, unique to each prospective teacher. For the most part, these prospective teachers were not aware of many of their motives. Instead, they were fixated on their current goals of learning how to teach mathematics, getting good grades, and/or having their knowledge experience acknowledge. The "emotional residue" left from their experience playing *Around the World* helped them to see some of these motives. And it helped them to re-orient them.

In what follows I provide a brief case study on one of the prospective teachers—Tara—selected for her clear articulation of motives in her writings. Tara's case is analysed through the lens of Leont'ev's theory on motives, emotions, and personality (2009).

Tara

Immediately after the *Around the World* activity Tara wrote that she was feeling a little anxious.

> Tara I'm feeling a little anxiety, because [she] did not want to look stupid if [she] got it wrong.

However, she also saw merit in this activity.

> Tara As a teacher I see the value in this activity. Students must be 'switched-on' and engaged. It forces them to use their brains and everyone must participate. The likelihood of everyone getting the correct answer is unlikely so no one will feel bad if they don't get to sit down. It also creates a competitive environment and opportunity for kids to shine.

The hierarchy of motives from Tara's post-activity journal indicates that students being 'switched-on' is one of the primary motive for her as a teacher (see Figure 1).

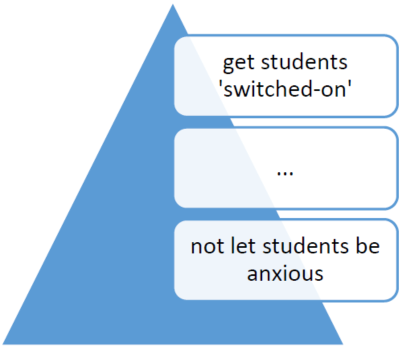

Figure 1: Tara's initial hierarchy of motives

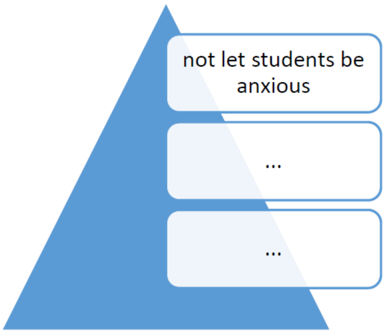

Figure 2: Tara's final hierarchy of motives

Later that night, when responding to the journal prompt her motivations had changed somewhat.

> Tara Today when Peter sprung the "stand up and get ready to answer multiplication facts" activity, my first feeling was fear and anxiety. I was worried I'd get the answer wrong and look stupid in front of the class. [..] This exercise made me think about my own classroom, how or whether I would use an activity like this. I think I would, that being said, would my students feel the same anxiety I did? Most likely they would, but I think after getting into the game they would enjoy the competition. The environment I plan to create in my class would assure them that I was not having them do this activity to humiliate them but to use mental calculation and practice their skills.

Tara's new hierarchy of motives (see Figure 2) can now be seen as having concern for her student's anxiety at the top and the motive to 'switch-on' students has dropped away. The few hours that she had to reflect on her experience with the activity and the *emotional residue* it left has seemingly caused her to re-orient her motives.

And this residue endures. At the end of the course Tara continues to talk about her motive to not let students become anxious, although not quite as explicitly.

> Tara I will never just stand at the front of a class and 'teach'. [..] Basically, I won't be afraid to teach outside the box ... the traditional box that I learned in and that we all know so well. I want to inspire my students. [..] I now know math doesn't have to suck ... the way it did for me in grade school.

CONCLUSION

So, what is it that changed for Tara and for the rest of the prospective teachers who 'played the game' of *Around the World*? One possible explanation is that it was their motives. More specifically, their hierarchies of motives were re-oriented – re-oriented by the emotional residue left after the intensely negative experience of being told that they would be playing *Around the World*. For 36 out of 38 of these prospective teachers, such a re-orientation resulted in a motive to not cause their students anxiety took its place as the primary motive at the peak of the hierarchy. This was not a new motive, but rather a motive that promoted up the ranks as a result of their emotional experience. And even after six weeks, and after 50 activities and 400 pages of literature, the concern for student anxiety remained as the primary motive. Leont'ev's (2009) theory allowed us to view emotions, not as fleeting abstract notions, but as robust and powerful contributors to the motives and future action cycle.

ACKNOWLEDGEMENT

The results of the research in this paper were presented, in part, as a keynote at the Mathematical Views (MAVI) conference in Falun, Sweden in October 2014.

"Let's play! Let's try with numbers!": Pre-service teachers' affective pathways in problem solving

Francesca Morselli and Cristina Sabena

University of Turin, Torino, Italy, francesca.morselli@unito.it, cristina.sabena@unito.it

The paper focuses on the intertwining between affect and cognition in pre-service primary teachers, with the twofold goal of studying teachers' affect when facing problem-solving activities and of exploring paths for teacher professional development. 81 future teachers were proposed problem solving activities with specific "affective documentation" requests. We present here the first results of data analysis, and describe the main affective pathways emerged. Results are then discussed also with respect to methodological issues and to implications for teacher education activities that include the affective factors as relevant variables.

Keywords: Emotions, affective pathways, problem-solving, teacher education.

INTRODUCTION AND THEORETICAL BACKGROUND

This paper originates from our double interest as researchers in mathematics education and as teacher educators and investigates the intertwining between affect and cognition in problem solving processes carried out by future primary teachers.

Starting from the seminal work of Polya (1945), problem solving is a crucial issue in mathematics education (Schoenfeld, 1992), and constitutes also a fertile ground for studying the influence of affective factors in mathematical thinking processes (McLeod & Adams, 1989; Gómez-Chacón, 2000; Furinghetti & Morselli, 2009; Pesonen & Hannula, 2014). In fact, the solving process encompasses cycles, deviations and stops, and is influenced by resources, control, methods, heuristics, and affect (Carlson & Bloom, 2005). In particular, DeBellis and Goldin (2006) speak of the *affective pathways* as "established sequences of (local) states of feeling that interact with cognitive configurations" (ibid, p. 134). They underline also the importance of meta-affect, defined as "affect about affect, affect about and within cognition about affect, and the individual's monitoring of affect through cognition" (*ibid.*, p. 136). From a methodological standpoint, studying the interplay between affect and cognition is quite a complex issue. Pesonen and Hannula (2014) use screen recordings and emotional states automatic recognition, to study upper secondary students problem solving with dynamic geometry software. Other approaches are based on self reports or self study. Gómez-Chacón (2000), for instance, proposed the Problem Mood Map "for the diagnosis of emotional reactions and the subject's self-evaluation" (p. 152). In her study, local affect is self evaluated and registered by students during and at the end of the mathematical activity, by means of a special iconic code. The aim of such an instrument is to provide teachers information on students' affect during problem solving, but also to "foster in the pupil an awareness of his own emotional reactions" (p. 153).

The affective dimension plays a crucial role in future mathematics teachers, because it can endanger the success of their professional education processes and their future teaching processes (Hannula et al., 2007). Many studies have been arguing that what teachers believe and feel have a clear influence on what students believe and feel (e.g., see Hodgen & Askew, 2011). This issue is especially crucial for teachers at the primary school level, since in most countries they are not specialist in mathematics, and may have developed negative experiences with the discipline in their past experiences as students (Di Martino & Sabena, 2011; Lutovac & Kaasila, 2014). Coppola and colleagues (2013) have focused on future teachers' *attitude towards mathematics and its teaching*, stressing the importance of considering emotional disposition, view, and perceived competence—components of attitude, following Di Martino and Zan (2010)—both with respect to mathematics and to its future teaching. In this research, great attention is given to the link between the *past experiences* of pre-service teachers as students and their *future perspectives* of becoming mathematics teachers: also pre-service teachers with negative past experiences may show positive attitude towards its teaching (Coppola et al., 2013).

In our view, it is crucial promoting in future teachers the reflection on the intertwining between affect and cognition, and to work on the meta-affective dimension, as important steps in their professional development path. In this paper we present the first analysis of one activity conceived within this perspective, i.e. the problem-solving with "affective documentation" requests.

METHODOLOGY

The context

The study was carried out on the university students attending to the first year of the master degree to become kindergarten and primary teachers of the University of Turin (academic year 2013–14), in which the authors are in charge of the Mathematics Education courses. Throughout the math education course, pre-service teachers were asked to engage in various kinds of activities (problem posing, problem solving, analysis of children's solutions, classroom discussion transcripts analysis, and school textbooks analysis), individually or in group-work, as well as in collective discussions mediated by the teacher educator.

A preliminary study on prospective teachers' affect, performed according the model of the attitude towards mathematics and its teaching, suggested that pre-service teachers education should act in two ways: in *continuity* with respect to the need for a personal reconstruction with the discipline ("math redemption" in Coppola et al., 2013) and with the beliefs about the importance of affect in the teaching and learning processes, but also in *discontinuity* with the widespread procedural view of mathematics (Morselli & Sabena, 2014). On the base of these results, we set up a series of three problem-solving activities, coupled with specific "affective documentation" requests.

The affective documentation requests

We set up problem-solving tasks with specific additional questions about the *description of the solving process* and the *description of the emotional states* (affective documentation request) perceived in three different moments: at the reading of the text, during the solution phase, and reconstructed at the end of the activity. To this aim, specific open questions were inserted on the working sheet. The first question was immediately after the text of the problem: *"Describe how you feel when reading the text"*. Then, the solvers were asked to report their solving process *and* emotional state: *"Now try and solve the problem... Don't use another sheet, try to write down here all your attempts, thoughts and FEELINGS when solving the problem (your reasoning, emotions, blockages...)"*. Finally, once reached a solution, they were asked to write down the story of the solving process: *"Now, tell the story of your solving process, describing as much as possible the emotions you felt during the process"*.

This methodology has some common points with Gomez Chacon (2000)'s instrument, since the final aim is to gather information on local affect and also to promote meta-affect during and after the solving process. Also, our approach has some links with the teacher education interventions performed by Chapman (2008), where self-study has a key role. One way of fostering self-study is asking students to narrate stories of their solving process. Affective documentation can be considered also as a special case of story.

Our approach has the double aim of studying the intertwining between affect and cognition, and of making pre-service teachers more and more aware of the influence of affect during mathematical activities, in order to increase their ability to fruitfully manage it. Thus, asking solvers to document their own thoughts and emotions, although a demanding and non-neutral requirement, was valued also for its meta-affective outcome. It is important to underline that prospective teachers were not used to such a kind of request.

The 1089 task

During the course we presented three problems with an increasing complexity as regards the expected solving processes; also the requests of affective report are made more and more explicit. Here we focus on individual reports to the 1089 problem, the third presented to the future teachers (text inspired by Coles, 2013):

> Pick any three digit number (e.g. 752) with 1st digit bigger than 3rd. Reverse the number (in

the example, 257) and subtract (in the example, 752-257=495). Reverse the answer and add (in the example 495+594). [*the example is also written in column; the final result, 1089, is written*]

a) Now, try with another three-digit number (with the first digit greater than the third one) and do the same procedure: what result do you get?

b) Can you find a result that’s is NOT 1089? Why?

To answer question a) it is sufficient to carry out the same procedure as in the worked example. Question b) is the real challenge. A first exploration on numerical examples may lead to a counterexample (for instance, starting form 423 one gets 198 as final result). Once found the counterexample, the problem is solved; nevertheless, expert solvers could go on with the reflection, in order to see whether it is a sort of “isolated” counterexample or there is a regularity in the set of counterexamples. Indeed, all 3-digits numbers where the first digit is equal to the third digit plus 1 are counterexamples. Moreover, for all the counterexamples the result is 198. One could even come to a general conjecture: if the starting number of the type “first digit is equal to the third digit plus 1” the result is always 198, otherwise the result is always 1089. In the case in which the solver finds all numerical examples that end up always with 1098, she/he is expected to move from an explorative phase to the formulation of a conjecture, and the search for a justification on the general plane. This passage from numerical examples to mathematical argumentation was crucial to the aims and contents of the teacher education course.

Research questions

We explore the potentialities offered by the “affective documentation” requests to research affect in mathematical problem-solving. At the same time, we investigate whether such kind of tasks for pre-service teachers may have professional development value.

The research questions guiding the study are: 1) What affective pathways emerge? How do they intervene in the solving process? 2) Is it possible to establish some link between attitude towards mathematics and affective pathway? 3) What indications for teacher education come from the intertwining of solving and affective pathways?

In this paper, we will face the first question, and try to get some insight on how to direct future research in order to tackle the other (more ambitious) questions.

ANALYSIS

The 1089 task was faced by 81 students (all those who were attending the specific lesson). As usual in the lessons, students were allowed to collaborate in small groups: actually most of them chose the group-work; however, they had to fill the sheet individually and to write down the names of the groupmates. The subsequent qualitative analysis is performed on the individual reports.

The first approach to the problem

Considering the emotional reactions at the reading of the text, 48 future teachers (59%) declare only positive emotions, while 13 (16%) declare only negative emotions. The most quoted emotion is *curiosity*, mentioned in explicit way by 35 students (43%). Curiosity (but also incredulity) comes often along with the *cognitive needs* of understanding and discovering, which push towards undertaking with trust the resolution of the problem. An example is Schirry: “*I feel curiosity and desire of discovering, which push me to engage in solving the problem as a challenge*”.

Among positive emotions we remark also *astonishment*, indicated by 11 students. In some cases, astonishment is due not so much to the content of the problem, but to the novelty given by the typology of the problem (Betty: *“I feel astonished because I never focused on these types of problems”*). Among the students that signal mixed emotions (i.e. both positive and negative) we find mostly curiosity and interest combined with puzzlement (FedePeri: “*At the first reading I feel a bit of puzzlement, curiosity about the outcome and desire of trying with other numbers to discover if the results is always the same*”). In these cases, puzzlement, if accompanied with positive emotions such as curiosity, can constitute an important engine for the solving process, pushing towards the exploration phase. Some students welcome the activity even with enthusiasm, underlying its disruptive character with respect to the mathematical activities of their past experience (Amy: “*Let’s play! Let’s try with numbers! No proof for which it is needed to have studied so much!*”). Though rare (3 cases out of 81), this kind of enthusiastic welcome to a complex problem out of classical schemas can be considered as another sign encouraging us in continuing in this direction, on an intervention plan. On the other hand, also the few students who indicate only negative emotions do undertake the solving process, with some success (possibly due to the collaboration with their mates during the group-work).

Finally, some students, rather than indicating an emotional aspect, underline their cognitive needs when facing the problem. In particular, some of them express the necessity of reading the text several times. Sometimes we can trace the reference to interiorized schemas, which guide the solving process (Lia: “*I had to read the text several times, because during the first reading I try essentially to seize the general sense of the problem*”), and even the description of the kind of performed reading, as G.C.: “*I had to read the text several times lingering especially on the key-words and on the example. Once understood the text, I thought how to solve the problem*”. Students who quote the necessity of reading carefully and several times the text, typically show also strong elements of meta-cognitive control over the solution.

All the aforementioned examples refer to an intertwining between text reading (as a first step in the problem solving process) and *emotional disposition* (one component of the construct of attitude). Other examples refer to the role of *perceived competence* (another dimension of attitude) in text reading: a sense of tranquillity is juxtaposed to the awareness of knowing how to face what is requested (perceived competence), while restlessness and discouragement are quoted when the students foresee, by the first reading, not to be able to solve the problem. Some students make an analytical separation between the two requests of the problem, declaring opposite feelings in relation with opposite competences perceived to face them; an example is Chi: “*For what concerns the first part (the first question) I can say I am quite tranquil, because the request is clear and manageable. The problems come out with the second request, because I do not feel I am able to give a valid argument for that*”.

The solving process

The specific formulation of the task, providing a precise indication on how to start the solving process, appears to prevent “initial blocks”. The first solving steps engage the students a lot, on the one hand thanks to their procedural nature (a kind of mathematical activity in which the students feel at easy, as it emerged from the questionnaires); on the other hand, the task allows for a certain freedom for the exploration. This latter aspect is underlined as a positive factor by some students, as Lavixx94: “*It is a problem which allows us initially a certain freedom in our choices and this can be a positive factor that does not create anxiety in solving it, providing already given numbers to solve. One can so get to solve the passages in a quiet way*”. The second request (*Can you find out a number…*) is the actual core of the task. Some students start the exploration without any well-defined goal; some others are instead oriented since the beginning towards finding out a counter-example. As concerns the emotional aspects, we remark that outcomes that are *analogous* from the mathematical point of view are accompanied by very *different* emotional reactions, ranging from tranquillity to frustration, as we detail below.

Let us consider first those who obtain always 1089 (32 out of 81). Some of them are comforted from the regularity of the result, and as a consequence pushed to exploring and understanding. Others are satisfied with finding out other examples giving 1089, but feel stuck in proving it. In few cases (5) the reference to the need of a proving phase is completely missing, while a sense of amazement is the final step of the process. It is the case of Elis94, who checks only one example and comments “*Amazement, we did not think that it turned indeed into 1089!*”, but also of Estestest, who explores with six numerical examples. A third category is formed by those who feel sad, frustrated, or even angry for not finding out any counter-example (Martitea93: “*I remain astonished because I cannot realize of not being able of finding out a starting number that does not give 1089. I felt so to say also some anger*”). In the last two categories we can signal a lack of *knowledge at a meta-level on the mathematical activity*, which would lead to recognize a regularity in the absence of the counter-example, and hence to searching for a general explanation. Probably those who feel frustrated are too much focused on the question “Can you find out…”, as if it were a rhetoric question (“*Surely I have to find it out!*”). In this case, the emotional reaction would be strictly related to the *problem formulation* or to the *problem interpretation*: this appears to us a viable route to work on with the students, in an intervention perspective.

The majority of the students (59 out of 81) found out one or more counter-examples (leading to 198). An analogous range of emotional reactions, from surprise to puzzlement, can be detected. In other terms, we want to stress that it is not the result *per se* to provoke a certain emotional reaction, rather its interpretation within the mathematical activity, which in particular is determined by one's own *expectations on the problem* and *meta-mathematical knowledge*.

Dually, the same emotion may be linked to very different behaviours in the solving process. The most meaningful case relates to *astonishment*: it is sometimes indicated as final emotion, not stimulating further reflections (especially in students who obtain always 1089), whereas in other cases it is the engine for questioning and continuing the mathematical work (DadiLuca: *"With this example I don't find 1089 and I feel a sense of astonishment. Will it maybe be because the 3rd digit is less than the 1st only of 1?"*).

Generally, we can observe that the positive emotions, when are the *only* mentioned emotions, are not necessarily associated with a good solving process or high quality mathematical activities. In our data we can trace a serious *dark side of positive emotions as the only emotions*: students indulge on their positive feelings, do not receive boosts to further verify their results, to question their process, to check it. Their solving process burns out early, with little control at meta-cognitive level. Furthermore, it often happens that the negative emotion is felt later, when the students talk with their mates or the teacher, and realize their low performances.

On the contrary, those who indicate only negative emotions during the solving process do not always carry out poor or uncorrected mathematical activities. In many cases, an initial *negative* reaction is followed by a *positive* reaction associated with a discovery. For instance, Kika narrates in this way the story of her solution: *"At first we took numbers at random, seeing that it always came out 1089, hence we were resigning ourselves to the fact that it always came 1089. Then we tried to take numbers in sequences (e.g., 421-422-423) and we noticed that the results changed with 423, where the last digit was smaller than the first of 1 only. Hence we chose other two numbers with this structure (e.g. 524 and 726) and we transformed the hypothesis in a theory! What a satisfaction!"*).

The cases with more complete and effective solving processes are also those that document *quick up-and-downs of emotions* linked to the different solving moments (e.g. quick sequences of discomfort-new exploration-discomfort- astonishment). An example is given by Giuly who writes down three examples, finding 1089 in all cases and commenting "*Astonishment, wow, happy*", then finds an example with 198 ("*Ops I did something wrong*"), finds another case of 198 and writes "*OK, maybe I understood the rule, we feel yet more accomplished*".

This emotional swing ends up sometimes with a negative emotion, especially frustration or dissatisfaction, which may be linked to three different reasons:

1) feeling unable to communicate properly a certain conjecture, explanation, or argument, as Rubinorosso: "*curiosity-get lost-illumination-frustration in not being able to express well our discoveries*";

2) feeling unable to understand why there is a certain result, as Vios: *"But we cannot understand why it is always 198"*;

3) feeling unable to prove a certain result, as Chi: *"The discomfort is due to the fact that I am not able, in logical-mathematical terms, to prove the reason why, considering a number with the first digit greater than the third one, and the second and third the same, I got a number different from 1089"*

Generally, the final dissatisfaction is indeed related to greater mathematical and meta-mathematical competences. The typical cases are given by those pre-service teachers that express a global sense of success (for being able to find out examples) but also regret, delusion and resignation for not finding a general rule to distinguish the two sets of cases 1089 and 198. Asking where the counter-example comes from, and why only with some classes of numbers you find 198 is a typically mathematical curiosity: as future teachers educators we interpret in a very positive way these final students' dissatisfactions.

DISCUSSION AND CONCLUSIONS

A preliminary reflection concerns our method for studying the affective pathways in problem solving, i.e. the series of affective documentation requests. Even if prospective teachers were asked to report their emotions after text reading, during the solving process, and once solved the problem, many of them did not report emotions *during* the solving process, they rather commented immediately after having accomplished the task, or wrote twice the same comments. As a consequence, we organized our analysis in two sections (emotions after text reading and affective pathways in problem solving), without distinguishing between documentation within and after the process. Actually, writing down emotions and feeling when solving the problem is a demanding task, since the solver should stop the process in order to comment it. In light of these findings, in future interventions we would skip the request of documentation during the process and just ask for a report after the solution: in terms of meta-affect, this should be a valuable request as well. Also, we did not focus on the possible effect of group work on the affective and solving pathways. Future research could be organized so to distinguish between the two levels of “individual emotions” (reported when working individually) and “group emotions” (reported when working in group).

Concerning the results of the study, data analysis confirms the deep intertwining of affective and cognitive factors in problem solving, and reveals some patterns in the affective pathways (first research question): rich and complex problem solving processes are characterized by emotional pathways with a “continuous swinging” of emotions. Such emotional states are both cause and effect of the exploration, conjecture and proving steps. On the contrary, “fixed” emotional pathways, with a more stable (positive or negative) emotional state that persists throughout all the process, occur when solving processes are poor and non efficient. In order to interpret the different affective behaviours, we need more research on the possible link between awareness of the emotional pathway, meta-affect and attitude towards mathematics and its teaching.

As a provisional answer to the third research question, we discuss some possible routes for teacher education. A first result concerns the generally positive emotional disposition at the first reading of the text. It confirms the opportunity of engaging prospective teachers in such a kind of activity, which may be seen also as an occasion to experience new ways of doing mathematics. Another reflection comes from the reported emotions at the end of the solving process. We highlighted that different solvers report the same emotions in different situations and that, finally, it is not matter of positive or negative states. For instance, dissatisfaction and frustration may be linked to the need of better understanding or to the awareness of difficulties at epistemic and/or communicative level. Thus, negative emotional states may be read in terms of competence at meta-mathematical or mathematical level. Conversely, positive emotions such as satisfaction may be linked to a lack in meta-mathematical competence. The 1089 problem is a highly demanding task for pre-service primary teachers, also because of its theoretical nature: the core is constituted by conjecturing and proving, which we value as fundamental mathematical activities. However, pre-service teachers with low competencies at mathematical and meta-mathematical level happened to live the experience of solving the 1089 problem—with correlated positive emotions—and to discover their failure only later through the confrontation with more expert mates or the teacher educator: in this case, a negative emotion is likely experienced, risking to be the most persistent result of the overall activity. The crucial point, for us as teacher educators, is to find out efficient ways to intervene on the latter cases. This also opens the discussion on what kind of mathematical activities are worth to be proposed, and how to push the reflection at meta-level. We need more research on the design of suitable tasks for promoting prospective teachers’ awareness of their emotional pathways during problem solving.

About relationships in the affect domain

Manuela Moscucci and Cecilia Bibbò

University of Siena, Department of Information Engineering and Mathematical Sciences, Siena, Italy, manuela.moscucci@unisi.it, bibbo@student.unisi.it

During the last decade, learning/teaching environment has assumed an important role in affect research due to the socio-constructivist account of learning/teaching mathematics. Despite this, the concept of interpersonal relationship, which is an important variable of the environment, has not yet been considered explicitly in affect research. The first aim of this paper is to show the importance of studying explicitly this concept in affect. The second aim is to underline a first characteristic of the interpersonal relationships. In the light of neuroscience results about mirror neurons, the authors observe that a relationship is characterized not only by the perceptible senses communication, but also by a hidden communication that takes place through mirror neurons sets and perhaps through other means not yet been discovered.

Keywords: Affect, relationships, neuroscience, mirror neurons, theoretical framework.

INTRODUCTION

Until the '90s, researches about affect in mathematics education have always been rooted in the historical constructs, beliefs, emotions, attitudes (McLeod, 1992) and values (DeBellis & Goldin, 1999). However, during the last decade, many scholars underlined the need of expanding and reorganizing the field, which appeared to be not sufficiently complete (Hannula, 2002; Hannula, Evans, Philippou, & Zan, 2004) and clear about the correlations among the constructs (Hannula, 2011; Hannula et al., 2004; Leder & Grootenboer, 2005). During the same period, other constructs, such as motivation, self-esteem, anxiety, were studied in affect domain. At the same time, some researchers (e.g., Goldin & DeBellis, 2006) switched from the consideration of an individual itself to an individual in his environment, analyzing both beliefs, emotions and attitudes of a person, student or teacher, (intro-affect), and the external/interpersonal ones of others belonging to the same environment (inter-affect). In conclusion, during the last decade, affect researchers have highlighted two requirements: the extension of the theoretical framework and the necessity of taking into consideration the environment of growing and learning/teaching of people holding emotions, beliefs, attitudes, values etc.

TOWARDS RELATIONSHIPS STARTING FROM AFFECT LITERATURE

Affect constructs' social component has been studied by many researchers (e.g., De Corte, Op't Eynde, & Verschaffel, 2002; Evans, 2000; Goldin & DeBellis, 1997) who argued that context matters. Already at the beginning of the 90s, some researchers (e.g., Bishop, 1988; Halliday & Hasan, 1989; Henriques, Holloway, Urwin, Venn, & Walkerdine, 1984) were aware of the fact that affect variables are socially constructed in the educational environment. However, only years later, it was claimed the importance of context in affect research. Op'T Eynde, De Corte, and Verschaffel (e.g., 2006) and Evans, Morgan, and Tsatsaroni (e.g., 2006) analyzed in depth affect in the complex environmental system. This means that thanks to affect literature we realize that social context has a key role in the quality of emotions, beliefs, attitudes, values of people. But now, we would highlight that the characterizing element of an environment are the interpersonal *relationships* that all individuals, of the considered context, establish among each other, and with all components of that social environment. The relationships guide the ability of regulating emotions and developing beliefs about ourselves, others and the environment itself. Creating, renovating, modifying beliefs and regulating emotions depends on relationships. The aim of this paper is to underline that in affect there is a hidden key element that has never been explicitly recognized: the interpersonal relationships and relationships, in general (in the following, named only relationships). This 'new' perspective could gain clarification of the notion of belief, emotion and attitude toward mathematics. We believe that relationships could be studied both as what links together affect constructs in a single framework, and what adds new meaning to all constructs. However, as we will see, there is much more. The relevance of relationships comes out not only from the affect literature, but also from the neuroscience one.

ORIGIN OF THE IDEA

The embryonic idea arose a long time ago. In the ‘80s Moscucci noticed a strange circumstance regarding a primary school teacher, who we will call Rose. Despite not having relevant professional skills, Rose was getting surprising results with her students. Rose’s students were generally quite wealthy, but not always of high cultural caliber. Rose, as it used in Italian schools, was the only class teacher of all subjects and taught her students from the age of 6 years old up to age of 11, for 5 consecutive school years, in a small Italian city. Moscucci was astonished by the fact that Rose’s students were almost all good students when they went to the high school. This statement does not derive from a statistical survey, but only from Rose’s recognized reputation in the city. Moscucci began to look at the case of Rose after a first cycle of Rose’s students. Moscucci was struck by the fact that, right at the beginning of the following cycle of teaching, Rose expressed her satisfaction to Moscucci for the skill of her students in the new cycle: children of 6 years only and that Rose had met only a few months before but had already defined as talented and very gifted kids. At the same time Moscucci knew that Rose’s students from the first cycle, who were also defined by Rose as exceptional students, were very good in high school. EvenE Moscucci did not study Rose’s case, it remained in her mind, as a researcher in mathematics education, the curiosity to formulate a hypothesis to explain a fact so strange.

Another story. During the last fifteen years Moscucci has conceived and directed many school projects, in Italian schools, aimed at overcoming students’ difficulties in mathematics, as, for example, those described in Moscucci, Piccione, Rinaldi, Simoni, and Marchini (2005). In the first part of their realization, the projects were conducted according to a particular educational path, called MBSA, Meta Beliefs Systems Activity (Moscucci, 2007), which aims to rebuild students’ relationship with math. Here it is not important what the whole structure of MBSA is, but only the activity “My story with math” planned in MBSA, when the participants are asked to tell their story with math, with the explicit request to focus their attention above all on emotions experienced during math activities. This activity is widespread in research (e.g., Di Martino & Zan, 2010). So, in those circumstances, Moscucci gathered many significant sentences spoken or written by students with difficulties in mathematics and reflected on them. Beside every sentence, there are questions that arose spontaneously.

> *“Even if the teacher told me I was good at math, she seemed to think the opposite”* (Ada, 15 years old). “In what sense “she seemed”? What did Ada mean?”

> *“I know that my teacher believes I am not good at math”* (Lisa, 15 years old). “How did Lisa know what her teacher believed?”

> *“Even if my teacher always smiles at me, I never feel sure and relaxed about what I’m doing”* (Lea, 16 years old). “Why didn’t Lea feel sure and relaxed, if her teacher was so nice to her?”

> *“When I do math homework together with my brother, I feel like he thinks I am slow”* (Sara, 14 years old). “How did Sara realize that her brother thought that she was slow? What did Sara mean when she said “I feel”?”

> *“When my father is in the kitchen, I am not able to do math homework”* (Giulia, 14 years old). (From the whole interview we knew that usually Giulia did her homework in the kitchen and that Giulia thought of her father believing she was not good at school). “What is it that stopped Giulia?”

> *“Even if the teacher told me I was good in math she seemed to think the contrary!”* (Amy, 16 years old). “Did Amy really believe that her teacher was thinking the opposite of what she told her?”, “Why?”

> *“When my teacher gave me the report card, I heard her voice in my mind saying ‘You will never really understand mathematics!’”* (Deb, 15 years old). We have reached the pinnacle! This girl not only made assumptions about the thoughts of others, but even claimed ‘to hear a voice in her mind’, her

teacher expressing an opinion. Was it just a way of saying or did she really hear a voice?

We want to point out that the reported sentences were said by students during a school project organized on a vocational school to overcome difficulties in math. So, all the involved students were not good students in math.

NEUROBIOLOGICAL BASIS TO SUPPORTING RELATIONSHIPS

The importance of context in learning processes concerns, of course, any discipline, not just math. However, regarding affect, such importance is justified not only as a sector of mathematics education, but it is amplified by the choice of its constructs, emotions, beliefs, attitudes and values. They are just the product of the interaction between the person with his/her environment. Hence, in our opinion, the necessity of including relationships in affect research studies. Relationships are widely studied and investigated by neuroscience. However, we intend to bring to the attention of affect researchers that is not enough to use the neuroscience results, since it appears to be particularly relevant in this context. Science considers human beings as in continuous interaction with their environment, and neuroscience has already stated the essential role of human interpersonal relationships in the construction of any kind of thought and knowledge. The brain is a 'social organ' of the body, it is exquisitely social, and emotions are its fundamental language (Siegel, e.g., 1999, 2000, 2001). Learning is a relational process that encloses regulation of emotions, that is fundamental in the development of all knowledge. So, what are exactly relationships from a neuroscientific point of view? Neuroscience, at this time, does not give a definition of relationship. However, affect researchers must not retrace the beaten track for decades in search of a definition of beliefs. We may see relationships as a primitive concept and settle for partially characterizing the relationships and study their characteristic elements even if not fully characterizing. We mean, maybe, in the future, other characteristics of relationships might be discovered and studied and we might arrive at a completely satisfactory characterization. The neuroscience result that, in our opinion, is a matter of great interest for affect research, concerns mirror neurons, that are a specific type of neurons. They are involved in a kind of communication unknown until now, at least from a scientific point of view. Mirror neurons, discovered by Gallese and Rizzolatti (University of Parma, I) in 1995, are one of the most important relatively recent discoveries in neuroscience. Mirror neurons "appear to play a fundamental role in both imitation and action understanding" (Rizzolatti & Craighero, 2004, p. 169). The activation of mirror neurons is, indeed, able to generate an internal motor representation (potential act) of the act observed, from which learning ability through imitation depends (Rizzolatti & Sinigaglia, 2006). In particular, these neurons should seem to play an important role in imitation learning. They are activated subconsciously, allowing people to trigger processes of imitation and communication without awareness. *The human brain has many and many mirror neurons that specialize in carrying out and understanding not just the actions of others but also their intentions, behavior and emotion, through direct feeling* (e.g., Gallese, Keysers, & Rizzolatti, 2004). According to researchers, in social relationships, the functions of mirror neurons allow an immediate understanding of what others are doing, without any kind of mediation or interpretive reasoning. Mirror neurons constitute a scientific proof of the existence of a sort of not perceived communication. So, we may claim that communication has visible (or at least sensitive perceived) and conscious components, such as body languages and other sensitive human expressions, but also unconscious and invisible components. We will refer to the last type of communication, with the diction *hidden communication*. The discovery of hidden communication between two people influences the view of the quality of relationships, and it is clear how the consideration of this element of interaction between people intervenes in studies about human relationships. Let's say even more explicitly. Communication through the mirror neurons sets shows that a relationship between two persons is not constituted only by the set of the interactions between them, perceptible by senses, as, for instance, verbal communication. There is much more. We mean that, at the moment, a relationship between two people is an entity which has to be described fully. In fact, we have said: "*Communication through mirror neurons sets*", but, despite us not being neurobiologists, we believe we can say, as a highly probable hypothesis, that almost certainly mirror neurons are nothing more than a kind of transmitting and receiving antenna. As a matter of fact, knowledge of the functioning of mirror neurons determines a new vision of interpersonal relationships and an absolutely innovative approach to the study of the nature of the relationships. In addition to this, recent evidences suggest that mirror neurons are involved in what is usually called *empathy,* which is the capacity of feeling the same emotions that others feel. Indeed, we can say that this gives a scientific link to something that, up to now, was guessed, imagined, perceived too, but had not a scientific root. *"Empathy, or the ability to share feeling states with other individuals, is an important aspect of affiliative, prosocial behavior in modern-day humans"* (Nelson, 2012, p. 179). Empathy is thus a form of hidden communication. "At a neurobiological level, empathic responding is thought to reflect activity within distinct neural circuits subserving other social processes such as understanding person-specific experiences (theory of mind) and reflexive activation of observed experiences in others (mirror neurons)" (ibid, p. 1). Mirror neurons allow us to feel the mind-state of another person. They automatically and spontaneously pick up information about intentions and feelings of those around, creating emotional resonance and behavioral imitation as they connect the internal state with those around, even without the participation of a conscious mind. All these means that mirror neurons enable us to connect with each other. They dissolve the wall between one and the others. These results have a significant impact on the study of beliefs and emotions in general. In fact, through mirror neurons, we continuously receive information from all those who take part to our environment. This information, of which we are unaware, greatly contribute to the construction of beliefs or patterns of interpretation of the reality, and therefore the quality of our emotions. Then beliefs, emotions, attitudes and values depend on the relationships that a person has structured over the time, in every context of life, family and school in the first place. Therefore, the consideration of these findings in neuroscience is, in our opinion, a starting point for collaboration between neuroscientists and education researchers, and particularly between neuroscientists and affect researchers. Indeed, there is much more from the point of view of affect research. Indeed, all this not only means that there is an interconnection among emotions and beliefs of people, but also that there is a link rooted in neurocerebral mechanisms. All this stresses the importance of the analysis of the relationships of the person, student or teacher of mathematics, in order to understand deeply the quality of his/her emotions, beliefs, attitudes and values. And, all this is not only due to the importance, for affect, of the context from a social constructivist point of view, as it has been highlighted above, but on the basis of new scientific results from related fields of research.

A last observation about the case of Rose. When Moscucci first met Rose she was particularly intrigued by some Rose's personal characteristics: her enthusiasm for her students, her firm belief that all her students were good at learning and very intelligent, and her joy about working with children. The results about mirror neurons allow to hypothesize that Rose transmitted to her pupils her enthusiasm that affected positively their self-esteem and their confidence whose role on learning is well known.

ABOUT RELATIONSHIPS

The discovery of mirror neurons states that there are hidden information shared between people, which are absolutely independent from people will. We must take in account that when we work with the relationships we are working with the brain structure. Scientific results about mirror neurons constitute the first step to characterize the concept of relationship also from a neuroscientific point of view. They allow us to talk about *interaction between individuals* not only as communication, in the usual sense of the word. In particular, communication is an exchange of information based on sensory perception. But researches show that the interaction between two individuals is not just communication. A relationship is something much more complex than the set of information of interpersonal communication, even if we look at it in all its forms: verbal, gestural, mimics, tactile, postural, kinesthetic, etc. Then we might refer to these types of communication such as characteristics of the *rapport* between two people, while the *relationship* is characterized by the *hidden communication*, due to mirror neurons, and, perhaps, due to other things yet to be discovered, but, without doubt, due to the hidden communication, that is proved existing. We might say that *sensory communication gives rise to a rapport, while the hidden interaction, or hidden communication, gives rise to a relationship*. The relation between rapport and relationship deserves to be investigated scientifically. For the moment, we can make some considerations based on observation of what happens in the usual social contexts. For example, the experience leads us to believe that there may be a rapport, maybe for many years, between two people between whom there is a weak relationship, while there may be a strong relationship between two people who have just met, and between whom there is a very weak rapport. This may be one reason for distinguishing rapport from relationship. We may say that usually, a relationship and a rapport are co-present, but now we cannot exclude any relation between relationship and rapport. In fact, it is well known that particularly linked people can communicate with each other some moods that are affecting them emotionally, even at a distance. In the literature (e.g., Segal, 2000) there are reports about identical twins, who never met, so without having any rapport, one could perceive fear, for example, experienced by the other. However, although we cannot exclude that there are people between whom there is a relationship, but not a rapport, we must admit that these are really *limit cases*. Hence, when we talk about relationship we mean the set of rapport and hidden communication. To sum up, the study of relationships must take into account their dual nature of communication: explicit and hidden, and the hidden communication will be the component that, henceforth, will contribute more to the advancement of research. The hidden communication that occurs through mirror neurons and on which, at least in part, is based empathy, affects beliefs, emotions, attitudes, values. The consideration and inquiry of the relationships in their entirety can really help affect researchers to progress about their studies.

RELATIONSHIPS IN THE AFFECT DOMAIN

Affect researches identify beliefs and emotions as essential elements to understand how students build their mathematical knowledge. Learning processes have their origin in the experience, and experience depends on the relationships established between a person and every single other person in his/her environment, and the environment itself. In fact, through relationships, a human being, but surely even animals, begins, early in his/her childhood, to interpret his/her experiences and, in turn, through these experiences of interpretation, s/he builds models of interpretation. These models constitute the basic references to interpret his/her next experiences and, in particular, his/her emotions, along all his/her life. So, emotions are a result of the use of models built through the relationships. In addition, beliefs are shaped through relationships and they are involved in the interpretation of experiences. Then, emotions and beliefs are closely linked and influence each other, because of their nature and their construction which occur through the relationships. As a consequence, affect constructs have their roots in relationships, and should be seen in absolute dynamicity and synergy. It is really difficult to deal with one of them independently from the others. These are the main aspects which have led us to consider relationships as a key element in the affect domain and, in our opinion, just these arguments are absolutely compelling for considering the relationships in the affect domain. However, we claim that there is another reason, perhaps even stronger, requiring researchers to extend their studies about the relationships and, at the same time, strengthening them. The study of the principles of quantum physics supported again the ideas that have allowed this work to take shape. As we said, many affect researchers have emphasized the importance of the correlation between the constructs. We believe it is useful for the research climate in affect domain, to borrow a principle of quantum physics. Quantum physics shows that the properties of objects manifest themselves as such, only when the objects interact with each other. Then, it is important, in affect, to study not only what are the constructs themselves, but also the relations between them, just to understand their nature. In fact, constructs' nature may emerge completely from the study of the relationships which contributed or contribute to the construction of a certain belief or value, to the manifestation of a certain emotion, to the structuring of a given attitude, or motivation etc.

CONCLUSIONS

The findings of neuroscientists about mirror neurons will certainly have many repercussions in the educational research. The suggestions that we deducted from the research on mirror neurons, convinced that much more come out from research in neuroscience. For example, studies on the contagion of yawning in primates, may allow to make the assumption that the importance of the hidden communication between teachers and students is a possible research hypothesis, and we will make it explicit and deal with in future papers. Studies about the "hidden communication" might really give great impetus to the research in the field of human communication and in all fields in which communication plays an important role, such as education, and, particularly for us, affect. And we absolutely intend to face this issue in the near future. For the development of affect research we support the importance of bringing to light *relationship*s as a real construct and studying it explicitly. The processes of teaching/learning are about people and how people interact. The relationships among people, students and teachers, are involved in these processes. Relationships intervene substantially in these processes and, therefore, must be considered a variable to evaluate the processes of teaching/learning. So far we have studied the relations between emotions, beliefs and attitudes of the student and, to a minor extent, of the teacher. Now affect researchers have to study emotions, beliefs and attitudes of the student closely connected with emotions, beliefs and attitudes of the teacher, namely as a result of the quality of the interpersonal relationship between student and teacher! Which kind of teacher's beliefs, emotions and attitudes could be inhibitory to the student learning process? And which ones could affect positively? How could we act on teacher's inhibitory beliefs, emotions and attitudes? This is just to give some examples of research questions that could really be addressed in affect research, in mathematics education and, more in general, in education. Investigating the profound influence on us of those around us, or what Siegel (e.g., 1999) calls "the neurobiology of we", it will represent another step forward in the development of a comprehensive view of human learning processes, even if these further investigations could not meet our original expectations. At this stage, we may say that the way in which we perceive students regarding the development of their potentialities and abilities in mathematics, could likely affect their success in mathematics and the development of their general potentialities. Within the realm of affect, taking into account relationships means considering not only belief systems and emotions of students, but also those of their teachers, and not only that. It means to consider these belief systems and emotions as a complex structure, not as static, but dynamic and continuously evolving.

This paper aims just to gain the attention of affect researchers regarding the possible implications that a deeper investigation about relationships could have in the understanding of affective variables in mathematics education.

On the role of affect for sense making in learning mathematics – aesthetic experiences in problem solving processes

Eva Müller-Hill[1] *and Susanne Spies*[2]

1 University of Cologne, Cologne, Germany, eva.mueller-hill@uni-koeln.de

2 Siegen University, Siegen, Germany

Sense making is one important goal of learning processes in school mathematics. Empirical studies on genuine sense constructions of mathematics students show the importance of sense construction categories with a subjective and an inner-mathematical orientation at the same time. From a theoretical point of view, we investigate two ways of fostering such sense constructions within school mathematics, by means of aesthetic experiences on the one hand and through reflection of problem solving processes on the other. In both cases, affective aspects play an important role. We also discuss the merits of intertwining aesthetic experiences and problem solving processes regarding sense construction. We finish with some remarks on possible ways of employing our theoretical results practically.

Keywords: Sense making, mathematical beauty, problem solving, beliefs, affect.

INTRODUCTION – THE ROLE OF SENSE MAKING IN LEARNING MATHEMATICS

Sense making is a general, and at least from the viewpoint of constructivism of course quite natural goal for the learning of mathematics. Nevertheless, the meaning of "sense" within the educational debate is underdetermined, sometimes vague. A great variety of different aspects of sense have been brought up in this debate, sometimes explicitly articulated, sometimes more implicitly. Such aspects are, e.g., purpose, benefit, intention, or merit. From an analytic point of view, most of these aspects have at least two dimensions: an objective-subjective and an inner-extra-mathematical dimension. With regard to these dimensions, a large part of the discussion in mathematics education focusses on rather objective, inner- and extra-mathematical issues of "sense making" (e.g., what is or what should be the "sense" of negative numbers, which lifeworld contexts are adequate to teach them). Subjective issues of sense making oriented to the learning subject, on the other hand, are usually discussed with regard to rather extra-mathematical themes, like incentives, personal relation to teacher, beliefs about the subject's own abilities in learning mathematics etc. However, there are also popular positions emphasizing subjective inner-mathematical aspects of sense making as of great importance for the learning of mathematics, as the work of Skovsmose (e.g., Skovsmose, 2005), or Ruf and Gallin's work on "core ideas" (e.g., Ruf & Gallin, 1998).

The guiding question of the following considerations is: How can subjective, inner-mathematical aspects of sense making in learning mathematics be addressed, and triggered within learning processes, and what role does affect play in this regard? To our mind, this question is less a question about methods of teaching. It is rather meant as a question about contents of teaching mathematics, on two different levels: In second order, it addresses the object level of mathematics itself (negative numbers, triangles, functions and graphs, variables etc.). In first order, it shall deal with "meta-units" of doing mathematics (problem solving, proving, discovering new connections, reconstructing solution processes and so on) which can be a basis for subjective inner-mathematical sense making in a learning process.

Our approach is to take inert sense making categories of learning subjects as a starting point. Vollstedt (2011) investigates such inert categories of sense making, "sense constructions" in her terminology, for the case of students of the lower secondary level (15 till 16 years old) in a qualitative, comparative empirical interview study (34 participants, 17 from Hongkong and 17 from Germany).[1] In a first step, she classifies sense constructions into some 3 times 3 matrix (Table 1).

The category "high individual orientation–high inner-mathematical orientation" (cell 3) corresponds to our "subjective inner-mathematical" dimension:

> **High intensity of inner-mathematical orientation**: The sense construction is in immediate relation to mathematical contents [and not to other aspects of learning processes in school, as, e.g., social interactions].
>
> **High intensity of individual orientation**: The individual itself is the focus of the sense construction, intra-individual relations dominate [and not social institutions or demands]. (ibid, pp. 130f., German in original, added brackets give short descriptions of value "low")

Vollstedt found that this category is empirically contentful, that is, sense constructions could be reconstructed from the interview data that fall into that category. In the following, we will concentrate on two of these sense constructions: "experience of autonomy" and "mathematical purism" (ibid, pp. 142–148). Vollstedt defines these two categories with reference to a "criterion of personal relevance" (ibid, p. 129, German in the original):

> *Mathematical purism*: Doing or learning mathematics is personally relevant to the individual if it appreciates the purism of mathematics stemming from its formality and logical composition and benefits from this appreciation regarding its understanding of mathematics.
>
> *Experience of autonomy*: Doing or learning mathematics is personally relevant to the individual if it experiences self-reliance in doing or learning mathematics, e.g., in terms of learning autonomy and original development of solutions to mathematical problems.

Answers coded as "mathematical purism" deal with a special fascination of pure mathematics, and describe a positive affective relationship to a special mathematical discipline (e.g., geometry or algebra) or express personal relevance of clear and logical mathematical structure (ibid, p. 146). Answers belonging to the category "experience of autonomy" describe positive experiences by, e.g., choosing exercises autonomously or finding individual ways of solving problems (ibid, pp. 142–144).

In the following sections, we discuss two kinds of "meta-units" of doing mathematics in relation to these two sense constructions. Both have a certain affective potential, and therefore specific merits regarding the initiation of sense making in learning mathematics. First, we argue that *aesthetic mathematical experiences* provide good opportunities for the learning subject to appreciate mathematical purism. For the case of autonomy, aesthetic judgments are distinctly different from right-or-wrong-judgments. Aesthetic mathematical experiences are often closely related to so called AHA! experiences, a highly affective type of individual understanding processes. Second, we look at *mathematical problem solving processes*, and, in particular, the affective components of those, in relation to the sense constructions "mathematical purism" and "experience of autonomy", and then turn to discussing the value of intertwining both perspectives to arrive at a particularly fruitful basis for sense construction within learning processes at school.

AESTETHIC EXPERIENCES AND PROBLEM SOLVING PROCESSES AS SOURCES OF SENSE CONSTRUCTION IN LEARNING MATHEMATICS

Sense construction and mathematical beauty

Relying on Spies (2013), we adopt the premise that though mathematical beauty isn't definable entirely, a concept of beautiful pieces of mathematics, cover-

Intensity of inner-mathematical orientation of sense construction	Intensity of individual orientation of sense construction		
	Low	medium	high
High	1	2	3
Medium	4	5	6
Low	7	8	9

Table 1: "Typology of sense construction" (ibid, p. 133, German in original)

ing for instance theorems, proofs, argumentation schemes, and heuristic strategies, can be explicated. Informed by mathematics as a scientific discipline it is also fruitfully employable within discussions of mathematics and beauty in mathematics education. The concept of mathematical beauty developed in (Spies, 2013) is explicated by four relevant attributes: *range*, *economy*, *epistemic transparency*, and *emotional effectiveness*. At least three of these attributes, range, epistemic transparency, and economy, are directly related to the sense constructions "mathematical purism" and "experience of autonomy" investigated by Vollstedt. Regarding the sense construction "mathematical purism" in detail, the following relations hold:

Range: There are two aspects of range often referred to when it comes to aesthetic value judgments in mathematics. On the one hand, a beautiful piece of mathematics connects different parts or branches of mathematics, for example the use of algebraic tools to solve a geometrical problem.

> A beautiful proof often makes unexpected connections between seemingly disparate parts of mathematics. A proof which suggests further development in the subject will be more pleasing than one which closes off the subject. (Stout, 1999, p. 10)

On the other hand, an argumentation owns a certain kind of beauty if the idea at the core of the argument is applicable to a variety of other cases, if the chosen heuristic is paradigmatic in some sense. Becoming aware of the range of an argument or a result may deliver *insight* in the system of mathematics itself. The awareness of broad connectivity of an argumentation or of the paradigmatic character of a heuristic may help to establish an appreciation of mathematics also as a self-contained system besides its applicability in extra-mathematical contexts.

Epistemic transparency: This attribute of beautiful mathematics underlines the subjective character of aesthetic experiences within mathematics. It explicitly stresses the importance of a subjective *understanding* of mathematical structures in connection with an aesthetic mathematical experience: A beautiful proof offers a special kind of deep understanding of *why* the result is true. Often, this is described as an illumination, as a spontaneous grasping of the whole argument from one moment to the other, as an AHA! experience, together with strong positive emotions.

> The mathematician's "aesthetic buzz" comes not only from simply contemplating a beautiful piece of mathematics, but, additionally, from achieving insight. (Borwein, 2006, p. 25)

Accordingly, an aesthetic mathematical experience is not only a product of positive feelings, but also linked to a special kind of deep individual understanding why.

Economy: Under the sense construction "mathematical purism", Vollstedt subsumes statements concerning the shortness of mathematical arguments, or the number of formulas you have to remember to solve a certain range of mathematical problems (Vollstedt, 2011, p. 147). The properties expressed by these statements correspond to economy as an attribute of beautiful mathematics, and link the attributes of range and epistemic transparency. As G.H. Hardy points out in his famous *Apology*:

> In both theorems [mentioned as examples for great mathematical beauty; author's remark] there is a very high degree of unexpectedness, combined with inevitability and economy. The arguments take so odd and surprising a form; the weapons used seem so childishly simple when compared with the far-reaching results; but there is no escape from the conclusions. There are no complications of detail–one line of attack is enough in each case. (Hardy, 1940, p. 113)

Hence, it is not shortness of an argument as an extrinsic property that releases an aesthetic value judgment. It is the impression of economy, that is, shortness of argumentation in relation to its range and with regard to epistemic transparency for the judging subject. There is a necessary connection between individually oriented and inner-mathematically oriented aspects to trigger aesthetic judgments, and thus, possible sense constructions.

Regarding the sense construction "experiencing autonomy", we take into account that aesthetic experiences of beauty undergone by an individual, by becoming aware of them, lead to conscious judgements of beauty, stated or not. These aesthetic value judgements are in a specific way opposed to the prominent excluded middle character of mathematics, and the focus on formal mathematical correctness (Müller-Hill & Spies, 2011). While the latter are rather related to experiences of special conformity and authority of mathematics, aesthetic value judgements transcend formal correctness and are, at least in part, subjectively justified. Nevertheless, they can usually be explained on the basis of inter-subjectively graspable criteria by the judging individual. In this sense, aesthetic mathematical experiences give room for autonomous, but negotiable judgements of beauty, and as a consequence, for responsible, self-relying decisions and actions based on these judgements.

The fourth attribute of mathematical beauty according to (Spies, 2013), *emotional effectiveness*, explicates the affective character of aesthetic mathematical experiences. When mathematicians talk about the aesthetic pieces of mathematics, they use a highly emotional and affective language. Leone Burton reports from an interview study with practicing mathematicians:

> The mathematicians discussed aesthetics [...] in terms that were emotive, full of expressed feelings. (Burton, 2004, p. 63)

Often, the expressed emotions are used to qualify one of the other attributes of mathematical beauty described above.[2] Terms of special relevance according to aesthetic value judgement seem to be *unexpectedness* and *surprise*. A beautiful argument may evoke the feeling of surprise about its (economical) form, of a "surprising twist" in the argumentation, or of unexpectedness regarding the heuristics employed in the argumentation. The feeling of *inevitability* of an argumentation seems to be another aspect of the emotional effectiveness of beautiful proofs (see also the above quote from Hardy, 1940, p. 113), as the mathematician Gregory Chaitin states vividly:

> After the initial surprise it [a beautiful proof] has to seem inevitable. You have to say, of course, how come I didn't see this! (Chaitin, 2002, p. 61)

Sense construction and central types of problem solving processes

Of course, problem solving is a widely discussed issue in mathematics education, and in turn there are a number of different conceptions of problem solving and ways or conceptual tools to describe and investigate problem solving processes. In the following, we discuss problem solving processes as a basis for sense construction in learning mathematics, and ask for the role of affect regarding this relation.[3] To this end, we lean on the synopsis given in (Schoenfeld, 1992), which explicitly embraces and explicates "beliefs and affects" as an important (cognitively effective) aspect of problem solving processes (see ibid, p. 348). The aspect "beliefs and affects" contains students beliefs, teachers beliefs, and also "general societal beliefs" about the nature of mathematics and doing mathematics. We will focus on the "belief system" (Schoenfeld, 1985) of the problem solver, encompassing beliefs, attitudes and opinions about mathematics itself (about „formal mathematics", his „sense of the discipline"; Schoenfeld, 1992, p. 359), about mathematics as a subject matter, and about doing and learning mathematics. Schoenfeld emphasizes the extraordinary powerful impact of the belief system on mathematical problem solving.

In the following, we distinguish two ways in which problem solving processes can generally be connected to sense construction in the above sense, that is, in which they can be meaningful and personally relevant to the problem solver. The first way refers to the *decisions* that are made throughout the process by the problem solver, and the motivations behind them. The second way considers *changes in the belief system* as responsible for subjective sense making. Such changes may be initiated by actual performance of, or by later reflection on, problem solving processes.

Decisions guiding the course of action throughout a problem solving process are potentially meaningful components of these processes. At least to a certain degree, they allow to infer something about what is personally relevant to the problem solver in terms of guiding motives and reasons for these decisions. Potentially subjectively meaningful decisions, and actions in turn, have to be autonomous at least to a certain degree, intentional, and goal oriented. Usually, decisions are also affectively driven, which strengthens their subjective relevance and, in the case of several alternatives, can even be the last instance to decide. Undergoing a process of problem solving also induces an interaction with the individual belief system of the problem solver. The belief system, being the network of conceptions, opinions, attitudes and beliefs related to mathematics, is per definition the basis of all subjective sense making in learning mathematics. Sense constructions on the basis of problem solving processes will therefore necessarily incorporate changes in the belief system, in the form of expansion, overwriting, or readjustment.

Regarding both decisions and changes in the belief system, it is not sufficient for fostering sense making just to get learning subjects involved in concrete problem solving processes. Sense construction in the way described above will usually not take place automatically. We suggest that *explicit reflection* of problem solving processes including decisions, action guiding motives, and affective aspects like emotions felt during the process or conscious changes of certain beliefs is necessary.

Reflecting on decisions as part of a problem solving process obviously encourages sense constructions of the type "experience of autonomy". But problem solving processes also have a specific sense making potential with regard to „mathematical purism", by focusing on recognizing *structural types* of mathematical problem solving processes. Reflections on characteristic elements of problem solving processes of a certain type can both lead to an appreciation of the formal structure of mathematics (regarding corresponding changes in the belief system), and lead to a better subjective understanding, as it may promote the ability to transfer problem solving approaches and strategies (regarding the orientation on a certain type of problem solving processes as a guiding motive for decisions in a concrete process). The latter also provides the opportunity for experiences of autonomy. The inner-mathematical focus can be increased by highlighting *central structural types* of mathematical problem solving processes. Mathematical problem solving processes of a central type employ certain, structural elements that are characteristic for working with central concepts of (branches of) mathematics like "function", "gauge", "number", or "area". [4]

Now in turn, we will argue that there are at least two ways in which a combination of problem solving processes and experiences of mathematical beauty can be particularly fruitful with regard to sense construction in learning mathematics, exploiting their affective elements in a specific way.

AN INTERTWINED PERSPECTIVE

As stated above, the decisions made during a problem solving process can be meaningful and relevant to the problem solver in terms of ideas, reasons or motives guiding them and the corresponding actions. These guiding ideas, reasons or motives are usually not merely rational, but decisions and actions are also guided by affect. Goldin (2000), e.g., investigates the relation between affective states (including aesthetic experiences) and chosen heuristics in problem solving processes. Though criticizing Goldin's subsumption of aesthetics under what he conceives as affective states, Sinclair in her (2008) also stresses the importance of aesthetics as coupled both with affective and cognitive aspects of mathematical problem solving. However, she emphasizes that

> the aesthetic and the affective domains each *function* differently in the problem-solving process: the aesthetic draws the attention of the perceiver to a phenomenon, while the affective can bring these perceptions to the conscious attention (ibid, p. 55, our emphasis).

In this sense, we consider decisions and actions driven by experiences of mathematical beauty as important, potentially sense-constitutive affective elements of mathematical problem solving processes. This is additionally underpinned and emphasized by a number of famous practicing mathematicians. For example, in his famous essay *The psychology of invention in the mathematical field,* Jacques Hadamard reaches the following "double conclusion" after reviewing psychological and philosophical literature on general and mathematical invention:

> That invention is choice. That this choice is imperatively governed by the sense of scientific beauty. (Hadamard, 1954, p. 31)

This observation from scientific mathematics can at least partly be adapted for problem solving processes in school mathematics: Choice is a meaningful element of problem solving processes. Choices are i.a. governed by subjective motives like perceptions of mathematical beauty.[5] To foster sense construction sustainably, the conscious attention of such aesthetic perceptions should be supplemented by explicit reflection on their role for the course of concrete problem solving processes.

With regard to the second form of sense making in problem solving processes, on the other hand, aesthetic experiences can help to initiate *changes* in the inner-mathematical component of the belief system due to their specific affective character as described above. This might be necessary when students fail in completing a problem solving process on their own because of holding certain constraining beliefs. Even if they succeed to finish the problem solving process with some help, the constraining beliefs might be abstracted from years of classroom experience (Schoenfeld, 1985). Hence, rational reflections of such single problem solving processes will usually have only little effect on their belief system, and therefore hardly trigger new sense making. Aesthetic experiences might catalyze the reflective impact in this regard. In particular, aesthetic mathematical experiences are often conceived as AHA! experiences. Empirical studies as (Liljedahl, 2005) show that there is a strong relation between the reflection of AHA! experiences and (even drastic) changes of student‘s beliefs about their learning of mathematics because of the affective, especially the emotional potential of AHAs (ibid., 231). AHA! experiences of mathematical beauty work in a quite similar way regarding unexpectedness, surprise, sudden inevitability (compare ibid., 226), and emotional effectiveness, but they are directed to attributes and relations of mathematical argumentations, formulas, diagrams, theorems, etc. The four attributes of mathematical beauty described above, range, economy, epistemic transparency, and emotional effectiveness, can be experienced jointly or in different combinations as aesthetic aspects of a certain piece of mathematics dealt with in a concrete problem solving process. Therefore, it seems promising to assume a similar impact of reflecting on aesthetic AHA! experiences in problem solving processes on student's beliefs on mathematics itself.

SHORT OUTLOOK ON DESIGN ISSUES

When we now direct the focus to designing issues in a short outlook, we rather have in mind developmental questions and the design of supporting learning material, not measurement issues. Our contribution must obviously be conceived as rather theoretical with regard to the design of concrete learning environments or teaching material. One reason for this is that from our point of view, sense construction is strongly tied to individual parameters of learners and learning groups. This makes it difficult to argue in favor of concrete designs in detail. Nevertheless, we think that we have generally identified good candidates to direct concrete designing attempts to. Problem solving is standard to school mathematics today. What might not be standard is guided reflection of concretely undergone processes with an explicit focus on action guiding motives, decisions, beliefs, or affects. Also still non-standard is the upgrading of aesthetic experiences as admissible and negotiable justifying reasons for choosing between alternative courses of action within problem solving processes. Future work will expand the view onto the scope of content didactics, aiming at a specification, e.g., of mathematical concepts, appropriate mathematical problems, and (types of) corresponding problem solving processes and beautiful pieces of mathematics as the subject matter of possible learning environments to foster subjective inner-mathematical sense construction. A point of practical interest in the design of learning environments will be the degree of guidance and instruction accompanying the problem solving activities of learners. Through a theoretical lense, this will link the perspective opened up here to questions about the role of creativity.

ENDNOTES

1. Vollstedt uses grounded theory methodology, not operationally defined items or coding categories. Due to space, we refer to the original source for more details on Vollstedts shaping of the categories based on her data.

2. Similarly, "emotional relation to mathematics" is described as part of "purism" (Vollstedt, 2011, p. 146).

3. See also (Presmeg, 2014) for another most recent, programmatic emphasis.

4. "Central types of problem solving processes" corresponds to "fundamental mathematical ideas" famously introduced by Bruner in the 1960s and discussed under a variety of readings. We will not enter this discussion here, because the explication of „central" is not necessary for the general arguments discussed. Further qualification of "central" will be necessary for future work, esp. from a content didactical point of view.

5. According to Hadamard, this assumption is quite obvious: "Between the work of the student who tries to solve a problem in geometry or algebra and a work of invention, one can say that there is only a difference of degree, a difference of level, both works being of a similar nature." (Hadamard, 1954, p. 104)

The role of multiple goals in students' motivation and achievement

Marilena Pantziara[1] and George N. Philippou[2]

2 Univeristy of Nicosia, Egkomi, Cyprus

Studies in the area of achievement motivation have made a distinction between mastery and performance goals. Many studies investigated the positive and negative outcomes from the adoption of each goal in students' behaviour and achievement. Recently, there is an ongoing discussion concerning the role of multiple goals in understanding students' behaviour and achievement. This paper addresses the role of mastery goals, performance goals and multiple goals, in students' mathematics achievement and motivation. Data were collected from 620 6th graders (study A, N=299 and study B, N=321). The results of both studies were consistent regarding the effect of the different multiple goals profiles on students' achievement and motivation.

Keywords: Multiple goals, motivation, achievement.

INTRODUCTION

In everyday school one can realize that some students perform better than others, tend to work harder, ask for help, are eager to participate in school activities and use more sophisticated learning strategies than other students. Researchers, mainly in the Educational Psychology domain, examine the role of motivation in the learning and teaching context in an attempt to interpret students' behavior and learning outcomes (Pintrich, 2003). Motivation has been found to play a key role in students' current and future academic success (Pintrich, 2003; Pantziara & Philippou, 2014).

In this respect a number of socio-cognitive frameworks have been developed and used in research on students' motivation in the school context (Pintrich, 2003; Elliot 1999). One of the most applicable and predominant frameworks is achievement goal theory (Elliot, 1999). Achievement goal theory focuses on goals, as the reasons and purposes for engaging in achievement tasks (Elliot, 1999). While there is a great amount of studies that examine the role of each of these goals in students' cognition, affect and behavior, as opposite constructs, few of them refer to students holding simultaneously multiple goals. Multiple goals and their interactions have been investigated mostly in secondary and college level (Mattern, 2005; Pintrich, 2000). The current study investigates the role of multiple goals and their interaction with elementary students' motivation and achievement.

BACKGROUND AND AIMS

Achievement goal theory

Over the past three decades, achievement goal theory has emerged as an important theoretical prospect on students' motivation in school settings, as it provides a satisfactory framework that emphasizes the importance of how students think about themselves, their tasks and their performance (Midgley, Kaplan, & Middleton, 2001). Rather than considering individuals' with low or high level of motivation, achievement goal theory focuses on why individuals are motivated. The theory posits that individuals engage in academic activities to accomplish different goals. Achievement goals are defined as the competence-relevant objectives that individuals attempt to achieve and these different objectives are associated with different quality of engagement in schoolwork and different cognitive, affective, and behaviour consequences (Elliot et al., 2005; Kaplan, Middleton, Urdan, & Midgely, 2002).

Within this framework, two achievement goals are described, mastery and performance goals. Mastery goals refer to an individual's objective of developing personal competence and growth (Kaplan & Maehr, 2007), while performance goals refer to demonstrating ability, focusing on attempts to create an impression often through the comparison with others

(Kaplan & Maehr, 2007). There has been noteworthy consistency over a large number of studies about the relation between mastery goal orientation and adaptive patterns of cognition, affect and behaviour. Indicatively, mastery goals were found to evoke positive processes like effort, expenditure, persistence self efficacy, self-regulated learning, positive affect and well-being (Elliot et al., 2005; Kaplan & Maehr, 2007). On the other side, research findings concerning performance goals were found to be inconsistent. A number of studies found that performance goals are associated with positive processes like positive affect, effort, persistence and graded performance (e.g., Elliot, 1999; Zusho et al., 2005). Other studies, however, reveal that performance goals are less adaptive and are related to negative affect, strategy use, and performance (Elliot & Church, 1997; Kaplan & Maehr, 2007).

In a revised goal theory perspective, researchers have distinguished between performance approach and performance avoidance goals. While performance approach goals focus on doing better than others, performance avoidance goals focus on the possibility of failure and on the attempt to avoid it (Kaplan & Maehr, 2007). Studies investigating mastery, performance approach and performance avoidance goals have consistently found that performance avoidance goals are related to maladaptive patterns of motivation, affect and performance (Pintrich, 2000).

Achievement goal theory and multiple goals

In an attempt to explain inconsistent effects of performance goals, research investigates whether students pursue these goals while at the same time pursuing mastery goals. It may be that in the classroom context, students can endorse both mastery and performance goals in different levels of each of these goals. Research so far examining mastery and performance goals, has often distinguished the effects of these two goal orientations without exploring how these two goals may jointly influence students' behaviour and performance. Qualitative studies revealed that students expressed multiple goals for engaging in school activities (Kaplan et al., 2002).

According to Pintrich (2000), there are two views as to how these two goals can be combined to give the best outcomes concerning students' behaviour and achievement. The first view, under the revised goal theory perspective, argues that having high levels of both of these goals could be the most adaptive. If there are positive effects for mastery and for performance goals, then a focus on mastery and a focus on trying to be better that classmates at the same time would result in positive consequences. The second view, under the normative goal theory, suggests that holding performance goals could have negative effects due to the distractions fostered by students' attempts to be compared with each other or to their negative judgments concerning themselves. In this perspective students' involvement fostered by mastery goals would be diminished and lead to less positive outcomes. Under this view the most adaptive pattern would be high mastery goals and low performance goals.

The effects of multiple goals have been examined using different methodologies like cluster analysis, median splits (examining individuals with different patterns of high and low goals) or by using regression analysis to investigate interactions between goal variables. Research examining the effects of different profiles of mastery and performance goals presents evidence that the low level of mastery goals in combination with the low level of performance goals is almost always associated with negative outcomes. In addition the combination of low mastery goals and high performance goals has also been shown to lead to negative outcomes, although less negative than the combination low mastery and low performance goals (Kaplan et al., 2002).

Concerning the profiles high mastery/high performance goals and high mastery/low performance goals, earlier studies have produced mixed results. Particularly, Meece and Holt (1993) investigated ele-

Intensity of inner-mathematical orientation of sense construction	Intensity of individual orientation of sense construction		
	Low	medium	high
High	1	2	3
Medium	4	5	6
Low	7	8	9

Table 1: "Typology of sense construction" (ibid, p. 133, German in original)

mentary students' (5th and 6th grade) different profiles of multiple goal orientation in science and revealed that the group of high mastery/low performance goals showed the most positive achievement profile. Pintrich and Garcia (1991) also found in their study with college students that the specific profile of multiple goals had the most adaptive profile. Similarly, Mattern (2005) found in her study within a foundational teacher education course, that students holding simultaneously high mastery/low performance goals had the highest achievement, followed by the high mastery/high performance group. In contrast Bouffard, Boisvert, Vezeau and Larouche (1995) in their study with college students, found that the group of students with high mastery/high performance goals had the highest level of motivation, cognitive strategy use, self-regulation and achievement, followed by the group with high mastery/low performance goals.

In one of the very few longitudinal studies, Pintrich (2000) examined the changes in the behaviour, affect and achievement of four groups of junior high school students (based on the combination of high and low mastery and performance goals) in their math classroom following them from the 8th to the 9th grade. The study revealed that the two groups (high mastery/high performance and high mastery/low performance group) did not differ significantly regarding changes in motivational beliefs, self-efficacy, task value and test anxiety in the 8th and later in the 9th grade. In terms of task value, the high mastery/high performance group reported higher levels of task value than did the high mastery/low performance group. Yet, both groups ended in the same level of achievement.

In addition some researchers have suggested that holding both high mastery and high performance goals could be more adaptive that holding only high mastery goals (e.g., Harackiewicz, Barron, & Elliot, 1998). They argue that students holding high levels of both goals may be able to motivate themselves to succeed in various achievement contexts. The mixed results of the investigation of multiple goals suggest that more research is needed in this direction. Specifically, more research might be needed taking into account students' age, context and task domain. In this respect, the purpose of the current study was to investigate 6th grade students' multiple goals in the mathematics classroom. Specifically, the study aimed:

— To examine the relation between the four profiles of multiple goals (high mastery/high performance, high mastery/low performance, low mastery/high performance and low mastery/low performance) and student's achievement and motivation.

— To investigate if there is consistency in the results of two studies regarding the outcomes from the adoption of different multiple goals profiles.

METHOD

Participants and instruments used

Data were collected from two studies in Cyprus. In the first study (Study A) the participants were 299 students (164 females and 135male) and in the second study (Study B) the participants were 321 students (185 females and 136 males). All students came from the 6th grade (average age, 11.5 years old).

In both studies the participants completed a questionnaire measuring their motivation in mathematics and a mathematics test assessing their performance in the concept of fractions. In both studies the data were collected in the mid of the second semester of the school year so as to allow for the evolution of certain motivational constructs and goals with the specific classroom context and the mathematics teacher.

The questionnaire measuring students' motivation was constructed for the needs of these studies and it comprised of 35 Likert-type five-point items (1-strongly disagree, 5-strongly agree). The questionnaire comprised of six subscales measuring: (a) mastery goals (e.g. It is important to me that I improve my mathematics skills this year), (b) performance approach goals (One of my goals is to show others that I'm good at my mathematics work), (c) performance avoidance goals (It's important to me that I don't look stupid in mathematics class), (d) self-efficacy (I' m certain I can figure out how to do the most difficult mathematics work), (e) interest (I am enjoying mathematics lessons very much), and (f) fear of failure (When I am tackling a challenging task, I find that I am reminded of my previous failures). The first four subscales were adopted from the Patterns of Adaptive Learning strategies (PALS) (Midgley et al., 2000). Students' fear of failure was assessed using nine items from the Herman's fear of failure scale (Thrash & Elliot, 2003). Interest was defined in terms of intrinsic motivation, the enjoyment of and interest in an activity for its own sake (Elliot & Church, 1997). Students' interest was measured using seven items from the Elliot and Church's study (1997).

The mathematics test measuring students understanding of the fraction concept in both studies comprised of fraction items from published research and they assessed students' understanding of fraction as part of a whole, as measurement, fraction equivalence, fraction comparison and fraction addition. More information about the tests can be found in Pantziara and Philippou (2012). Students' achievement was based on their total score in the fraction test; each of the tasks was graded with 0 (wrong) or 1(correct).

Data analysis

In study A we conducted exploratory factor analysis for the six motivational variables using the software SPSS and in study B we conducted a confirmatory factor analysis for the six factors using EQS software. Performance goals used in this study reflected on approach performance orientation to classroom work.

To examine the interactions between mastery and performance goals we dichotomized the two scales using median splits. For the mastery goals, students scoring below 4.6 in Study A and students scoring below 5 in Study B belonged to the low mastery group while the rest of the students to the high mastery group. For the performance goals, students scoring below 3 in both studies were classified to the low performance group and the rest of the students to the high performance group. The results of the procedure are presented in Tables 1 and 2.

Then an ANOVA analysis with multiple dependent variables was contacted in each study (A and B) to investigate for differences in groups with multiple goals concerning their motivation and achievement in mathematics.

RESULTS

A detailed description of the extraction of factors concerning the achievement goals and the motivational variables (fear of failure, self-efficacy beliefs and interest) can be found in Pantziara and Philippou (2014). Students' achievement in the fraction test was calculated regarding their total score on the tests. Specifically for Study A, the total score was 23 and for Study B the total score was 21. Tables 3 and 4 present the Mean, Standard Deviation and Cronbach's alphas for all affective variables for Study A and Study B respectively.

Low mastery N=122 (40.8%)	High mastery 177 (59.2%)
Low performance N=130 (43.5%)	High performance 169 (56.5%)

Table 1: Groups of Study A

Low mastery N=159 (49.5%)	High mastery 162 (50.5%)
Low performance N=150 (46.7%)	High performance 171 (53.3%)

Table 2: Groups of Study B

Factors for Study A	Mean (1–5)	SD	Cronbach's a
Mastery goals	4.52	.46	.71
Performance (approach) goals	3.08	.93	.80
Self-Efficacy	4.09	.62	.71
Interest	3.85	.89	.89
Fear of failure	2.20	.78	.66

Table 3: Means, Standard Deviations and Cronbach's alpha for each of the five factors-Study A

Factors for Study B	Mean (1–5)	SD	Cronbach's a
Mastery goals	4.62	.56	.68
Performance (approach) goals	3.02	1.08	.81
Self-Efficacy	4.03	.69	.66
Interest	3.84	.97	.84
Fear of failure	2.43	.80	.73

Table 4: Means, Standard Deviations and Cronbach's alpha for each of the five factors–Study B

As tables 3 and 4 present, both samples seem to have a positive view of mathematics. In both studies the mean for mastery goals is above 4.50, self efficacy above 4, interest above 3.5 and fear of failure below 2.5. Students in primary school in the specific educational setting seem to get involved in mathematics more for mastery reasons and not so for performance approach goals.

Regarding the specific objectives of the study, a one-way between groups analysis of variance was conducted to explore the impact of the different multiple goals profile on students' mathematics achievement and motivation (self-efficacy, interest and fear of failure). For study A, the results show a statistically significant difference at the $p<0.5$ level in scores for the four groups regarding achievement $F(3, 295) = 3.5$, $p=0.015$, for self-efficacy $F(3, 295) = 15.93$, $p<0.001$ and for interest $F(3, 295) = 18.36$, $p<0.001$. No statistically significant difference was found in scores for the four groups regarding fear of failure. Table 5 presents the scores for each group (mean and standard deviation) in each affective factor and achievement. Means within a row with the same subscript are significantly different from one another.

Post-hoc comparisons using the Tukey HSD test indicated that students in high mastery/low performance group had the highest achievement from all other groups. This difference was statistically significant only for the low mastery/high performance group. This group had a higher mean achievement than the group of students with high mastery goals (Mean=13.65). Students in high mastery/high performance group declared the highest interest following by the high mastery/low performance groups. These two groups had statistically significant difference from the low mastery/low performance group concerning interest. Students' in the low mastery/low performance group had the lowest self-efficacy from the students in the other three groups, and this difference was statistically significant.

For study B, the results show a statistically significant difference at the $p<0.5$ level in scores for the four groups regarding achievement $F(3, 317) = 6.35$, $p<0.001$, for self- efficacy $F(3, 317) = 19.06$, $p<0.001$, for interest $F(3, 313) = 23.32$, $p<0.001$ and for fear of failure $F(3, 311) = 10.77$, $p<0.001$. Table 6 presents the scores for each group (mean and standard deviation) in each affective factor and achievement. Means within a row with the same subscript are significantly different from one another.

Post-hoc comparisons using the Tukey HSD test indicated that students in high mastery/low performance group had the highest achievement from the students in the other three groups even though the difference

Dependent Variables	High mastery/low performance		High mastery/high performance		Low mastery/high performance		Low mastery/Low performance

a= p<0. 05, b=p<0.001, c= p<0.001, d= p<0.001, e= p<0.001, f= p<0.05

Table 5: Scores for each group (mean, standard deviation)-Study A

Dependent Variables	High mastery/low performance		High mastery/high performance		Low mastery/high performance		Low mastery/Low performance	
	M	SD	M	SD	M	SD	M	SD
Achievement	12.88^{a}	4.20	11.64	3.90	10.14^{a}	4.00	11.39	3.81
Interest	$4.00^{d, e}$	0.92	$4.33^{b, c}$	0.69	$3.63^{c, e}$	0.94	$3.33^{b, d}$	1.02
Self efficacy	$4.06^{f, g}$	0.68	4.47^{f}	0.45	3.84^{f}	0.67	$3.70^{f, g}$	0.70
Fear of failure	$2.06^{h, i}$	0.63	2.33^{j}	0.89	$2.69^{i, j}$	0.75	2.63^{h}	0.75

a= p<0.001, b=p<0.001, c= p<0.001, d= p<0.001, e= p<0.05, f= p<0.001, g= p<0.05, h= p<0.001, i= p<0.001, j= p<0.05

Table 6: Scores for each group (mean, standard deviation)-Study B

in students' achievement was statistically significant only from the group of low mastery/high performance goals. This group had a higher achievement than the group of students with high mastery goals (Mean=12.21). Students in high mastery/high performance group had the highest interest from all the students in the other three groups and the difference in scores was statistically significant for students in low mastery/high performance and low mastery/low performance group. Concerning self-efficacy, students in low mastery/low performance group had the lowest self-efficacy and this difference was statistically significant from the groups with the highest self-efficacy (high mastery/high performance, high mastery/low performance). As fear of failure is concerned, students in low mastery/high performance group had the highest fear of failure and this difference was statistically significant from the groups with the lowest fear of failure (high mastery/low performance, high mastery/high performance).

With respect to the second aim of the study, as it can be seen from tables 5 and 6 the two studies show remarkable consistency in the characteristics of the specific four groups regarding their motivation and achievement. Specifically, and concerning the groups with the most positive outcomes, the group with the highest achievement is the high mastery/low performance goals even though the mean difference was not statistically significant from the group high mastery/high performance goals. The group high mastery/high performance goals had the highest interest from all the other groups in both studies. Again the mean difference was not statistically significant for the group high mastery/low performance goals. The same group had the highest self-efficacy in both studies from all the other groups. In contrast, the group with the most negative outcomes related to achievement is the low mastery/high performance group and the group with the most negative outcomes related to motivation (self-efficacy and interest) in both studies is the group low mastery/low performance goals.

DISCUSSION

The aim of this study was to investigate the role of multiple goals and their interaction with elementary students' motivation and achievement. A general conclusion of the study is that both views - the one under the revised goal theory perspective and the normative goal theory - concerning multiple goals, are found in this study to be applicable to the development of elementary students' achievement and motivation. Specifically, in line with the first view that holding high levels of both, mastery and performance goals could be the most adaptive, in both studies (Study A and Study B), students in the group of high mastery/high performance goals had the highest interest and the highest level of self-efficacy beliefs. These findings are in line with the results of Bouffard and colleagues (1995) study with college students, who found that this group of students had the highest level of motivation.

In line with the normative goal theory, that the most adaptive pattern would be high mastery goals and low performance goals, results of both studies (Study A and Study B) indicated that students in the group with high mastery/low performance goals had the highest achievement from all other groups even though the mean differences from the group high mastery/high performance group was not statistically significant, a result similar to Pintrich's study (2000). An important finding is that in both studies (Study A and Study B) this group had higher achievement that the groups of students with single high mastery goals. From these findings it can be concluded that performance goals when combined with mastery goals does not diminish the positive effect of mastery goals. Students who are concerned at the same time about their mastery and about their performance in comparison with others seem to have an adaptive pattern of achievement and motivation.

In line with the normative goal theory and parallel to other studies (Pintrich 2000; Kaplan et al., 2002) both studies (Study A, Study B) showed that the groups low in mastery goals both in combination with low or high level of performance goals are associated with negative results. Students in both of these groups reported low levels of achievement, interest, self efficacy and the highest levels of fear of failure.

The results of our studies may lead to the conclusion that mastery goals lead to the most adaptive patterns. Even though the results could inform teachers to work for the development of mastery goals in the mathematics classroom, the combination of high mastery goals with high performance approach goals may also lead to adaptive patterns regarding students' achievement and motivation. It was found that performance approach goals alone usually do not have a positive effect on students' interest (Zusho et al., 2005), a key factor in students' life-long learning. In this study's results, the group with high mastery/high performance declared the highest interest.

In conclusion, we suggest that more research is needed in the domain of multiple goals in relation to students' age, different learning contexts, and different measures of students' achievement.

Affective transgression in learning mathematics

Barbara Pieronkiewicz

Pedagogical University of Cracow, Institute of Mathematics, Cracow, Polan, basiapieronkiewicz@o2.pl

Mathematics as a school subject raises a lot of negative emotions within students. It is seen as a difficult, detached from reality, full of useless in everyday life definitions and theorems field of knowledge. Not surprisingly, it causes a lot of anxiety, emotional tension and internal discord. Nowadays, many students declare their humanities preferences in purpose to justify the lack of involvement in learning mathematics. This article looks at this state of affairs through the lens of psychological concept of transgression. The first and foremost cornerstone of this paper is the notion of "affective transgression". It is introduced after a brief exposition of transgressive concept of a man. This theoretical approach sheds some new light on teaching and learning mathematics.

Keywords: Transgressive concept of a man, affective transgression in learning mathematics, beliefs, meta – affect.

INTRODUCTION

A lot of attention has been paid to students' achievement in mathematics so far. Although researchers and teachers' efforts seek to improve the quality and efficiency of mathematics education, there are still many students who – for several reasons – achieve low scores in this school subject. What is more unsettling, is that many students declare humanities preferences in order to explain and legitimize their lack of engagement for learning mathematics and even among those who reveal their potential, there might be a significant number of underachievers (Rimm, 2008).There is a general agreement amongst mathematics educators that, regarding students' achievement, neither affect nor cognition should be underestimated (e.g., McLeod, 1992; Vinner, 2013). In that sense, many researchers have been examining how affect influences the field of mathematics education (e.g., DeBellis & Goldin, 1997, 2006; Schlöglmann, 2005). Fortus (2014) goes even further, stating that all science educators ought to pay more attention to affect. He claims there is a great urgency to lift students from boredom and indifference, because "without engagement, learning is partial, at best".

It is thus, of fundamental importance to focus research on understanding the role that students' beliefs about the egalitarian nature of mathematics and the importance of mathematics education in their lives, in the process of learning mathematics. Considering the transgressive concept of a man within mathematics education, brings new ideas that address these issues. The last part of this paper, attempts to compress (Thurston, 1990) efforts and considerations made by affect researchers so far, into a thinkable concept (Tall, 2004) of *affective transgression*.

MATHEMATICS FOR ALL OR FOR MATHEMATICALLY GIFTED

Many students hold the belief that to be good at mathematics, one needs to have some innate predispositions to grasp it, and that ordinary students cannot be expected to understand this school subject (Schoenfeld, 1992). In contrast, some psychologists or educators try to convince the broad audience to the egalitarian nature of mathematics. Already in 1973, Piaget mentioned that fact:

> Any normal student is capable of correct mathematical reasoning, if attention is directed to activities of his interest, and if by this method the *emotional inhibitions*, that too often give him a feeling of inferiority in lessons in this area *are removed*. (...) There is no field where the "full development of the human personality" and the mastery of the tools of logic and reason which insure full intellectual independence are more capable of realization. (Piaget, 1973, pp. 98–99, 105)

Aligned with those thoughts, also Krygowska referred to the nature of mathematics:

> There are different levels of mathematical activity and with the exception of extreme cases, we can find an appropriate level of activity to any normal student. (...) When it comes to the development of mathematical thinking, we *must not write any student off*. (...) The student has to *take a fancy to mathematics*, *find pleasure* in solving mathematical tasks, even though it requires effort and difficult concentration. (Krygowska, 1975, p. 243)

Although these statements were given in purpose to emphasize that mathematical skills can be developed by any student, they also refer to affect and explicitly ascertain that it impinges on learning mathematics. It is reasonable to expect that students who are afraid to expose their emotional or intellectual shortcomings will tend to avoid doing mathematics (and consider that they are not able to learn it). Many students tend to have a distracting behaviour in classrooms in order to try to deviate their colleagues and teacher attention from their own mathematics difficulties. As part of my research, I have interviewed a high school student having low scores in mathematics. According to the information given by his teacher, the boy usually had side conversations, made sniping remarks and was playing around on every lesson. In an individual talk we had, the student confessed that he was showing off to get the rest of the class laughing. The real reason why he was doing that, was that he wanted to divert his colleagues' attention from his mathematical misunderstanding. He said that it seemed easier to hold on when they were all laughing with him, under his control, on the jokes he made, than to hear the laughter on his failure. Thus if we want to convince young people, especially reluctant and disobedient low-achievers, that they may become 'good at math', we need to take into account students' vulnerability to affective stimulation coming from mathematics. Among many features this discipline has, one of the most remarkable is that mathematics, like no other field of knowledge, evokes human's affective responsiveness. For example, in the scope of the theoretical review one can find many references to math anxiety, and only very few references to anxiety outside mathematics (e.g., "chemistry anxiety" or "biology anxiety"). Nobody likes to experience negative frustration, fear or helplessness, being, in this context, the teachers' responsibility to develop their work allowing students to overcome such experiences. That's why some students prefer to avoid mathematics, rather than take the challenge and confront the constraints. Paradoxically, all of these negative experiences related to mathematics, could be seen as a positive phenomenon. Intentional reversing negative affective patterns (Rimm, 2008) may be recognized as much more than just about the achievement in mathematics, being linked with the reinforcement of a widely understood personal development and fulfilled life.

(GOOD) REASONS FOR LEARNING MATHEMATICS

In light of the above remarks, it is no surprise that one of the most frequently encountered questions that student pose to their teachers is "Why do we have to learn mathematics?". Every teacher should have the answer well considered in advance. This problem opens up a long list of questions collected by Posamentier and colleagues (2013), who recognize this question as a symptom indicating that students do not appreciate mathematics. They deem convincing answers like, for instance, mathematics is useful in everyday life, it provides a wide range of career opportunities. However, the most important reason they give, refers to the remarkable nature of the discipline:

> Mathematics is a huge, logically and deductively organized system of thought, created by countless individuals in a continuous collective effort that has lasted for several thousand years and still continues at breathtaking pace. As such, mathematics is the most significant cultural achievement of humankind. It should be a natural and essential part of everyone's general education. (Posamentier et al., 2013, p. 3)

The reasons one can present for learning mathematics are wide different and can inclusively be controversial. Some of the possible reasons could be by the fact that mathematics is "beautiful", and it's worth learning this subject for its own sake (e.g., Davis, 1993; Lockhart, 2009). From another point of view, learning mathematics can be seen as a stepping-stone to further education at all levels of the academic studies (e.g., Vinner, 2013). Some authors emphasize the assumption that mathematics trains the mind, and provides universal mental tools that enable us to reason correctly (e.g. Dudley, 2011). Others pay attention to the role that mathematics plays in our daily life or in STEM-related professions (e.g., Fortus, 2014). Several publications consider mathematics as a source of social empowerment, a central element of culture, art and life, and the driving force for the development of civilizations (e.g., Ernest, 2010). Some of the reasons given above are controversial. For example, there is no consensus neither within the case of usefulness of mathematics in everyday life (e.g., Lockhart, 2009; Wu, 1997) nor the demand for mathematical skills in the workplace (e.g., Dudley, 2011; Vinner, 2013). As part of my research, involving high school mathematics teachers, participants were asked for reasons for learning mathematics. Most of the given answers, akin to taglines, were related to mathematics usefulness and importance for daily situations (e.g. counting money, shopping) and shaping logical reasoning. But there were also answers as:

> I tell my students they should learn mathematics today, so they could teach others mathematics in the future.
>
> I tell my students, there is no escape from mathematics! Mathematics is everywhere!
>
> Look at lawyers for example. Do you think they could do the same work as a simple worker does? [The answer was "Yes"]. And now, look at the worker. Do you think that he could do the same things as the lawyer does? ["No."] Hence, you see, it's worth learning more because it gives you a wider range of possibilities.

What are possible responses a student could give to refute these arguments? They are easy to figure out: "I'm not going to teach mathematics to anybody", "Oh, it sounds scaring! Though you say there is no escape from math, ... I will try the best I can". A friend of mine told me an authentic story about a woman who was trying to encourage her son to doing mathematics, so he could have better life opportunities than she ever had. The boy said: "There is no sense in learning. Dad is a scavenger, you are a cleaner. What future do I have? I'm sure I will be doing exactly the same".

However, there is one undisputed answer, that no student could ever debunk. The transgressive concept of a man, discussed further, provides a new reason justifying the value of learning mathematics. Moreover, the concept yields a new perspective on students as both learners and humans concerned about their growth. Finally, the idea of *affective transgression in learning mathematics* emerging from this psychological concept, may be successfully implemented in school practice and result in improving "weak" students' achievement.

TRANSGRESSIVE CONCEPT OF A MAN

The term *transgression* is defined in different contexts (e.g. geology and genetics). In geology *transgression* is the spreading of the sea over land as evidenced by the deposition of marine strata over terrestrial strata; in genetics it means a peculiar case of heterosis - the increase in growth, size, fecundity, function or other characters in hybrids over those of the parents. In its transposition into psychological ground, Kozielecki (1987) uses terms of an intentional and deliberate overcoming of physical, social or symbolic boundaries. *The concept of psychological transgression* is devoted to the importance of the role that crossing over personal boundaries and subverting limitations play in everyone's life. From this standpoint, a man is a self-directed, expansive creature who intentionally crosses the *boundaries* understood as demarcation lines separating what he is and what he owns, from what he may become.

Kozielecki (1987, 1997) has outlined four worlds of transgression wherein the exceeding boundaries can be taken towards: 1) material objects - territorial expansion in the physical world, 2) other people - expanding the control over other people but also altruism and extension of individual freedom, 3) symbols - intellectual expansion; going beyond the information given, development of knowledge about the world and 4) oneself - self-creation, self- development, unlocking one's potential, coping with one's weaknesses. In that sense, transgressions may be of different kinds: psychological or historical, individual or collective, constructive or destructive, but also, in other level, it can be creative or inventive and expansions (e.g., material, interpersonal, intellectual).

The human being is assumed to be able to carry both the *telic* (goal-oriented) and *autotelic* (intrinsically rewarded) actions. In the former, he acts in pursuit of a variety of goals and creates new values that satisfy his needs. In the latter kind of actions, the goal is less important than the satisfaction and pleasure simply coming from carrying out activities. Moreover, regarding autotelic actions indicated by high level of involvement, Kozielecki states that *goals emerge from activity* not conversely, because goals in this case have no distinguished status. The author notices that goal-oriented activities become exhausting and boring in a short time, hence when the motivational tension relieves and the goal is achieved, a person ends up the task and refuses further actions. On the contrary, those who are totally committed to any kind of activity, do not feel tired. They forget about the lapse of time and even experience the state of *flow* (Csikszentmihalyi, 1991). Kozielecki (1997) emphasizes that thanks to the commitment we become more self-governing instead of being just human – robots.

However, from the viewpoint of transgressionism, another distinction is of higher importance. Kozielecki (1987, 1997) focuses on two kinds of actions that entities undertake: *protective* - designed for the maintenance of the *status quo* and *transgressive* ones – exceeding the boundaries and enabling the development of personality. The juxtaposition of these two types of human activity is presented in the table below.

Kozielecki puts forward the view that personality is equipped with a kind of internal *comparator* (a part of human's will), which allows comparing plans with achieved state of affairs. It is also the comparator that decides whether to stop the action or continue. The salient feature of the protective actions is that they are directed by the *principle of negative feedback* – reaching the goal (namely restoring or maintaining the status quo) ends up the activity taken by a man. On the contrary, transgression is directed by the *principle of positive feedback* which works reversely: not only isn't the motivation reduced, but also it is sustained or even increases during the activity. The notion of *affective reallocation* is introduced to name the positive correlation between adaptation and negative emotions on the one hand, and between transgression and positive affective experiences on the other. *Hope* may serve as a good example of such a positive experience. It is defined as a multidimensional cognitive structure, in which the central factor is the belief that in the future one will be offered the good (achieve an important objective), and the degree of certainty, or probability, is stated (Kozielecki, 2006).

These two kinds of behavior exposed briefly above, differ also in terms of the motivation involved. Two kinds of human's motivation are distinguished by Kozielecki (1987): *homeostatic* – a typical motivation for protective actions, (however, sometimes transgressions could also be stimulated by this kind of motivation) and *heterostatic* – a specific motivation for transgressive actions. The former arises if and only if in human's brain there are two independent information at one time: one concerning the desired state of affairs (S) and the second one, involving the actual state (A). When the comparator ascertains the existence of discrepancy D(S,A), the organism engages in behaviors designed to reduce the psychological imbalance. To get back to homeostasis, considered as a preferable state, a man undertakes actions intended either to dismantle the deficits or to remove the excess. This process leads to satisfaction and relief.

Protective actions	**Transgressive actions**
play key role in adaptation and survival	satisfy higher needs of a human being
regulated by the needs of deficit	regulated by the needs of growth
undertaken to maintain the status-quo	orientated toward a meaningful change
other-directed; depend more on the changing external environment	inner-directed; depend on the components of personality, for instance, creativity, knowledge, motivation, courage, perseverance
necessary	Possible
"I know I have to"	"I know I am able to"
repeatable	non-recurring
planned	Spontaneous
often predictable	harder to predict
accompanied by negative emotions, especially fear	accompanied by positive affective experiences, especially hope
performed similarly to following an algorithm	inherently heuristic, fallible, underspecified

Table 1: Protective actions vs. transgressive actions

Homeostatic theory focuses on the maintenance of the internal physiological environment. However this theory doesn't describe all human's behaviors adequately. For example: it is not sufficient to explain why people sometimes explore their environment and intentionally seek for arousal disrupting the equilibrium. What underlies human's motivation in this case is the driving force of growth. The discrepancy D(L,A) between the level of aspiration (L) and the actual state (A) raises internal tension that leads to actions oriented on growth and satisfaction. However, a man seen as an insatiable creature can never reduce D(L,A) completely. This discrepancy exists permanently. The role of the comparator is then twofold: it detects the existence of D(S,A) and evaluates the extent and the content of persisting D(L,A). Overall, then, we can state that homeostatic motivation serves to minimize annoyance, whereas the role of heterostatic motivation is to maximize the pleasure.

There are two specific types of the heterostatic motivation that lead to transgression. The first one, which has been coined by Kozielecki, is the *hubristic motivation*, "conceived as a cluster of motives that make people assert and enhance their self-worth" (Kozielecki, 1987, p. 177). It is the major driving force of transgression. *Hubris* (also: *hybris*) is a term derived from Greek literature and philosophy. In the past it meant pride, insolence and arrogance, but here it is deprived of pejorative meanings. Transgressive concept of man takes into account that every human being has the desire, at some point, to be distinct from others, to be important, to shine the spotlight on others. The hubristic motivation manifests itself as striving for superiority or striving towards perfection. It is insatiable, very affective, sated with egocentric and hedonistic drives.

The second type of the driving force specific for transgression, is *cognitive motivation*. It is nonegoistic, instinct to master and competence, governed by the principle of growth. It can be stimulated by the novelty or complexity of the subject, uncertainty or lack of information, as well as by the cognitive conflict raised when two or more contradictory beliefs, ideas, or values are held at the same time, or when existing beliefs etc. are confronted by some new directly contradicting information.

AFFECTIVE TRANSGRESSION IN LEARNING MATHEMATICS

In this section the focus is on providing a clear link between transgression and mathematics education.

A wide range of affect literature from around the world provides a considerable number of research reports exploring, in its depth and breadth, affective conditions of learning mathematics. The common reason why all these efforts are taken, is the more or less implicit assumption that identifying obstacles for effective learning, will contribute to a meaningful change in the quality and effectiveness of teaching. Paraphrasing Thurston, we can say that mathematics education is amazingly compressible, and "once you really understand it and have the mental perspective to see it as a whole, there is often a tremendous mental compression" (Thurston, 1990). Attempting to compress previous considerations made within the affect domain, into a thinkable concept (Tall, 2004), I herby introduce the notion of *affective transgression in learning mathematics* (short: affective transgression).

By *affective transgression* I mean an intentional process of overcoming personal affective barriers that preclude one's mathematical growth and development. The process is a psychological, individual and constructive transgression toward oneself. It is, by definition, highly recommended for low- and underachievers. Affective transgression might occur if and only if a person a) has insight into emotions (s)he experiences, b) is aware of the belief systems (s)he holds and c) has the will to make changes, believing they are good and possible. Meta-affect, considered to be the most important component of affect (DeBellis & Goldin, 2006), is inevitably required here. It should be developed to make all emotional experiences productive for learning and accomplishment.

Learning mathematics, seen through the lens of transgressive concept of a man, becomes an activity leading to inner growth and personal development. This argument seems to be a good and irrefutable reason that provides powerful meaning to the learning of mathematics. From the concept of hubristic motivation, we can deduce that even if students reject mathematics (as a school subject or as a domain where they are expected to be active), they will never write themselves off. Hence, until students (especially low- and underachievers) don't see doing mathematics as an autotelic activity enhancing their self-worth, they might refuse commitment. What is of the utmost importance, transgression accompanied by positive affective experiences (i.e. hope, faith), has a great impact on the language being used to describe students' relationship with mathematics. Every *problem* becomes a *challenge* now, *impossible* turns out to be *achievable*, or *not easy to achieve* and *the harder to achieve, the more wanted*. Protective actions that students take (Vinner, 1997), are replaced by transgressive ones, they are encouraged to. Thanks to this approach, external goals (like passing exam or having good grades) are eclipsed by the pleasure and satisfaction coming from student's endeavour.

Teachers have to meet two general prerequisites to make the affective transgression possible:

1) establishing growth-promoting climate in the classroom – which requires genuineness, unconditional positive regard and empathetic understanding. What counts most in effective treatment (Rogers, 1995) seems to be not a particular technique, but the personal relationship between teacher and his student,

2) transgression – oriented teaching, comprising both (meta)cognition and (meta)affect (DeBellis & Goldin, 2006).

Meta-belief systems activity (Moscucci, 2007) and *diagnostic teaching* (Schoenfeld, 2011) enriched with affect and meta-affect, may serve as transparent examples of practices that might evoke student's affective transgression.

As belief systems constitute the *weak* element of affect structure (Moscucci, 2007), they need to be identified first. This may come through observation or individual interviews. There are also scales, constructed and validated in purpose to measure beliefs (i.e., Kloosterman & Stage, 1992). It is the role of a teacher to recognize students' beliefs and bring them to their attention. If beliefs turn out to be a hindrance for one's growth and achievement in mathematics, they need to be restructured. Counterexamples as well as class or small group discussions of beliefs can be effective for reflecting on negative beliefs (Kloosterman & Stage, 1992). This is already a stepping-stone towards overcoming them.

FINAL REMARKS

This paper has offered an explanation of what transgressive concept of a man is. It is my attempt to bring closer and describe the phenomenon of *affective transgression*, I have observed many times in my teaching practice. The notion of *affective transgression*, introduced in this paper, is hoped for to be powerful inspiration for researchers in the affect domain.

Given the paper length restrictions, I shall conclude by few brief personal comments. First of all, it is very hard to reach out to low- or underachievers. Whoever remains just a mere teacher instead of being a whole person, will surely fail. And the second remark (last but not least) is that *teaching to transgress* stands in relation to *ordinary teaching mathematics*, much as *giving a fishing rod* stands in relation to *giving a fish*. A student who has experienced his personal "mathematical transgression", will never stop hungering for more. Just like once turned into a beautiful swan, the ugly duckling felt neither ugly, nor the duckling.

Teachers' individual beliefs about the roles of visualization in classroom

Angela Schmitz[1] and Andreas Eichler[2]

1 University of Education Freiburg, Freiburg, Germany, angela.schmitz@ph-freiburg.de

2 University of Kassel, Kassel, Germany, eichler@mathematik.uni-kassel.de

This paper investigates mathematics teachers' beliefs regarding the roles of visualization for teaching fractions and algebra. The paper discusses the construct of beliefs and theoretical roles of visualization. We further give rationale for the qualitative approach of our study. In the results we compare two teachers' beliefs from a larger sample. We work out that, although both teachers use visual representations in a similar way, they assign different roles to their respective use. Their beliefs appear to be stable across subdomains. We discuss our impression that the teachers emphasize other roles of visualization than educational research implies.

Keywords: Teachers' beliefs, visualization, domain-specific, fractions, algebra.

INTRODUCTION

The use of visualization is regarded as important for the teaching and learning of mathematics. Possible *roles* of visualization are for example to promote students' understanding (Presmeg, 2006; Duval, 2006), to enable problem solving (Heinze, Star, & Verschaffel, 2009; Duval, 2014; Arcavi, 2003), to discover, to describe, and to explain (Rivera, Steinbring, & Arcavi, 2014).

The demands on teachers to appropriately teach using visualization are high, e.g. to use visual representations in a conscious and active way (cf. David & Tomaz, 2012; Presmeg, 2014). Accordingly, nowadays it is emphasized to incorporate strategies on how to use visual representation into teachers' education (e.g., Presmeg, 2014). Thus, on the one side, we gained a lot of knowledge about a theoretical framework of visualization and a framework for teaching with visualization. On the other side, teachers seem to have complex attitudes regarding visualization (e.g., Gómez-Chacón, 2015). Yet we gained scarce results regarding the question of how mathematics teachers define the *role of visualization* for their classroom practice, or why they define the role of visualization in an individual way. However the teachers' thinking or rather their beliefs are understood to crucially impact on both these teachers' classroom practice (Calderhead, 1996) and their willingness to receive new information about teaching and learning with visualization (Chapman, 1999).

For this reason, our study aims to investigate teachers' beliefs about visualization in more detail. We seek to identify individual perspectives and reasons as to how and why teachers do or do not use visualization in classroom and which roles the teachers assign to visualization. In this report we try to give first answers to the following research questions, by means of a comparison of two teachers' beliefs:

(1) What are secondary teachers' beliefs about the roles of visualization in fractions and algebra? (2) To what extent do these roles differ in specific domains?

For this, we first outline our theoretical framework, including definitions of the constructs of beliefs and visualization and including an overview of the roles of visualization. Afterwards we discuss our method. The main part of this paper refers to results relating to the beliefs of two mathematics teachers from a larger sample. These teachers point out their understandings of visualization and their beliefs regarding the role of visualization. The results represent an empirical counterpart to our theoretical knowledge about teaching with visualization.

THEORETICAL FRAMEWORK

Definition of beliefs

In order to answer our research questions the multifaceted term "beliefs" has to be clarified. We chose a description given by Philipp (2007) who combines many similarities of existing definitions in the context of teaching and learning:

> Beliefs - psychologically held understandings, premises, or propositions about the world that are thought to be true. Beliefs are more cognitive, are felt less intensely, and are harder to change than attitudes. Beliefs might be thought of as lenses that affect one's view of some aspect of the world or as dispositions toward action. Beliefs, unlike knowledge, may be held with varying degrees of conviction and are not consensual. Beliefs are more cognitive than emotions and attitudes. (p. 259)

For this study, several aspects are important:

— As individual judgments about the validity of statements beliefs differ from knowledge, but they contain a cognitive component (Baumert & Kunter, 2006).

— Beliefs can be understood as lenses in the way that they form a specific world view. They are assigned to influence perception and action (Philipp, 2007).

— Being gradual incorporates that a belief regarding a specific role of visualization can individually be more or less important for a person (cf. the term of central beliefs; Thompson, 1992).

— Beliefs are classified as rather stable (cf. also Hannula, 2012) and refer to specific content (Eichler & Erens, 2015). Regarding visualization, we look for the specificity of beliefs referring to a mathematical domain, but also for similarities if different domains are regarded.

Calderhead (1996, p. 719) identifies "five main areas in which teachers have been found hold significant beliefs". Of these, "beliefs about learners and learning" as "assumptions teachers make about their students and how their students learn", "beliefs about teaching" as "beliefs about the nature and purposes of teaching", and "beliefs about the subject" as "epistemological issues - what the subject is about" are of interest when investigating beliefs about visualization (ibid.).

Definition of visualization

This study uses a broad definition given by Arcavi (2003, p. 217):

> Visualization is the ability, the process and the product of creation, interpretation, use of and reflection upon pictures, images, diagrams, in our minds, on paper or with technological tools, with the purpose of depicting and communicating information, thinking about and developing previously unknown ideas and advancing understandings.

The definition integrates many facets of visualization. The following are especially relevant for this study:

— It integrates process and product. In everyday language, which is likely to be used by teachers, both terms are often used synonymously.

— It integrates different ways of how to handle visualization, especially the meaning of making something visual for oneself (often: to visualize) as well as to make something visual for somebody else (often: to use a visual representation). Both aspects are important in classroom.

— It mentions diverse kinds of pictures. Thus, everything not being completely symbolic could be considered as visualization.

— It defines visualization as goal-oriented and enumerates purposes like advancing understanding. Yet the purposes are not considered to be exhaustive.

Roles of visualization in theory

The purposes of visualization lead to the different roles of visualization: Quoting different researchers in the introduction, we mentioned a list of possible roles of visualization, i.e. promoting understanding, enabling problem solving, facilitating discovery and explaining. Partially overlapping, Arcavi (2003) enumerates in his definition the purposes "depicting and communicating information, thinking about and developing previously unknown ideas and advancing understandings". From an epistemic point of view the roles which Giaquinto (2008) mentions are also specific for mathematics: proving, discovering, heuristic aid, augmenting understanding, and enabling calculation.

A comparison of the different definitions of visualization yields that it might be common to these roles that they could be grouped in (1) understanding, explaining (2) discovery, problem solving, heuristic aid, and developing ideas, (3) describing, depicting, and communicating information, (4) enabling calculation, (5) proving.

Empirical studies on teachers' beliefs regarding the role of visualization

However, there are few studies about teachers' beliefs regarding the *role of visualization*. For this report we chose three studies. Stylianou & Silver (2004, p. 353) report in a study about problem solving that "experts and novices perceive visual representation use as a viable strategy. However, the two groups judge visual representations likely to be useful with different sets of problems."

Biza, Nardi, & Theodossios (2009) investigate how teachers use visual arguments in proving in the domain of functions. Teachers who at first glance appreciate visual arguments reveal differences in the acceptance in follow-up interviews.

Research results from text-picture-integration suggest that teachers for different domains have different views on the use of visualization (McElvany et al., 2012).

These studies suggest that the role of visualization from a teachers' point of view might be related to a specific content. They also support the idea of a qualitative approach, as all of them show that it is important to investigate the teachers' thinking in detail.

METHOD

The research questions are part of a qualitative study about how teachers want to use visualization in classroom. The study is carried out with twelve secondary teachers. Further, the study covers the domains fractions, algebra, functions, and calculus, since these domains cover secondary mathematics of all ages, and visualization can be used in different ways, e.g., as a typical means of illustration (like the pizza in fractions), as a mathematical object (e.g. the graph of a function), or with a rather structural focus (e.g., drawings in algebra). The teachers are chosen by a "theoretical sampling" (Glaser & Strauss, 1967) which aims at contrasting cases (e.g., regarding type of school, age).

In semi-structured interviews lasting three-hours the teachers talk about how and why they use visualization in classroom. The interviews address the same questions for each domain, e.g. regarding the teachers' use of visual representations, their aims, their perspective on students' learning and their use of technology. It is completed by general questions about mathematics and mathematics teaching.

The interview transcripts are analyzed according to Grounded Theory (Glaser & Strauss, 1967). In open and axial coding we developed categories concerning the function and the relevance of visualization for the teachers. The objective is to generate theoretical concepts. In part, the concept aims at a consistent perspective on teachers' beliefs regarding the role of visualization in classroom. The roles might be different from existing theoretical frameworks.

The study does not investigate how teachers act in classroom. To explain teachers' practices, many other factors, e.g. pedagogical orientation and context (Philipp, 2007, p. 275), are to be considered. However, the study is based on the assumption that teachers' beliefs impact their classroom practice.

RESULTS

In this paper, we compare the roles of visualization in classroom for two mathematics teachers. Alan is a teacher at a comprehensive school with about ten years of teaching experience. Claire has been teaching at an upper secondary school for about twenty years. We develop the roles of visualization regarding fractions and algebra (quest. 1), and we analyze in how far their beliefs regarding these roles are domain-specific (quest. 2). First, we analyze Alan. The part regarding fractions is rather detailed in order to provide also an insight into the development of the codes. According to grounded theory the resulting hypotheses influence the analysis of Alan's statements about algebra. Then we analyze Claire in the same way, but more briefly.

Alan: Fractions

For Alan it is very important that his students first develop a conception of a fraction as a "part of the whole". From his point of view it is paramount that they can relate fractions with images, see for instance the following quotation:

> Alan: There [in fractional arithmetic] it is very important that, at the beginning, students have an idea of what a fraction is in the first place. [...] And this is something which they always have to keep in mind. [...] They really have to have this image in their heads.

He stresses that students develop his intended conception of fractions if they can use many different geometric forms. Also as regarding calculation in fractions, Alan considers visualization helpful. Expressions like "see", "have pictures of something", and "understand" are used synonymously, as he did already for the conception of a fraction. Alan believes that *visualization supports students' understanding*:

> Alan: For many, this [addition of fractions with a common denominator] is not clear at first. If you just draw it, they see it immediately.

At the same time, visualization is for him a methodical aid for *explanation.* Alan appreciates good reasons. Visual means can support him with this:

> Alan: Visualization also helps with improper fractions and mixed numbers [...] This you can somehow also do well with pieces of pizza [...].
>
> Alan: Reducing and expanding with rectangles, [...] this can be done perfectly with horizontal and vertical lines, like here. And then, once they have figured it out, I move on quickly to the purely algebraic.

In addition, the preceding quotation, and also the following, highlights his objective of withdrawing from visualization and his orientation towards algebraic objectives, for example the mastering of calculation techniques:

> Alan: You see, when calculating with fractions, we do not always think of anything graphic, either. And that is where I want to guide the students, too, of course.

At first glance, a contradiction seems to arise: Alan regards it as very important that his students have a visual image of a fraction. He also uses visualization for explaining calculation. However, at the end, for Alan calculation is a symbolic manipulation. Taking into account the above quotes, for Alan it might be sufficient to show the deduction of constructs or methods with the aid of visualization. This hypothesis *visualization supports justification* is supported by the following quote:

> Alan: In this case, it is really a lot easier to have remembered that you divide by a fraction by multiplying by the reciprocal, and so on. Nevertheless, it is important for them, of course, to have first understood the principle why this is so. And this just works well with easy visualizations. But then they quickly have to get past this.

Alan expresses the value of using visualization when introducing a subject as a basis for the following:

> Alan: That is why this introduction phase with the drawings always takes quite a long time. As far as this is concerned, I'm of the opinion that this is the basis for everything else which comes later.

But he only gives justification for an operation if he thinks that this is feasible with drawings that are easy to use (cf. reducing and expanding fractions). On the other hand, when he does not know an easy visualization he does not give a justification:

> Alan: This [division by a fraction] is difficult, because this is about how often one fraction fits into another fraction. You can visualize that wonderfully if the result is a natural number. But if a fraction fits four seventh times into another fraction that becomes difficult to visualize.

Concluding this paragraph we can say that Alan values visualization for *understanding*, for *explaining* and as *justification*. He only uses drawings which he finds easy to understand. Mathematics seems to have a deductive character for him: New things have to be logically derived from the well-known. As soon as they are justified they can be used without knowing the reason or the visualization.

Alan: Algebra

Alan's beliefs regarding visualization regarding algebra are very close to his beliefs expressed regarding fractions. For example, for solving linear equations Alan uses a drawn beam balance to support students' *understanding*:

> Alan: None of them know a beam balance any more, but intuitively they grasp it immediately.

The aim of using visualization is that the students get a plausible reason for the later procedure (*justification*):

> Alan: This will enable them to see what the effect of what we are illustrating is in algebra. And this is intended as a first explanation as to why or how equivalence transformations work.

He further consistently expresses the belief that for him the deduction is very important. If a plausible deduction is easier with other means than visualization, he uses other means. Visualization is not automatically related to deduction, but when he uses it, then often for deduction.

Interim summary 1

Alan regards the role of visualization as an aid to *understanding*, *explaining,* and *justifying* (quest. 1). These beliefs can be identified in two domains. This could be an indication for a belief that is similar in different (mathematical) domains (quest. 2).

Claire: Fractions

We compare the results regarding Alan with Claire's beliefs. She also uses visualization intensively when introducing a subject. Afterwards her aim is to establish schematic calculation. We would like to know if she assigns the same roles to visualization. Claire, too, develops the conception of fractions using many drawings:

> Claire: That is very important, so that they just get this idea of a fraction. Divide something in five equal parts, take three of these parts. That you also just visualize it.

Similarly she uses visualization for the illustration of most calculation operations. But she is not as convinced as Alan that visualization is helpful for understanding:

> Claire: Four fifth divided by three, however [...] How does it suddenly get into the denominator? Thus, I again made a drawing. [...] But this is one which is difficult to draw. I doubt that this really helps the students. I rather did it because of the requirement that I once learned that you always have to visualize, and how important this is.

She rather uses visualization because she learned it in that way. To visualize seems to be a *norm*: "Teachers use visualization when they introduce a new theme." On the other hand, Claire sees a high benefit for her students in the fact that they can remember the contents later because of the visualization:

> Claire: I always try to select something that still is easy to remember.

Although Claire shows quantities and development of the use of visualization in fractions similar to Alan, she associates different roles with it. She rather uses it as a *mnemonic aid*. Even if she is not convinced, she uses visualization for explanation. She rather seems to conform to an educational *norm* she learned at university.

Claire: Algebra

In algebra, too, Claire - like Alan - uses a balance for solving equations. She appreciates the possibility to *reactivate* knowledge once the subject is manifested:

> Claire: That is also something you can well remember later; once this has been understood, you can always come back to the balance [...], standing there with your hands on the left and right side.

She does not claim to present every subject in a visual way, as algebra seems to be a rather abstract domain, not related to visual elements:

> Claire: Algebra is something which is incredibly abstract, actually. [...] To get somewhere

in algebra, it is not always visualizations that does the trick.

Interim summary 2

One important reason why Claire uses visualization is a *mnemonic aid*. In fractions, she additionally associates visualization with a *norm*, in algebra she does not (quest. 1). The role of a mnemonic aid seems to be similar in different domains. Also her orientation on perceived norms, which might influence her beliefs about the role of visualization, seems to be similar in different domains (quest. 2).

DISCUSSION

This paper identified and compared beliefs regarding the role of visualization when teaching fractions and algebra, analyzing two secondary teachers, Alan and Claire. Both intensively use visualization as part of the introduction of a new subject, and both teachers tend to emphasize schematic calculation. However, in a deeper analysis, they show different beliefs about the roles of visualization. This result is in accord with Biza and colleagues (2009) who found teachers' beliefs about visualization to be similar at first glance, but to be considerably different upon closer inspection.

The identified beliefs about the roles of visualization are about learning (*understanding aid, mnemonic aid*), about teaching (*explaining aid, norm*), and about the subject mathematics (*justify*). The investigated beliefs appear to be rather stable across domains.

In comparison to existing frameworks, we find *understanding* as a role for both teachers, with high intensity for Alan. Both teachers use understanding "in the sense of one's grasp of a definition [...]" (Giaquinto, 2008, p. 36). Alan also uses it "not only [for] grasping the correctness [...], but also [for] appreciating why it is correct" (ibid.), which is related to the role of *justification*. Both teachers do not express much consciousness about the "conversion of representations" (Duval, 2006, p. 121) as a source of understanding. *Explaining* and *justifying* could be beliefs that are in a cluster (Thompson, 1992) with *understanding*.

From a teaching point of view the aspect of classroom practice as learned in teacher education, the *norm*, is important for Claire. This could be related to sociological and cultural aspects of using visualization in mathematics teaching (cf. Arcavi, 2003).

Finally, the *mnemonic aid* is a role which does not seem to be very important in the literature about teaching and learning of mathematics, but possibly in practice.

For these two teachers we found only a few indications related to discovery and problem solving (Heinze et al., 2009; Duval, 2014; Arcavi, 2003), especially when making a sketch related to an application-oriented task. There are also indications that visualization can serve to "enable calculation" (Giaquinto, 2008, p. 39); both teachers recognize the "visio-spacial nature" (ibid) of some algorithms they teach.

In our study, we did not prove that the teachers enact their professed beliefs. However, "under specific conditions the teachers' espoused beliefs could explain the teachers' enacted beliefs" (Eichler & Erens, 2015, p. 197).

Prospectively, we will compare our results to more domains, e.g. also functions and calculus, to see if the teachers' beliefs are stable across other domains. We further expect to find other beliefs regarding the role of visualization like using visualization as a method for overcoming students' fears, seem to be relevant. We hope to develop a theory of beliefs regarding the role of visualization for teachers.

Is boredom important for students' performance?

Stanislaw Schukajlow

University of Münster, Münster, Germany, schukajlow@uni-muenster.de

This experimental study of 192 ninth and tenth graders was conducted to investigate a connection between performance on different types of problems and boredom using task-unspecific and task-specific questionnaires. Students were randomly assigned to one of two groups and were asked about their boredom either before (Group 1) or after (Group 2) task processing. In Group 1, the relation between performance and boredom was different for different types of problems. In Group 2, students who achieved higher scores reported lower boredom across different types of problems. The connection between performance and task-unspecific and task-specific boredom did not differ significantly and ranged from 0 to -.36.

Keywords: Emotions, performance, boredom, modelling.

INTRODUCTION

In the current study, I focused on students' boredom and on the connection between boredom and performance as students solved different types of problems. The problems that were selected as content for the current study either had or did not have a connection to reality and could be solved by applying linear functions or Pythagoras' theorem. The research questions pertained to (1) the connection between performance and boredom, (2) the correlation between students' performance and task-unspecific boredom in comparison with the correlation between performance and task-specific boredom, and (3) the relation between performance and boredom compared across three types of problems.

THEORETICAL FRAMEWORK AND RESEARCH QUESTIONS

Boredom as a negative emotion

In educational research, emotions are defined as complex phenomena that include affective, cognitive, physiological, motivational, and expressive parts (Pekrun & Linnenbrink-Garcia, 2014). One important dimension of emotions is their valence. Researchers have often distinguished between positive and negative emotion/affect without specifying the kind of emotion they were interested in. Hannula and colleagues (2009) underlined the importance of overcoming such a simplistic view on emotions and suggested that researchers should identify which positive or negative emotions they are focusing on. For example, anxiety, frustration, and boredom have a negative valence and enjoyment and happiness have a positive valence. Another dimension that illustrates the importance of specifying emotions is the degree of activation or deactivation. This dimension describes the psychological states (activating excitement vs. deactivating relaxation) that humans report about emotions (Pekrun & Linnenbrink-Garcia, 2014). Negative activating emotions include anger, anxiety, and frustration. Hopelessness, and boredom are typical negative deactivating emotions.

Students' emotions influence their career aspirations and thus also their current and future lives. Self-perceived levels of boredom depend to a large extent on students' general experience at school and in particular on their experiences in specific school subjects (Jablonka, 2013). A control-value theory of achievement emotions assumes that the value of learning materials and the controllability of learning activities are important for students' emotions (Pekrun, 2006).

Boredom is one of the most frequently reported negative emotions in the classroom, and some researchers see boredom as a key problem of modern society (Klapp, 1986). For several decades, research efforts in education were focused on the negative emotion of anxiety, whereas the role of other negative emotions (e.g., boredom) in educational contexts and their relations to other emotions, learning goals, motivational variables, and performance were not yet well understood. However, in the last 20 years, theoretical models of emotions have been improved considerably. As boredom is a deactivating emotion that decreases human activity, a negative connection between boredom and performance or academic achievements can be expected. The few studies on the connection between boredom and performance often used students' final grades as an indicator of performance. These studies identified negative correlations between boredom and grades at school and at university (-.24 and -.64, respectively) (Goetz, Frenzel, Pekrun, Hall, & Lüdtke, 2007). Similar results were also found for the relation between boredom and grades or performance in elementary school (Sparfeldt, Buch, Schwarz, Jachmann, & Rost, 2009). However, as far as I am ware, in the only study conducted on students in early secondary school to investigate the connection between boredom and performance, no significant correlations between boredom and ninth-graders' argumentation, reasoning, or proof were found (Heinze, Reiss, & Rudolph, 2005). These contradictory results indicate the importance of enhancing research on the relation between boredom and performance using different approaches to the conceptualization of boredom in order to clarify the value and valence of this relation.

Measurement of emotions

The most commonly used measures of students' emotions are questionnaires, but analyses of self-reports given in interviews and analyses of students emotions during problem solving are also widely used in mathematics education (Jablonka, 2013; Pesonen & Hannula, 2014). Questionnaires used to assess students' emotions have shown high reliability and validity in previous research (Pekrun, Goetz, Frenzel, Barchfeld, & Perry, 2011; Sparfeldt et al., 2009). Questionnaires allow researchers to access data from large samples and to distinguish between different emotions such as hope, enjoyment, pride, anger, anxiety, boredom, and others (Pekrun et al., 2011). However, because of the complexity of emotional reactions, a multi-method approach can be helpful for accessing affect (Hannula et al., 2009; Schukajlow et al., 2012; Zan, Brown, Evans, & Hannula, 2006). One way to increase the coverage of questionnaires may be to take object-specific aspects of affect into account. Following this idea, two types of questionnaires for the measurement of boredom were applied in the current study (c.f. for enjoyment and interest Schukajlow & Krug, 2014a): task-unspecific affective scales, which were validated in other studies (Pekrun et al., 2011), and a new task-specific questionnaire applied in recent studies (Schukajlow & Krug, 2014a; Schukajlow et al., 2012). Another important factor that may influence students' boredom is task processing. Thus, we measured students' boredom before and after they solved problems in two randomized groups in order to compare the stability of the relation between performance and boredom.

The development of task-specific questionnaires is based on distinguishing different objects (or subjects) of students' affect. Similar approaches can be found in educational psychology, where achievement, epistemic, social, and topic emotions are separated according to their object focus (Pekrun & Linnenbrink-Garcia, 2014) or in mathematics education in the beliefs area, where the question of the subject-specific structuring of beliefs was suggested by Törner (2002). Object-specificity varies from very general such as "learning" or "mathematics" to specific ones such as "mathematical topic" or even "mathematical problem" (cf. Figure 1).

Sample statements for boredom illustrating the different levels of object-specificity are: "I get bored in classes", "I get bored in mathematics classes", "I get bored solving equations", and "I get bored solving the equation $3 + 2x = -4x$", respectively. Measurements for which statements with a high level of object-specificity are used (1) provide exact information about the kind of mathematics the researcher is interested in, (2) allow the investigation of new research questions that focus on the comparison of affective measures regarding different mathematical topics or kinds of problems, and (3) reveal high sensitivity to the changes in students' affect that can emerge from interventional programs. Empirical research has shown the importance of the differentiation between different domains and thus indicates the importance of object-specificity in measuring emotions (e.g., differentiating between boredom in mathematics and physics classes) (Goetz et al., 2007). As task-unspecific and task-specific questionnaires assess the same construct, I did not expect

Object	learning	mathematics	mathematical topic	mathematical problem
Level of object-specificity	low →			high

Figure 1: Objects and levels of object-specificity for affect

performance to be more or less strongly correlated with task-specific measures than with task-unspecific measures. This supposition was confirmed for interest and enjoyment (Schukajlow & Krug, 2014a), but it is an open question for boredom.

It is essential to distinguish between prospective affect (measured before task processing), current affect (measured during task processing), and retrospective affect (measured after task processing) (Ainley, 2006; Efklides, 2006; Schukajlow & Krug, 2014a). Each point of measurement reveals information about affect with regard to problem solving, and it can be important for past or future achievements.

Problems with and without a connection to the real world

To measure students' task-specific boredom, three types of problems that differ in their strength of connection to reality and are typically distinguished in research in modelling and application (Blum, Galbraith, Henn, & Niss, 2007) were selected. The types of problems were modelling, "dressed up" word, and intra-mathematical problems. All problems could be solved using the Pythagorean theorem or linear functions as mathematical procedures. To solve modelling problems, students need to understand the situation described in the task and must be able to construct a situation model of the task. Then they simplify the situation model by structuring and mathematizing, and they generate a mathematical model. The mathematical model can be transformed using mathematical procedures to create mathematical results, which have to be interpreted and validated. In the "dressed up" word problems, a mathematical model is "dressed up" by the situation; thus, students need to "undress" the problem, mathematize it, and use mathematics to solve it. Therefore, the problem solving process is not as complicated for this type of problem. As intra-mathematical problems are not connected to reality, students begin their problem solving process directly by using a mathematical model.

On the basis of the results of our previous study (Schukajlow & Krug, 2014a), we expected that there would be no significant differences in correlations between different measures of performance and boredom. Students with higher scores on performance tests were expected to be less bored when solving the problems.

Research questions

The research questions we addressed were:

1) Is students' performance connected to task-unspecific and task-specific boredom in mathematics measured before and after problem solving?

2) Is students' performance connected more strongly to task-specific than to task-unspecific boredom?

3) Are correlations between performance measures and task-specific boredom different for different types of problems (modelling problems, "dressed up" word problems, and intra-mathematical problems)?

METHOD

One hundred ninety-two German ninth and tenth graders from 4 middle-track and 4 grammar school classes (53.6% female; mean age=16.1 years, SD=0.86) participated on the present study. Students in each class were randomly assigned to two groups. In Group 1, the participants solved the problems first and afterwards reported on their task-unspecific boredom and on their boredom with regard to each problem. Students in Group 2 were asked about their task-unspecific and task-specific boredom and then worked on the performance test. The same tasks and questionnaires were administered to both groups (see Figure 2), and the students in these groups were given the same

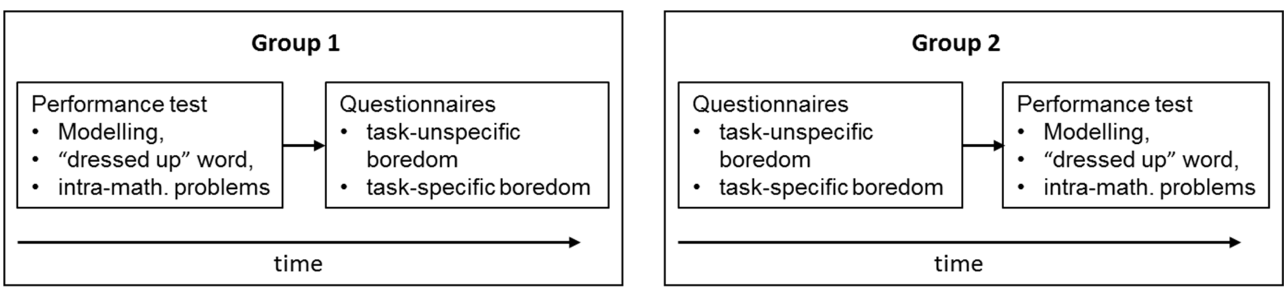

Figure 2: Design of the study

Maypole

Every year on Mayday in Bad Dinkelsdorf there is a traditional dance around the maypole (a tree trunk approx. 8 m high). During the dance the participants hold ribbons in their hands and each ribbon is fixed to the top of the maypole. With these 15 m long ribbons the participants dance around the maypole, and as the dance progresses a beautiful pattern on the stem is produced (in the picture such a pattern can already be seen at the top of the maypole stem).

At what distance from the maypole do the dancers stand at the beginning of the dance (the ribbons are tightly stretched)?

Figure 3: Modelling problem "Maypole"

amount of time to solve the problems and to fill out the questionnaires.

Sample problems

Eight modelling, eight word, and seven intra-mathematical problems were selected for this study. Sample tasks with and without a connection to the real world that could be solved using Pythagoras' theorem are presented in Figures 3 and 4. The maypole, football pitch, and side c were classified as modelling, "dressed up" word, and intra-mathematical problems, respectively (for more sample tasks and detailed analysis of classification see Krug & Schukajlow, 2013; Schukajlow et al., 2012).

Performance tests

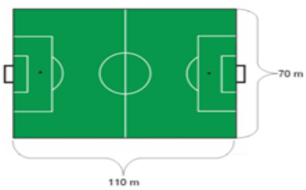
A performance test was developed for each type of problem. All tasks were examined within the framework of other projects. The Cronbach's alpha reliabilities were .59, .67, and .52 for the modelling, word, and intra-mathematical tests, respectively, and were acceptable for the small number of items and their diversity (across different contexts and/or different mathematical procedures).

Task-unspecific and task-specific boredom

Task-unspecific boredom was examined with a scale used in other studies (Goetz et al., 2007) and consisted of 4 statements that were answered on 5-point Likert scales ranging from (1=strongly disagree) to (5=strongly agree). A sample statement is "I am bored in mathematics classes". Cronbach's alpha was .85.

On the task-specific questionnaire, each of the 23 problems was followed by a statement about students' boredom. Both groups (cf. Figure 2) were instructed: "Read each problem carefully and then answer some questions." Group 2 was then told: "*You do not have to solve the problems"* because they were going to solve the problems after the boredom ratings, whereas Group 1 had already solved the problems, so they were told: "*You do not have to solve the problems (again)!*" After task processing, students in Group 1 were asked to rate the extent to which they agreed or disagreed with the statements "It was boring to work on this problem." Students in Group 2 were asked before task processing to rate the statements "It would be boring to work on this problem." A 5-point Likert scale was used to record their answers (1=not at all true, 5=completely true). 3 scales that measured task-specific boredom were formed across eight modelling problems, eight "dressed up" word problems, and seven intra-mathematical problems. The Cronbach's alpha reliabilities were .91 for boredom with the modelling and word problems and .85 for boredom with the intra-mathematical problems.

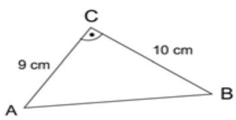
Football Pitch



Trainer Manfred would like to carry out a diagonal run with his team. To do so he would like to know how long the diagonal of the football pitch is. Can you help him?

Calculate the diagonal length of the football pitch.

Side c



Calculate the length of the side c = |AB|.

c= ________

Figure 4: "Dressed up" word and intra-mathematical tasks "Football Pitch" and "Side c"

Treatment fidelity

To examine the differences in the implementation of the treatment in Groups 1 and 2, a 5-point Likert item: "Before I agreed or disagreed with the statements (about task-specific boredom), I solved the problems" (1=not at all true, 5=completely true) was administered. Means and standard deviations were 4.3(1.17) for Group 1 and 2.19(1.01) for Group 2. The comparison of students' responses using an unpaired *t* test showed a significant mean difference between the two groups ($t(179)=13.07$, $p<.0001$, Cohen's $d=1.93$). This result shows that the students in Group 1 solved the tasks significantly more often than students in Group 2 *before* they reported their task-specific interest or enjoyment.

RESULTS

First, the connection between students' performance and boredom was analysed (correlations for Groups 1 and 2 are presented in Tables 1 and 2). As expected, students who solved the word problems better reported lower boredom on this type of problem. A similar result was also found for the relation between modelling and task-unspecific boredom. However, correlations of zero were observed for intra-mathematical problems and a weak and nonsignificant relation for the connection between performance and task-specific boredom on modelling problems.

In Group 2, in which students reported their boredom before solving the problems, negative correlations that ranged from -.24 to -.36 were found for all types of problems. Thus, students who felt low task-specific and task-unspecific boredom showed better results on the performance tests.

In order to answer the second and third research questions, Fisher's z transformation was applied, and then the z-scores were compared using a statistical procedure from Cohen & Cohen (1983, p. 54). This procedure provides information about the statistical significance of the difference between two correlations. The analysis of correlations for different types of problems presented in Table 1 and Table 2 showed that the largest difference between correlations was for the modelling problems in Group 1 (-.13 vs. -.33). However, the difference between correlations was not significant (z-score = 1.45, p = .14). Thus, students' performance was comparably related to task-specific and task-unspecific boredom.

The third research question addressed a comparison of correlations across different types of problems. The analyses of the values presented in Table 1 showed valuable differences between correlations for intra-mathematical and for "dressed up" word problems (0 vs. -.25) for task-specific boredom and between correlations for intra-mathematical and modelling problems (-.09 vs. -.33) for task-unspecific boredom. Both differences were significant at the 10% level (z-score = 1.74, p = .08; z-score = 1.72, p = .08, for task-specific and task-unspecific boredom, respectively). Thus, the correlation between performance and boredom with regard to the intra-mathematical problems tended to be weaker than the correlation between performance

		boredom			
		ma	w	mod	task-unspecific
performance	ma	0			-.09
	w		-.25*		-.29*
	mod			-.13	-.33*

		boredom			
		ma	w	mod	task-unspecific
performance	ma	-.36*			-.34*
	w		-.30*		-.28*
	mod			-.24*	-.28*

Note: *p<.05; ma intra-mathematical, w word, mod modelling problems; sample size N=92

Table 2: Pearson correlations between performance and task-specific and task-unspecific boredom in Group 2

and boredom with regard to the word problems for students who solved the problems before reporting on their boredom. Similar differences were also found for the correlation between performance on the intra-mathematical problems and task-unspecific boredom and the correlation between performance on the modelling problems and task-unspecific boredom. However, another pattern of correlations was revealed for Group 2. Higher levels of boredom were connected with lower levels of performance across all types of problems for Group 2.

DISCUSSION

In this paper, the relation between performance and boredom was analysed using task-unspecific and task-specific scales. The results were not univocal. When students reported on their boredom before they solved the problems, their level of boredom was negatively connected to their performance (see similar results by Goetz et al., 2007). Somewhat different results were found for students who estimated their boredom after task processing. Students who achieved low scores on the intra-mathematical problems reported about the same value for boredom as students who achieved high scores. Similar results were found for the connection between performance on argumentation tasks and boredom (c.f. Heinze et al., 2005).

The correlations between performance and boredom were comparable between task-specific and task-unspecific boredom. The analysis of this question with regard to interest and enjoyment in the previous study showed the same result for enjoyment and interest (Schukajlow & Krug, 2014a). However, the correlations for task-specific boredom deviated across the different types of problems more than they did for enjoyment and interest. This result confirms the importance of differentiating between different affective measures as called for by Hannula and colleagues (2009).

The comparison of correlations across different types of problems showed that the correlations tended to be lower for intra-mathematical problems than for word or modelling problems in Group 1. Thus, the type of problems may be an important factor that has to be taken into account in future studies. According to our findings, teachers should put more effort into decreasing their students' boredom when presenting word or modelling problems because boredom on these tasks is negatively connected with students' performance.

One important future research question is about the direction of connection between performance and boredom. Longitudinal and interventional studies need to be conducted to answer this question. More research has to be done for the development and validation of research instruments for the measurement of boredom. An interesting approach may involve using software to identify students' emotions (Pesonen & Hannula, 2014). Research on developmental models of emotions is another future area of research. Such research should examine whether general affective changers emerges from changes in task- and situation-specific affect. Finaly, we need more research on instructional elements which could deacrease boredom. A promicing teaching approach could be prompting students to find multiple solution for problems with missing information, which found to affect students' expirience of competence and interest (Schukajlow & Krug, 2014b).

Promoting cognitive engagement in secondary mathematics classrooms

Karen G. Skilling[1] and Gabriel J. Stylianides[2]

1 King's College London, Department of Education and Professional Studies, London, UK, karen.skilling@kcl.ac.uk

2 Univeristy of Oxford, Department of Education, Oxford, UK

Cognitive engagement (including self-regulation) is crucial for promoting student learning, but research suggests that teacher beliefs about cognitive engagement are less refined than their beliefs about other kinds of engagement. We used surveys and interviews from 40 teachers across 8 secondary schools to investigate teacher beliefs and practice that the teachers report using to promote cognitive engagement in their classes. Participants responded to questions about two fictitious teacher scenarios. About half of them identified with Teacher A, believing in the importance of completing practice questions and providing students with a list of revision topics. Those who identified with Teacher B favoured encouraging students to self-assess their competency, monitor their progress, and develop individual revision plans.

Keywords: Cognitive engagement, self-regulation, mathematics.

LITERATURE REVIEW

Promoting student engagement, interest, and participation in mathematics is considered important for students' learning and subsequent study in mathematics. In educational research high levels of student engagement are consistently linked to academic success (Wang & Holcombe, 2010) and are a predictor of students' achievement (Gettinger & Walter, 2012). There is a general agreement that engagement comprises three types—behavioural, emotional and cognitive—operating together (Fredricks, Blumenfeld, & Paris, 2004). Although engagement is considered a multidimensional construct with different types of engagement operating at varying levels of intensity, this research is concerned with the role of cognitive engagement in mathematics teaching and how teachers report promoting students' self-regulated learning in their classes.

Cognitive engagement

Cognitive engagement refers to students' approaches to academic tasks as well as their psychological investment in, and willingness to, master complex concepts (Fredricks et al., 2004). Conceptions of cognitive engagement draw on goal orientation and cognitive strategy use, whereas self-regulation theories that have historically been connected with motivational processes and academic functioning (Cleary & Zimmerman, 2012; Wolters & Taylor, 2012). Cognitive engagement includes thinking deeply and broadly about concepts while using strategies such as organisation, rehearsal, and elaboration as well as regulating and managing the learning process. Students' level of cognitive engagement is influenced by their goal orientations, the range of strategies students use, and students' underlying motivational factors. Components of self-regulated learning are considered particularly relevant to student cognitive engagement as they are both concerned with and are "used to understand students' functioning and performance with regard to academic contexts" (Wolters & Taylor, 2012, p. 635). For this study, frameworks for engagement and self-regulation are considered to be complementary, with the processes of self-regulation being considered important for cognitive engagement and involving a range of motivational factors as depicted in Figure 1. Although the focus of this study is on cognitive engagement and self-regulation frameworks, Figure 1 depicts how cognitive engagement is "dynamically interrelated" (Fredricks et al., 2004, p. 60) with behavioural and emotional engagement, while also acknowledging the influence of motivational and contextual factors on all types of engagement.

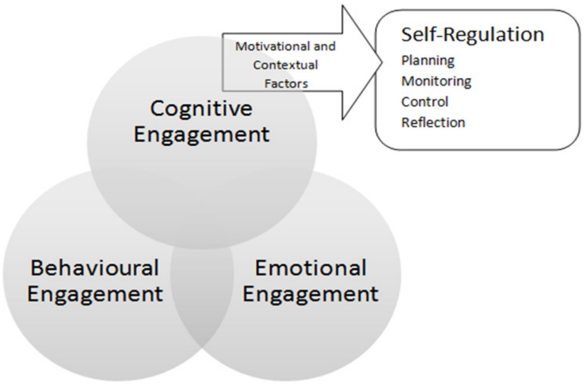

Figure 1: Types of engagement and self-regulation processes

Self-regulation

Self-regulation involves several important processes or phases for promoting deep learning. The phases include: forethought (goal setting and planning), monitoring and control, and reflecting on learning (Pintrich, 2004; Zimmerman, 2002). Self-regulation is centrally concerned with student agency and the degree to which students are active participants in their own learning. Therefore, while engagement frameworks tend to be more concerned about what students do, self-regulation frameworks focus on the processes students use to support their cognitive and behavioural functioning for managing their learning (Wolters & Taylor, 2014).

Self-regulated learners tend to be more aware of their knowledge, beliefs, motivations, and cognitive processes and, this awareness, allows these students to judge how successful or effective they are in their learning (Butler & Winne, 1995). The extent to which students are engaged in academic work and use self-regulatory processes is likely to be influenced by their goal orientation (Anderman & Patrick, 2012). Goal orientation is often determined by the student and influences the amount of time students spend prior to and during tasks on activities such as planning, organising, studying, monitoring, and reflecting. Students with high mastery goal orientations not only tend to use a variety of self-regulatory processes but also display a number of adaptive motivational factors such as self-efficacy, value, and persistence. Additionally, students' emotions play a central role in cognitive processing and engagement and should be considered together in learning settings; this is because student thinking and emotions are intrinsically linked to underlying motivational factors that influence cognitive processing (Hannula, 20006).

However, not all students have high mastery goal orientations or hold adaptive motivational factors. In any classroom the goal orientations of students are likely to be varied, and it is expected that not all students will use (effectively) self-regulative processes. Accordingly, students' ability to plan, organise, monitor, and reflect on their learning will also differ. Apart from individual goal orientations, in school settings sustained engagement in academic work is mediated and influenced by classroom contexts. Classroom contexts that can shape student engagement include the classroom environment and goal structures which are established through explicit and implicit teacher practices and teacher-student interactions (Anderman & Patrick, 2012; Reschly & Christenson, 2012). This means that what teachers do and say in their classrooms can influence students and mediate the use of self-regulatory processes, such as promoting forethought, considering prior knowledge, directing attention to key components, making effective strategy choices and reflecting on achievement to foster student cognitive engagement (Cleary & Zimmerman, 2012).

Teacher beliefs about and practices they use to promote cognitive engagement

In an earlier investigation, Skilling (2013) found that mathematics teachers' beliefs about cognitive engagement were less extensive and detailed than their perceptions about behavioural and emotional engagement. This may be in part because it is more difficult to identify signs of cognitive engagement (e.g., they are less observable than student behaviours) or because mathematics teachers feel less confident about assessing indicators of cognitive engagement. In addition, Skilling (2013) found that teachers reported practices for promoting cognitive engagement that were restricted to completing homework and study strategies focusing on behavioural aspects, such as time management; little did the teachers report about planning, monitoring, and evaluating student learning during lessons. Moreover, similar to a finding by Hardré (2011), the majority of teachers reported using practices that met students' immediate motivational needs such as explaining relevance, future use and application of mathematics concepts compared to few teachers who used practices that met students internal motivational needs, supported autonomous learning and mastery of concepts.

The focus of this study

The study we report in this paper builds on the research we described above by exploring teachers' beliefs about cognitive engagement and how these relate to the practices that the teachers report using to promote cognitive engagement in their mathematics classrooms. For this research, beliefs are defined as "psychologically held understandings, premises, or propositions about the world that are felt to be true" (Richardson, 1996, p.103). Teacher beliefs, therefore, vary according to their bearer and fundamentally reflect the relationship between what the teacher is considering when planning and executing instruction (Mason, 2008).

To conclude, this study focuses on the following research questions:

1) What are teachers' beliefs about cognitive engagement in early secondary mathematics classrooms?

2) What practices do teachers report using to promote student cognitive engagement?

METHODOLOGY

Data were collected from 40 teachers across eight secondary schools in England. The schools included five mixed ability comprehensive schools and three selective schools. There were two phases to this investigation: a teacher survey phase and a teacher interview phase. The designs of the survey and interview questions were guided by the components of cognitive engagement and self-regulation phases described earlier.

The teacher survey phase asked participants to respond to questions about two fictitious teacher scenarios (see Appendix). The scenarios outlined how Teacher A and Teacher B prepared the Year 7 students (11 years olds) in their classrooms for a mathematics test. Each scenario drew on literature from cognitive engagement and self-regulation to embed particular phrases as 'markers' to emphasise the different strategies and processes used by Teacher A and B.

The scenarios differed by the degree to which Teacher A and B promoted student involvement and used particular strategies and processes when preparing their students for a class test. For example, Teacher A handed students a list of topics for revision and told them to revise at home by looking over their notebooks, whereas Teacher B asked students to reflect on how competent they felt about particular concepts, to contribute to a 'class revision list' and to develop an individual revision plan. Teacher A told students it was important to get a high grade in the test, to ask for help if needed, and offered a small number of practice questions in class for those who may not have been revising at home. In contrast, Teacher B told students to focus on mastering concepts they did not understand, checked their revision plans and asked them how they felt about their test preparations. There were limited expectations by Teacher A about the range and depth of self-regulatory processes the students would use and there was an emphasis on performance rather than mastery goals. Teacher B, however, displayed expectations that students would use a range of self-regulation strategies and asked students to set their own goals based on their self-assessment, to make plans for mastering concepts, and to monitor and reflect on their revision preparation.

In the surveys, the participants were asked to respond to eight open-ended questions about the fictitious scenarios by referring to relevant line numbers provided for each scenario that they felt provided evidence for their responses. For example, participants were asked to compare their practices with those used by the teachers in the scenarios, to identify perceived similarities and differences between Teacher A and Teacher B, to list practices in the scenarios that they considered important or not important for student test preparation, to consider if their practices change with different groups of students (e.g., grade level, gender, achievement), and to indicate with which of the two teachers in the scenarios they identified more.

The second phase used semi-structured interviews with 17 participants who completed the first phase. The interview questions were guided by the survey questions and asked the participants to elaborate on selected survey responses. This included questions about their beliefs and the practices they report using to promote cognitive engagement in their classrooms. Questions probed participants' approaches toward setting goals and planning revision for assessments, and about monitoring and regulating learning processes during revision and when completing tasks in their classroom. The participants were also asked about ways they encouraged their students to self-monitor their progress. Finally, participants were asked to describe ways they provided feedback to their students about achievement, setting goals, regulating and reflecting on learning. The interviews were recorded and transcribed.

The analysis of the surveys and interviews drew on the cognitive engagement (Fredricks et al., 2004) and self-regulation frameworks (Pintrich, 2004; Wolters & Taylor, 2012), as components of these were reflected in the design of the two teacher scenarios. The responses to each survey question were listed and coded in association with the phrases or 'markers' that were embedded in the two teacher scenarios. The categories were then enriched with any additional practices that were reported by the teachers, providing data for addressing the research questions (Constas, 1992). This paper reports on key findings from the surveys supplemented by interview data.

FINDINGS

Of the 40 participants surveyed (coded T1-T40), 17 identified with Teacher A and 14 identified with Teacher B. From the remaining participants, six identified with both teachers and the other three identified with neither. This paper reports the participants' responses from three selected survey questions. The three questions were chosen because together they revealed participants' beliefs about (a) which teacher they identified with and why and (b) the practices of each teacher in the scenario that the participants believed to be (not) important in the context of the scenarios. Specifically, Question 1 asked participants: "Overall, which teacher do you identify with the most and why?" Questions 2 and 3 asked, respectively, participants to list up to two things that each teacher in the scenario did that they believed were important / not important for supporting the students' test preparation.

Participants who identified with Teacher A

The 17 participants who identified with Teacher A provided a total of 25 responses explaining their reasons for why they identified with Teacher A. The main reason given was that Teacher A was seen to have greater teacher control/structure/leadership (36%), with a strong "teacher led focus" (T9), and "a more structured approach and more control" (T4). The second most frequent reason was that Teacher A practiced concepts in class (16%) for example, stressing the "importance of practising the concepts" and holding a "revision lesson before a test to support [students]" (T7). The next most frequent reason was attending to student needs (12%), as several participants commented on the students being "needy" (T8) and that Teacher A "gave the students the most information about the test...to highlight individual weaknesses" (T2). The fourth most frequent reason was that Teacher A made better use of time in class (12%). See T6's response, for example:

I tend to like to direct my students towards their problem areas rather than let them take time to find them for themselves. Time always seem to be too much of a factor.

In response to Question 2, the participants who identified with Teacher A made a total of 33 responses to describe teacher practices in the scenarios that they believed were important for test preparation. The following practices were noted as being particularly important: setting practice questions in class (30%), for example slotting "tests in lessons leading to the main test" (T4); supporting students seeking help (24%), for example "making time to help students both in and out of lessons" (T8); and providing a list of topics for revision (21%), such as "handing out a sheet with key concepts (T9).

In response to Question 3, participants who identified with Teacher A provided 14 responses about the practices of Teacher B that were not important for supporting the students' test preparation (several participants did not provide a response). The three main practices believed to not be important were: developing individual revision plans (29%), asking students to self-assess their competency (21%), and contributing toward creating a class list (21%). Some participants questioned the value of asking students to develop their own revision plans because they felt that students "may not assess themselves accurately" (T2) or that students might "identify only what they think may be included" (T5) in the test. Creating a class list was believed by three of the teachers to be a waste of time wasting, such as for T6:

It takes time to develop a topic list as a class, which could have been spent more usefully completing actual questions. Would all students be able to manage their time to successfully draw up a revision plan and fulfil it?

Participants who identified with Teacher B

The 14 participants who identified with Teacher B provided a total of 20 responses explaining their reasons for aligning with this teacher. The main reason was the emphasis Teacher B placed on student self-assessment (40%). For example, these participants believed that students should be "reflecting as much as possible" (T27) on their work and should be "actively engaged in their own learning" (T26). Participants believed that an important feature of Teacher B's approach was that:

More emphasis is placed on students assessing what they can do and what they need to improve on and then going and working on those topics (T30)

The second reason was that Teacher B encouraged independence and student responsibility (30%). For example, several participants believed in encouraging student independence, noting that Teacher B used "strategies to encourage the students to engage with all aspects of their revision independently" (T23) and also handed "over ownership of revision to students" (T31). The third reason was the use of revision skills to plan improvements (25%). One participant believed that the purpose of revision was for "trying to get the students to understand which areas they need to improve on" (T28). Another participant noted:

Allowing students to identify their own areas to improve and implement their own plan is a step towards them improving because they want to, not because I am telling them they need to (T24)

In response to Question 2, the participants who identified with Teacher B made a total of 28 responses to describe teacher practices in the scenarios that they believed were important for test preparation. The most important practice included student self-assessment (32%), such as asking students "to assess their competency in each area" (T21) and encouraging students "to think about what might be in the assessment and self assess their confidence in these areas" (T24). The next most important practice was developing individual revision plans (29%), with one participant reporting that encouraging the "creation of revision lists and individual preparation gives the students' responsibility for their learning" (T24). The third most important practice was monitoring revision plans (18%) with several participants noting that the value of checking "revision plans to make them [the students] self-aware and in control of their revision" (T22).

In response to Question 3, the participants who identified with Teacher B provided 22 responses about the practices of Teacher A that were not important for supporting the students' test preparation. The main practice viewed as not important was "telling students it was important to achieve a high grade" (T20) (32%), as this was seen as "controlling and vague" (T23). It was also reported that "telling students to study more" (T24) was not important (27%) or that students should revise everything for a test (14%), as they "may not need to revise each concept" (T21).

CONCLUSION

Overall, participants who identified with Teacher A felt that this teacher tended to "be more structured" rather than giving students "freedom to think". Students were perceived as "needy" and Teacher A was believed to provide students with the "most information about the test". Additionally, participants who identified with Teacher A did not believe that making individual revision plans, asking students to self-assess, or contributing to a class list were important for supporting student test preparation.

In contrast, those who identified with Teacher B believed that practices such as student self-assessment, making individual revision plans, and monitoring revision progress were important. Participants who identified with Teacher B believed that this teacher's strategies encouraged "students to engage with all aspects of their revision independently". These participants also explicitly referred to specific processes of self-regulation such as planning, monitoring, checking and reflecting when responding to the survey questions (Cleary & Zimmerman, 2012; Wolters & Taylor, 2012), with the majority referring to at least two self-regulatory processes in their responses. Furthermore, participants who identified with Teacher B made comments about the importance of students being actively cognitively engaged in their learning by "allowing students to identify areas for improvement and implement their own plans"; they also emphasised student autonomy and responsibility for learning. The findings also suggest that the participants who identified with Teacher B believed in the importance of fostering student autonomy, independence and strategies for learning by using pedagogical practices that are associated with classroom mastery goal structures (Anderman & Patrick, 2012) and with promoting cognitive engagement and self-regulatory skills in their mathematics classrooms.

In this study just over half the participants identified with Teacher A and just under half identified with Teacher B, indicating that teacher beliefs about ways to promote cognitive engagement are potentially diverse. The results revealed that participants who identified with each teacher had strong beliefs about the practices they believed were and were not important for using in mathematics classes. Subsequently, one may hypothesize that participants who identified with Teacher A – and did not seem to believe in the importance of students developing individual revision plans, self-assessing their competency, or contributing to class revision lists – may be less likely than participants who identified with Teacher B to promote cognitive engagement and self-regulatory practices in their classes.

For this study the participants responded to scenarios that specifically asked about teacher practices for test preparation with Year 7 students. It is possible that different responses would be made for other situations, such as a 'typical' lesson covering a new topic or lessons with students of a different age. Future research can build on the findings of this study to investigate teachers' beliefs and self-reports about cognitive engagement and teachers' use of specific self-regulatory processes in their classrooms. For example, do teachers promote goal setting but not specific planning processes? In what ways do teachers promote students' self-monitoring of their learning? Do teachers ask students to reflect on their thinking and feelings as they work through and master difficult concepts?

APPENDIX: TEACHER SCENARIOS

Context: Two Year 7 mathematics classes at one school will complete a topic test during second term. The teachers of each class provided students with information a week before the test about ways they could prepare. Below are suggestions by Teacher A and Teacher B. Please read each scenario and respond to the questions at the end. The line numbers for each scenario can help to make references to the text.

Scenario involving Teacher A

Teacher A reminded students about the upcoming topic test and handed out a sheet with an outline of the key concepts that would likely be covered in the test. The teacher suggested that the students set aside time for revision and to make sure they practised each concept, by looking over their notebooks as it was important for them to achieve a high grade on the test. The teacher also mentioned that the students should ask questions in class if they were unsure of the steps to solve questions. Alternatively, they could come and see the teacher during break time to clarify any questions before the assessment. In each lesson before the test the teacher set five practice questions in case students had not been revising at home and students who got three or less correct were advised they needed to study more.

Scenario involving Teacher B

Teacher B also reminded students about their upcoming topic test. The students were asked to look through their mathematics notebooks and textbooks during the lesson and recall specific topic concepts that they thought would likely to be included in the test. Based on their class work, the students were then asked to record how competent they felt about each concept. During the lesson, the teacher also asked the students to draw on their self-assessment notes and contribute to the creation of a ‘class’ revision list, from which examples could be revised during lessons before the test. The teacher also told the class that it was expected that each student would develop individual revision plans. Students would work on their individual plans at home, making time to focus on mastering the concepts they believed they needed to improve on. Throughout the week the teacher checked the revision plans of each student and asked how they felt about their preparations.

The restricted yet crucial impact of an intervention on pupils' mathematics-related affect

Laura Tuohilampi, Liisa Näveri and Anu Laine

University of Helsinki, Helsinki, Finland

Past research clearly indicates that students' mathematics-related affect develops destructively during school years. However, not many efficient interventions have been done. The efficiency of the interventions may become minor if other factors dominate the development of affect structures. Also the methods in order to measure the impact might be insufficient. However, the negative development of affect must be taken seriously. Especially the most harmful consequences, such as girls' unnecessarily poor self-efficacy, needs to be tackled. Here, we present a three-year intervention designed to improve primary school pupils' problem solving skills, and consequently mathematics-related affect. The impact was restricted but crucial: girls' affect regarding mathematics decreased less in the intervention group.

Keywords: Mathematics-related affect, gender differences, development of affect, intervention.

BACKGROUND

Numbers of studies show that students end up having an unnecessary negative affect towards mathematics when they leave school (international results, e.g., in Lee, 2009; Sjøberg & Schreiner, 2010; national results, e.g., in Tuohilampi & Hannula, 2013; Hirvonen, 2012). In addition, affect develops destructively: children tend to have very positive affect (e.g., they view the learning subjects enjoyable, and see themselves very capable) when they come to school (Tuohilampi, Hannula, & Varas, 2014; Harter, 1999), but during the school years the affect turns negative (the enjoyment turns into dislike, the feelings of capability decreases) and harmful for learning (Tuohilampi, Hannula, Laine, & Metsämuuronen, 2014). Especially girls suffer from having negative emotions towards mathematics already after first three years of schooling. Also girls' self-efficacy has been noticed to be unnecessary low: even when performing well, a girl might feel incapable in mathematics (Tuohilampi, Hannula, Laine, & Metsämuuronen, 2014). The presented development is to some extent natural, as it is indeed necessary for children to get social responses, including negative ones, in order to be able to modify their self-concept. After an almost omnipotent view of the self in the childhood (Harter, 1999), a certain number of negative, significant responses contribute to a more realistic self-view. When it comes to mathematics, the worrying thing is that the students do not become only realistic, but also remarkably negative. Unfortunately, having negative affect towards mathematics makes people avoid such future choices where mathematics is included (Tuohilampi & Hannula, 2013). Further, there is some evidence that negative affect connects with poor participation with other students and learning activities (Kirshner, 2014). In addition, students' poor wellbeing, such as a negative self-concept in mathematics or disaffection (see Lewis, 2014), should be significant per se.

Tuohilampi, Hannula, Laine and Metsämuuronen (2014) noticed in their recent study of Finnish students that the deterioration of mathematics-related affect begins very early, already after 3rd school year. It is particularly interesting that this happens in Finland that has a reputation of a remarkable performance level acknowledged by national studies (e.g., Metsämuuronen, 2013), and by international studies (PISA-studies, see e.g. OECD 2010): this makes Finnish primary school pupils an interesting population when it comes to examine how to prevent the deterioration. Letting the affect become negative in the first place is particularly problematic, as repairing it has noticed to be hard work (Hannula, 2006). Also, cumulative disappointments can lead to the cycles of failure, fear, the expectancies of failure and test anxiety (Pekrun, 2006). This is why it would be wise to concentrate on maintaining the affect as positive as possible throughout the school years, with a special focus on the early school years.

Most mathematics-related interventions seem to concentrate on performance or cognitive problems, such as dyscalculia (see a review of mathematics-related interventions in Dowker, 2009). Fewer interventions have been done to improve affect. These interventions have had a focus on students' self-control, and social interaction. For example, in an intervention by Rimm-Kaufman and colleagues (2014) there was a Responsive Classroom approach (RC) in use, aimed to foster relationships in the classroom and support students' self-control to enhance student achievement. This goes in line with the studies of Pekrun (2006), who has introduced control to be one of the defining elements of optimal affect structure and its development. For example, Pekrun (ibid) argues that when the learning demands exceed pupil's individual capacities, she/he loses her/his control over the activity. This may lead the pupil to reduce the value of the activity in question, and make the experience boring. Finally, boredom may reduce the pupil's engagement with the activity by decreasing the effort one puts in an activity, consequently reducing future success.

Having control over the action (action-control expectancies) and trusting that the action will lead to the expected outcome (action-outcome expectancies) are the key elements in Pekrun's (e.g., 2006) control-value theory of achievement emotions. When it comes to mathematics, one cannot always see the path to the outcome at the beginning. Thus, in mathematics a certain degree of resilience and tolerance towards mistakes might be necessary. However, the pupils should experience their actions effective. This can be done by allowing the pupils to proceed through small and various steps. Pupils should have the expectation that their efforts are worth to be done. If the tasks would allow different strategies in order to find the solution, many of the pupils' efforts would be beneficial. That is how they can have action control expectancies. On the contrary, there are less action-control expectancies if the pupils just either know or do not know the only possible solution. The expectancies the pupils have also connect with the amount and quality of responses the pupils get from their significant others. If it is a clear cut that a pupil either knows or does not know the solution, the evaluation the pupils make about themselves may become very polarized. Some pupils can make it, some pupils cannot. If, on the other hand, there are plenty of possibilities to proceed within the tasks, and the steps are small enough, it should be more likely that every once in a while even the weakest pupils succeed, and the strongest pupils make an incorrect effort. In such circumstances, the peer evaluation becomes versatile, and the responses the pupils get from their efforts diverse. That in turn plays a role on pupils' affect structure construction.

In addition to control and social interaction, improving mathematical understanding may be one path to achieve more positive affect: in a longitudinal study of Tuohilampi and Hannula (2013), high performance was the biggest cause of positive affect in future. These three elements connected with the optimal affect structure development suggest that an intervention could, or even should include the following goals: 1) minimize negative responses that are unconstructive, 2) give students possibilities to control their actions and 3) support students' understanding about the content of learning. However, even a good intervention faces a challenge of affect structure's resilience, as the dispositions of the students are noticed to be fairly robust. Chapman (2002) for example has shown that there is a need for open conflict that is meaningful to the holder before a change in the affect structure is likely.

One way to reach the presented three intervention goals is to use open ended problems. In such problems, more than one solution can be possible, and to find a solution, pupils need a linear or a cycling problem solving process where they use their resources, heuristics, beliefs, and abilities of monitoring and self-regulation (Schoenfeld, 2012). Because of the nature of the open ended problems, there are usually many opportunities where to start and how to proceed. Following that, there is typically at least something a pupil can initiate and perform. In addition, because of the several options of how to find an answer (or answers), the pupils' own actions ought to produce a positive outcome in most cases. Thus, using open ended problems should lead to high action-control expectancies, as well as high action-outcome expectancies (Pekrun, 2006), and consequently, the possibilities to control actions and learning is guaranteed to the pupils (the intervention goal number 2). These elements, on the other hand, widen the strategy options and thus decrease the number of "wrong choices". Following that, the negative responses from significant others regarding pupils' actions could be minimized (the intervention goal number 1). Open ended problems may also enhance pupils' understanding as they allow connections to several or untypical contexts. A traditional instruction, wherein specific learning content is mostly connected with the same, isolated context makes pupils' knowledge structures fragmented, and does not help pupils to generalize their thinking. In their study about students' conceptions Saglam, Karaaslan, and Ayas (2010) show that fragmented, isolated knowledge structures, produced by restricted contexts, cause students to fall short in solving problems across contexts. Thus, the use of open ended problems having less limited contexts may help pupils to create deeper and more applicable understanding (the intervention goal number 3). In this study, we report how an intervention that is built around open ended problems, guaranteeing the three intervention goals presented above impacts primary school pupils' affect structure development.

INTERVENTION

Here, we examine a three-year intervention from 3rd to 5th grade which included a monthly activity with a mathematical problem. The problem was in most cases an open ended and they were selected or developed by the research group. The teachers were allowed and instructed to execute the problem solving sessions according to their preferences. In most cases, the teachers used collective activities wherein pupils were allowed to discuss the problems, to move, and to work collaboratively.

We will introduce two of the problems that were used during the intervention. The first one to be presented is "Divide a square: Make such a division to a square that makes the two parts of the square totally equal. How many different solutions can you find?" This problem was implemented in the 3rd grade and it was the second problem in the project. In the pupils' solutions, five levels of thinking were present: level 0 = no solution; level 1 = the two most obvious solutions (two triangles and two rectangles); level 2 = division by a straight line that is not diagonal, nor passes the middle points of the sidelines of the square; level 3 = the thinking of level 2, replacing the straight line with a curve; and level 4 = clearly understanding the central symmetry of the task (Laine, Näveri, Pehkonen, Ahtee, Heinilä, & Hannula, 2012). Because of the five levels of understanding, the active nature of the task (a pupil could easily just use a pen to figure out the solutions), and the collaboration the pupils were allowed to have during the task, the intervention goals presented above were fulfilled. The second problem to be presented here is "*Etana-Elli (= a snail called Elli): Etana-Elli climbs up a wall very slowly. During some of the days she gets up 10 cm, during some of the days 20 cm, during some days she sleeps and does not move, and during some days she is in a very deep sleep and descends 10 cm. The wall is 100 cm high. After ten days of climbing, Etana-Elli is on a halfway of the wall (which means that she has mounted 50 cm).What could have happened during the first 10 days? Describe as many scenarios that are possible.*" This problem was implemented in 4th grade being the 7th problem in the project. Also in Etana-Elli -problem the pupils could easily initiate actions, and several solutions were possible. Thus the intervention goals got fulfilled within the problem.

METHOD

The data used in this study was gathered within a research project that aimed to develop mathematics learning and affect structure among pupils in Finland and Chile (see further description of the project in Laine, Näveri, Pehkonen, Ahtee, Heinilä, & Hannula, 2012). Here, we focus on Finnish pupils' data, wherein the number of pupils that participated either the pre-test, the post-test or both tests was 320. The pre-test data was collected in regions near to Helsinki at the beginning of the academic year 2010–2011 during September-October 2010. The post-test data was collected within the same classes at the end of the academic year 2013–2014 during April-May. The schools are fairly uniform in Finland (see OECD, 2010, p. 87), so the data can be considered representative to urban pupils in Finland. In the pre-test, there were 25 classes involved. 10 out of these classes were intervention groups, the rest of them being control groups. In the post-test, six control groups were not reached and three intervention groups had left the project (they quit doing the tasks, but yet participated in the post-test). Among the three classes that quit, one had participated in the project for two years whereas the other two had participated only one year. We decided to include the class that had participated for two years (i.e. more than 50 % of the intervention tasks) but exclude the classes that had been participating just one year (i.e., less than 50 % of the tasks). Moreover, there was a teacher change in two of the included intervention groups, and some movement regarding the pupils had happened, as there were pupils in the pre-test but not in a post-test and vice versa: those pupils' data were excluded from the analysis. In sum, we included in the data pupils who had participated in all the intervention tasks or at least 2/3 of them, and that had participated both of the measurements, but might have had a new teacher during the intervention.

The following factors of affect were measured in the questionnaire: self-competence, (spice item: "I have made it well in mathematics"), self-confidence ("I am sure that I can learn math"), the difficulty of mathematics, referred to as DoM ("Mathematics is difficult") representing cognitive dimension; the enjoyment of mathematics, referred to as EoM ("I have enjoyed pondering mathematical exercises") representing emotional dimension; mastery goal orientation, referred to as MGO ("On every lesson, I try to learn as much as possible") representing motivational dimension; and effort ("I always prepare myself carefully for exams") representing behavior. The purpose of the instrument was to catch the trait aspect of affect (see discussion on the cognitive, emotional and motivational dimensions, and the state - the trait aspects of affect in Hannula, 2011). The instrument was a shortened and simplified version of the instrument used by Hannula & Laakso (2011) to measure 4th grade Finnish pupils. The instrument worked well in that context and seemed suitable for measuring mathematics-related affect within Finnish population. In the instrument there was a 3-point Likert scale in use ("true", "partly true", "not true"). Bearing in mind that the pupils were just 9-year old in the pre-test it was justified to use only three points, as this makes the instrument simpler. The scale is an ordinal scale, as the middle option, "partly true", may situate differently between the two ends depending on the examinee. In the questionnaire some of the items were direct (e.g., "I have made it well in mathematics"), while some were indirect (e.g., "I am not very good in mathematics"). For the analysis, the items that had an inverse content were recoded to share the same direction with directly stated items.

Before starting the analysis, we constructed a sum variable of all the questionnaire items regarding both measurements. The reliabilities (measured by Cronbach alpha's) were satisfactory: $\alpha = .895$ in the pre-test and $\alpha = .858$ in the post-test. To find out the answer to our research problem, we calculated the distributions of pupils' affect within both measurements. A paired sample t-test was used to compare the means of the distributions regarding the two measurements and an independent sample t-test was used to compare the means of the distributions regarding intervention and control groups and genders.

RESULTS

In Table 1, there are the distributions of all items' sum variable regarding all pupils, intervention group, and control group.

The mean of all items for all pupils in the pre-test was 1,37 (1 = positive, 3 = negative), and the standard deviation was 0,30. In the post-test, the mean of all items for all pupils was 1,64, the standard deviation being 0,29. In a paired samples' t-test there was a statistically significant difference between the pre-test and post-test regarding all the pupils ($t(193) = -11.88$; $p < .000$), the intervention group ($t(108) = -9.72$; $p < .000$), and the control group ($t(84) = -6.98$; $p < .000$). The results indicate that there is a remarkable decline in pupils' affect regarding mathematics from the beginning of the 3rd to the end of the 5th grade in both the intervention group and control group.

When it comes to the differences between the intervention and the control group, no statistically significant difference was found with respect to all items

	Group	Positive	In between	Negative	N
Pre-test, all items	All pupils	168 (75,3%)	54 (24,2%)	1(0,4%)	223 (100%)
Post-test, all items	All pupils	90 (32,4%)	186 (66,9%)	2(0,7%)	278 (100%)
	Intervention group	41 (33,9%)	80 (66,1%)	0 (0%)	121 (100%)
	Control group	49 (31,2%)	106 (67,5%)	2 (0,4%)	157 (100%)

Table 1: Distributions regarding all pupils, intervention group, and control group

in post-test ($t(276) = -.67$; $p = .505$). Looking further at the differences between the groups factor by factor in post-test did not change the picture: $t(287) = -.06$, $p = .954$ regarding self-competence; $t(294) = -.79$, $p = .433$ regarding self-confidence; $t(290) = -1.50$, $p = .134$ regarding the difficulty of mathematics; $t(290) = 0.62$, $p = .533$ regarding the enjoyment of mathematics; $t(294) = -.57$, $p = .571$ regarding mastery goal orientation; and $t(290) = .62$, $p = .536$ regarding effort. Besides the non-significance between the groups, no trend was found regarding the minor differences regarding the different variables, as with respect to one variable the mean could be lower for the control group, but with respect in another the mean could be lower for the intervention group.

When it comes to the gender differences, we still did not find any significant differences in either of the tests (gender difference in pre-test: $t(122) = 1.05$, $p = .295$; gender difference in post-test: $t(140) = 1.57$, $p = .118$). However, when testing the control group's and intervention group's difference in the post-test separately to genders, a statistically significant difference was found regarding girls' development (girls: $t(67) = 2.08$, $p < .05$; boys: $t(87) = .42$, $p = .634$). The mean of the control group girls in the post-test was 1.82, and for the intervention group girls 1.65. This means that the girls had benefitted from the intervention, but not boys. The significance in the development came through two factors: self-confidence ($t(729 = 2.39$, $p < .05$), and EoM ($t(72) = 2.47$, $p < .05$).

DISCUSSION

We have reported the impacts of a three-year intervention aimed to improve primary school pupils' mathematics-related affect through focusing on pupils' control on their learning, social interaction, and mathematical understanding. According to our results, the impact was not as strong and widespread as one would have hoped. For the sake of future interventions sharing the same goal, it is necessary to gain knowledge about why it had such a minor impact. Even the effects of a well-designed intervention may become disguised by other features in school, more significant to the pupils. As Chapman (2002) has shown, a significant conflict is needed to allow affect structure to become reorganized. The pupils in an intervention may get positive experiences, yet those experiences might be less significant than school expectancies, peers' perceptions, or teacher's actions effect.

The other perspective is the method used here. Perhaps a questionnaire based quantitative data does not reveal all the possible nuances that might have been affected during an intervention. Qualitative analysis could perhaps better show less visible changes and thus reveal a stronger result. A mixed method approach could be advisable. However, as there was no significant difference between the whole intervention and control groups, it seems likely that a stronger change in the practices is needed. In our intervention, there was a monthly problem solving class for three years. Maybe the amount of doing was too little for the pupils, or maybe such classes would need different school culture to be more effective. For example, pupils in Finland do not rate their learning environment as positive as their mates in other cultures do (Tuohilampi, Laine, Hannula, & Varas, submitted). Thus, pupils in Finnish classes might need support to become effective with working socially among problem solving. The intervention presented here would possibly have become more efficient if there had been more support for pupils to become socially active.

The benefit for girls in the intervention related to their self-confidence and enjoyment of mathematics. This is extremely critical, as girls suffer poor and unrealistic mathematical self-confidence worldwide (Syzmanowics & Furham, 2011) and in Finland (Tuohilampi & Hannula, 2013). This makes girls avoid mathematics in future (ibid.), so even the impact was restricted on girls, it was extremely welcome. Girls' emotions towards mathematics have also been critical (ibid.), and it is delighting that the intervention could help girls to maintain their emotions more positive. Hannula, Kupari, Pehkonen, Räsänen, & Soro (2004) have presented that collaborative atmosphere and learning methods connect with increasing self-confidence and mathematical performance especially regarding girls. This seems natural, as while girls feel less confident with mathematics in general, they might find it helpful to work in co-operation with others. Thus the benefit for girls might have come through the increase in collaboration. Girls also differ from boys in their interests, as boys are more oriented towards technical aspects of science whereas girls tend to show more interest in human issues (Sjøberg & Schreiner, 2010). It is possible that there are different cognitive styles between genders, and the non-competitive context affected more to girls' style. To give some critique, one has to be reminded that making several t-tests may lead to misleading statistical significances raised just by a coincidence. However, what the girls benefit is in line with their needs, and the p-values were very near to $p < .01$.

This study has given us the insights of the possibilities and the restrictions an intervention may have. We continue to work with the rich data collected during the research project to contribute our knowledge of the development of mathematics-related affect in even more nuanced ways.

Emma’s mathematical thinking, problem solving and affect

Hanna Viitala

University of Agder, Kristiansand, Norway, hanna.l.viitala@uia.no

This paper aims to understand one pupil’s mathematical thinking through problem solving and mathematics related affect. The results reveal a successful, though quite unsure, problem solver whose affective state (connected to problem solving) seems to tell the same story as her affective trait (view of mathematics). The differences between results on affective state and trait seem to be connected mostly to emotions.

Keywords: Mathematical thinking, problem solving, affect.

THEORETICAL FRAMEWORK AND RESEARCH QUESTION

Developing mathematical thinking is one of the three tasks of instruction listed in the Finnish National Core Curriculum for Basic Education (Finnish National Board of Education [FNBE], 2004, p. 158). Some aspects of mathematical thinking are evaluated through tests at school, at the national (e.g., Rautopuro, 2013; Hirvonen, 2012) and international (e.g., OECD, 2014; Mullis, Martin, Foy, & Arora, 2012) levels. However, we lack a deeper understanding of the mathematical thinking pupils’ take into their lives and possible further studies after comprehensive school.

Mathematical thinking is not defined in the curriculum, but a list of thinking and working skills is provided as evaluation criteria for every age group. These lists include learning objectives such as pupils’ use of logical elements in their speech, judging truth of simple propositions and noticing parallels and regularities between different events (FNBE, 2004, p. 166). For sixth to ninth graders, ‘thinking skills and methods’ is also introduced as its own entity in the learning objectives parallel to core contents such as algebra and geometry (Mathematics curriculum, ibid, pp. 158–167).

When thinking skills and methods are listed in the curriculum, problem solving is repeatedly referred to. The term ‘problem solving’ is not defined. However, in final-assessment criteria for ninth graders, four problem-solving phases are introduced. These phases are similar to Polya’s (1957) problem-solving phases. The process view on problem solving also guides this study where (in line with the curriculum) pupils’ activities, actions and explanations during problem solving are interpreted as visible signs or expressions of their mathematical thinking.

In this study, thinking is considered mathematical when it relies on operations that are mathematical (Burton, 1984). Furthermore, a mathematical task is called a problem if the solver has to combine previously known data in a new way to her to solve the task (e.g., Kantowski, 1980).

When mathematical thinking is described, in addition to cognitive aspects, we should also explore affective factors (e.g., DeBellis & Golding, 2006; Vinner, 2004) and seek to understand the interrelationship between affect and cognition (e.g., Hannula, 2011; Zan, Brown, Evans, & Hannula, 2006). Instead of categorizing affective factors for instance as beliefs, attitudes or values, affect is seen as a mixture of cognitive, motivational and emotional processes:

> Cognition deals with information (self and the environment), while motivation directs behaviour (goals and choices). Success or failure in goal-directed behaviour is reflected in emotions (e.g., shame). These emotions, in turn, act as a feedback system to cognitive and motivational processes. (Hannula, 2012, p. 144)

Affect is seen as a psychological domain with its state and trait aspects (Hannula, 2011). In connection to problem solving, we focus on rapidly changing affective states. The more stable affective traits follow the categorization of pupil's view of mathematics introduced by Pehkonen (1995; discussed also in Op't Eynde, de Corte &, Verschaffel, 2002). These categories are mathematics, oneself as a learner and user of mathematics, learning mathematics, and teaching mathematics.

In an aim to understand the interrelationship between cognition and affect in mathematical thinking, we look at one pupil's, Emma's, problem solving and explanations on affect related to mathematics. The information from this exemplary case can later be combined with other cases to form a more informative view on mathematical thinking at the end of Finnish comprehensive school. So, with the question '*What characterizes Emma's mathematical thinking?*' we try to understand the mathematical thinking Emma takes from comprehensive school into her life and further studies (cf. mission for basic education in FNBE, 2004, p. 12).

METHODS

The data was collected in three cycles. Emma's results from the first cycle are discussed in Viitala (2015). This paper adds both problem solving and affective results and reports on findings from all three cycles of data collection.

Participant

Emma is a high achieving girl (mathematics grade 9 on a whole number scale of 4 to 10) who was selected for this paper based on a previous report (Viitala, 2015). The data collection was organized in the first semester of 9th grade when Emma was 15 years old.

Data collection

The data was collected from mathematics lessons and interviews over the course of three months. In each of the three cycles, one mathematical task was solved in an ordinary classroom situation as a 'main task'. In Emma's case this meant that the pupils solved the tasks individually but they were allowed to talk about the tasks with a friend or ask for help from the teacher. In each of the three cycles, Emma was video recorded while she solved the task(s) in class and her solution on paper was collected.

The interviews took place either on the same day, or on the next day after solving the task in the classroom. The interviews contained two parts. The first part concentrated on affective traits and treated the following themes: pupil's background, mathematical thinking, and pupil's view of mathematics (following the categorization of Pehkonen, 1995; see example questions in Table 1). This part of the interview was semi-structured and focused (Kvale & Brinkmann, 2009).

The second part of the interview was about problem solving. The classroom data was used as stimuli when Emma's problem solving was discussed. Emma explained her actions and thinking and responded to questions such as, 'What are you thinking now?' and 'Why are you doing so?' Also, some affective and metacognitive questions were asked, for instance, 'What did you feel when you read the task?' and 'Did you think about your own thinking when solving the task?'

Finally, Emma was asked to assess her confidence before, during and after solving the problem(s), as well as her confidence in school mathematics using a 10 cm line segment (scale from 'I couldn't do it at all' to 'I could do it perfectly'; cf. estimation of certainty, e.g., in Merenluoto, 2001). All interviews were video recorded.

The tasks used in this paper are released PISA items. PISA tasks are well tested and based on real-life situ-

Theme	Example questions
Background	Tell me about your family.
Mathematical thinking Mathematics	What does mathematical thinking mean? / How do you recognise it? What is mathematics as a science? / Does it exist outside of school? (How? Where?)
Oneself and mathematics	Is mathematics important to you? / Does it help you think logically? (How?)
Learning mathematics	How do you learn mathematics? / Is it most important to get a correct answer?
Teaching mathematics	Does teaching matter to your learning? (How?) / What is good teaching?

Table 1: Interview themes and example questions

	Task	Given information	Why chosen?
Holiday, Q1	Calculate the shortest distance by road between Nuben and Kado.	Map of the area, Table of distances, Answer given in kilometres.	Complex situation, Combining different data
School excursion	Which (bus) company should the class choose, if the excursion involves a total travel distance of somewhere between 400 and 600 km?	Written explanation of the situation and rates that the bus companies charge.	Uncertainty, Decision making
Indonesia, Q3	Design a graph (or graphs) that shows the uneven distribution of the Indonesian population.	Table of the population of Indonesia and its distribution over the islands.	Open task

Table 2: Descriptions of some of the tasks used in the project

ations (e.g., OECD, 2006, p. 108). The 'main' PISA tasks, Holiday, School Excursion and Indonesia (ibid, pp. 77–78, 87, 111, respectively), were solved in the classroom. These tasks are open with respect to solution strategy (see task examples in Table 2). Indonesia also included two additional questions in which Emma's skill to read a table was tested (referred to as Indonesia Q1 and Q2).

In class, Emma also started to solve Carpenter (OECD, 2009, p. 111) which was added in case of extra time. In the interviews, Emma answered questions from the tasks Distance (OECD, 2006, p. 102; modified to 3 and 5 km), Growing up (OECD, 2009, p. 106; Q's 3 and 1) and Braking (ibid., pp. 128–129; also Q49 from a Web page of the Finnish Institute for Educational Research).

Analysis

The analysis was divided into two sections: Problem solving, and Affect related to mathematics. In problem solving, the main focus is on the cognitive problem solving process written in the curriculum for grades 6–9 as core content or final assessment criteria of thinking skills and methods. These phases follow the problem solving principles described by Polya (1957) and will be reported accordingly.

In connection to problem solving, pupil's thinking about their own thinking as well as control and self-regulation (e.g. keeping track of what is being done during problem solving) will be discussed as a part of metacognition (Schoenfeld, 1987). The pupil's motivation to solve the tasks as well as confidence and feelings during problem solving is reported as part of the psychological affective state.

In affect related to mathematics, pupil's view on mathematics is reported (see Table 1). These results can be referred to as affective traits. The discussion on metacognition concentrates on the aspects listed as learning objectives in the curriculum (e.g., trusting oneself; FNBE, 2004).

The results are descriptive. More information related to methods and methodology can be found in earlier publications (Viitala, 2013, 2015).

RESULTS

Problem solving

Understanding the problem. Emma uses much of her time for understanding problems and the given information (in class 2–5 minutes which is some 30–55 % of total solution time). She seems very thorough and she says that she wants to understand every aspect of a task before starting to plan and solve it. On one hand, this seems to be a key element in her success as a problem solver. On the other hand, this might hinder her to solve a problem (not understanding all the mathematical expressions in Braking Q49) or to give a correct answer (she was prone to give an answer which she can completely understand in Braking Q49).

Emma uses graphs (maps and diagrams from the tasks) to assist her thinking when putting the given information together (e.g., marking routes and distances to the map in Holiday), understanding a problem (e.g., the graph in Braking for Q49) making a plan to solve a problem (e.g., routes in Holiday) and reflecting on the task when solving it (e.g., connecting the question to the graph in Growing up). The use of tools and drawings that assist thinking is part of mathematics learning objectives.

Making a plan. After taking the time to understand a problem and given information, Emma does not need much time to make a plan. Making a plan seems to happen on the third reading of the question, after reading the question quickly through on the first reading and putting together the given information on second reading (according to her explanations, e.g., for Holiday Q2 and School excursion).

If a task feels hard, Emma says she thinks of alternative ways to solve it (in Holiday she calculated a second route to confirm her result). Additionally, if the task feels too simple, she might try to calculate the task further after getting the answer (Indonesia Q2, this calculation was later erased because 'it felt stupid').

Carrying out a plan. Emma seems careful and thorough in solving mathematical tasks. After understanding the task, Emma is fluent in transforming a text to a mathematical form (mathematical expressions e.g. in Holiday and School Excursion). She says she can return to the task description as a confirmation also in the middle of solving a task (e.g. in School excursion). She proceeds step-by-step with the tasks.

If Emma has different options to solve a task, she says that she chooses the one that feels more 'probable' (e.g., routes in Holiday) or has less doubt (e.g., choosing a point where to calculate School excursion). For a task that had more than one answer (Distance), she spontaneously found two answers and a third one after being probed. In most cases Emma was able to justify her actions and conclusions.

Looking back. Emma says she checks tasks only in tests. In the research project, the first class situation felt like a test situation for Emma and it was the only time she checked her answers (Holiday). Other answers to PISA tasks she checked from a friend (Holiday and School excursion) or left it until the interview. In addition, Emma feels that she does not need to check her calculations when a calculator is used.

If Emma is not sure whether she has understood the task or given information correctly, she chooses the interpretation that feels most reasonable and proceeds with that (e.g. table in Holiday, and Q1 and Q2 in Indonesia). This aspect of 'looking back' is done during the process of solving the task.

Affect related to problem solving. Emma feels unsure when faced a word problem. She might 'panic' if the task has a lot of text (Holiday Q2) or numbers (Indonesia), or she cannot understand all the given information (e.g. table in Holiday and mathematical expressions in Braking Q49). When she gets stuck with the task description, she seems to lack efficient tools to overcome the situation (Holiday Q2, Braking Q49, also visible in Emma's explanations about doing homework and learning mathematics; on getting stuck, see, e.g., Mason, 2015). In these cases, asking questions helps her to overcome the difficulties and proceed with the task.

Getting help (Holiday Q2, before solving the task) or asking the correct answer from a friend after solving the task (Holiday and School excursion) seems to have a direct influence on Emma's confidence. Similarly, not checking her answer (Indonesia) seems to make her feel very uncertain and anxious even in the interview (until the results were given). See Emma's confidence related to problem solving in Table 3.

Emma might experience many different feelings when facing, planning and solving a problem (e.g., in School excursion: nervous, unsure, doubtful, 'normal' and relieved chronologically, cf. Table 3) but she agrees that her feelings do not necessarily affect her more stable feeling of confidence. The main motivation for Emma to solve the given tasks was the video camera. However, when a mathematical obstacle was encountered, Emma was motivated to learn from it (e.g., not understanding some mathematical part of the discussion in an interview, such as graphs for companies in School excursion, or percentages when discussing Indonesia or Braking).

	Confidence *after reading* the task	Confidence *while solving* the task	Confidence *after solving* the task
Holiday, Q1	5.5	5	7.25
Holiday, Q2	3.75	6.25	7
School excursion	5	6.25	7.25
Indonesia, Q1-Q3	3.25	4	4

Table 3: Emma's confidence (0–10, ±0.25 mm) for the tasks solved in the classroom

Affect related to mathematics

Mathematics. Emma's view on mathematics is very much tied to a school subject. For her, mathematics is calculating, both as a school subject and as a science. Mathematical knowledge is gained by calculating and correctness of mathematical knowledge can be verified by asking the teacher. Emma thinks mathematics is useful and needed for instance in other school subjects (e.g. civics, physics and chemistry). When asked, it is hard for her to see connections between mathematics and real life. Emma uses mathematics outside of school when she is shopping.

Oneself and mathematics. Emma is motivated to learn mathematics. The feeling of success drives her forward and succeeding with a difficult task makes her feel proud of herself (intrinsic motivation). She values the opportunity to show her skills to her teacher and classmates by going to the black board to calculate tasks. It feels rewarding and it motivates her to learn 'the next thing' (extrinsic motivation).

Emma likes mathematics and thinks it is 'quite fun' and interesting. However, in her own words, she does not feel 'very confident' in mathematics (cf. Table 4). However, she thinks that this might be a good thing: If you are too confident, you might not use that much time for thinking or check the calculations of a task. Emma thinks that confidence and mathematics grades are two separate things. Her grade (9) is the best she thinks she can achieve.

Interview 1	Interview 2	Interview 3
6.25	5.5	5.5

Table 4: Emma's confidence (0–10, ±0.25 mm) in mathematics

Learning mathematics. Emma, together with her friends and family, values learning mathematics and thinks that mathematics is useful. She also agrees that the atmosphere with regards to mathematics in her class is positive. Emma seems to trust that if she studies mathematics she can succeed and get better in it. The feeling of success, the belief that mathematics is worthwhile and useful, and future studies motivate her to learn mathematics.

For Emma, learning mathematics is 'understanding', in addition to 'memorizing' and 'reasoning'. Understanding means you are 'able to use a method'. Learning as well as understanding takes time for Emma. Understanding comes from calculating, asking questions, and proceeding little-by-little from easier tasks to more difficult ones. Rote learning is important. Emma learns new things as independent issues and does not actively seek for connections to previous knowledge. She 'forgets things quite quickly' and an indication of this was seen also in the interviews (calculations with percentages).

Emma's feelings in learning mathematics are also closely connected to understanding. Learning mathematics is fun when she understands or succeeds in mathematics. Not being able to understand is irritating. Sometimes learning mathematics is also tiring. Mathematics is easy for her 'but only a little' (cf. Table 4). Emma seems to take the responsibility of her own mathematics learning. She says that if she succeeds with a test, it is because she has studied for it and learned in class. Failure, on the other hand, means that she has not done enough work.

Teaching mathematics. Mathematics teaching methods and the mathematics teacher play a great role in Emma's learning of mathematics. She believes that without teaching she could not learn mathematics. A good mathematics teacher offers opportunities to ask questions, gives time for (rote) learning, does not proceed too quickly to the next thing, and proceeds from easier tasks to more difficult ones. These all are features that Emma's current mathematics teacher seems to possess (according to Emma's explanations and the researcher's observations from the classroom).

In some respect, Emma seems to connect her feelings and success in mathematics to her teacher. In elementary school she did not get along with her teacher. She was an average pupil (grade 7–8) who was not interested in mathematics, did not succeed in it and mathematics felt like torment for her. In lower secondary school Emma got a new mathematics teacher who she liked, and whose teaching she liked. Since then, Emma says she has liked mathematics and been a high achiever.

SUMMARY AND DISCUSSION

Results from Emma's problem solving and affect related to mathematics seem to give a well-matching picture of Emma's mathematical thinking. Emma is a reflective learner and problem solver who needs time for understanding. Her thoroughness and tendency to ask questions (both from friends and the teacher) seem to be the key to her success in both respects. Emma is not very confident in mathematics or problem solving (though slightly positive, cf. Hirvonen, 2012) but, as a consequence, she seems to be very careful with her thinking and working. Moreover, her uncertainty might be a reason for her success both in problem solving and mathematics.

The results showing differences between problem solving and affect related to mathematics seem to be connected to less stable affective traits. As an example, Emma's confidence has more variance in problem solving than in mathematics and her feelings experienced during problem solving have more tendencies to negative feelings (e.g. unsureness) than her feelings in learning mathematics. What is notable regarding Emma's affect in mathematics is that, contrary to previous research results (e.g., Tuohilampi, Hannula, Laine, & Metsämuuronen, 2014), Emma's feelings towards mathematics have become more positive since elementary school.

Throughout the study, Emma worked in a sustained and focused manner with the problems. Even though she is not very confident in mathematics, she seems to trust herself as a mathematics learner (e.g., aiming to learn more mathematics so she can succeed in advanced mathematics in upper secondary school). She also seems to take responsibility for her own learning (e.g. reasons for succeeding or failing in tests). All these aspects (listed in the curriculum; FNBE, 2004) together with her problem solving skills seem to offer her a solid foundation for future studies.

In addition to preparing pupils for further studies, basic education must also provide opportunities to obtain the knowledge and skills pupils need in life (FNBE, 2004, p. 12) and mathematics teaching should help pupils to see the connection between mathematics and real life (ibid, p. 158). Nonetheless, even though the PISA tasks that were used were situated in the real world, Emma saw them purely as mathematics tasks. Additionally, she struggled to see where she uses mathematics in her own life outside of school (homework, shopping). After analysing all the cases in the project, we can see if this might be a possible trend among Finnish pupils.

The upcoming curriculum (FNBE, 2014; will be implemented in 2016) draws more attention to mathematical thinking and real-life connections. For instance noticing connections between learned concepts and applying mathematics in other school subjects and surrounding society are written as individual learning objectives and as final-assessment criteria (ibid, p. 433–434). It is hoped that this will direct pupils' attention more towards their thinking and connections between mathematics and real life, at the same time making mathematics more worthwhile and enjoyable.

Investigating sources of pre-service teachers' self-efficacy for preparing and implementing mathematical tasks

Bilge Yurekli[1], Mine Isiksal[2] and Erdinc Cakiroglu[2]

1 Gazi University, Ankara, Turkey, bilgeyurekli@gazi.edu.tr

2 Middle East Technical University, Ankara, Turkey

The goal of this study was to understand pre-service teachers' self-efficacy beliefs for preparing and implementing mathematical tasks and to explore which sources of self-efficacy they wighted and interpreted when judging their capabilities as a result of attending a mathematics teaching methods course designed with a focus on mathematics teaching through tasks. Nine pre-service teachers participated in this study and they were interviewed at the end of the methods course. Findings revealed that methods course provided opportunities for mostly vicarious experiences and physiological states sources, and participants were feeling highly efficacious to prepare mathematical tasks, but they had doubts about their capabilities to implement tasks effectively.

Keywords: Mathematical tasks, pre-service teachers, self-efficacy, sources of self-efficacy.

INTRODUCTION

Learning mathematics with understanding requires active student involvement in the process of learning *through* problem solving where students solve problems, evaluate and explain their solutions, make connections among concepts, create and use different representations of mathematical ideas, and communicate their mathematical thinking (National Council of Teachers of Mathematics [NCTM], 2000). Because problem solving is the center of this learning process, the problems (i.e., mathematical tasks) that are presented to students mainly determine the quality of learning environment in classroom and the level of students' understanding (Stein, Smith, Henningsen, & Silver, 2009). A mathematical task is a problem (or a set of problems) "the purpose of which is to focus students' attention on a particular mathematical idea" (Stein, Grover, & Henningsen, 1996, p. 460). As research showed, to prepare and implement challenging tasks which promote students' higher-order thinking skills, teachers should have the required knowledge (Sullivan, Clarke, & Clarke, 2009). However, having necessary knowledge not always guarantee successful performance because self-efficacy is a strong determinant of performance (Bandura, 1997).

Researchers have reported that teachers' self-efficacy beliefs, or teachers' beliefs in their capabilities to bring about students' learning and achievement (Tschannen-Moran & Woolfolk Hoy, 2001), have the power to influence their instructional behaviors, attitudes toward teaching, their classroom management, as well as their students' motivation, achievement, and self-efficacy (Caprara, Barbaranelli, Steca, & Malone, 2006; Pajares, 1992; Woolfolk, Rosoff, & Hoy, 1990). When teachers hold strong efficacy beliefs, they spend more time with students who have difficulty in learning and try to improve their teaching; teachers with doubts in their capabilities, on the contrary, tend to experience burnout, job dissatisfaction, and leave the profession (Caprara, Barbaranelli, Steca, & Malone, 2006; Klassen, & Chiu, 2010). Thus, it is essential that teachers have strong beliefs in their capabilities to prepare mathematical tasks and enact them effectively with students.

Because of its crucial role in effective teaching, teachers' self-efficacy beliefs were studied in various domains, such as science and mathematics. However, studies were mostly focused on inservice teachers' self-efficacy (Klassen, Tze, Betts, & Gordon, 2011). Since efficacy beliefs are most likely to change during skill development (Bandura, 1997), it is important to study pre-service teachers' self-efficacy and find ways to help them develop strong beliefs in their capabilities through teacher education programs. According to Bandura (1997), self-efficacy is developed through four different sources: Mastery experiences, vicarious experiences, social persuasions, and physiological states. Mastery experience, also the most powerful source of self-efficacy, is the information gained from personal performances where success boosts self-efficacy and failures undermine it. Vicarious experience refers to the information gained from observing or comparing oneself with model's performances. Model similarity determines the effect of this source on self-efficacy, the greater the assumed similarity is, the more persuasive the model's success or failures are. Social persuasion is the feedback received from others about personal capabilities. Finally, physiological states such as stress, anxiety, and mood during performances provide information for self-efficacy development (Bandura, 1997).

In order to help pre-service teachers build strong efficacy beliefs, it is necessary to understand factors that serve as sources for their self-efficacy. However, there is a lack of research on these sources because researchers have often been interested in exploring correlates and outcomes of teachers' self-efficacy (Klassen, Tze, Betts, & Gordon, 2011). Based on hypothesized sources of self-efficacy (Bandura, 1997), there were a few quantitative attempts (e.g., Poulou, 2007) which failed to examine the predictive power of each of the four self-efficacy sources. The quantitative nature of these studies did not allow for the exploration of which sources could be provided by teacher education programs, either. A qualitative approach, on the other hand, can contribute more to our knowledge of how factors related to teacher education program operate through sources for pre-service teachers' self-efficacy. This way, teacher educators can also be provided with a clear guideline for improving their programs to support self-efficacy of future teachers.

Concerned with the gap in the literature on sources of pre-service teachers' efficacy beliefs, this study was designed as an attempt to explore sources of pre-service elementary mathematics teachers' self-efficacy in the context of a mathematics teaching methods course. The focus of this study was on pre-service teachers' self-efficacy beliefs for preparing and implementing mathematical tasks, which was defined as their beliefs in their capabilities to prepare (select, adapt, modify, or create) challenging mathematical tasks and enact these tasks in classrooms effectively.

METHOD

The present study was aimed at exploring sources of pre-service teachers' self-efficacy for preparing and implementing mathematical task after completing a mathematics teaching methods course. In order to reveal the insights of pre-service teachers upon enrolling in the methods course, qualitative case study method was employed. The context of this case study was Elementary Mathematics Education Program, more specifically, the methods course offered by this program at a large public university[1] in Ankara, Turkey. Nine out of 46 junior pre-service teachers studying in this program constituted the cases.

The methods course

As a part of Elementary Mathematics Education Program, pre-service teachers were required to enroll in the mathematics teaching methods course in their third year. This two-semester-long methods course was designed to help pre-service teachers learn to teach mathematics through challenging mathematical tasks, as well as to use and prepare manipulatives and integrate technology in mathematics education. The focus of this course was on both the Elementary Mathematics Curriculum (Ministry of National Education, 2013) covered in Turkey and NCTM Principles and Standards (NCTM, 2000). Methods course was taught by an associate professor for 14 weeks per semester and took place twice a week. On every Monday, there was a meeting for lectures on a chapter from the textbook, *Elementary and Middle School Mathematics: Teaching Developmentally* (Van de Walle, Karp, & Bay-Williams, 2010). Pre-service teachers were expected to read assigned chapters every week before attending lecture meetings. There were also several unannounced quizzes prior to these meetings. Two to three questions related to the weekly subject were asked in each quiz. After this two hours of theoretical study (i.e. lectures), on every Wednesday, there was a lab meeting for pre-service teachers' presentations of tasks they prepared about that week's topic. They worked in groups of 5–6 to create tasks and enact their tasks in the lab with their classmates. The instructor was giving feedback on

1 At this university, English was used as the medium of instruction.

each group's work, following their implementations. Pre-service teachers were expected to provide feedback to their peers as well. There were also a midterm and a final exam.

Participants

Nine junior pre-service teachers accepted to participate in this study. Eight of the participants were women and one was man. Required courses pre-service teachers had to complete throughout the program included mathematics content courses (e.g., calculus, analytic geometry), courses related to educational sciences such as educational psychology and classroom management, as well as Turkish, English, and basic physics courses. Elective courses on mathematics education were also offered by both Elementary and Secondary Mathematics Education programs. Participants were going to enroll in field experience courses in their last year as senior pre-service teachers.

Data collection and analysis

Data were collected through semi-structured interviews which were mainly guided by a list of questions prepared for pre-service teachers to gain an understanding of their perceived efficacy beliefs (e.g., *How confident are you in your capabilities to prepare challenging mathematical tasks effectively?*) and to provide deep information about the sources of their self-efficacy (e.g., *Which components of methods course made you feel confident about your capabilities to prepare challenging mathematical tasks effectively?*). The first author joined class meetings throughout the methods course to build trust with participants and interviewed participants at the end of the second semester of methods course. Each interview lasted around 30 minutes. Interviews were first audio-recorded and then transcribed by the first author as well.

Data were coded through constant comparative analysis method (Merriam, 2009), and data analysis process was two-fold. First, data related to participants' efficacy judgments for preparing and implementing tasks were coded. *Self-efficacy for preparing tasks* and *for implementing tasks* were the two categories used in this part of analysis because participants regarded their efficacy beliefs for preparing and using tasks separately. Then, data related to the efficacy-relevant information which participants referred to when judging their capabilities were coded using hypothesized sources of self-efficacy (Bandura, 1997). That is, *mastery experiences* (when participants talked about the efficacy-relevant information gained through their own performances, like in group work), *vicarious experiences* (when vicarious learning occurred, like through observing peers' presentations), *social persuasion* (when participants mentioned the effects of feedback, like the feedback they received from the instructor on group work), and *physiological states* (when emotions and mood of participants were perceived as sources of self-efficacy, like having fun while creating tasks) were the categories used for coding the sources of participants' self-efficacy beliefs. Subcategories were created regarding components of methods course (i.e. lectures, group work, peers' presentations, feedback on group work, textbook, unannounced quizzes). A mathematics education researcher participated in coding process. A coding sheet was generated and both researchers (the first author and the coder) coded a randomly selected interview transcript. When results of each researcher's codes were compared, a 92% coder agreement was reached.

FINDINGS

Findings revealed that participants completed the methods course mostly with high sense of efficacy for preparing and implementing mathematical tasks. More specifically, 8 of the participants expressed strong self-efficacy for preparing tasks (e.g., "At this point, I feel really really efficacious because, like I said, we have activities about almost every subject in the curriculum, we prepared all of them," Participant 8 [P8]) and one expressed moderate self-efficacy ("I feel so-so [confident], I cannot claim that I can prepare real good activities," P5). Five participants were feeling strongly efficacious for implementing tasks, whereas 4 of them had doubts about their capabilities to implement tasks effectively (e.g. „I wish we had more chance to implement [tasks], so, like I said, I have doubts about putting [tasks] into practice," P1). Participants who were concerned about possible classroom management issues and felt the need for real classroom practices expressed less confidence in their capabilities to implement tasks than their counterparts.

Findings regarding the sources of pre-service teachers' self-efficacy showed that participants used efficacy-relevant information provided by all four hypothesized sources of self-efficacy as a result of their enrollments in the methods course.

Mastery experiences

The methods course was found to support participants' efficacy development by providing mastery experiences through lectures, group work, and unannounced quizzes. Participants expressed two ways of mastery experiences that lecture hours provided. First, the instructor used questioning method where questions were aimed at promoting participants to explain how they would enact tasks from the textbook with their future students and to generate ideas for (accommodation or modification of) those tasks. This method nurtured participants' thinking to enhance and master their knowledge for preparing and implementing mathematical tasks, and participants' successful performances boosted their self-efficacy. Second, the expectations of the instructor from participants affected the level of effort they put forth, and the amount of effort participants expended influenced their self-efficacy.

As a source of mastery experience, participants expressed positive effects of working as a group to design mathematical tasks and implement those tasks in class during lab hours. However, one participant had problems with her group members and she didn't believe that group work contributed to her efficacy development.

When judging their capabilities, participants referred to their performances in unannounced quizzes they had to take before lectures. Findings showed that these quizzes operated through mastery experience source for participants' efficacy beliefs.

Vicarious experiences

Vicarious experiences as another source for self-efficacy of participants were provided by lectures, group work, peers' presentations, and the textbook. The effect lectures created on participants' self-efficacy was perceived as vicarious experience source, where the instructor was transmitting her knowledge and skills. The instructor's lecturing with an emphasis on the features of challenging mathematical tasks and "tips" to use such tasks effectively in classroom context were believed to positively affect participants' efficacy development.

Group work was regarded as a different vicarious experience source. Working as a group was perceived as a more positive influence than working on a task alone, for it gave participants the chance to learn from each other vicariously.

As findings revealed, participants viewed their peers' presentations in the lab as a learning source which contributed to their self-efficacy vicariously. Their peers were also models to whom participants referred when judging their own capabilities. Thus, peers created the opportunity for social comparison. When participants compared themselves with their counterparts, they mainly focused on competent ones. Such successful examples motivated participants to do better.

Additionally, the textbook was perceived as a symbolic model for learning and operated through vicarious experience source. Reading prior to lecture hours also increased participants' understanding from lectures. Participants stated that they could benefit more from lectures, since they were prepared for the class. Participants appreciated the quality of the book, too; yet they experienced trouble with reading it. First, the book was written in English and it required extra time to finish reading a chapter than reading any text written in Turkish. Second, participants thought the second semester's readings were longer and more complicated, which took more time to complete reading assigned chapters and caused them struggle to understand. Thus, participants sometimes did not even finish reading before attending lectures.

Social persuasions

Feedback on group work which participants received during methods course operated through social persuasion source for participants' self-efficacy. At the end of each group's presentation in the lab, pre-service teachers and the instructor provided feedback about each group's work. These feedback (i.e. evaluative feedback) contained information about their capabilities and were perceived as a way of self-assessment. Among the three sources of feedback (i.e. the instructor, group members during group work, and peers during lab hours), the instructor was found to be the most effective because, with her knowledge and experiences, she was more credible. However, participants thought the instructor was being judgmental from time to time.

In addition to feedback provided during lab hours, participants regarded lectures as a social persuasion source. Recall that participants uttered the difficulty of reading long and complicated chapters. Thus, they believed that readings should be supported by lectures, since they sometimes misinterpreted the information in the textbook or sometimes "didn't even understand what the book was saying" (P3). This way, lectures worked as corrective feedback, a social persuasion source for self-efficacy which helped participants learn from their mistakes and improve their knowledge.

Physiological states

Findings showed that the methods course provided physiological states source for participants' efficacy beliefs through group work, peers' presentations, feedback on group work, textbook, and unannounced quizzes. First, group work operated through physiological states source, and participants interpreted their emotions and mood during preparing and implementing tasks when judging their capabilities. Participants mostly enjoyed working together in a group to create and present tasks. On the contrary, one participant uttered that she felt anxious when presenting tasks in the lab, but she was still confident that she would enact tasks with her future students effectively because she believed she would feel more comfortable with students.

Participants expressed positive affective states like having fun when working on peers' tasks, too, but they got bored and showed reluctance to participate when they were assigned to low quality tasks. According to Bandura (1997), positive moods enhance self-efficacy and negative emotions lower it. Since participants did not experience negative emotional arousal (e.g. getting sad, angry, or stressed), it could be asserted that peers' presentations mostly contributed to participants' self-efficacy.

The feedback received from the instructor were perceived as a negative influence for some participants. Like mentioned earlier, there were participants who thought that the instructor could be judging and criticizing. Therefore, when preparing tasks, some participants were affected negatively from the instructor's criticism and either doubted their capabilities or experienced negative arousal (e.g. anxiety).

As a physiological states source, reading the textbook caused boredom for one participant. She explained that she was bored with reading in English.

Even though unannounced quizzes were viewed as a "push" for studying for lectures and in turn actively participating on Mondays, they also caused stress and anxiety. When participants didn't have time to complete reading assigned chapters or when they failed to understand ideas presented in the textbook, they felt distressed because these quizzes were added up to overall grades.

DISCUSSION

In this study, the aim was to investigate sources of pre-service elementary mathematics teachers' efficacy beliefs for preparing and implementing mathematical tasks. In addition to detecting which sources pre-service teachers relied on to construct their efficacy beliefs, this study was an attempt to define components of methods course which predicted pre-service teachers' self-efficacy. Findings revealed that methods course provided all four sources for self-efficacy beliefs of pre-service teachers. That is, various components (i.e., lectures, group work, peers' presentations, feedback on group work, textbook, and unannounced quizzes) of the course operated through different sources and contributed to the development of pre-service teachers' efficacy beliefs. When compared to other sources of self-efficacy, components of methods course mostly operated through vicarious experiences and physiological states sources for self-efficacy. It could be that participants weighted these two sources of self-efficacy more than mastery experiences, since their mastery experiences were limited to group work, involvement in lectures, and unannounced quizzes.

An important finding was that lectures had the power to operate through mastery experiences for pre-service teachers' efficacy judgments, when the instructor used questioning method in her lectures. Participants of this study mainly perceived lecture hours as a vicarious experience source, like one would expect because lecturing is the transmission of knowledge and skills (Bandura, 1997) from the instructor to pre-service teachers, but the instructor was able to take this further by using questioning method. Questioning promoted participants' thinking and generating ideas about preparing and using mathematical tasks, and participants relied on experiences gained through cognitively enacting and verbally sharing their ideas. Teacher educators then should design courses where pre-service teachers are encouraged to actively participate in lectures and share their thoughts on preparing and implementing tasks.

Modeling is a strong influence on self-efficacy (Bandura, 1997), and findings showed that participants gained vicarious experiences through models similar to them (i.e. peers), the instructor as a competent model, and the textbook as a symbolic model. Therefore, teacher educators should promote vicarious learning of pre-service teachers from each other, which might be achieved by letting them work in groups or asking them to evaluate peers' tasks and give feedback. Classroom discussions might also create the environment for pre-service teachers to contribute to peers' learning. Teacher educators should also share either their own experiences or other teachers' experiences on preparing and implementing tasks, by using video recordings for example, to provide pre-service teachers with various vicarious learning opportunities. The quality of textbook used is also found to be an important issue that teacher educators should take into account. Task samples in the textbook and clear and detailed information proposed there can help pre-service teachers gain experiences vicariously and contribute to their efficacy development. Reading chapters as a requirement of methods course, as findings showed, might enable pre-service teachers to benefit more from the lectures. Thus, it is important to motivate them do the readings prior to lectures. One way of providing such motivation could be unannounced quizzes, like findings showed. Yet, quizzes might cause stress and anxiety, if pre-service teachers have difficulty in completing reading assignments. Choosing a textbook easy to read and understand might prevent pre-service teachers from experiencing negative affective states.

Findings also revealed the crucial role of physiological states in the development of pre-service teachers' efficacy beliefs. Even though participants talked about mainly positive emotions and moods, when faced with criticism, they experienced negative affect. Bandura (1997) stated that "moderate levels of arousal heighten attentiveness and facilitate deployment of skills" (p. 108). Teacher educators, therefore, should be cautious in controlling the level of arousal pre-service teachers' experience. Creating a classroom environment in which pre-service teachers will feel comfortable and voice their thoughts without being criticized can boost their self-efficacy.

Upon completing methods course, almost all of the participants (8 out of 9) regarded themselves strongly efficacious for preparing tasks, whereas only 5 of them expressed high level of efficacy for implementing tasks. Participants stated that they had doubts about classroom management and in turn they didn't express strong efficacy for implementing tasks. From this aspect, the lack of mastery experiences in actual classroom contexts might have caused lower level of development in pre-service teachers' self-efficacy. As Bandura (1997) asserted, mastery experience is the most powerful source of self-efficacy. Thus, offering fieldwork experiences as a part of methods course might help pre-service teachers to benefit more from this course.

The importance of this study is its attempt to describe how methods course provided sources for pre-service teachers' self-efficacy than simply defining which sources pre-service teachers used to develop their efficacy beliefs, as in previous research (e.g., Poulou, 2007). However, because this study is limited with 9 pre-service teachers, examining sources of pre-service teachers' self-efficacy with a larger sample can reveal how different elements of methods course support pre-service teachers' efficacy development. One way of achieving this can be using open-ended questions, and findings of this study might help researchers with the design of such questions.

Longitudinal studies can also show how pre-service teachers construct their efficacy beliefs over the time of methods course and the ways sources for their self-efficacy interact. Such an approach can also disclose the influence of other courses and experiences pre-service teachers engage in outside of methods class.

Considering the power of physiological states on self-efficacy, a broader approach to the investigation of pre-service teachers' efficacy beliefs as perceptions of competence (e.g., Coppola, Di Martino, Pacelli, & Sabena, 2012) and the role of emotions on the construction of self-efficacy can illuminate the pathways to support future teachers' beliefs through teacher education programs.

Teachers' perspective on group dynamics

Chiara Andrà, Domenico Brunetto, Nicola Parolini and Marco Verani

Polytechnic of Milan, Department of Mathematics, MOX, Milan, Italy, domenico.brunetto@polimi.it

In groupwork activities, interaction plays a crucial role. We focus on two affective variables that frame interaction: one's own perceived competence ("I can") and the competence that one recognize to the others ("you can"). In this poster, we show different interpretations of mathematics secondary school teachers about students' "I can" and "you can" from observations of video excerpts of students working in groups. We discuss agreement/disagreement among teachers' interpretations.

Keywords: Group interaction, teacher noticing, perceived competence.

Interactionist research acknowledges that learning in mathematics occurs in and through interaction, which is framed by the students' "I sense" and "I can" (Andrà & Liljedahl, 2014). "I can" may prompt the student to intervene in a conversation. "I can't" may push a student to stay silent (see Andrà & Liljedahl, 2014). Each student may (or not) recognize a competence to each one of her classmates. Therefore, there is another dimension: "you can". "I can" and "you can" are seen as interior states, whilst utterances, postures, etc... are the external expressions of such internal states.

The teacher also plays an important role, intervening and driving the activity (Radford, 2014). Since emotions take a significant part in determining the outcome of the activity, it is crucial for the teacher to detect them and to react accordingly. Specifically, we aim at examining teachers' noticing (Sherin, Jacobs, & Philipp, 2011) with respect to the "I can"-"you can" frame. Our hypothesis is that becoming conversant with this frame allows the teacher to better ground her meaningful actions/interactions within the complexity of group activities. For example, in the case of a non-cooperating leader, it would be necessary to provide feedbacks that temporarily decrease her "I can" and increase her "you can"; indeed, in the case of a student with low "I can", it is important to provide feedbacks that increase her self-confidence, but also increase her mates' sense of "you can" towards her.

Andrà, Brunetto, Parolini, & Verani (this volume) analyse a video excerpts (from a probability course to prevent gambling abuse), codified as follows: a point corresponding to the student under analysis is placed on the one of the four cells of the 2x2 table representing the internal states "I can" – "I can't", "you can" – "you can't". Dwelling time is represented by a circle: the longer the time, the bigger the circle. Transitions are represented by oriented arrows. The result is a trajectory.

The excerpt comes from a group of 4 grade-10 (15 years old) students: Alice (A), Barbara (B), Carola (C), and Dora (D). They are analysing a slot machine (3 rolls, 9 symbols), and have to compute the expected winning. B starts as cooperative-leader ("I can"–"You Can"), then she becomes leader, suddenly she is not able to come up but she trusts her classmates, eventually she comes back to collaborate with her classmates on the task.

We firstly observe a group of teachers interpreting the same data presented in Andrà and colleagues (this volume) and asking them to fill in a 2x2 table like the one presented in Figure 1. We collected also teachers'

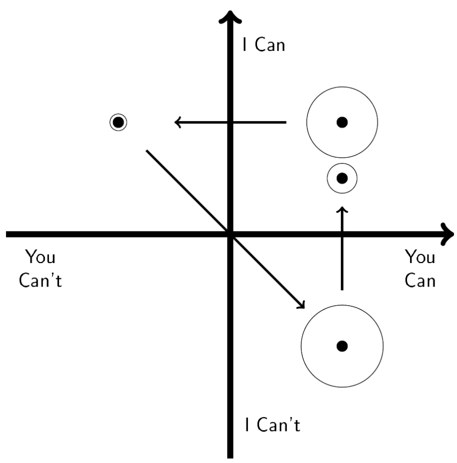

Figure 1: B's trajectory

extended comments. We seek for agreement/disagreement with respect to our interpretations, focusing only on one student per group as an initial step.

There is a certain degree of agreement among teachers, and between teachers' interpretations and ours. In the poster we show some data that allow us to claim that collecting the teachers' views according to the "I can" – "you can" frame goes beyond the purpose of validating a methodology: it is a way of observing, collecting and giving sense to affective moves that may drive the teachers' decisions and behaviour in classroom. There are emotional issues that emerge with respect to the teachers' perceived expectations in the "management" of group activities, as well as their specialised knowledge of group dynamics.

ACKNOWLEDGEMENT

Project funded by Politecnico di Milano through the 5x1000 Polisocial Award 2013 in collaboration with Fondazione Politecnico di Milano.

Attitudes of secondary school students towards work in learning situations

María del Socorro García González[1] and Rosa María Farfán Márquez[2]

National Polytechnic Institute, Center of Research and Advanced Studies, Cinvestav-IPN, Ciudad de México, Mexico, mgargonza@gmail.com, rfarfan@cinvestav.mx

The purpose of this paper is to characterize the attitudes of Mexican secondary school students (12–15 years old) when carrying out mathematical activities. In order to study attitude, the tripartite model of attitude was adopted and a methodological design was organized based on the adapted model. So far a learning situation focused on the subject of proportionality has been applied, in which we have been able to identify two attitudes: Acceptance and collaboration.

Keywords: Attitude, secondary school, characterization.

INTRODUCTION

Over the years, research regarding attitudes towards mathematics has grown and has studied students ranging from basic level to higher education students and teachers from the same levels. Acknowledging, the relevant role that attitude plays in the teaching of mathematics (Di Martino & Zan, 2010; Gómez-Chacón, 2000; Hannula, 2012; McLeod, 1992), our aim was to characterize the attitudes of a group of secondary school students in relation to proportionality. We considered attitude to be like the assessment carried out by a student of the resolved mathematical activity. We adopted the tripartite model (Rosenberg & Rovland, 1960), which considers attitude to be composed of emotions, beliefs and behaviors.

PROCEDURE FOR DATA COLLECTION

The learning situation regarding proportionality was carried out during a first year secondary school mathematics class. 28 students participated, working in teams. The students' activity was filmed. In order to carry out individual interviews regarding the work carried out and some aspects of a personal and academic nature, 3 teams were selected: a) 2 men, b) 3 women and c) 1 man and 3 women.

RESULTS

We identified a system of attitudes formed of two attitudes: 1) Acceptance of the activity and 2) Collaboration between classmates. Both formed a collaborative work system and were coherent with and related to each other. They were linked to emotions, beliefs, behavior and factors shown in Table 1.

The extent to which attitudes identified throughout the activity were manifested, increased and decreased. There were cases in which, at the beginning of the activity, the level of collaboration was very low, but

Emotional reactions	Beliefs	Behaviors	Attitudes	Associated factors	Associated agents
Shock Confusion Happiness	Problems containing few operations are easy. Division problems require information regarding what is being divided and between how many people it is being divided.	Empathy between classmates Willingness to work as a team	Acceptance Collaboration	Learning contract Goals of the student Interests of the student	Parents Classmates Teacher

Table 1: System of identified attitudes

thanks to interaction between classmates, the level increased, students managed to get involved in the work and to resolve the activity. By carrying out interviews, we discovered that there were agents that indirectly influenced the attitudes of students including classmates who helped to solve problems, the teacher who assessed them and parents for whom mathematics was important and who demanded that their children obtain good grades, even better than for other curriculum subjects.

Formative scaffolding: How to enhance mathematical proficiency, prevent and reduce mathematics anxiety

Annika Grothérus

Linköping University, Department of Social and Welfare studies, Linköping, Sweden, annika.grotherus@liu.se

I present the Formative scaffolding approach, a method for teaching, evaluation and assessment in mathematics, describing a study, where 22 upper-secondary social science students' perceptions and experiences of using formative scaffolding with respect to a test in mathematics are explored. Results indicated that formative scaffolding might reduce mathematics anxiety and enhance mathematical proficiency. Students emphasise the opportunity for a second chance and that the learning process is visualised.

Keywords: Formative assessment, scaffolding, mathematics anxiety, proficiency.

In this poster a method for teaching, evaluation and assessment in mathematics is presented. The method is referred to as the formative scaffolding approach, see Figure 1, in which the concepts of scaffolding (Wood, Bruner, & Ross, 1976), formative assessment (Black & Wiliam, 2009) and writing to learn (Kågesten & Engelbrecht, 2006) are intertwined with each other (Shepard, 2005). Learning comprises cognitive, social, emotional and cultural embedded processes and involves construction of knowledge (Bransford, Brown, & Cocking, 1999; Shepard, 2005). Allowing learners to actively participate in constructing knowledge may provide them with a deeper understanding, more self-confidence and motivation in using their knowledge (Smith, Maclin, Houghton, & Hennessey, 2000). Enabling learners to actively participate in constructing their knowledge and visualize their learning is a fundamental core in formative scaffolding. The overall objective of this study is to present and

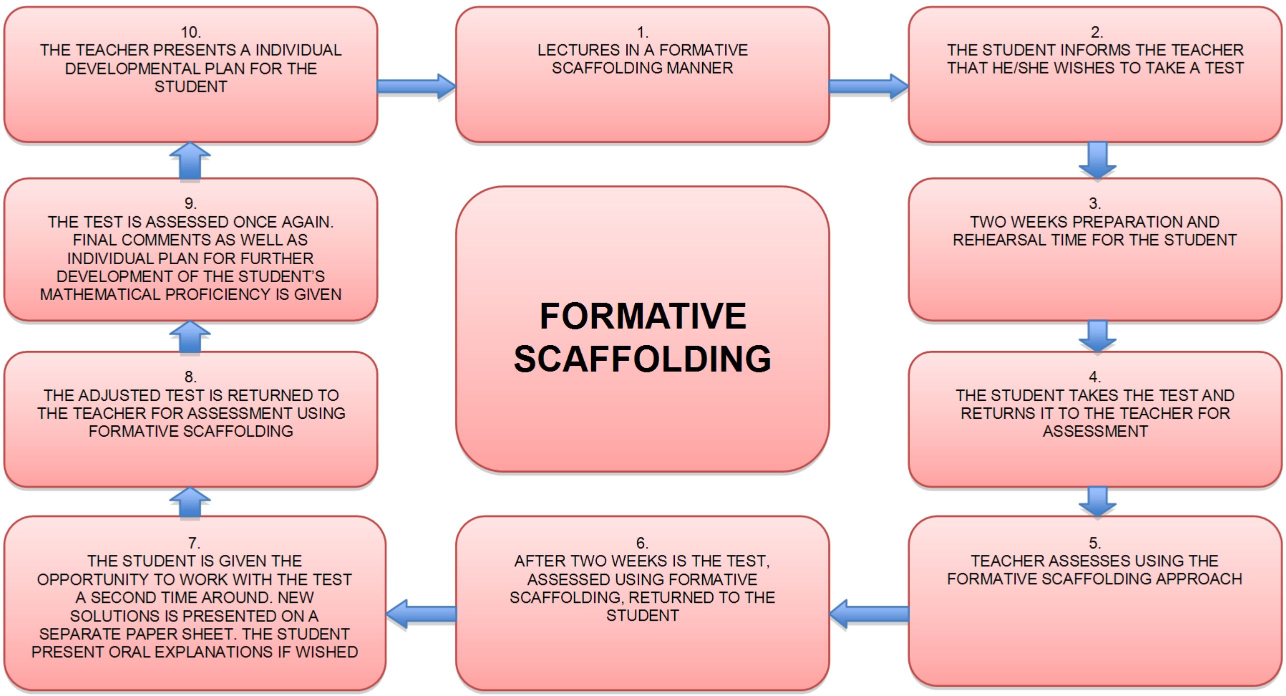

Figure 1: Overview of the formative scaffolding approach process

describe the teaching, assessment and evaluation method – formative scaffolding, see Figure 1 – and explore twenty-two social science students (age 17–18 years) experiences of the method with respect to mathematical proficiency and anxiety in mathematics. The participants constituted one class in upper secondary school. Through an exploratory action research study we investigated: experiences of formative scaffolding in relation to ordinary test in mathematics; effects of formative scaffolding in relation to mathematical proficiency and mathematics anxiety. Possible limitations in the design of the study was that the class it self was acting as a control group. The present study is to be viewed as a pilot study providing important information about the method as such and how to design a larger future study. Data were collected through short written narratives and one Likert type structured question. Students written responses and indication on the structured question were analysed using thematic coding analysis (Boyatzis, 1998). Emerging themes and illustrative quotes of the students' experiences is going to be presented. Results indicated that formative scaffolding might reduce mathematics anxiety and enhance mathematical proficiency. Students emphasise the opportunity for a second chance and that the learning process is visualised. We suggest that the proposed formative scaffolding approach may be added to the list of other potential tools for learning, and, this approach can be used to make summative tests in mathematics to an additional opportunity for learning.

Why mathematics? Students' narratives about failing in compulsory school mathematics

Oana Hansson

Malmö University, Faculty of Education and Society, Malmö, Sweden, oana.hansson@mah.se

BACKGROUND

This study is concerned with students on an introductory programme where they are supposed to compensate for earlier failure in mathematics in compulsory school. Having worked for several years with students in this category, I have noticed that some of them have passed in other subjects where mathematics is used as a tool. The question then becomes: Why mathematics? Thus, the focus is on students who have passed in other subjects, including physics and chemistry, in compulsory school, but not in mathematics.

According to official statistics, 8.6 % of all students who finished the Swedish compulsory school in 2011 failed to pass in mathematics (Skolverket, 2012). The Swedish compulsory school consists of nine years of schooling. Students who have received a pass in Swedish, English and Mathematics in addition to certain other subjects are eligible for a three-year upper secondary school education. For students who are not eligible, there are five introductory programmes, which lead either to further study or to work.

Generally, the frequency of low achievement in mathematics increases during compulsory school age (Magne, 2006), which makes it interesting explore what goes wrong in those years. As Magne (2006) points out, there is not much research on students with low achievement in mathematics.

In order to research low achievement in mathematics, it seems relevant to consider students' perceptions of mathematics teaching. According to Samuelsson (2007) students' feelings range from satisfaction to anxiety and fear. Gierl and Bisanz (1995) describe mathematics anxiety as a lack of enjoyment in mathematics. When a student with mathematics anxiety is faced with the requirement to work with mathematics, a chain of reactions like panic, frustration, paralysis and mental disorganization could appear (Foire, 1999; Bandalos, Yates, & Thorndike-Christ, 1995). According to Nyroos, Bagger, Silfer and Sjöberg (2012), the presence of test anxiety is significantly present as early as in the Third Grade.

Reasons for students' mathematics anxiety could be the activities that they are supposed to do (Greenwood, 1984) or the teacher's ability to create a positive learning climate (Samuelsson, 2008) or boredom (Ingram, 2009). The study seeks to contribute to research by focusing on school mathematics as the single subject where the student has not passed, and implications of the study could be a better understanding of students' emotional states like affect or anxiety in relation to school mathematics.

PURPOSE AND RESEARCH QUESTION

The aim of the study is to develop an understanding of what may affect students in such a way that passing in mathematics turns out to be impossible. The study is based on students' narratives and the research question is:

— How do students explain why they have failed in mathematics while they have passed all other subjects in compulsory school?

My poster shows students' utterances and visual connections (arrows) to some aspects like affect, anxiety, motivation etc. Background, research question and methodology are presented in text blocks.

TWG09

Mathematics and language

Challenges and research priorities in the context of TWG09: Mathematics and language

Núria Planas[1], Anna Chronaki[2], Frode Rønning[3] and Marcus Schütte[4]

1 University Autonomous of Barcelona, Barcelona, Spain, Nuria.Planas@uab.cat
2 University of Thessaly, Karditsa, Greece
3 Norwegian University of Science and Technology, Trondheim, Norway
4 Technical University of Dresden, Dresden, Germany

We begin by briefly examining the relevance of the study of language in mathematics education research, as well as some of the collaborative forms in which TWG09 is moving the study of language forward in the field. To provide reasons for the recent contributions by TWG09, we summarise lines of concern and tendencies that come from our reading of the set of papers and posters presented at CERME9. We build on the review work by Morgan (2013) to argue for the consolidation of such a diversity of lines of concern and tendencies in the contemporary agenda of the domain. The discussion of accomplished goals of the agenda points to a number of challenges and priorities in the context of TWG09 – its participants, their interaction and their activity.

Keywords: Language, mathematics education, mathematics education research, understanding, challenges.

OVERVIEW

The study of language in mathematics education research is a relatively young domain, however, with well-organised academic initiatives on an international level. One of the activities promoted by the European Society for Research in Mathematics Education (ERME) is the Thematic Working Group 'Mathematics and Language' (see Rønning & Planas, 2013, for a brief historical overview of the group since its origin). The Thematic Working Group 'Mathematics and Language' at CERME9 (TWG09) has brought together a collection of papers and posters that analyse a wide spectrum of topics, theoretical traditions and analytic approaches in this domain.

The fact that the study of language is at the core of intersections between many topics and theories inevitably has an effect on the nature, composition and evolution of our group. In 2015, for instance, some senior researchers in the field (i.e., researchers who have been active in the study of mathematics education for many years, although not necessarily keeping a regular focus on the study of language) have come to our group to discuss aspects of their work. They have shared expertise with, on the one hand, senior researchers in the group (i.e., researchers who have been active in the 'Mathematics and Language' domain within ERME for many years) and, on the other hand, with a large number of early researchers in the field (i.e., researchers who are new to both the study of mathematics education and the study of language issues with relation to mathematics education).

The purpose of this introductory text is to provide a conceptual and scholarly context for the papers and posters presented at CERME9. The rest of the text is organised into three sections. The first section deals with arguments for the relevance of the study of language in the field. The second section provides a description of how our domain is being constituted in ways that include a number of perspectives on language; following this, we trace a diversity of lines of concern and tendencies which come from our reading of the set of papers and posters. The third section concludes with reflections on how to mould the future activity of participants in TWG09. Collaboration among researchers from different countries, social realities and theoretical traditions are crucial aspects of what is needed to push boundaries further and explore new horizons in the study of language with relation to mathematics teaching, learning and education. One of the problems to be addressed is, in view of what is needed, what can be done and how it can be done in the years to come.

THE STUDY OF LANGUAGE IN MATHEMATICS EDUCATION

While questions addressing the relationship between language and mathematics have been a focus of study for over 30 years (see, e.g., Pimm, 1987), we still understand little about how and why language develops in interaction with mathematics teaching and learning development. Despite the fact that much remains to be researched, substantial knowledge in this regard is being produced inside and outside of ERME. We have arrived at the present destination – in which our domain is well recognized, established and differentiated in the field – after a long journey.

In 1974, an international symposium on "Interactions between Linguistics and Mathematical Education" was held in Nairobi, Kenya, sponsored by UNESCO in cooperation with ICMI and the Centre for Educational Development Overseas. Up to that moment, there had been no international events focusing on the relationship between mathematics and language. The final report of that symposium (UNESCO, 1974) revealed the lack of studies and research experience in this domain; moreover, it urged the international scientific community to adopt an agenda by identifying key issues, questions and needs at the intersection of mathematics education and language. Five years later, a review paper, with potential for founding an early agenda, was published by Austin and Howson (1979) in *Educational Studies in Mathematics*. A total of 240 references on language and mathematics education were compiled to indicate possible areas for investigation as well as areas in which research activity had already commenced.

In 2015, more than four decades after the Nairobi symposium, the examination of key issues, questions and needs at the intersection of mathematics education and language continues. Some of the newest issues and questions reveal, for instance, the increasing interest in a range of language uses in school mathematics contexts. Such uses may vary from one classroom to another, and more generally among school cultures, histories and pedagogies of teaching, but overall they may be dependent on who the involved users are (Planas, 2014). A large amount of evidence for the complexity of language use can be found in *Mathematics Education and Language Diversity*, the abbreviated title for the volume of the New ICMI Study Series edited by Barwelland colleagues (2015), which is one of the latest milestones of the long journey in the consolidation of the study of language in mathematics education.

Another step in the journey toward the maturity of the domain has been undertaken by Barwell (2014) and Morgan (2014), in their respective synthesis of reasons for the relevance of the study of language in mathematics education in two of the entries in the *Encyclopedia of Mathematics Education*:

> The teaching and learning of mathematics depend fundamentally on language. Mathematics classrooms, for example, may feature discussion among students, lectures by the teacher, printed curriculum materials or textbooks, and writing on a blackboard or on a screen. (Barwell, 2014, p. 331)

> While some aspects of mathematical language, such as its high degree of abstraction, may be an obstacle to participation for some people, doing mathematics is highly dependent on using its specialized forms of language, not only to communicate with others but even to generate new mathematics. In making this claim, we need to be clearer about what mathematical language is. (Morgan, 2014, p. 388)

During recent years, many new studies, journal articles and conference papers have contributed to reporting empirical findings and accurate theoretical developments in the domain. The creation and revision of knowledge in these works is being guided, either implicitly or explicitly, by common basic questions, whose origins can be traced back to the early work on language and teaching dilemmas by Adler (1998): *Where is language in this? Why does it matter? How can it be researched in ways that are idiosyncratic to mathematics education?* All in all, the existing variety of contemporary lines of concern in the domain can be thought of as different epistemological and analytical strategies of approaching these questions.

COMMON QUESTIONS, DIFFERENT LINES OF CONCERN

In her CERME8 plenary, Morgan (2013) offered a range of possibilities around what language enables mathematics education researchers to study, and how much the study of language challenges the ways in which we carry out research in the field. Moreover, she provided a thorough literature review concerning the work presented in the Thematic Working Group 'Mathematics and Language' over recent decades. In that plenary, Morgan claimed that the quality of research on language in mathematics education is influenced by a number of studies whose ideas have been at some time presented and discussed in ERME. We interpret the range of possibilities posed by Morgan (2013) in terms of potential lines of concern which map the contemporary domain and whose research has been initiated, inside and outside of ERME, with different levels of intensity. We refer to research concerning:

1) Communication and interaction in mathematics teaching and learning.

2) The representational systems in creating/structuring mathematical knowledge.

3) The role and use of languages in mathematics education practices.

4) The features of codes/registers in the construction of mathematical language.

5) The intervention of discourses in knowing and thinking in/about mathematics.

These five lines of concern illustrate how the agenda regarding the study of language in mathematics education has introduced new complexities and, thus, has evolved toward building a domain much wider than that imagined in the 1970s. In this respect, it is not surprising that the lines of concern suggested by Morgan to show the range of possibilities already opened for research in 2013, have emerged from our reading of the papers and posters presented in TWG09 during CERME9. While the limited collection of papers at CERME9 cannot totally reflect the scope and wideness of the contemporary domain, it confirms that some work is being done in each of these five directions. For the purpose of organising the discussion around the set of papers and posters accepted for presentation at the time of the conference, we used five abbreviated descriptors, respectively aligned with specific dimensions of the indicated lines of concern. These descriptors are:

1) Communication, interaction and gestures.

2) Epistemic, cognitive and structural aspects.

3) Multilingualism and sociocultural aspects.

4) Mathematical language and language use.

5) Discourse, practices and positioning.

In what follows, we summarise some of the lines of concern and tendencies which can be traced in the collection of papers and posters. As a whole, the process of grouping papers and posters has provided a straightforward picture of how and how much language is approached as a bundle of notions that other notions (gestures, registers, diagrams, talk, multilingual, mathematical objects, etc.) transverse, all of them with a diversity of attributed meanings and understandings. This is why the location of contributions is not univocally determined. It reflects our interpretation of the knowledge privileged by the authors in their texts. We may have overlooked ideas that some of the authors consider essential. Nevertheless, as the intention is to map the work in TWG09 and not to give a detailed account of each single paper or poster, we hope that all authors will see their work represented.

Communication, interaction and gestures

Six papers by Reinhardtsen, Carlsen and Säljö; Nordin and Björklund-Boistrup; Boukafri, Ferrer and Planas; Vogler; Farsani; and García Moreno-Esteva and Hannula, along with one poster by Roubicek, constitute the works in the direction of *Communication, interaction and gestures*. All these authors understand verbal (oral and written) and non-verbal (gestures, facial expression and visual contact) forms of language as communication strategies in classroom interaction. Language, in its verbal and non-verbal forms, is conceived as an instrument of communication, also in its various forms: individual, collective, peer-based, etc. In this way, diverse language use is tantamount to communication, learning and teaching.

In the presented works, we see two major tendencies or emphases that can be found at the intersection of several interrelated lines of concern. One is the tendency of the study of interaction through the study of gestures in classroom contexts of mathematics teaching and learning. In Farsani, for instance, gestures are proven to provide direct data for researchers to examine communication between teachers and learners. Here, a joint finding with the work by García Moreno-Esteva and Hannula is the role of gestures in the production of successful instances of mathematical communication, with a number of opportunities for mathematics teaching and learning. Closely related to the analysis of gestures, the production of intertextuality and multimodal texts to represent classroom data is also examined by these authors.

Another tendency in some of these works is the study of communication through and with digital media as part of the language environment for mathematics teaching and learning. The shift from text-based paper-and-pencil communication to multimodal digital communication is viewed as a qualitative change in the practice of mathematics teaching. It is generally noted that multimodal dynamic texts produced by teachers and students should be reproduced by researchers in different kinds of multimodal dynamic transcripts. Here, the potential interplay between multimodal resources, digital technologies and mathematical modes of communication is discussed by Reinhardtsen, Carlsen and Säljö, at a methodological level, through the development, application and evaluation of analytic tools created *ad hoc*.

Epistemic, cognitive and structural aspects

Six papers by Ruthven and Hofmann; Erath and Prediger; Krause; Fetzer and Tiedemann; Meyer; and Mellone and Tortora, together with a poster by Zwetzschler, constitute the collection of works in the direction of *Epistemic, cognitive and structural aspects*. All these papers address the study of ways in which mathematics classroom discourse develops grounds for and access to (school) knowledge and (school) knowledge claims. In this respect, an elusive area of concern regarding epistemic issues in school mathematics has been present in TWG09.

One identifiable tendency in this direction is the conducting of classroom studies. Ruthven and Hofmann introduce the term *epistemic order,* which refers to a system used to describe how ideas are developed and evaluated in the classroom. Their work expands the classical Initiation-Reply-Evaluation and Initiation-Response-Follow-up patterns of interaction (e.g., Sinclair & Coulthard, 1992) by including codes to explain who is responsible for what, and who takes the initiative. The work by Erath and Prediger also deals with how students participate in the configuration of the mathematics classroom discourse. These authors are interested in understanding how students' learning opportunities relate to forms of participation in the discussion of epistemic issues concerning knowledge about the construction and justification of school mathematics knowledge. The paper by Krause investigates the epistemic function of gestures. In a study of tenth graders, she looks for evidence that gestures may support reasoning actions when mathematical knowledge is constructed.

The other papers are oriented toward how language use relates to what is knowable, which indicates another tendency in this direction of papers. Fetzer and Tiedemann look at the interplay between language and manipulatives. They show how a fairly simple language can become mathematically more complete when it operates in connection with both human and non-human objects. Meyer is concerned with transformations of algebraic expressions, and with how learners convey the structure of an algebraic expression to other learners with the use of language. The paper by Mellone and Tortora is of a more theoretical nature, although based on experience from working with learners. These authors discuss how an idea of ambiguity, often implicit in school mathematics, can be explicitly used in the teaching activity.

Multilingualism and sociocultural aspects

Five papers by Barwell; Poisard, Ní Ríordáin and Le Pipec; Ní Ríordáin and McCluskey; Chronaki, Mountzouri, Zaharaki and Planas; and Klose, together with one poster by Šteflíčková, constitute the collection of works in the direction of *Multilingualism and sociocultural aspects*. All these papers share the basic conceptualisation of the students' languages as pedagogic resources and entries to learning identities, though they may take different perspectives on how language(s) and speakers relate to mathematics teaching and learning.

In these works we see two tendencies. One is the tendency of putting together design experiments and case studies. Chronaki and colleagues examine the case of a learner whose dominant language is not the language of instruction in a way that leads to the design, implementation and assessment of strategies for language use in mathematics classroom interaction. This approach is also taken by Barwell in his research with bilingual students in Canada. Barwell relates language use and its outcomes to the distinct language identity of certain groups of students in the multicultural mathematics classroom. In particular, he suggests that the construction of mathematical learning in multilingual settings is often guided by views of languages other than the languages of instruction and their speakers, rather than views of mathematical competence, performance and achievement.

A second tendency comes when examining the number of considerations at a political level made by the authors in their papers. All the presented papers in this direction focus on the perspective of languages as resources while considering the dilemmas involved in the choice and use of languages. These dilemmas indicate the extent to which the deficit perspective, in the study of language and language diversity, is more and more contested nowadays, particularly due to the impact in the domain of studies recurrently cited by some of the participants in TWG09 (e.g., Moschkovich, 2002). Poisard, Ní Ríordáin and Le Pipec, for instance, reflect in their paper on some of the enduring compensatory responses in the interpretation of the needs of students whose home languages are different from the language of instruction or the *lingua franca*.

Mathematical language and language use

Six papers by Edmonds-Wathen; Segerby; Tiedemann; Söbbeke; Albano, Coppola and Pacelli; and Engvall, Samuelsson and Forslund, along with one poster by Arce, Conejo and Ortega, comprise the collection of works in the direction of *Mathematical language and language use*. Most of the research focuses on the learning of mathematics at primary, secondary and university levels, while there is also a study in an indigenous population. It is shared an understanding of language use and language development for mathematical development through writing, reading and talking.

We identify a tendency around the analytical distinction of writing, reading and talking. Segerby focuses on the kinds of writing of young children in mathematics lessons. She finds that children write more in calculations as they progress through primary school, at the expense of transactional and poetic modes. Arce, Conejo and Ortega focus on the diverse uses of written notebooks by students at school secondary level. Albano, Coppola and Pacelli cover writing and reading since the pupils in their study are asked to develop written arguments from reading graphs. They find evidence of the complexity of switching between colloquial and literate registers. In a paper related to talking, Engvall, Samuelsson and Forslund draw conclusions about the relationship between communicative teaching strategies and students' development of procedural and conceptual language. On the other hand, Tiedemann addresses the notion of linguistic norms to examine classroom talking.

All papers in this direction show the extent to which the use of language in mathematical situations is determined by the mathematics, and by the situations and the people interacting within them. The abstractness of mathematics is highlighted, which often influences mathematical language by making visualisation impossible, along with the cultural situatedness of this mathematical language, in which for example the centrality of spatial prepositions is not necessarily true. Taken together, the papers show that there is no common, fixed mathematics constituting the language we use in mathematical situations. From a primary classroom in Germany, where students have to negotiate the linguistic norms of mathematics lessons, to the negotiating of concepts of motion in an Australian indigenous language, language is constituted by specific mathematical situations and by the participants in them. The construction of mathematical meanings as a basis for learning mathematics is therefore in constant interplay with the use of mathematical language.

Discourse, practices and positioning

Six papers by Nachlieli and Tabach; Ingram and Pitt; Wagner, Dicks and Kristmanson; Jung and Schütte; Dooley; and Hess-Green, Heyd-Metzuyanim and Hazzan constitute the collection of work in the direction of *Discourse, practices and positioning*. All these papers address the study of classroom discourse for the identification, production and analysis of interconnected teaching, learning, positioning and identity-work practices. Across papers there is a common tendency concerning theoretical integration and theories networking.

Nachieli and Tabach, along with Hess-Green, Heyd-Metzuyanim and Hazzan, address discourse in mathematics classrooms through a variety of theoretical perspectives such as commognition (Sfard, 2008), discursive psychology and theories of identity, while Wagner, Dicks and Kristmanson develop connections between socio-linguistics, pragmatics and theories of positioning for the purpose of their research. More generally, different authors base their notion of discourse on different theoretical approaches. Some of the papers are focused on socio-cultural approaches where discourse is not seen merely as individual word meaning or as linguistic utterances located in a classroom; here, the authors embrace theories of language where the subject is seen as a social, historical and political interlocutor. Mathematical discourse is related to varied ways of talking, reading, representing, interacting, moving, silencing, believing, valuing, identifying, performing and acting.

The tendency in these papers appears at the intersection of a diversity of lines of concern, whose collective reading provides opportunities to unpack the discourse(s), diversity, ethics and epistemologies of learning mathematics. In Nachieli and Tabach, and also in Ingram and Pitt, we find the study of the construction of competency and success in the course of classroom interactions where different representations of 'competent' and 'successful' students are at play. Moreover, we find the study of the role of vague language and politeness in mathematical conversations in Dooley, of notions of uncertainty in students' discourses related to prediction and conjecturing in Wagner, Dicks and Kristmanson, of young children's participation in decontextualised mathematical discourse in Jung and Schütte, and of emotions in experiences of discourses on achievement and learning in Hess-Green, Heyd-Metzuyanim and Hazzan, amongst other lines of concern.

WHERE TO GO FROM HERE

In this final section, we build on our discussion of the contemporary research agenda of our domain inside and outside of ERME, to shortly reflect on the potential of TWG09 –its participants, their interaction and their activity– in the further refinement and development of this agenda. We see TWG09 not only as a space for researchers who share interests concerning language issues in mathematics education, but more importantly as a space for researchers who may have an influence on each other through their interactions at the time of the conferences and during the in-between periods. This second perspective represents a mature stage in the process of constructing a group with a strong scientific identity, capable of quality group work.

By the end of CERME9, the team of co-leaders asked participants of TWG09 to suggest reflections on how to mould the future activity in the group. An e-mail communication sent by one of the participants, who was attending her first CERME, revealed her vision of TWG09 as a rich space though still in an early stage of group work maturity. This is an instance of what this participant shared with us:

> It is important to get to see, as a group, the enormous challenges waiting for us to work on them. What I have missed though, is explicit consideration of how we are going to organize the near future so that we face these challenges by building on each other. (Participant of TWG09 at CERME9, e-mail communication)

This participant critically raised the issue of building on each other as a group. This is an insightful comment on the importance of building seriously on relevant work and ideas by other participants in order to strengthen the domain and our potential as contributors to its progress. The view by this participant may not be unique. We must continue to learn how academic collaboration within TWG09 can be reinforced in order to jointly face the many challenges posed at present and in the years to come in the study of language in mathematics education, both inside and outside of ERME.

Collaboration and regular work within the context of our group can contribute to moving the international agenda forward in directions that address, for example, the role and use of gestures in the bilingual mathematics classroom, the anticipation of forms of interaction for dialogic-based class discussion, the development of cross-linguistic analysis of mathematical cognition, the evaluation of content- and language-integrated approaches to learning, or the introduction of multimodal resources for the benefit of mathematics thinking. All in all, TWG09 – its participants, their interaction and their activity – can contribute to expanding our knowledge of a number of issues, questions and needs, with implications for the achievement of quality mathematics instruction and equitable learning environments. By building on each other, we can learn more about how talk and interaction develop throughout mathematical activity. We can particularly learn how preferences for exploratory talk and inquiry-based lessons are validated by rigorous empirical work, and how variations of these preferences have an effect at different stages of mathematical learning. Insights from research in this domain can assist in developing interventions to improve mathematics teaching and learning practices. Thus, one of the challenges is to conduct and promote research that increases our understanding of how mathematics teaching and learning develops, but that also allows us to identify effective strategies and ways of improvement in practice.

It is our hope that the following set of papers and posters will stimulate interest in and appreciation of work across a wide number of language aspects. Regardless of the aspects that we decide to highlight in our work, the centrality of language must always be kept in mind. We invite our colleagues in the field, as well as teachers, teacher educators, curriculum developers, policy makers, etc., to think along with us.

Reading data from graphs: A study on the role of language

Giovannina Albano[1], Cristina Coppola[2] and Tiziana Pacelli[2]

1 Università degli Studi di Salerno, DIEM, Fisciano, Italy

2 Università degli Studi di Salerno, DipMat, Fisciano, Italy, ccoppola@unisa.it

The work described in this paper is framed in a larger study focused on written argumentations produced by university students in tasks regarding graphs, conversions between graphs and their analytic properties and relations among different graphs. Using the functional linguistics framework, we analyse difficulties related to an examination task on functions and their derivatives. The use of colloquial and literate registers in mathematics problem solving is the lens through which we analyse and discuss the errors. We draw attention to the difficulties concerning the use of literate registers and how these difficulties influence the errors in the interpretations of texts and figures.

Keywords: Language, colloquial and literate registers, written argumentations.

INTRODUCTION

In this paper we focus on the analysis of written argumentations, produced by undergraduates to justify their answers in problems concerning graphs, relations among various graphs and their coordination with analytic properties.

The study was born in a first year University context, and, in particular, concerns Biology freshman students attending a basic mathematics course. According to the goals of mathematics instruction in applicative domains, such as Biology, the course primarily is aimed at allowing students to interpret and compare graphs of elementary functions. The need for argumentation comes from the need for preventing them from answering at random and for promoting a more-in-depth understanding.

Our research is framed in the context of the language as the key point in learning processes (Sfard, 2001) and of the importance of writing to learn (Morgan, 1998). In this framework, languages are seen as constructors of the meanings themselves. From this viewpoint, the quality of language influences the quality of thinking and this requires educational attention to the correspondence between semiotic activities and linguistic competency of the participants (Ferrari, 2004). In fact, evidence shows how some learning difficulties in mathematics can be ascribed to poor linguistic competence (Ferrari, 2004).

In the following we are going to investigate the protocols produced by a sample of students that were required to compare graphs and to produce an argumentation to justify their choices. A lot of difficulties emerged at different levels, in particular, in data reading, even with visual data.

We interpret these difficulties, which are linguistic or semiotic in nature, using the functional linguistic framework. In particular, we focus on the use of colloquial and literate registers in mathematics problem solving.

Our research question is the following: How the level of linguistic competence, particularly the difficulties concerning the use of literate registers, influences the way of interpreting texts and figures. More in general, in a Vygostkian framework (Vygotskij, 1934), we are interested in investigating how the language does (or does not) support thinking in the interpretations of texts and figures.

THEORETICAL BACKGROUND

Language is growing as one of the most relevant issues for research in mathematics education. Several authors have studied the interactions among the different semiotic systems in mathematics learning.

From the cognitive point of view, Duval's (2006) investigations have highlighted how the coordination of various semiotic representations is the key to comprehension in mathematics.

According to O'Halloran (2005) three main groups of semiotic systems can be devised: verbal language, symbolic notations and figural representations, which are strongly interwoven in doing mathematics.

Sfard (2001) interprets thinking as communication and regard languages not just as carriers of pre-existing meanings, but as builders of the meanings themselves. So, under this perspective, language should heavily influence thinking.

As already said, there is evidence that a good share of students' troubles in mathematics can be ascribed to improper uses of verbal language (Ferrari, 2004). More precisely, students often produce or interpret mathematical texts according to linguistic patterns appropriate to everyday-life contexts rather than to mathematical ones. The difference is not just a matter of vocabulary, grammar or symbols, but it heavily involves the organization of verbal texts, their functions and relationships with the context they are produced within. This is why Ferrari has assumed a pragmatic approach to interpret students' behaviours. This means focusing on the language use and on the different functions it plays rather than just on grammar. In this respect, a further characteristic of verbal language has to be taken into account, the multivariety, that is the use of language in various registers (intending register as a linguistic variety based on use) (Leckie-Tarry, 1995).

According to Ferrari (2013), in mathematics we need both the colloquial registers, to construct the concepts without paying much attention to the form of their representation, and the literate registers, including symbolic representations, which can be considered as extreme forms of literate registers. The latter ones are essential to express relations among concepts, to elaborate generalisations and to explain solving procedures. Ferrari (2004, 2013) has shown how many of the students' errors can be traced back to the use of typical styles of colloquial registers whereas more advanced styles would be necessary.

METHODOLOGY

The sample taken into account for our research consists of 64 students attending the first year of a 3-year BSc degree in Biology and taking part in a 48-hour

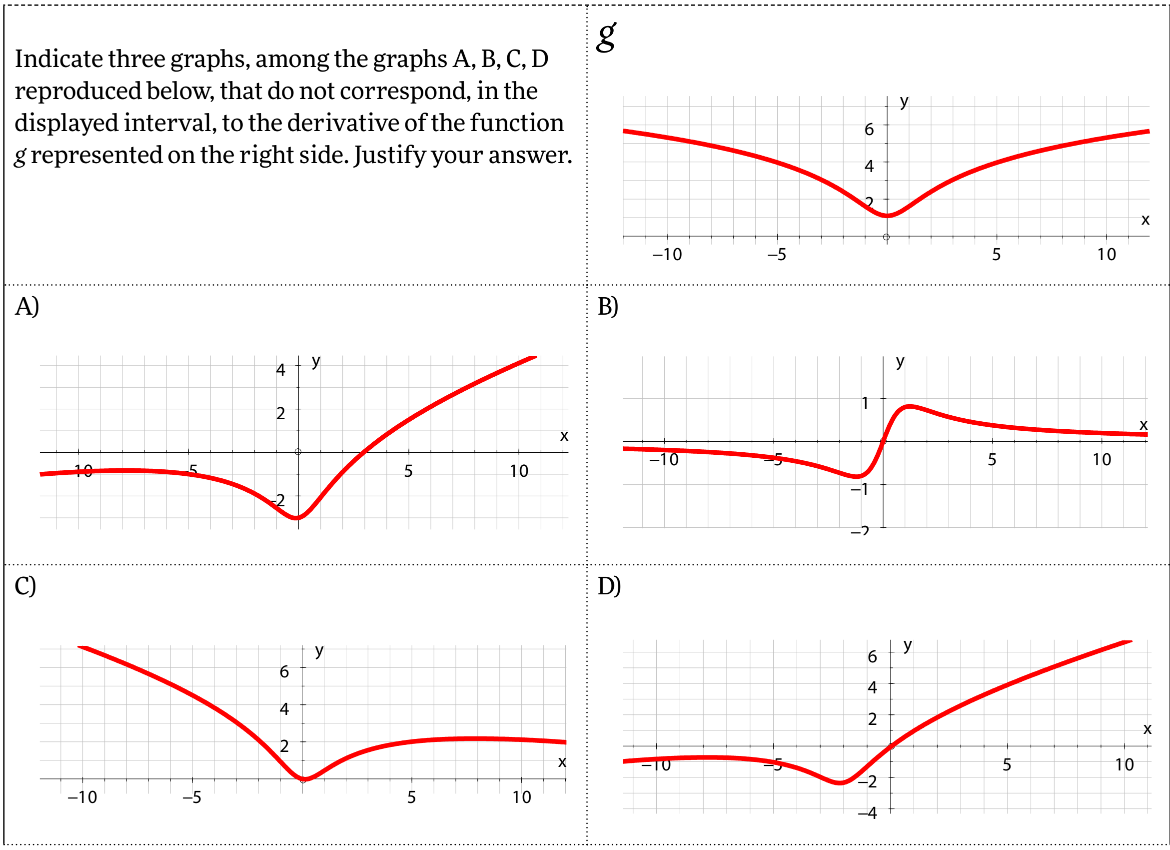

Figure 1: The task in the study

Literate register	Colloquial register
Context of culture: links with other texts and knowledge are activated.	*Context of situation*: the text is linked to the specific situation in which it is interpreted or produced (the exam situation). In this case, students face the problem starting from the text and the images in the task without referring to other knowledge, on the basis of general heuristics (an example is "if f is increasing, then f' is increasing") or looking for analogies (in the graph itself or in other tasks previously carried out).
Lexicalization: words are used according to well-known and shared definitions or descriptions.	*Lack of lexicalization*: everyday meaning of words (that is vaguer) prevails over the one based on definitions (think, for example, of such words as "increasing", "inflexion point", "concavity").
Propositions' explicit structure: subject, complement, conjunctions. Text organization is ruled by grammar and is based on subordination relationships (causative, consecutive, temporal propositions).	*Propositions' implicit structure*: subject or complements are often missing. Text organization is realized by means of spatial nearness of the sentences, or by means of graphical artifices (such as arrows, colours) or textual markers that are vague (for example "and") or randomly (as an example, "therefore" wrongly used).
Stability: text interpretation and production is quite stable, thanks to the explanation and use of verifiable definitions.	*Instability*: text interpretation and production result from factors out of control, e.g. how the students use words, the mental images they activate instead of definitions, previously carried out tasks that they remind of.
Metaphoric-symbolic organization: the link between representations and their content is not natural but conventional or metaphorical.	*Congruent-iconic organization*: organization and form of the representation are not arbitrary but they naturally correspond to organization and form of the meaning.

Table 1: Categories of errors

module in mathematics. According to the aims of the course, the lectures and the tutoring sessions were not based on a deductive approach (that is, definitions, theorems and applications), but they aimed at involving students in activity of coordination of various semiotic systems (Duval, 2006) concerning functions (formulas, graphs, tables, verbal texts).

In accordance with the lectures, in the exams the students were required to master graphical representations of functions and to be able to coordinate graphical and analytic properties of functions and their derivatives. Moreover, argumentation abilities were required to justify their answer.

In the examination task the question was posed in "negative" mode: given a function graph, the students had to indicate three out of four graphs "not" corresponding to the derivative of the given function, justifying their answer (Figure 1).

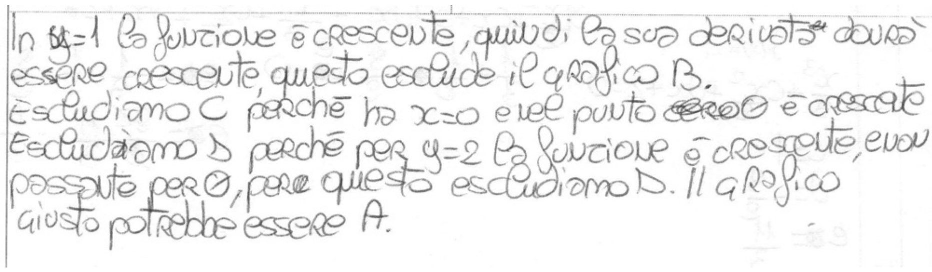
Our analysis was focused on the argumentations given by the students, even if the answer was correct (i.e., A, C, D), and we looked at them through the lens of the distinction between colloquial and literate registers. We point out that 23 students answered correctly. The errors that emerged have been classified according to typical linguistic categories (Leckie-Tarry, 1995), as listed in Table 2.

ANALYSIS OF PROTOCOLS

We report some protocols of special representativeness, and explain part of our analysis, using the described categories in Table 1. We present the pictures of the original protocols in Italian and our corresponding English translations.

A09: In y =1 the function is increasing, so its derivative has to be increasing, this rules out the graph B. We rule out C because it has x = 0 and at the point 0 is increasing. We rule out D because for y = 2 the function is increasing, and not passing through 0, for this reason we rule out D. The right graph could be A.

In protocol A09 (Figure 2), there is a quite inaccurate and "careless" language and confusion in the reading of graphs. The student refers to a context of situa-



In ~~y~~=1 la funzione è crescente, quindi la sua derivata dovrà essere crescente, questo esclude il grafico B.
Escludiamo C perché ha x=0 e nel punto ~~zero~~ 0 è crescente
Escludiamo D perché per y=2 la funzione è crescente, e non passante per 0, per questo escludiamo D. Il grafico giusto potrebbe essere A.

Figure 2: Protocol A09 – Answer: B, C, D

tion using the interpretation that identifies a function's properties with the properties of its derivative. Moreover the structure of propositions is implicit and there are repetitions. Language appears quite vague in "*We rule out C because it has x=0 and at the point 0 is increasing*". Maybe it is meant to say that the function represented in C assumes 0 as the value for $x = 0$. But being increasing in 0, how can this exclude graph C?

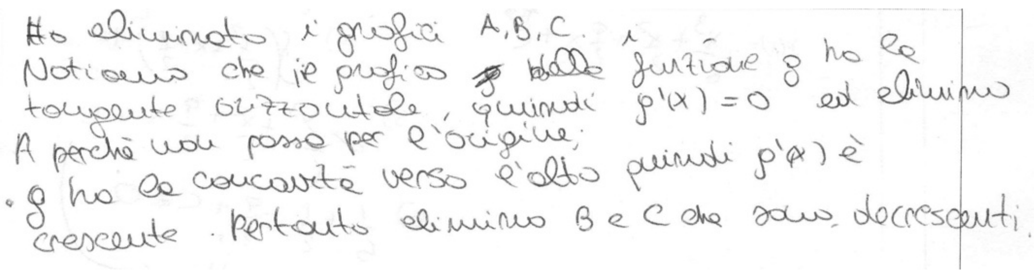
Besides, he/she writes "*In y=1 the function is increasing*", where 1 is the *y*-coordinate of the intersection of the graph of the function with the *y*-axis: an iconic organization seems to prevail. The same happens when the student writes "*for y=2 the function is increasing and not intersecting 0*", reading 2 on the *y*-axis and meaning the point in which the function assumes a value equal to 2.

Students, like the one in protocol A09, do not consistently apply some convention to name the points on the graph (e.g. indicating the *x*-coordinate only, or both the *x* and the *y*-coordinates) but they seem to choose the label that is nearer to the point. In other words, the spatial relationship between signs prevails on their defined meanings as well as on the conventions that regulate their use. As shown in Table 1, iconicity is typical of colloquial registers, whereas in literate ones conventions or metaphors are the standard ways of conveying meaning.

A07: I ruled out the graphs A, B, C. Let's notice that the graph of the function *g* has got horizontal tangent, so $g'(x) = 0$ and I rule out A because it does not pass for the origin; *g* displays an upward concavity so $g'(x)$ is increasing. Therefore I rule out B and C that are decreasing.

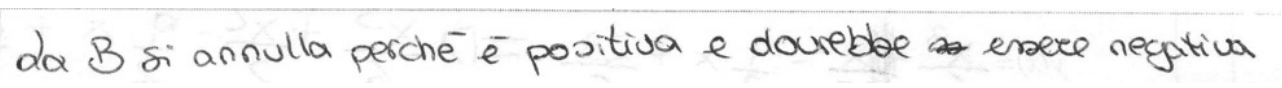
Also in protocol A07 (Figure 3) the language is quite inaccurate and there is a strong presence of the characteristics of colloquial register categories (Table 1). The student writes: "*the graph of the function g has got horizontal tangent, so g'(x)=0*", without specifying where there is a horizontal tangent in the graph of function *g*. By writing *g'(x)=0*, does he/she mean that the derivative is identically vanishing? Maybe, in a context of spoken communication, the sentence would be followed by a negotiation with the interlocutor, to explain the exact meaning.

Moreover he/she writes "*g displays an upward concavity*", showing a lack of conceptual control of the image and a lack of lexicalization: maybe the everyday meaning of the word "concavity" influences the answer (it could be that the student is reminded of a "standard" image of parabola). Also in the expression "*I rule out B and C that are decreasing*" a poor conceptual control of the image seems to emerge.



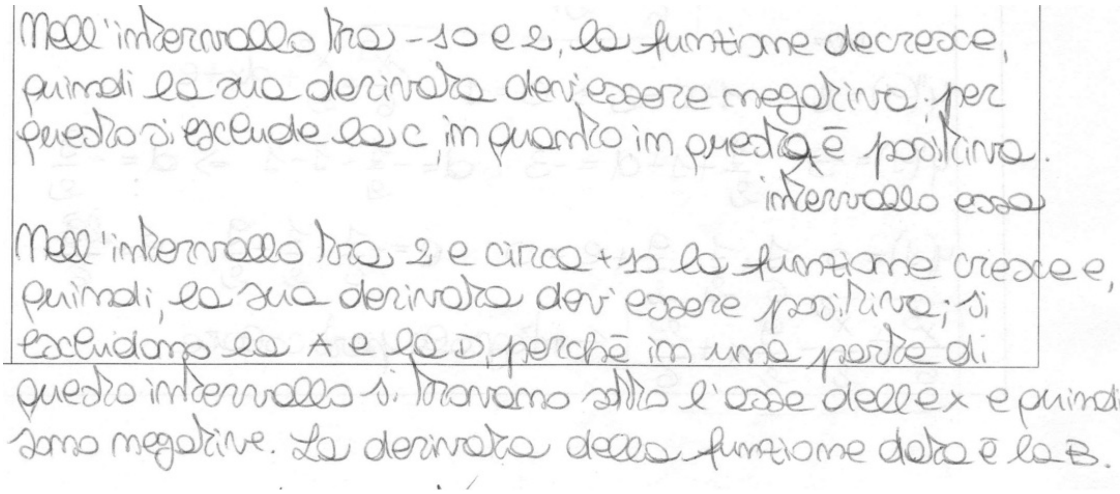
Ho eliminato i grafici A, B, C.
Notiamo che il grafico ~~g~~ della funzione g ha la tangente orizzontale, quindi g'(x) = 0 ed elimino A perché non passa per l'origine;
g ha la concavità verso l'alto quindi g'(x) è crescente. Pertanto elimino B e C che sono decrescenti.

Figure 3: Protocol A07 - Answer: A, B, C



da B si annulla perché è positiva e dovrebbe ~~a~~ essere negativa

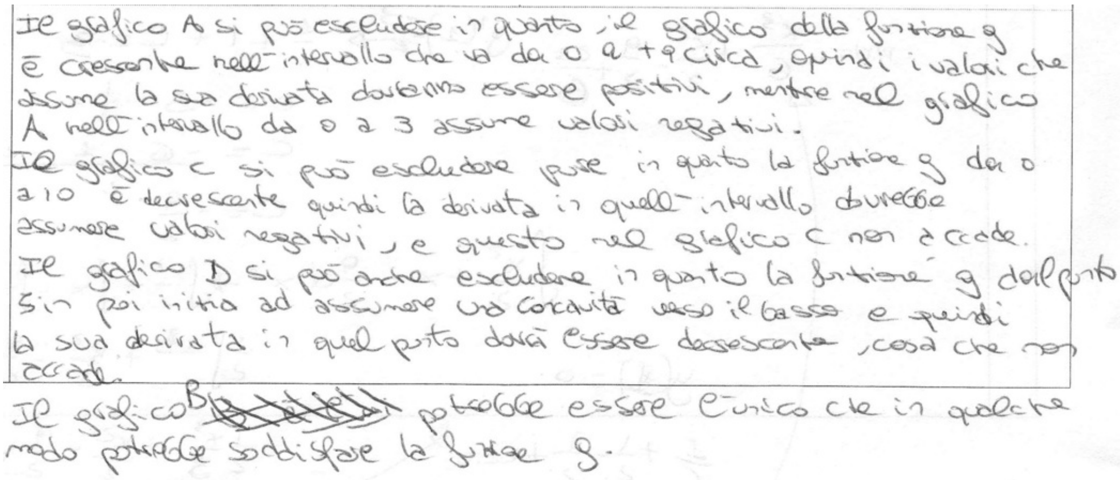
Figure 4: Protocol A21 – Answer: A, B, C



Nell'intervallo tra -10 e 2, la funzione decresce, quindi la sua derivata dev'essere negativa; per questo si esclude la C, in quanto in questo intervallo essa è positiva.

Nell'intervallo tra 2 e circa +10 la funzione cresce e, quindi, la sua derivata dev'essere positiva; si escludono la A e la D, perché in una parte di questo intervallo si trovano sotto l'asse delle x e quindi sono negative. La derivata della funzione data è la B.

Figure 5: Protocol A55 – Answer: A, C, D



Il grafico A si può escludere in quanto il grafico della funzione g è crescente nell'intervallo che va da 0 a +9 circa, quindi i valori che assume la sua derivata dovrebbero essere positivi, mentre nel grafico A nell'intervallo da 0 a 3 assume valori negativi.
Il grafico C si può escludere pure in quanto la funzione g da 0 a 10 è decrescente quindi la derivata in quell'intervallo dovrebbe assumere valori negativi, e questo nel grafico C non accade.
Il grafico D si può anche escludere in quanto la funzione g dal punto 5 in poi inizia ad assumere una concavità verso il basso e quindi la sua derivata in quel punto dovrà essere decrescente, cosa che non accade.
Il grafico B potrebbe essere l'unico che in qualche modo potrebbe soddisfare la funzione g.

Figure 6: Protocol A06 – Correct answer: A, C, D

A21: B vanishes because it is positive while it should be negative.

Together with the lack in the conceptual control of the image ("*B…is positive*"), we found the protocol A21 (Figure 4) interesting for the use of the verb "vanish" instead of "rule out". The student here uses a word belonging, in some sense, to the mathematical register instead of using a word of everyday language, maybe because the task he/she is carrying out is a "mathematical" task.

A55: In the interval between -10 and 2, the function decreases, so its derivative has to be negative; for this reason the C is ruled out, for in this interval it is positive. In the interval between 2 and about +10 the function increases and, so, its derivative has to be positive; A and D are ruled out, because in a part of this interval they are below the x-axis and so they are negative. The derivative of the given function is B.

The argumentation used in protocol A55 (Figure 5) is quite accurate, but there is a strong presence of iconicity. The student writes "*In the interval between -10 and 2, the function decreases*" reading -10 on the x-axis and 2 on the y-axis which are explicitly written in the diagram (while 0 on the origin is not written). Maybe he/she chooses the most evident label, or the label nearest to the point he/she wants to indicate. He/she writes again: "*In the interval between 2 and about +10 the function increases*", showing once more an iconic interpretation of the diagram.

In ruling out graph D ("*A and D are ruled out, because in a part of this interval they are below the x axis*"), the student shows not only a lack of conceptual control on the image, but, maybe, again iconicity: it seems that the student considers the interval between -2 and +10, instead of the interval +2 and + 10; he/she refers to the label -2 or to the label 2, indifferently, as if both the labels indicate the same point.

A06: Graph A can be ruled out because the graph of function *g* is increasing in the interval going from 0 to about +9, so the values of its derivative have to be positive, whereas in graph A in the interval from 0 to 3 it assumes negative values. Graph C can be ruled out too because function *g* from 0 to 10 is decreasing, so the derivative in that interval should assume negative values, and this does not happen in graph C. Graph D can be ruled out too because function *g* from point 5 on begins displaying a downward concavity so its derivative in that point has to be decreasing, and this does not happen. Graph B could be the only one satisfying in some way function *g*.

The student of protocol A06 (Figure 6) gives the correct answer (he/she rules out graphs A, C and D), produces a detailed conversational argumentation and shows a good capability of reading of graphs and linking data to conclusions. Nevertheless also in his/her protocol, we can find an expression such as: "*function g from 0 to 10 is decreasing*". He/she expresses like one looking at the graph from the origin to the left and from the origin to the right.

Indeed this behaviour emerges from several protocols: a lot of students privilege their own point of view with respect to definitions and to the shared and well-known rules of using representations.

DISCUSSION AND CONCLUSIONS

From the protocols' analysis three macro-groups of students' behaviours seem to emerge. These macro-groups are based on the categories of errors (in Table 1), categories that in students' behaviours are continuously interwoven.

The first macro-group is represented by the protocols of those students that do not apply the usual conventions (the "grammar") of the Cartesian plane but use the image they see. Students belonging to this group do not refer to the *context of culture* evoked by the representations but to the *context of situation*.

In some protocols, as an example, we can observe that, in order to designate the points of the Cartesian plane, the students tend to label the points only by their ordinate value. Probably, they choose this value just because it is the label nearest to the point. Conversely some students use a point of the plane in order to indicate the starting point of an interval on the *x*-axis (see Protocol A55 in Figure 5).

In this macro-group we can find also other students' behaviours: for example students exploring the graph starting from the origin of the Cartesian axis and considering as "positive" the direction from 0 to $-\infty$; other students take into consideration in different graphs points that look the same (as an example, points that are minimum) instead of comparing points that have the same *x*-coordinate. These students remain in an *iconic interpretation of the diagram* and privilege their own point of view (related to the context of situation, i.e. the diagram drawn on the paper as a material object), instead of the recognized rules or conventions for using representations (which are obviously related to the context of culture).

A second macro-group is represented by the protocols of students having some difficulty in the *use of the vocabulary*. For these students some words, such as "positive", "increasing", etc., have a vague and unstable meaning. As a consequence they make errors also in reading the graphs. In such a situation students write sentences such as "*I rule out B because it should be positive for $x > 0$*", probably having in mind the concept "increasing".

Another behaviour related to this macro-group is mixing up the subjects in sentences like "*the derivative vanishes ↔ the function vanishes*".

All these behaviours are typical of the use of colloquial registers.

The last macro-group is represented by the protocols of students having some problems in the *organization of the text*, i.e. the meaning of the words related to their position in the text.

As an example we can observe some protocols in which the students use the expressions "increasing", "positive", "upward concavity" for describing properties related to an interval even if these expressions are true only in a part of the interval.

This behaviour is linked both to that one, above described, characterized by taking into consideration the first image or the first concept that seems to work well without making further inferences, and to how the students tend to organize the text in the colloquial registers. In the last case they are not used to specify the complements because in a context of spoken communication the meanings could be negotiated later. In this way the meanings become unstable and vague and as a consequence it is hard reading the images and making further argumentations.

The outcomes of the analysis seem to suggest the need for a stronger educational attention to linguistic issues in mathematics. It is fundamental the capability of using both literate registers, which support scientific thinking, and colloquial ones, which are indispensable too in the construction of mathematical concepts. Thus switching back and forth between colloquial and literate registers is a crucial process in mathematics learning. These skills are not natural but have to be developed and fostered, by specifically planned teaching activities, from primary school onwards.

Linguistic stratification in a multilingual mathematics classroom

Richard Barwell

University of Ottawa, Ottawa, Canada, richard.barwell@uottawa.ca

There has been a good deal of research on interaction in multilingual mathematics classrooms, with an increasing emphasis on the socio-political dimension of language in shaping students' and teachers' language choices. I argue that this approach remains under-theorised and offers a limited perspective on the politics of language in mathematics classroom interaction, largely focused on language choice. To deal with this problem, I draw on ideas from the contemporary sociolinguistics of multilingualism, including the notions of heteroglossia and orders of indexicality. To illustrate these ideas and their utility, I present an analysis of an episode observed in a sheltered elementary school second language mathematics classroom in Canada. My analysis shows how the two students are marginalised by the interaction.

Keywords: Multilingual mathematics classrooms, second language learners, heteroglossia, linguistic stratification.

INTERACTION IN MULTILINGUAL MATHEMATICS CLASSROOMS

Research on interaction in multilingual classrooms has increasingly emphasised the socio-political dimension of language and language use (Setati, 2005; Planas & Civil, 2013). I refer to any classroom in which any of the participants uses more than one language in their daily life as multilingual. This definition includes classrooms commonly referred to as bilingual or second language classrooms, as well as those in which the languages of some students are not used and not recognised. This is consistent with sociolinguistic perspectives that challenge rigid separations between languages or language situations (Makoni & Pennycook, 2007). In such classrooms (indeed, in any classroom), language is not simply a means of communication or a tool for thought; the way language is used means that some participants may be privileged in different ways, while others may be marginalised. Such influences are sometimes systemic and reflect wider social forces, such as those of racism or class. I refer to these influences as the socio-political dimension of language.

While research has identified the significance of the socio-political dimension of language, its effects on mathematics classroom interaction are poorly understood. Research on mathematics classroom interaction in multilingual settings dates back at least to the 1990s. Much of this work has adopted a view of language as a 'resource'. Research on teaching practices includes Adler's (2001) identification of dilemmas that arose for several teachers in different multilingual mathematics classrooms in South Africa; Khisty's (1995) comparison of three teachers in Spanish-English bilingual classrooms in the USA and Moschkovich's (1999) study of a Spanish-English bilingual mathematic class also in the USA. These studies highlight the challenges many teachers face in working with students who draw on multiple languages in the mathematics classroom. In all three studies the dilemma, to use Adler's term, of whether or not to give explicit attention to mathematical language or focus on the mathematical ideas emerged a challenge. Research on students' participation, meanwhile has identified several resources on which students may draw in mathematical discussion. These resources include code-switching (Setati, 2005; Planas & Setati, 2009); genre and narrative (Barwell, 2003, 2005); and gestures, writing and diagrams (Moschkovich, 2009).

While the majority of these studies show some awareness of the socio-political dimension of language, this awareness is not always apparent in the design and conceptualisation of the research. In recent years, research has emerged that gives more explicit attention to this dimension. Setati's (e.g., 2008) work, in particular, has highlighted how learners' and teachers' language choices are influenced by the broader politics of language in South Africa. By choosing to study mathematics in English, for example, students hope to get access to better opportunities in higher education or employment. The value of these "social goods" outweighs the challenges that such students may face in studying mathematics in a language that they may only use at school. Similarly Planas and Civil (2013), drawing on data from Catalonia and Arizona, show how the choices of the students and teachers in their study about language use in their mathematics classrooms are politically mediated. In particular, and rather like Setati, they argue that the pedagogical value of students' home languages may be overridden by broader political considerations.

It is clear, then, that the socio-political dimension of language influences what happens in mathematics classroom interaction. The research I have discussed, while making a contribution to the field, has, however, generally avoided a theorisation of this aspect of language use. This work has tended to focus on one single aspect of language use: the choice (if it is a choice) of language. Thus, in Setati's (2008) work, the choice is between English and an African language or languages; in Planas and Civil's (2013) study, the choice is between Spanish and English, or Catalan and Spanish. The socio-political dimension of language is, however, likely to influence mathematics classroom interaction in many other ways than participants' choice of language. To investigate these influences, additional theoretical ideas are needed.

I propose to address this problem by drawing on theoretical ideas from the contemporary sociolinguistics of multilingualism. These ideas are illustrated through analysis of data collected in a second language mathematics classroom in Quebec, Canada. My aim is to demonstrate that these theoretical tools make it possible to develop a more nuanced understanding of how language is implicated in the stratification of students' participation in mathematics and hence how it has an impact on their opportunities to learn mathematics.

HETEROGLOSSIA AND ORDERS OF INDEXICALITY

There have been some significant shifts in how multilingualism (and language itself) is conceptualised and understood in recent years. Many of these shifts can be traced, in part, to the work of Bakhtin (1981) who developed a view of language as situated, dialogic and tension-filled. Bakhtin's ideas have led to a view of multilingualism that, rather than focusing on discrete, clearly defined languages and associated clearly defined groups of speakers, looks at language as social practice situated in social and political contexts (Blackledge & Creese, 2010, p. 25). More specifically, Bakhtin defines the key concept of heteroglossia as "the social diversity of speech types" (Bakhtin, 1981, p. 263). He describes this diversity as follows:

> At any given moment of its evolution, language is stratified not only into linguistic dialects in the strict sense of the word [...] but also [...] into languages that are socio-ideological: languages of social groups, "professional" and "generic" languages, languages of generations and so forth. (pp. 271–272)

Heteroglossia, then, refers to the many patterns that arise within language and which can be associated with some group of people, situation, activity or other social formation. There are two important points to note about this account. First, the many different patterns within the diversity of language overlap and intersect. The language of teachers, the language of mathematics and the language of a region may all be present in the same utterance. Moreover, the distinctions between the speech types to which Bakhtin refers are produced by these practices; they are not pre-given. Thus, what counts as an accent, as 'teacher talk' or even as a language, is locally produced (Bailey, 2007). The way that language practices can 'point to' such associations, allowing as to recognise particular activities, group memberships or situations, is called indexicality. This aspect of language is important in framing particular utterances, so making them interpretable. In previous work, I have examined the role of heteroglossia in the language tensions that have been reported in multilingual mathematics classrooms around the world (Barwell, 2012, 2014).

Second, these ideas make a link between moments of language use and broader social patterns and forces:

> Linguists have increasingly turned to the works of Bakhtin and his collaborator Volosinov because their theories of language enable connections to be made between the voices of social actors in their everyday, here-and-now lives and the political, historical, and ideological contexts they

> inhabit. In familiar terms, Bakhtin's philosophy of language contributes to the means by which we may understand the structural in the agentic and the agentic in the structural; the ideological in the interactional and the interactional in the ideological; the "micro" in the "macro" and the "macro" in the "micro." (Blackledge & Creese, 2009, pp. 237–238)

Ways of talking both reflect the socio-historical dimension of language and create this dimension for the future.

Third, these different ways of talking are stratified; some ways of talking are considered more valuable than others. To explain how this stratification arises in the context of multilingualism, Blommaert (2010) focuses on indexicality:

> Ordered indexicalities operate within large stratified complexes in which some forms of semiosis are systemically perceived as valuable, others as less valuable and some are not taken into account at all, while all are subject to rules of access and regulations as to circulation. That means that such systemic patterns of indexicality are also systemic patterns of authority, of control and evaluation, and hence of inclusion and exclusion by real or perceived others. (p. 38)

This kind of stratification typically maps onto scalar differences in practices, so that local, idiosyncratic practices are perceived as less valuable than more widely used, standardised practices (Blommaert, 2010, p. 35).

Blommaert discusses several examples to illustrate these ideas. For one, he refers to a price list for cold drinks found in London's Chinatown (p. 31). The price list is written in Chinese characters and in English. The English includes "quite spectacular typos" (p. 31), such as "Lced" for "Iced" and "Coffce" for "Coffee". Blommaert points out that for many customers in London, the Chinese characters are "a meaningless design", but which index "Chineseness" and a link with wider Chinatown. He also imagines the sign being printed somewhere in China, where the English would be equally meaningless, simply symbols to be reproduced in printed form. To customers in London, the spelling mistakes might be a source of amusement, but might also index less favoured or less valuable forms of English literacy. Hence, indexicality is itself situated, dependent on who is producing or interpreting language or text, as well as where they are and what they are doing. Blommaert (2010) illustrates this point as follows: "the English spoken by a middle-class person in Nairobi may not be (and is unlikely to be) perceived as a middle-class attribute in London or New York" (p. 38).

RESEARCH SETTING: A SECOND LANGUAGE MATHEMATICS CLASS

From 2008–2012, I conducted an ethnographic study of mathematics learning in different second language settings in Canada, a country with two official languages, English and French. In this paper, I refer to data from one of these settings, located in an Anglophone school in the French-majority province of Quebec. The data come from interactions with a Grade 5–6 sheltered class for students identified by the school as falling behind in both English and mathematics. The students therefore studied these two subjects in a separate class from their regular classmates. I visited the class regularly throughout the 2009–2010 academic year. During that time, enrolment in the class varied quite a bit but never went over 9 students.

For most of the year, all of the students in the class were Cree, one of the original peoples of Canada. The children's families originated in communities in northern Quebec. The students spoke Cree as a first language. They also spoke English, though with a range of proficiency levels. In the move from James Bay to the city, the students went from being part of the majority in small Cree-speaking communities, to part of a minority in a city dominated by French and English.

During my visits to the class, I acted as a participant observer, making field notes during teacher-led activities, and interacting with the students during small-group work. The teacher often asked me to work with small groups of students. I made numerous audio recordings of whole-class interaction and some small-group work, including my own work with groups of students. I collected samples of students' work and photographs of other artefacts, such as posters, work written on the blackboard and anything else that seemed relevant. After each visit, I wrote a brief report summarising my observations.

In the next part of the paper, I present and analyse an episode that I observed during the study. I have described aspects of this episode elsewhere (see Barwell, 2014) but have not previously examined the stratification that arose in the students' interaction.

THE TULIP FESTIVAL PROBLEM

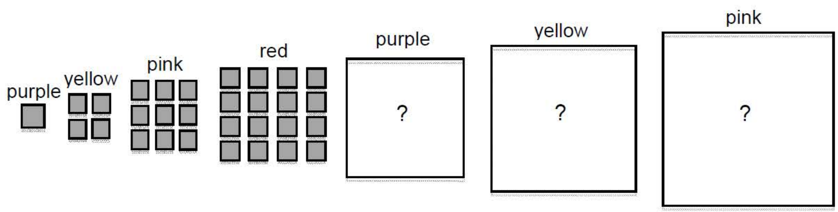
The episode occurred in February 2010, during a part of a class in which the students were working at activity stations. I worked with two students, Curtis and Ben, at a station in which they had to solve the problem reproduced in Figure 1.

> Every year Ottawa holds a world-renowned tulip festival in the month of May. There are different gardens in various locations, one of which is on Parliament Hill. The Canadian Tulip Festival was established to honour Queen Juliana of the Netherlands, in 1953. [...] You are a gardener hired to plant tulip bulbs for the Canadian Tulip Festival in May. You decided to arrange the flowers in a V for Victory format. You decide to use a pattern to make your design. Here is the design you started.

The problem text has a number of indexical features relevant to the students' subsequent work. First, the text is in English. The first part indexes factual registers typical of textbooks or informational texts, such as tourist brochures. Second, the text is an elaborate form of word problem, with a scenario, some information and a mathematical calculation to be carried out. The presentation and structure of the text thus indexes the genre of mathematical word problems. This genre is widespread in Canadian mathematics classrooms and this particular form, known in Quebec as a situational problem, is a common form of assessment item in the province. Third, the text indexes a particular place, Ottawa, and a particular event, the Tulip Festival, with which people in the region might be expected to have some familiarity. More specifically, and crucially for this episode, the text assumes a familiarity with tulips, a flower that is very common in the spring in this region. These associations, combined with the register used in the first part of the problem (e.g. Ottawa as the national capital, "world-renowned"), perhaps also index a form of 'Canadian-ness'. Fourth, the text indexes certain mathematical forms, particularly geometric patterns indicated by the diagram. Thus the text indexes a nation, a region, an event, speakers of a language, a register, a genre and finally, some mathematics.

I began by asking Curtis and Ben to read the problem to themselves and then initiated a discussion about the content [2]:

RB:	okay (.) so what's it about?
Curtis:	its about (.) world's biggest flower=I don't know
RB:	ottawa's biggest
Curtis:	tu (.) lip festival
RB:	tulip festival (.) do you know any of those? (.) do you know what a tulip is? [hm
Curtis:	[flower
RB:	flower right (.) have you ever seen a tulip?
	[...]
Ben:	(...) it's white
RB:	they are lots of different colours white ones red ones
Curtis:	like a rose?
RB:	yellow ones say again
Curtis:	rose
RB:	no it's a bit different from a rose (.) roses yeah (.) tulips just come up in the spring and have a nice flower for about two weeks (.) then they are fin-



How many purple, yellow, and pink tulips do you need to complete the design? Show all your work.

Figure 1: The Tulip Problem [1]

ished (.) there we go (.) let me see your picture
Ben, Curtis: [*laughter*]
RB: have you seen flowers like that
Ben: ^no^
Curtis: yeah (.) in a store

It is apparent from this exchange that the two students have some trouble interpreting the text in the way it was presumably intended. For them, "tulip" initially indexes something rather vague: a kind of flower – they mention roses and, at another point, poppies. And while the text might be designed to index a place and an event, and by extension, some aspects of Canadian-ness, the two students do not make this connection. In this way, the text serves to alienate the students.

Our discussion, which continues in similar vein to clarify what 'bulbs' are and what 'a gardener' does, can be read as an encounter between different "speech types": those of the text, the students and me. Over the next few minutes, the students work at the problem, interacting with the diagram, as I recorded in my notes:

> Ben moved first, drawing in rows of tulip bulbs in the boxes shown in the diagram. He did 5x5 in the first empty box and then moved on to the next box. Curtis looked at what he was doing and then did something similar. At some point, Curtis came up with a solution, fairly quickly. He just wrote three numbers at the bottom of the answer box. I didn't understand his solution but explained that he needed to explain how he worked it out. He wrote a sentence along the lines of 'I added the tulips' – something quite general. So I said he needed to be more precise, to explain what calculation he did. At this point he explained to me verbally and I invited him to write it down. What struck me was that he had little trouble solving the problem, and that most of the time was spent on writing it down in an 'acceptable' way.

My account suggests that the students do relate to the mathematical pattern indexed by the diagram and are able to interact with it and, in particular, to extend it. At some level, then, there is some alignment at this point in the forms of language (including graphic elements) used in this part of the text, and the students' own linguistic repertoires. Their expression of their work, however, remains 'local'; that is, it makes sense to them but does not index more widespread forms of mathematical language (for which, in the interaction, I am positioned as the arbiter):

RB: you have to explain now that you've got these totals okay otherwise if somebody comes along and reads it they will wonder where the number comes from in these kinds of situational problems its quite important that you explain some how how you worked it out

My remarks make it explicit that the goal is to write in a way that is interpretable to some kind of generalised 'somebody' and a generalised situation "these kinds of situational problems" (which are typically used as assessment items). This is an example of what Blommaert (2010) calls 'scale jumping'. The students' linguistic productions index their own locally developed forms; my intervention indexes language forms and communicational requirements associated with people (e.g., teachers) and situations (e.g. assessment) that are more widespread and more valued.

The two students spend a relatively long time working on showing "all their work". Their interactions with me, including the following extract, indicate that this part of their work was quite challenging:

RB: so (.) that's a good beginning (.) but you need to explain like the calculations that you did (.) you need to say what kind of calculations you did
Curtis: times
RB: yup but precisely what did you times what did you add
Curtis: I timesed seven (.) times seven (.) six times (.)
RB: right right
Curtis: seven plus that's it
RB: so like when you worked out for purple
Curtis: I did five times five
RB: uhum
Curtis: plus one
RB: right so I would write purple and then exactly what you just said

The interaction between different speech types is particularly clear in this extract. My use of the word 'need', twice, again indexes expected mathematical ways of talking or writing and, indeed, implies they are a requirement. Through the interaction between Curtis and I, an account of his calculations is pieced together and to some extent endorsed by me. Nevertheless, Curtis's account makes use of relatively local forms of mathematical expression, particularly 'times', rendered as a participle 'timesed'. Throughout this extract, including in my own reflections shown in my notes, my utterances index acceptable ways of talking and writing about mathematics. Through the episode, there is some convergence in the students' utterances towards more conventional mathematical language. Needless to say, these conventions, indexed by the problem text and by me, do not make any reciprocal convergence towards the students' forms of mathematical expression.

DISCUSSION AND CONCLUSIONS

For the students and I, this episode involves an encounter with otherness, with difference, with what Bakhtin calls the alien word (see Barwell, 2014). The point I want to highlight in this paper, however, is that the speech types involved in this encounter reflect prevailing orders of indexicality. The students bring speech types from the periphery: those of Cree-speakers from James Bay for whom English is a second language. Their speech types also include local forms of mathematical language that make sense to the students, either individually or among themselves. The word problem text and I both deploy more authoritative speech types, where this authority comes from an indexing of assessment, of the requirements of the genre and of communicating one's work to a generalised other ("someone"). The encounter between the students, the word problem and me is filled with indexical complexity, but this complexity is ordered; the language of the encounter is stratified, with a hierarchy apparent in which local and peripheral speech types are less valued than more widely standardised forms of mathematical language.

The theoretical sociolinguistic ideas I have drawn on in this paper make it possible to see how the interaction in this second language mathematics classroom episode marginalises the two students. The concept of heteroglossia highlights the way specific utterances in the class are linked to broader, stratified, social patterns and the notion of indexicality facilitates a detailed analysis of this stratification as it plays out in the classroom. This is not to say that the students should not learn 'standard' forms of mathematical language in English; the indexicality of language is part of what makes communication possible. Blommaert, however, distinguishes between the indexical order, which refers to the patterns of language that allow us to recognise references to groups, activities or situations, and orders of indexicality, which refers to the stratification of language and which is implicated in processes of marginalisation. It is through the indexical order that the students recognise the geometric pattern and are able to work on it and find a solution. It is the ordering of indexicalities, however, that marginalises much of the students' repertoire of language practices. Unfortunately, there is no neat way to decouple these processes. This analysis sheds some light on how the socio-political dimension of language influences these students' participation in a mathematics classroom activity.

ACKNOWLEDGEMENT

The project was funded by the Social Science and Humanities Research Council of Canada, grant 410-2008-0544. I am grateful to the school and students for their generous participation. The transcription was prepared by Jennifer Chew Leung.

Mathematics learning in whole class discussion: A design experiment

Kaouthar Boukafri, Miquel Ferrer and Núria Planas

Universitat Autònoma de Barcelona, Barcelona, Spain, kaouthar.boukafri@uab.cat

In this report, we examine the interacting use of whole class discussion and concrete manipulatives in the learning of geometry in a secondary mathematics classroom. We draw on our prior works on the generation and exploitation of learning opportunities in order to elaborate an example of opportunity for further reflection. In the analysis, two basic aspects are considered: (i) actions of collective argumentation and (ii) types of orchestration involved in the production of the students' learning. We illustrate the analysis through a moment of classroom talk in which a student is the initiator of an opportunity that leads to a situation of mathematics learning. We argue that the teaching activity is decisive in the joint exploitation of the opportunity.

Keywords: Whole class discussion, students' mathematics learning, problem solving, collective argumentation, concrete materials.

CONTEXT, QUESTION AND GOALS

The reported work needs to be situated in the context of a project strategy that includes the study of various mathematics lessons with different mathematical contents in use. All the work in the project is expected to contribute to the knowledge of mathematics learning by broadening the understanding of how mathematics learning opportunities may be created and exploited in classroom talk. Within this context, we address results from a research guided by the following question:

What are the actions involved in the creation of mathematics learning opportunities in whole class discussion with problem solving and manipulatives?

In the classroom for the conduction of the experiment, concrete manipulatives that could be physically handled by students were offered to explore and investigate mathematical concepts and processes for finding solutions to geometry problems. The potential role of whole class discussion and problem solving with manipulatives in the generation of mathematics knowledge was a key assumption in the design of the three-lesson intervention. In particular, a concern to this work was that by examining the role of manipulatives as mediating artefacts in classroom talk, certain learning opportunities in mathematics might be better examined and characterised.

For the time devoted to whole class discussion in each lesson, the same procedure for the analysis was considered. We searched for moments of classroom talk where an approach to the resolution of the problem was being discussed. For each moment and when possible, we identified mathematics learning opportunities and related them to particular mathematical contents. What we present in this report is the analysis applied to one of the identified learning opportunities. Elsewhere (Ferrer, Morera, & Fortuny, 2014) we have detailed our procedure for the detection of learning opportunities and we have examined the role of the teaching activity. In what follows we outline our theoretical orientation, describe the experiment, provide our methods, and discuss our data, findings, and future directions.

THEORETICAL PERSPECTIVES AND NOTIONS

A major problem in mathematics education research has to do with understanding and framing learning. Nevertheless, researchers in the field have reached important agreement on the fact that evidence of learning cannot be gathered in isolation, neither at the level of individuals nor at the level of groups (Sfard, 2001). Without denying the importance of the individual, social theories take the system of actions and practices as the starting and explanatory main component of learning.

In the line of social theories of mathematics learning (Goos, 2004), our work is placed within the tradition of design experiments in mathematics education research. As said by Cobb, Confrey, diSessa, Lehrer and Schauble (2003), this type of experiment aims at identifying and explaining successive patterns emerging from the study of connections between the students' learning and the classroom circumstances in which it is developed. For the conduction of an experiment, the phases are planning, implementation, evaluation and iteration. In this report, we refer to data coming from the first round of implementation of the planned teaching sessions.

As part of our project strategy, design experiments are supported to develop knowledge on mathematics learning, and in particular around mathematics learning opportunities. The notion of mathematics learning opportunities is central to our research as a way to link the social aspects of classroom activity to the students' development of mathematical ideas (Planas, 2014). In our analysis of practices that potentially foster learning opportunities during classroom talk, we give priority to actions of collective argumentation and types of orchestration, which actually are specific types of sequenced actions. To this respect, we plan design experiments in which conceptual and procedural forms of mathematics learning are expected to be facilitated by means of an interacting system involving inquiry-oriented tasks and pedagogical resources such as physical artefacts.

As claimed by Miranda and Adler (2010), there is little literature on the role and use of concrete manipulatives in the teaching and learning of mathematics. From the perspective of the teaching activity, it is argued by these authors that the presence of manipulatives in the development of a task needs explicit and reasoned justification so that students are told the importance of using those resources. This is why we collaborated with the teacher to foster responsibility for a form of teaching activity that privileged the use of manipulatives not only during the time for group work but also during the presentation of the task and its discussion in whole-class talk.

THE CLASSROOM EXPERIMENT

The experiment consisted of three lessons in a classroom of 12 years-old in a school of Barcelona, Catalonia-Spain. What was first selected was the teacher, on the basis of her expertise in teaching mathematics for several years and her active involvement in our research team. She was given in advance the sequence of three geometry problems and she made relevant contributions in order to adapt the wording and content to the particular group of students. The lesson dynamics was also negotiated with the teacher. The students were first asked to read the problem, to work in small groups, and finally to participate in a whole class discussion. During group work, the students were provided with problem-based concrete materials and had to produce written individual responses; after thirty minutes of group work, the teacher took the materials away in order to encourage finishing the responses. The teacher had the materials for manipulation in her guiding of the interaction with the students during whole class discussion. It was possible, and in fact it was promoted, to complete, revise or modify responses up to the end of the lesson. The students in this classroom were used to similar dynamics but the work with manipulatives was new to them.

Packing glasses

We have 12 glasses, each of them measuring 92mm (height) and 74mm (diameter of the major circle). We want to find the cheapest box for all glasses, that is, the box requiring the least material. In addition we want:
– The base of the box to be rectangular.
– All glasses to be facing up in the box.
– No glasses inside each other.
Under these conditions:
What are the minimum dimensions for the box to contain all the glasses?
Which data will you give the shop owner to order the box?

Figure 1: The problem of the second lesson

'Packing glasses' (see Figure 1) was the problem for the second lesson. It was adapted from a problem created by the Millennium Mathematics Project at the University of Cambridge (for the original wording see http://nrich.maths.org/880). The problem was thought of as useful for dealing with early geometrical modelling and optimization of area and perimeter. Several approaches and resolutions are possible, as well as follow-up questions depending on the evolution of the students' talk. The teacher was asked to first introduce the problem and the material, and then to handle the final class discussion with attention given to the mathematical talk of the students. There were two main objects: glasses and boxes. All small groups were given 12 plastic glasses. In the facilitation of whole class discussion, the teacher had three scaled boxes that represented the three possible solutions (with glasses being aligned in one row of twelve, two rows of six, and three rows of four) and the box that represented the case for one glass (one row of one). It was assumed that the manipulation of glasses and boxes would help better understand the problem and the required optimization processes to solve it.

METHODS OF A TWO-SIDED ANALYSIS

Lessons were video-taped and whole class discussions were transcribed. Each transcript was organized into shorter transcripts around moments of class discussion with students exploring an approach to the resolution of the problem. The difficulty of determining the exact turn on which the discussion of an approach started and finished, was addressed by including the turns that were dubious for some reason. On the other hand, participants commented on the same approach at different stages of the discussion; this is why the transcript of a moment did not necessarily consist of consecutive turns. In fact, the moment for illustration in this report is an example of non consecutive turns having been grouped together on the basis of the resolution strategy being under discussion. Its transcript stands for the explicit talk around the required quantity of material for any of the solution boxes.

The construction of transcripts was followed by the search for learning opportunities arising from the interaction among participants in classroom talk. Drawing on the notion of learning opportunity, special attention was paid to reactions of students that serve for clarification, exemplification, generation of new questions…, and which might be explained as provoked by prior interventions of other participants in that lesson. In case of differing interpretations within the team, we went back to the videos until we agreed on a decision. Actions and reactions were initially associated with opportunities to participate and interact in classroom talk, and only when mathematical content was at focus, they were regarded as mathematics learning opportunities. It was during the observations and analyses conducted in other school settings (Ferrer, Morera, & Fortuny, 2014), that the relationship between opportunities to interact in classroom talk and opportunities of mathematics learning was decided as an effective way to approach the detection of mathematics learning opportunities.

Actions of collective argumentation and types of orchestration

After having linked the transcript of a moment to a mathematics learning opportunity by reflecting on the mathematical contents in use, we split the analysis into two parts according to the characterisation of actions of collective argumentation, on the one hand, and types of orchestration, on the other. The selection of this two-sided analysis responds to the idea that the kinds of talk in the mathematics classroom can be interpreted in terms of the quality of the collective argumentation (Krummheuer, 2007) and the variety in the orchestration (Ferrer et al., 2014). Elsewhere (Planas & Morera, 2011) we have commented on collective argumentation among students in the construction of mathematics knowledge in two secondary classrooms.

The distinction of actions of argumentation was carried out at the micro-level 'within-the-moment'. All turns of talk were studied in order to decide whether mathematical reasons for particular statements were being provided. Further, we observed how the different contributions were taken up, either individually or collectively in public classroom talk. There may be a wide range of mathematical reasons depending on the complexity of the inquiry activity (Goos, 2004): from the mere description of an answer, a property or a fact, to the thoughtful proof of a conjecture. Mathematically wrong reasons in the context of the considered statement were not excluded as they helped to understand the coherence in the progression of mathematical talk. We drew on the idea that mathematics learning occurs in the coordinates of the combined potential movements between mathematically wrong and correct actions of collective argumentation in classroom interaction.

The distinction of types of orchestration was also carried out at the micro-level 'within-the-moment'. We used the following six types: exploring the artefact, explaining through the artefact, connecting artefacts, discussing the artefact, discovering through the artefact and experimenting the instrument; and we added the type 'replacing the artefact' to refer to situations in which participants pointed to different artefacts (blackboard, boxes, applets, glasses...), but did not establish connections among them. The importance given to the use of artefacts in the broader project (for findings about mathematics learning in whole-class discussion with dynamic geometry software, see Ferrer et al., 2014) comes from our interpretation of who the relevant others in the interaction are. Classroom talk is developed in interaction with subjects and objects, and consequently the others are not always individuals, students or teachers, but may be represented by sorts of artefacts.

The two-sided analysis applied to moments in which learning opportunities had been identified became a powerful tool for the detection of mathematics learning. It allowed us to conclude that certain opportunities had been exploited into mathematics learning. To this respect, convincing evidence was found, either in classroom talk or in students' written responses, of changes in the understanding of mathematical contents that had been involved in actions of argumentation in interaction with the orchestration of specific artefacts. Exhaustiveness in the identification of learning opportunities and learning was not attempted through the application of our two-sided analysis, and in fact it was in some cases deliberately avoided, since the extent to which mathematical talk had evolved in some turns was difficult to interpret.

EXAMPLE OF LEARNING OPPORTUNITY

We have selected an example of mathematics learning opportunity where it can be acknowledged the role of a student, Aloma, in the introduction in classroom talk of ideas that lead to cohesive reasoning and progress in the resolution of the problem (see Figure 1). It is an example in which a diversity of actions of argumentation and types of orchestration are involved with respect to three main artefacts: blackboard, glasses and cardboard. We draw on the analysis of this example as evidence in support of the potential of the teaching activity in interaction with classroom talk, collective argumentation, and problem solving with manipulatives. We begin by reproducing most of the transcript of the moment related to the opportunity (Roman numerals are included for organization of cross-referenced contents in Table 1):

1 Teacher: Come on, Aloma.

2 Aloma: A way for knowing it would be, for instance, to take into account that each glass, it touches up and down...

3 Teacher: That is, if we put each glass in an individual box [working on the blackboard], it would touch all four [pointing to the drawn lateral] walls; but in this one [indicating the drawn one row of twelve], the second glass would touch here and here [pointing to two drawn lateral walls] and those in the corner would touch three [pointing to three drawn lateral] walls.

4 Aloma: [I] This way we use plenty of cardboard, [II] but with the box of three per four we need less cardboard for the glasses in the corners.

5 Teacher: [I] This glass, for instance, it only touches one wall, while this one does not touch any [pointing to the box with three rows of four]. [II] Here we have built a model for the individual box with the real measures as said by Aloma. (...) Aloma's reasoning is great! [III] She is trying to reduce all these walls as much as possible. Thus, if I want to build a box for the twelve glasses and place the individual small boxes within the three per four, then when two walls get in contact, we can eliminate them because we only want those that are external [in the video Figure 2]. [IV] That is, the glasses in the four corners contribute with two pieces, the others with only one piece, and those in the middle with none. (...)

6 Teacher: What Aloma explained, is it clear? What she said about saving walls, eh? Here [showing the box with three rows of four] we need a total of fourteen walls. But with this [showing the box with two rows of six] we need sixteen walls, and finally, this [showing the box with one row of twelve] needs a total of twenty-six walls. Yes, everyone? Clàudia?

7 Clàudia: The less glasses touching the walls, the best.

8 Teacher: The less glasses touching the walls, the less quantity of cardboard.

Figure 2: Teacher explaining through cardboard

The eight turns that constitute the moment in this transcript were analysed according to the detection of actions of argumentation and types of orchestration. Table 1 situates the turns in relation to actions and types, and summarises some of the curricular mathematical contents involved in the explicit talk. The joint analysis of the transcript and Table 1, along with the video of the lesson indicates the creation of at least a learning opportunity around the optimization of the geometric variable corresponding to the surface of a rectangular volume. Aloma is the student who acts on the glasses and the cardboard to justify the need for establishing the individual box for only one glass as the surface and volume unit of measurement (i.e., the small box is presented as a box of capacity one glass), and simultaneously as the unit of counting on the basis of how many individual boxes can be placed in the considered solutions and how they can be placed. Through talk, manipulation and interaction with the teacher, Aloma grounds her reasoning on the quantity of cardboard for the different considered boxes by comparison with the unit box.

The talk initiated by Clàudia provides evidence of exploitation of the identified opportunity into learning. The teacher also provides further evidence of exploitation of the reasoning introduced by Aloma and expanded by Clàudia. This happens, however, later in whole class discussion, when the teacher modifies

Table 1: Actions, types and contents in a moment of the second lesson

the condition of a rectangular base for the box. It is a modification that leads to different options for the solution boxes, but still keeps valid the conjecture, "The less glasses touching the walls, the best." From there the mathematical discussion moves toward the problem of isoperimetric space figures and the visualization of cylinders.

By examining how mathematics learning opportunities can be promoted through whole class discussion with problem solving and manipulatives, we have detected opportunities for our conceptual understanding of mathematics learning and the classroom environments in which it may occur. Our research shows that certain actions of argumentation in interaction with certain types of orchestration are positively related to the creation and exploitation of learning opportunities around mathematical contents that are not strictly procedural (see Table 1). We are striving to understand, however, features of the teacher's teaching activity that are decisive in the process that goes from classroom talk to learning opportunities, and from there to mathematics learning. Although important, we have not started looking at whether differences in teaching activity explain differences in learning moves.

FINAL CONSIDERATIONS

We have examined the relationships between actions of argumentation and types of orchestration in the generation of mathematics learning opportunities. We still know little about why and how mathematics learning occurs. Nevertheless, our study provides some light on lessons with problem solving and manipulatives in which learning relates to the development of collective argumentation in interaction with the orchestration of particular materials. The progressive sophistication of argumentation is probably fostered by the role and use of materials, but in the empirical context of our study it is too early to conclude on this. What we already know is that these issues, actions of argumentation and types of orchestration are clearly important for the understanding of the dynamics of learning. First, the notion of collective argumentation has been used to illustrate the importance of interaction among participants –subjects. Second, the notion of orchestration has been used to illustrate the importance of interaction with materials –objects. Other two-sided analyses would be possible under the same idea of keeping balanced the interaction with subjects and that with objects in the mathematics classroom.

Researchers interested in the role and use of artefacts may focus their questions on processes and tools through which students elaborate their thinking strategies in interaction with dynamic geometry software, physical manipulatives, virtual manipulatives, etc. Other researchers concerned with the role and use of talk may focus their questions on outcomes of pair work, small group, whole class discussion, etc. Similarly to Fetzer and Tiedemann (2015), our conceptualization of learning as learning-by-talking-and-doing seeks for integrated approaches. We are aware of the risks of misrepresenting any approach, and more generally, of the few empirical studies in the field taking a balanced subject-and-object perspective. By means of the example in this report, we have attempted to explain that the integration of subjects and objects, instead of its distinction, is at the root of our social view of mathematics learning. Manipulation of objects (either Platonic mathematical objects or concrete manipulatives) and talk with subjects (either one self or others in the class) are expressions of the same basic realization called mathematics learning.

Number words in ‘other’ languages: The case of little Marram

Anna Chronaki[1], Georgia Mountzouri[1], Maria Zaharaki[1] and Núria Planas[2]

1 University of Thessaly, Department of Early Childhood Education, Karditsa, Greece, chronaki@uth.gr

2 Autonomous University of Barcelona, Barcelona, Spain

The present paper, based on a small scale critical ethnographic study, explores the process of experimenting collaboratively with multiple language use for number words as part of young children's mathematical learning activity. Data from a teaching experiment called 'Number words in 'other' languages' is utilized to illustrate the creation of a culturally responsive context with children aged 4 to 6, their parents, the classroom teacher and the researchers. The focus is on the case of little Marram, a Pakistani girl who lives in Greece and who experiences participation by sharing number knowledge in her dominant home language, Urdu. It is highlighted how discourses on gender and language determine Marram's learner identity-work in the multilingual preschool classroom.

Keywords: Early mathematics, language use, gender, discourses, classroom practice, identity-work.

INTRODUCTION

In a number of previous studies we have denoted the benefits of diverse language use in the mathematics classroom as a matter of resourcing learning (Planas, 2014), creating dialogicality (Chronaki, 2009) and, also, troubling essentialist identities embedded in school mathematics discursive practices (Chronaki, 2011). We now focus on an experimental collaborative project, *Number in 'other' languages*, where the design of learning for number and number word is orchestrated around the utilization of the participants' languages in a Greek classroom. Multiple language use can be interpreted as a resource for engaging children from ethnic minority groups, and as a space for reconfiguring subject positions in processes of learner identity-work. Taking into account that ethnic minority learners experience marginalized subject positions in school, the shifting relations encouraged via opening the learning of numbers in multiple languages may create conditions for breaking the certainty of hegemonic discourses and provide space for accessing dialogicality. As a Bakhtinian concept, dialogicality weaves a way to critique language formation in literary texts. Bakhtin in a series of texts (1929/1981) negates language as an abstract system and emphasizes its intersubjective consciousness. By perceiving language use as social in nature he conceives language, communication and identity as interactive multi-voiced phenomena rooted is specific localities. As such, the idea of teaching number words in multiple languages becomes a gesture of how mathematical knowledge can be approached as culturally and politically situated. In this way, mathematics becomes a space for providing access to children's own trajectories as part of their own identity-work and subjectivity configuration (Chronaki, 2009, 2011).

During the development of the present collaborative project, the first two authors observed, depicted and interpreted the complexity of the teaching activity as experienced by children coming from socially marginalized groups. The experiment was designed to serve goals of counter education (Gur-Ze'ev, 2005), in ways that challenge stereotypes and affective positions toward dialogical participation. For the case of little Marram, a Pakistani girl aged 5 years, we analyze how the chance she is given to express out in her mother-tongue the number words, offers a chance to explore her position in the class. It helps us understand complexity throughout actions in the classroom, the family and the school community. Our analysis searches for opportunities to access mathematical knowledge, identity-work and subjectivity that place learners into positions of participation in the classroom. Some opportunities, from Marram's position as a Pakistani girl in a mathematics lesson, are examined.

Educators and researchers who are, like us, interested in focusing on the complexity of the social, cultural and political contexts of mathematics classrooms face the challenge to develop tools and interventions in order to analyze, discuss and re-configure issues connected to relationships amongst authority, knowledge, identity-work and subjectivity. In our research contexts, we draw on critical approaches for mathematics teaching and learning in multilingual classrooms where children are taught the norm of school knowledge while they co-configure mathematical subjectivities as part of broader social requirements for identity-work as learners of mathematics (Chronaki, 2009, 2011; Planas, 2011). Below, the methodology of the study is outlined and the data analysis is organized around three sections.

METHODOLOGY: CRITICAL, COLLABORATIVE AND EXPERIMENTAL ETHNOGRAPHY

The reported work is situated in the qualitative tradition of educational research, and more specifically in the context of critical, collaborative and experimental ethnography. This study is critical in the sense that it intends to critique what is taken as 'reality' in the mathematics classroom, to disrupt taken for granted 'truths' about who is the competent learner and what is valuable mathematics, to trouble discourses that tend to support the construction of hegemonic interpretations and, also, to imagine how things could have differently happened (Thomas, 1993; Skovsmose, 2014). It is a collaborative study in that it emerges from the need of dialogue amongst participants. The project was held in close collaboration with children and their parents who contributed with information concerning their own ways of using language for number words and counting (Lassiter, 2005). It was, also, organized as a teaching experiment in collaboration with the classroom teacher as it aimed to expand the formal mathematics curriculum on counting and to provide links with children's funds of knowledge. Children coming from different ethnic minorities could perform early number activity (e.g. counting, related number word and number symbol in both oral and written genres) in their mother tongue and share number knowledge amongst them. Multiple perspectives of an issue were discussed, debates were constructed and all these helped data interpretation and inference of conclusions.

The methodology is experimental in the sense that the research process was organized as a series of interactive events in a teaching experiment on number that took place for two weeks during the school year 2011–2012 in a class of a public nursery school in Athens. The experiment encountered the urge to teach number in relation to opportunities for intercultural education as has been required by reforms of the Greek curriculum (Department of Education, 2011). The successive arrangement of the teaching experiment covers the sections on which the Greek curriculum focuses on number and aims to investigate its conduction in a multilingual classroom in order to achieve intercultural contact, mathematical participation and the subversion of stereotypes concerning curricular contents and who is capable of expressing opinions about mathematics and of arrogating mathematics as a cultural or symbolic commodity. Specific material was devised as seen in Table 3, but also Tables 1 and 2. During the implementation phase, the teacher was allowed to modify parts of the interventions, while one of the researchers in the team was integrated as an active participant and internal observer in the classroom.

Participants were the twenty children of the class, seven of whom had not Greek nationality at the time of the study, their parents and the classroom teacher. The home languages of these children were Albanian, Russian, Armenian, Filipino, Turkish and Urdu. Many of them had been born in Greece and their parents are either economic immigrants or political refugees. Marram came from Pakistan and her first language is Urdu although her mother uses English as a means of communication as well. In what follows, we will focus on an event when little Marram is encouraged to speak out loud the number words in Urdu. This event points to a number of difficulties, dilemmas, challenges and achievements of Marram, in a situation of struggle amongst local and globalized discourses about school mathematics, girls, and ordinary languages. Pereen (2007) based on Brandist (2002, p. 179) explains that for Bakhtin 'personal identity' transforms into 'an intersubjective dynamic' that is continually renewing itself. Subjectivity, instead of personal identity, is captured in terms of 'being-as-event' in Bakhtin's words and as such it needs to be conceived as situated in the ongoing eventness of everyday practices in the school classroom.

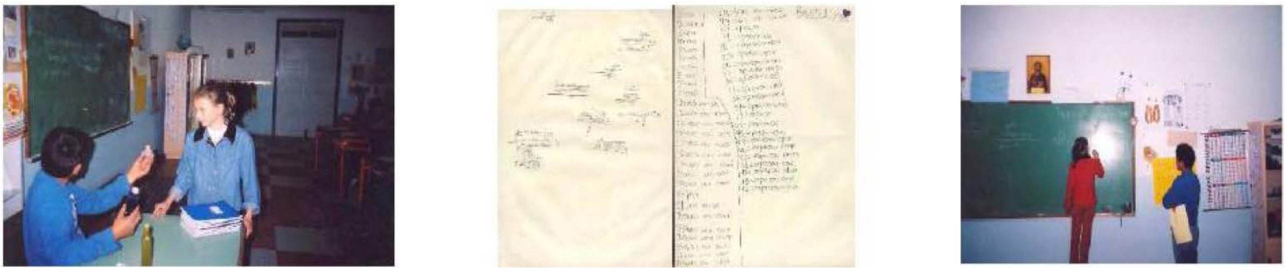

Table 1: Romany and Greek number words (Chronaki, 2009, 2011)

Table 2: A playful outdoor activity on number (Chronaki & Mountzouri, 2009)

DIVERSITY OF NUMBER WORDS: GETTING TO KNOW THE 'OTHER'

The project *Number words in 'other' languages* is part of our attempts during the last years to approach mother-tongue use in classroom mathematical activity as interlinked with learning, identity-work and dialogicality. In Chronaki (2009, 2011), and Chronaki and Mountzouri (2009) we have discussed this perspective first as part of project work in a primary classroom with Roma and non-Roma students (Table 1) and then as playful outdoor activity based on the explorative use of the languages of Greek, Romany and Arabic (Table 2).

The experiment presented here expands into seven languages so that to include all children in the lesson whilst focusing on number counting through number words. A board with number words in all languages was prepared (Table 3).

Children were asked to read words on the board in collaboration with the teacher in whatever manner was feasible for them providing their competence. Although children were familiar with reading, reading and interpreting numbers was a collaborative process with all children involved with teacher's help. Children recognized number digits from 0 to 10 in the vertical axis and country names in the horizontal axis. It was aimed to have all children watching the number words in each of the spoken languages and making comparisons based on both oral sounds and visual stimuli. In parallel, children had the chance to spot specific countries on a given world map. Later, children were asked to refer to the board (Table 3) and speak out the numbers in their mother-tongue. After some discussion they arrived at questions and conclusions like: Which number words are common in languages other than Greek? (0 was linked to all three languages) Which ones have a similar sound? (tre-tree-treea and u-do) Which ones do we use today in Greek? (dort, dortia as used in the dice).

Table 3: Reference material for 'number words in 'other' languages'

NUMBERS IN MY LANGUAGE?! INTEREST AND EMBARRASSMENT

Most children experienced both interest and embarrassment when they were asked to rehearse counting in their mother tongue. Children from ethnic minorities had experienced 'mother tongue' as forbidden in the monolingual school context where Greek is the only language of instruction. In the case of little Marram, although shyness predominates, the co-presence of interest and embarrassment was evident, as can be seen in the event below, and provided the opportunity to discuss parts of how her mathematical subjectivity evolves (Episodes 1 and 2).

Episode 1. First steps into oral counting in Urdu

Researcher: Which child in our classroom is from Pakistan?

Christina: (raises her hand smiling) Marram!

Researcher: Marram, come here! Marram, I would like you to tell us numbers in Pakistani (*invites her to stand in the centre of the circle; she uses the word Pakistani because children know that Marram comes from Pakistan*). I am asking her in English because possibly she cannot understand in Greek. (*to Marram*) I want you to tell us the numbers in Urdu (*Marram smiles, touches her cheeks with her hands, twirls a lock of her hair but does not answer*). Let's do this, sifr, ek... sifr, ek... I'm gonna help you, sifr, ek, do, let's go!

Episode 2. Marram's oral counting in Urdu

Researcher: She has told us before. Do you remember it? Come on! Come on, Marram! Sifr...

Marram: Sifr, ek, do, tin, char, panch, che, saat, at, no, das... (*counting fast; when she finishes she covers her eyes with her hands [Figure 1]*)

Researcher: Well done! But I want you to do it slower. Slowly, okay? Let's do this! You will do this as so: sifr, ek, do...

Arian: Sifr. (*Arian from Albania reminds her the word for zero*)

Researcher: Let's do this! Sifr...

Marram: Sifr, ek, do, tin, char, panch, che, saat, at, no, das. (*slowly*)

Researcher: Well done! Please, applaud her! Well done Marram, thank you!

Attempting to interpret Marram's position in the above two episodes, we denoted at least two significant issues that determine how her subjectivity becomes reconfigured as part of this specific activity and mediate her efforts towards performing counting; shyness and the use of English language. Both of these issues are discussed below.

Being shy: A gendered position for Marram?

Marram showed shyness and intense embarrassment when asked to express loudly the numbers in Urdu -her mother tongue. Embarrassment or shyness are, often, embodied through a variety of facial expressions and awkward body (especially hand) movement. They are also linked to reluctance of taking an initiative attributing thus a weak, passive or idle subjectivity. However, in the words of Marram's mother, shyness needs to be also considered as a 'female' feature of virtue in Pakistan and its expression is something not only normal but highly desirable for young girls. During an interview with Marram's mother and whilst discussing the significance of the above episodes, she explains:

> "Women in Pakistan, we are shy, it's our nature, in our culture. Even here, most people do not know the meaning of shyness... Many children in countries like ours feel shy and do not often participate in every single activity of the classroom. I want my children to make it not only in

Figure 1: Facial expressions by Marram whilst counting

> mathematics but also in all fields.” (Interview with Marram’s mother)

Shyness from the mother’s perspective is a female attribute in Pakistan denoting that young girls grow into women and they become sensible of their femininity. It is performed by women, especially young or non-married. In Pakistan shyness is considered an ethically proper behavior and is linked to virtues like rationality and modesty. Marram’s mother, however, was worried during this part of the interview and asked the interviewer if her daughter was behaving too shy in the classroom. Her concern was based on her fear that Marram’s shyness might not be suitable or compatible with modern cultural norms such as competition, assertion and reclaim. She showed awareness on how Marram’s reluctance could create difficulties for negotiating her position and presence in the public place and believed that her daughter needed to grow confident, assertive and participatory. In Civil, Planas and Quintos (2012) the relevance of considering the family contexts of the learners to better understand some of the classroom events and its participants has been argued. For the case of Marram, the conversations with her mother became crucial for making sense of the girl as participant in the nursery classroom and, specifically, on how she experiences learner subjectivity as she is being caught among various cultures and maybe in the margins of all of them. Civil et al. write about identity issues that immigrant children confront in feeling caught amongst the parents’ culture and the culture in their new country. From this perspective the theme of shyness needs to be interpreted in the case of Marram as a matter of both culture and gender.

English language mediation: What is the status of ‘mother’ tongue?

One can argue how Marram is growing up bilingual as she speaks Urdu at home and understands Greek at school. Talking with her mother, we realized that she needs to be considered as trilingual since she also uses English, mainly with her mother. According to Skourtou (2001), bilingualism refers to the “alternative use of two or more languages from a single person” (p. 199) - a definition that can be expanded to trilingualism. The use of English by the researcher in the class was made to accommodate Marram’s needs and competences. It was a subtle wish by Marram, expressed during initial interviews where she asked the researcher to speak in English. Marram often switched codes not from Urdu to Greek but from Greek to English and vice-versa. By code switching we mean “the practice of using two or more languages in the same communicative act” (Tsokalidou, 2000, cited in Skourtou, 2001, p. 184). When Marram could not describe something she wanted in Greek, she spontaneously used English in the interviews, but she did not do so in the class where her peers and teacher were present. She might think English was not proper in the lesson with other children who could not understand English.

With respect to this second theme, the family context also plays an important role. For Marram, the use of English is symbolically reinforced by the fact that her mother used to work as an English teacher and was head of an English-learning centre in Pakistan (country in which English is still considered an official language for instruction based on the national curriculum); when she came to Greece, however, she began to work at a wax factory. Her mother values English as ‘international’ language, acknowledging its colonialist influence in Pakistani educational system and its globalized hegemony. She wants Marram to reach better access to English language in order to upgrade socially through her studies and future profession. An important point for the mother is the issue of English language learning in the school context. She stated that the fact that the other teachers of her daughter could not speak English caused her difficulties in the communication with them and was a main reason why she did not often visit them at school. Also, in her words it was an ‘insane’ educational choice, as she argued in one of the interviews:

> “English should be spoken at school apart from Greek. But here, at schools there is not an English system. This is bad due to the fact that English is an international language.” (Interview with Marram’s mother)

In the described event, the use of English by the researcher played a significant role in the process of code switching between Greek and Urdu and empowered Marram to participate more fully in the public space of the classroom. More generally and during several classroom events, it was seen that the use of a third language (here, English), which Marram had learnt (and valued highly) from her mother, played an intensively mediating role in this learner’s mathematical participation. Despite Marram knew the number words in her dominant language, for instance, she needed encouragement in a third language which she could easily use, and with which she feels familiar to express them out loud. Thus, English appears to act as a tool facilitating her public presence in the class. It was not only constant encouragement but particularly the language selected by the researcher at different times that acted positively in her occasional overcoming of shyness to mathematically participate by counting numbers in Urdu.

CONCLUDING REMARKS

In this report, the case of little Marram rehearsing numbers in her mother-tongue has served as an event that exemplifies how mathematics teaching and learning in the school classroom is mediated by participation issues that are not directly concerned with curricular content or with didactic methods. According to our research data (teaching experiment observation and interviews) as well as our interpretation of Marram's case as a whole, it seems necessary to draw on a broader perspective of mathematical subjectivity as related to the complexity of children's participatory experiences, identity-work and learning that is, simultaneously, personally, culturally and socially shaped.

Our study has identified the important role of using multiple languages (Greek, Urdu and English) related to a child's worlds in forming the background of the mathematical experience of a single learner (Marram) through exploring her classroom interaction with an adult who acted as a teacher and who was particularly concerned with the fact of language issues intervening in mathematics teaching and learning. Taking into account that the mediation of English is fundamental in the Pakistani school system, as reported by an informed adult and, in this case, a relative of the child (Marram's mother) secures and increases awareness. The adult's attention to this very fact comes to facilitate the orchestration of English as a tool for the expression of ideas but also for the realization of strategic movements of code switching between languages other than English (Greek and Urdu).

The project *Numbers in 'other' languages* discussed here has forwarded the launching of mathematical ideas of others to all children in a classroom. Such an activity facilitates and bridges the connection of informal knowledge that children acquire through their family environment or home languages and formal knowledge that is being taught in the school context. In this way, all children's self-confidence is boosted as they are bestowed with the chance to perform their learning abilities, skills or competences as part of their own sociocultural experiences. The above are consistent with a broader perspective of mathematics as a cultural, social and political asset that teachers are willing to accept through various interpretations and ways of expression from children.

A similar project can be potentially implemented using not only language but also artifacts, objects or materials related to mathematics and emanated from 'other' cultures and social practices. Presmeg (1999) mentions that the use of objects originated from the specific cultural positions they come from, facilitates the connection amongst mathematics in school and society. Although the perils of exoticization, mysticism and idolization of mathematical knowledge still lurk, and dilemmas, challenges regarding learning process are many, their inclusion in pedagogical design continues to be necessary and important to explore further. The present team of researchers shares a mutual understanding of these emerging themes being fundamental for interpreting Marram's experience and accounting the complexity and multiplicity of mathematical subjectivity in modern times. The first theme –being shy– deals with the emotional and affective dimension of the learner and reveals how far she has progressed throughout the discursive practices of school mathematics in order to speak out the numerical sequence in Urdu. The second theme –mediation of English in code switching– deals with the communicative dimension of the participants in the lessons and reveals the role and use of language diversity and language hierarchies in mathematics teaching and learning.

Vague language and politeness in whole-class mathematical conversation

Thérèse Dooley

St. Patrick's College, Dublin, Ireland
Dublin City University, Dublin, Ireland, therese.dooley@dcu.ie

Politeness theory is based on the notion that individuals in a conversation are endowed with face – positive face is concerned with a desire for social approval and negative face is concerned with a desire to be unimpeded. The theory is relevant in the context of whole-class discussion of mathematics where a teacher has to facilitate development of students' disciplinary understanding and, at the same time, reduce their threats to face as they make contributions in public. In this paper, it will be shown that a teacher's use of vague language can play a role in protecting threats to student face and thereby facilitate participation in argumentation and reasoning. It will also be shown that the competing claims on a teacher's attention in this context render his/her role highly complex.

Keywords: Politeness, face, vague language, whole-class discussion, primary mathematics.

INTRODUCTION

At a time when there is an emphasis in mathematics teaching and learning on the co-construction of meaning by teacher and students, it can be challenging for a teacher to take a supportive role in the classroom and, at the same time, steer students towards increasingly sophisticated understandings of mathematics. This challenge is exacerbated in the context of whole-class discussion where the teacher has to take account of the vulnerability that students might feel when they make a contribution in the public forum of a classroom. The strategies that he/she often employs to meet both of these demands are generally indirect, e.g., the use of questions, or revoicing (Brodie, 2010). The use of such indirect strategies relates to politeness theory – a theory that was constructed by Brown and Levinson (1987) to describe pervasive features of social interaction. Politeness theory has been used as an analytical framework in a range of contexts, including the teaching and learning of mathematics (Bills, 2000; Rowland, 2000; Weingrad, 1998). Rowland (2000) has focused on the role that vague language plays in supporting politeness in mathematical conversations between teachers and individual (or small groups of) students. In this paper, the role of vague language is extended to politeness in whole-class mathematical discussion. It will be shown that a teacher can use it as a means of developing a learning environment where children take intellectual risks and develop a view of mathematics as a subject that is a human activity and a social phenomenon (Hersh, 1997).

POLITENESS THEORY

One of the ideas upon which politeness theory is built is that each participant in a conversation is endowed with *face* (Brown & Levinson, 1987). Face, a term used metaphorically to represent respect, esteem and sense of self, takes two forms: positive face, a desire to be appreciated and valued by others, a desire for approval; and negative face, a concern for freedom of action, a desire to be unimpeded.

However, certain acts threaten face. Such face-threatening acts (FTAs) can be directed towards positive or negative face. For example, criticism and disagreement threaten positive face whereas orders and requests threaten negative face. Moreover, the seriousness of FTAs is influenced by factors such as the power relation or social distance[1] between speaker and hearer.

Threat to face can be mitigated by use of redressive actions which include positive politeness (oriented to positive face), negative politeness (oriented to negative face) and use of hints and metaphors. It is in the mutual interest of persons involved in a conversation to maintain each other's face, as part of a strategy for maintaining their own face. Brown and Levinson present a range of strategies that are available to a speaker in order to protect, or not, the face of a hearer. For example, if an individual solves a mathematical problem incorrectly, a colleague might deal with it in one of the following ways (see Rowland, 2000, p. 86):

1) Don't do the FTA – simply agree or keep quiet.
2) Do the FTA by
    a) going 'off record', that is implicating the FTA rather than doing it directly (e.g., 'I wonder if we have done a problem like this before...')
    b) going 'on record' either
        i) baldly – making no attempt to respect face ('That is not correct')
        ii) positive politeness ('You have come up with a really interesting way of solving that problem but I thought that ...')
        iii) negative politeness ('Would you mind showing me how you applied this formula here...')

While there is a variety of ways in which teachers endeavour to protect the face of students in small-group conversation (Bills, 2000) or in whole-class discussion (Weingrad, 1998), of particular interest to this paper is the way in which vague language used in mathematical (and other) contexts – in particular, (a) the pronoun *we* and (b) linguistic hedges – can be exploited by a teacher to serve this purpose.

VAGUE LANGUAGE

Rowland (2000), amongst others, maintains that coming to know mathematics is imbued with uncertainty and that the use of vague language – for example, hedges and pronouns - points to these uncertainties.

Hedges

Linguistic vagueness is encoded by *hedges* which are words "whose meaning implicitly involves fuzziness - ... whose job is to make things fuzzier or less fuzzy" (Rowland, 2000, p. 471). Rowland (2000) developed a taxonomy of hedges with reference to the discourse of mathematical conjecture. The first major type of hedge, *a shield* indicates some uncertainty in the mind of the speaker in relation to a proposition. There are two types of shield: (a) a *plausibility shield* and (b) an *attribution shield*. A plausibility shield (e.g., "I think", "probably", "maybe") can suggest some doubt on the part of the contributor that the statement will withstand scrutiny. For example, in the statement, "I think that the sum is twenty", the speaker injects a level of vagueness into his mathematical assertion and thus implicitly invites feedback on his solution. The attribution shield implicates some degree or quality of knowledge to a third party (e.g., "Ann got an answer of twenty"). The second major category of hedges are termed *approximators*. The effect of the approximator is to modify the proposition rather than to invite comment on it. One subcategory of the approximator is the *rounder* which comprises adverbs of estimation such as "about", "around" and "approximately" (e.g., "The answer is around twenty.") The second type of approximator is the *adaptor* – it indicates vagueness concerning class membership such as "somewhat", "sort of", "pretty much", e.g., "I am pretty sure that twenty is an even number."

In the interviews conducted with individual (and small groups of) students, Rowland (2000) found that teachers used shields and adaptors in recognition of the face wants of students, whereas students used rounders and plausibility shields to serve their own face wants. He found that, in general, young students seemed to be less sensitive to the face wants of a teacher than to their own. This could be explained by a perceived power difference between a young student and his/her teacher. In the context of whole-class conversation where argumentation is encouraged, a teacher might have competing demands on his/her attention in terms of addressing face wants of different students. Moreover, students might well decide to protect or not the face of their peers. In the excerpt that follows, consideration is given to how vague language is used by a teacher to deal with such complexities.

The pronoun "we"

Bills (2000) says that one of the strategies for positive politeness used by teachers is the use of "we" or "us" to infer inclusion, e.g., "Let's try starting with this one". Rowland (2000) expands on the uses of pronouns (particularly, "it", "you" and "we") in mathematical learning contexts. He suggests that while the pronoun "we" can often be used to indicate a teacher's solidarity with a student (or group of students), the term can also be used to convey distance – "to associate the speaker with a select and powerful group ... to urge acquisition of the 'proper way' of doing [mathematics]" (p. 98). In a classroom situation it can also serve to assuage a command, thereby mitigating threat to negative face (e.g., "We add the units and then the tens...").

METHODOLOGY

In order to investigate the construction of new mathematical ideas by pupils in the context of whole-class discussion, I conducted a classroom design experiment in three different primary schools in Ireland (that is, a series of lessons in each school consecutively). This approach has its roots in the teaching experiment, the central elements of which include instructional design and planning, ongoing analysis of classroom events, and the retrospective analysis of all data generated (Cobb, 2000). Because of its focus on theory development, the teaching experiment has been subsumed into design-based research and, more recently, has been termed a "classroom design experiment" (Cobb, Gresalfi, & Hodge, 2009). I taught 32 lessons (some of which extended over more than one class period) in all to pupils aged 9 – 11 years. I, as researcher-teacher, taught the lessons but the class teacher assisted in planning, teaching and post-lesson analysis. The main data collected were audiotapes of whole-class and group interactions – video recordings were not used due to ethical constraints. Data collection and data analysis were interwoven. Retrospective analysis was conducted on micro- (between lessons) and macro- (between and after cycles of research in the three classrooms) levels. The analytical approach I adopted was microethnography (Erickson, 1992) in which I first considered whole events such as lessons and gradually filtered them to explore the construction activities of individuals, focusing particularly on the sequential emergence of talk and action. This construction sometimes happened within a short period – at other times, it occurred in a zig-zag fashion over the course of a lesson or indeed a few lessons. The use of vague language by children was a crucial element of construction activity in mathematics lessons (e.g., Dooley, 2011). In particular, such language allowed them to engage in the conjecturing activity that is central to the development of novel ideas. Furthermore the follow-up actions by me, the teacher, to their contributions was salient, e.g., revoicing or press moves allowed for pupils to build on each others' thinking (e.g., Dooley, 2009). Re-analysis of the data to explore my use of vague language revealed that I and, to a lesser extent, the pupils used vague language as a means of being polite. In this paper, I examine the issue of politeness in whole-class conversation – in particular, how my utilization of vague language within follow-up moves was another core dimension to children's mathematical constructions. I draw on data derived from lessons that I taught in the first and third schools. I chose these lessons because they exemplify how vague language on the part of the teacher can be used to support contributions by those traditionally excluded from mathematics while, at the same time, move the group towards mathematically correct ideas. Such vagueness encouraged peers to be the arbiter of correctness in the lessons concerned.

EXCERPTS FROM TWO LESSONS

The Grasshopper Lesson

This lesson was one of eleven lessons that I taught in the first school. The school was of middle socio-economic status. There were 30 pupils, 17 girls and 13 boys, aged 10 - 11 years in this class and Mr. Allen was the class teacher[2]. The problem reads as follows:

> A grasshopper is journeying across a mat that is 1 meter long. He starts at the top of the mat, jumps half-way across and takes a short rest. He then jumps half-way across the remaining bit and takes a short rest. He then jumps half-way across the next bit and so on. What are his landing points? Will he ever get to the end?[3]

I drew a line on the blackboard, the initial point of which was marked *0* and the end point was marked *1m*. I asked the group to name his first landing-point and then I drew an overarching loop from 0 to ½. I explained that the grasshopper would next jump half-way across the remaining section. I invited a pupil to mark the second landing-point and again asked the group to name this point (¾). The lesson continued thus. As expected, identification of the fourth landing-point (15/16) challenged some pupils because they had not yet been formally exposed to sixteenths. While some agreed with Jack (a pupil of "average" mathematical attainment on the basis of standardised test scores) that it was fifteen sixteenths, others aligned with an idea proposed by Kate (a pupil of "below average" mathematical attainment) that it was seven and a half eighths. The transcript that follows centres around this episode[4]:

104 TD: What do you think is going to happen next?

105 Chn: It's going to half it//half it//half...

106 Jack: It's half of seven eighths (whisper) [ ]
125 Jack: He's on fifteen sixteenths.
126 //Ch : Seven and a half eighths.
127 Chn: No.
128 TD: He's on fifteen sixteenths, seven and a half eighths or fifteen ...
//Ch talking ... So you think he's on fifteen sixteenths. Where are you getting fifteen sixteenths from?
129 Jack: Cos I think, I think em ... I think a half an eighth is sixteen ...
130 TD: Right.
131 Jack: and eh ...
132 //Ch: I know ...
133 Jack: when ...
134 //Chn: Seven and a half!
135 Jack: and then another sixteenth ... if she went another sixteenth (*other children talking in background*), she'd be there but she didn't go another sixteenth, so she went fifteen sixteenths.
136 Ch: Three quarters ...(*in background*)
137 TD: Fifteen sixteenths ... and who said seven and a half eighths, who said that?
138 Paula: Me.
139 TD: It was yourself, what is your name?
141 Chn: No, it was Kate//it was Kate.
142 TD: I thought it was this girl down here, was it? Yes, Kate ...well maybe both people said it ... that's fine, I thought it was Kate.
143 Kate: It was seven eighths and if he went eight eighths, he would be at the end, so if you go half of it, then it's seven and a half.
144 Mr. Allen: Good girl!
145 TD: Seven and a half eighths and do you think ... Dan? [ ]
159 TD: The jumps ... oh, I know what you mean. So what do we call ... will we call it seven and a half eighths or fifteen sixteenths?
160 Chn: Seven and a half //Fifteenth sixteenths//Seven and a half is easier to manage// No, it's not//Cos you are going two, four, eight//Seven and a half is easier.
161 TD: I think ... you could call it seven and a half eighths but we normally these things ... normally they are brought up to full numbers. But seven and a half eighths would be ok but ... normally it's brought up to something like fifteen sixteenths. (*I write both on blackboard.*)

When Jack proposes fifteen-sixteenths, I ask him to explain his thinking. Although he initially hedges by using a plausibility shield, "I think," in line 129 (l.129) – possibly due to his uncertainty about the fractional name for half an eighth, his reasoning in l.135 is cogently expressed, reflecting his conviction around the argument that he is making. It is interesting that I do not evaluate his contribution in l.137 which, at this juncture, might have had the effect of closing off other contributions (O'Connor & Michaels, 1996). I respond by maintaining his input ("fifteen sixteenths") and then following up on the "seven and a half eighths" contribution. The question that I pose in l.137 ("[W] ho said seven and a half eighths?") may well be due to the fact that I genuinely do not know who has made the input. However, my remark in l.142 ("I thought it was Kate") could be a redressive action in anticipation of an FTA - that is, by not asking Paula directly if she has said it, there is no need for her to admit that she has not done so. In this instance, Paula replies that it is she who volunteered the contribution and immediately other pupils in the class claim it to be Kate's idea. By redressing the threat to Kate's positive face, they make no effort to respect Paula's positive face. In l.142, I make some effort to redress what might be perceived as a combative situation (Kate versus Paula):

> 142 TD: *I thought* it was this girl down here, was it? Yes, Kate ... *well. maybe* both people said it ... that's fine, *I thought* it was Kate.

I indicate that I believe the contributor to be Kate rather than Paula but distance myself from the assertion by use of the plausibility shield, "I thought." In this way I am effecting a double save, that is, with regard to Paula's face (protecting her from possible embarrassment) and to Kate's (if she had not been the originator of the comment). While I give Kate credit for the idea, my "[W]ell, maybe both people said it" represents a further effort on my part to redress Paula's face. Rowland suggests that the particle, *Well,* delays a reply on the part of a speaker (thus inferring refusal or disagreement) – as such, it is one of the ways that threat to positive face can be lessened. In this instance, my use of the term suggests doubt on my part that both people did in fact make the contribution. My subsequent action (giving Kate the floor) suggests that my main motive here is to save Paula's positive face. My gamble – for that is what it is – seems to pay off as, like Jack, Kate justifies her argument ably, indicating that she has indeed constructed a way of naming this point.

In my question in l.159, "Will we call it seven and a half eighths or fifteen sixteenths?," I am probably hoping that the children will resolve the issue. My use of the pronoun "we" in this instance infers solidarity. Failure to agree will offend my positive and negative face wants (as I am the teacher and they are the pupils). On an individual level the children do as required but take different positions on the issue. While this may be due to mathematical preferences, it could also be that the children themselves are engaging in face-saving acts with respect to Kate or Jack (but, not in this instance, both). My discomfort in l.161 is palpable. I am aware that this is a critical event for Kate who does not often make contributions in mathematics classes. I first hesitate – "I think – you could..." referring to the mathematical correctness of her idea. However, I also seem to feel some duty to conventional correctness when I suggest that "we normally ... normally they are brought up to full numbers." In this instance the "we" refers to the general mathematical community – I am suggesting that, while seven and a half eighths is acceptable, the convention is to *round up* denominator and numerator. The "seven and a half eighths would be ok" is a positive redressive action (directed towards Kate). Interestingly, I use the adaptor "something like" with Jack's "fifteen sixteenths" (although I know this to be conventionally correct). In fact, most of my politeness is directed towards Kate rather than to Jack and this may be because I perceive Jack – at this juncture – to have less face want than Kate. My ultimate resolution is to write both suggestions on the blackboard. In the next part of the lesson, other pupils built on Kate's idea to justify their naming of further landing points on the line.

The Gauss Lesson

The Gauss lesson concerned the sum of numbers from 1 - 100 and was a lesson that I taught in the third school. In a previous CERME paper (Dooley, 2009) I reported how one pupil, Anne, used linearity inappropriately to determine the sum. She had suggested that the solution could be found by multiplying 30 (what she thought was the sum of 1- 10) by ten. After some disagreement by others in the class, she revaluated her method. She then made a new estimate and there follows an excerpt of the conversation that followed:

166 Anne: I think the answer would be a thousand.
167 TD: You think it's going to be a thousand. Do you agree with Anne that it's about a thousand? Brenda?
168 Brenda: Eh, no, cos when I em added up forty for it and, em, I got more than a thousand.
169 TD: Oh, wait till we see now, so Brenda is thinking of the problem we were doing yesterday. Brenda yesterday added one plus two plus three plus four plus five all the way up to forty. And what did you get when you added, do you remember when you added up to forty?
170 Brenda: Eh a thousand and something.
171 TD: I think, do you know something, I think it was ... I am not completely sure ... I think it might have been seven hundred and eighty, but I am not sure about that.
172 Brenda: I know it was a thousand.
173 TD: You think it was a thousand ... Anyway Brenda added up, yes Fiona?
174 Fiona: Well, yesterday, forty was seven hundred and eighty.

On the previous day, Brenda had used a calculator to sum numbers from 1 to 39 in order to find a solution for a different mathematical task. When Anne conjectured that the sum to 100 was a thousand (l.166 above), Brenda intimated that this could not be the case by making an implicit reference to the result of this sum. Her recall is inaccurate as she had found the solution to be 780. However, I am interested in drawing pupils' attention to her contribution, as it is a means of moving the lesson forward, that is, of making an accurate estimate for the sum, 1- 100. I use the pronoun "we" (l.169) to do so – "Oh, wait till *we* see now...". I broadcast her input ("Brenda is thinking of the problem we were doing yesterday") although I am inferring this since she has not mentioned the problem of the previous day explicitly. I also rebroadcast the contribution that she made in the previous lesson ("Brenda yesterday added one plus two plus three plus four plus five all the way up to forty..."). I made an error in this rebroadcast by suggesting that Brenda "added up to forty" when she in fact added up to 39. My evaluation of her estimate ("a thousand and something") is marked by vagueness:

171 TD: *I think* do you know something *I think* it was ... *I am not completely sure* ... *I think it might* have been seven hundred and eighty, but *I am not sure* about that.

My recourse to the plausibility shield is interesting – I am quite sure that the solution found by Brenda was 780 and want to indicate this to the rest of the pupils in a way that respects her positive face. I obviously do not wish to engage in the FTA baldly (by telling Brenda that she is incorrect) and thus distance myself from giving the correct solution ("I am not completely sure", "I think it might have been..."). In l.174, Fiona provided the correct solution. She prefaced her input with

"Well" to infer disagreement in a way that lessened the threat to both my and Brenda's positive face. This excerpt, though brief, marked a turning point in finding a solution to the problem concerned - most notably because Brenda drew attention to the lesson that had taken place the previous day where pupils found a formula for adding consecutive whole numbers.

CONCLUDING REMARKS

In a classroom where argumentation and negotiation of mathematical meaning are encouraged, a teacher has to take several factors into account in her moment-to-moment decisions. The excerpts above are interesting not because they are models of exemplary teaching but because they offer an insight into the complexity of teaching in an 'adventurous way' (Weingrad, 1998). Rowland (2000, p. 173) says that:

> Quasi-empirical teaching, inviting conjectures and the associated intellectual risks, is unimaginable if the teacher is not aware of the FTAs that are likely to be woven into her/his questions and 'invitations' to active participation. Redressive action dulls the sharp edge of the interactive demands that the style places on the learner.

In whole-class discussion, there is even more onus on the teacher to 'dull the sharp edges'. In the Grasshopper lesson, children tended to use vague language only to defend their own face. It is true that they did engage in FTAs and some redressive action and this is probably due to their sense of an equitable relationship with their peers. However, they generally engaged in FTAs baldly (e.g., making no attempt to respect Paula's face) in an effort to protect overtly the face of others (e.g., Kate's). There was more politeness in the exchange between Fiona and Brenda – probably because of the task involved. In both instances, my redressive actions were directed towards pupils who would not have been overly confident about their mathematical competence. I, as teacher, had to encourage their participation and, at the same time, focus on the development of mathematical thinking by the whole class, that is, I had to be attendant to the ethical dimensions of teaching mathematics (see Davis, 1997). The use of vague language – because it lessened threat to pupils' positive face and because it seemed to instigate mathematical argument by other pupils – was a means of doing this. The question of how it can best be exploited so that pupils do not develop incorrect mathematical ideas remains to be explored.

The grammar and conceptualisation of motion in Iwaidja

Cris Edmonds-Wathen

Charles Darwin University, Darwin, Australia
Umeå University, Umeå, Sweden, cris.edmonds-wathen@umu.se

Different languages have different ways of using spatial language, grammatically and conceptually. This paper reports on aspects of the language of motion in Iwaidja, an indigenous Australian language. The way that Iwaidja groups and separates spatial concepts such as direction, height and movement in relation to another object are briefly described using examples from a route description task. The implications are discussed in terms of how understanding these grammatical features can help teachers of Indigenous students, as well as providing keys to cross-linguistic investigations of mathematical cognition.

Keywords: Spatial language, motion, grammatical structures, Indigenous, cognition.

INTRODUCTION

The language we use for mathematics, the mathematical register, can have words and grammatical structures that are specific or specialised for their purposes in the register, but it is built on or out of everyday language. The linguistic structures of individual languages affect how the languages can be used and developed for mathematical thinking. Grammatical structures can constrain what is possible but they can also offer opportunities. Improving mathematical learning outcomes for Indigenous language speaking students in Australia requires a better understanding by non-Indigenous teachers of how their students think and talk mathematically. Describing the variety of mathematical expression can also assist other teachers who are teaching in multilingual classrooms, as well as enrich researchers' appreciation of the scope of variations in mathematical conceptualisation in different languages.

This paper considers the expression of motion in Iwaidja, an indigenous Australian language spoken in Northwest Arnhem Land, Northern Territory, and how this expression might affect mathematical thinking. Spatial language is an area of everyday language with mathematical impact. This impact is direct in relation to those parts of mathematics that are overtly spatial, such as the description of position and movement in the early years that progresses into the languages of mapping and of coordinate systems. Spatial language is also used in areas of mathematics that at first thought may not be appreciated as spatial, such as the manipulation of numbers. In particular this can involve the use of spatial metaphors (Edmonds-Wathen, 2012).

Iwaidja is an Australian language spoken predominantly at Minjilang, a community of approximately 300 people on Croker Island, Northwest Arnhem Land in Australia's Northern Territory. There are also speakers in other nearby communities. Investigating mathematical features of Iwaidja provides insights into mathematical ways of thinking and speaking that are shared by speakers of nearby and related languages such as Mawng and Kunwinjku, as well as contributing to broader knowledge and understanding about the breadth of how languages can express mathematical concepts.

RESPONSES TO DIVERSITY IN MATHEMATICAL LANGUAGE

Some grammatical features of mathematical language have been described; one is that mathematical language tends to nominalise processes (Halliday, 2004). Barton (2009) notes that the English language copes particularly well with the nominalisation processes of mathematics compared with some other languages. Some languages are less conducive to nominalisation than others because they begin with stronger roles for their verbs than other languages. Lunney Borden (2011) has described dynamic verb-based features of the Mi'kmaw language. She advocates the use of a verb based discourse pattern for teaching mathematics to Mi'kmaw children, for example focusing on the active properties of geometric objects, rather than identifying and naming their parts. It does not necessarily mean using the first language of the students, but of responding to some of the ways meaning is made in their languages. Lunney Borden talks about teaching Mi'kmaw children in English, but targeting her English in a manner that used more verbs to describe things and processes and fewer nouns.

In the Navajo language, shapes are also verbs: there is no circle, there is circling. Pinxten, van Dooren and Harvey (1983) describe the worldview of the Navajo as premised on the dynamic nature of the world. Inspired this description, and working with John Mason, Barton (2009) explored mathematical implications of treating shapes as verbs, as actions, calling it Action Geometry. For example, the static view of a circle is all the points that are equidistant from a centre point, forming a planar shape. In a dynamic view a circle is movement with a constant speed and with a constant rate or turn: "circling is actually a special case of spiralling" (p. 31). Barton stresses that Action Geometry is not an actual practice of the Navajo, but was invented by mathematicians.

Responses to diversity in spatial language thus can include teaching about and within the cultural worldview (Pinxten et al., 1987), developing new mathematics (Barton, 2009) and responding to discourse patterns to bridge to the Western mathematics (Lunney Borden, 2011). The example of Action Geometry shows how investigating linguistic diversity can enrich mathematics and stimulate mathematical innovation.

FRAMING PATH AND MANNER

Languages also differ in how they package meaningful components, in what they put together at a word level and what they put together at a sentence level. An example of this is Talmy's (1985) widely used distinction between verb-framed and satellite-framed languages. Verb framed languages present the path of motion on the verb, with manner as a subordinate addition, as in the Spanish *La botella entró en la cuerva (flotando)* 'The bottle moved-in to the cave (floating)'. In satellite-framed languages such as English, the manner is contained in the main verb, as in *The bottle floated into the cave*, where the preposition *into* indicates the path (examples from Talmy, 1985, p. 69). As Talmy notes, while English also has the verb-framed pattern, it is not characteristic, and the verbs that can be used with it are almost all borrowings from Romance languages.

Possible cognitive effects of this distinction are most likely to involve the differences in these expressions in which parts are compulsory to make a full utterance and which are optional extras. Slobin (2006) found differences in the mental imagery of Spanish speakers from English speakers related to this distinction. Similarly, an investigation of language and event perception using eye movements found while the language used does not affect event perception, it does affect their memory of events (Papafragou, Hulbert, & Trueswell, 2008).

The ways in which different languages express motion events is relevant to mathematics education because of the importance of spatial language in mathematics, both directly and metaphorically. Mathematics educators may have a tendency to interpret the way that their own language uses spatial language for mathematics as necessarily linked to the mathematics. Jorgensen (2010) declares that "coming to learn mathematics is heavily associated with the use of prepositions" (p. 29). One example in English might be the phrase "Two goes into six three times". Note that "goes into" is being used in a metaphorical sense; it would be erroneous to say that two *enters* six. The extensive use of spatial prepositions, of course, is a feature of satellite-framed languages such as English. Jorgensen makes her statement in the context of comparing English and Pitjantjatjara, an indigenous Australian language with far fewer prepositions than English. However, it might be useful to ask what mathematical functions Are performed by these prepositions, and then ask what other ways do other languages express those functions.

Furthermore, not all languages fit within one of Talmy's two groups. Some languages favour a serial verb construction, in which both path and manner can occur in verbs used sequentially, and these verbs can have equal status within an utterance (Slobin, 2006). Serial verb constructions have been noted in various languages such as Ewe, spoken in Ghana (Ameka &

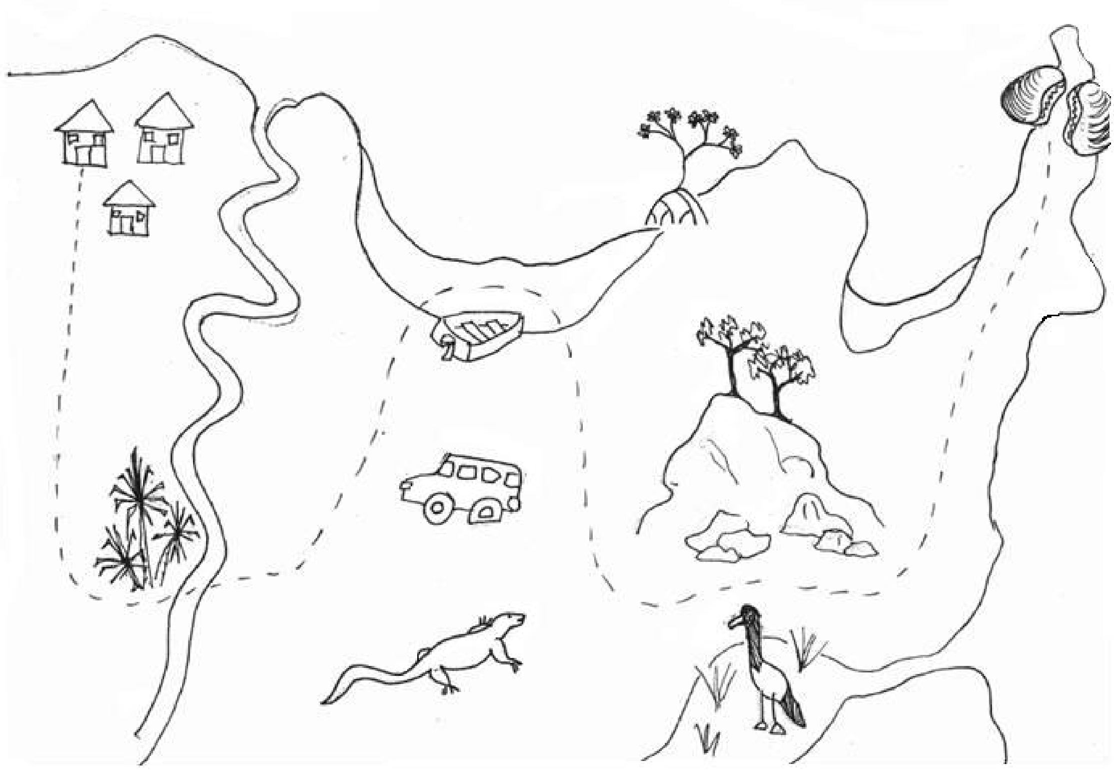

Figure 1: Example of a Director's map showing route

Essegbey, 2006) and Kilivila, spoken in Papua New Guinea (Senft, 2006). Serial verb construction is common in Iwaidja, and the actions themselves can be sequential or simultaneous (Pym, 1985). The remainder of this paper will present some examples of the language of motion in Iwaidja in terms that could enrich our thinking for mathematics education.

THE MAP TASK

This paper reports on some of the results from a Map task designed to elicit route descriptions. It was a barrier task for two participants, derived from the HCRC Map Task (Anderson et al., 1991). One participant, the Director, was given a map with a route marked on it. The other participant, the Matcher, had the same or similar map but without the route. The Director described the route to the Matcher and the Matcher drew the route on their map. I designed the maps to contain items that would be familiar to all participants. An example of a Director's map is shown in Figure 1. The maps differed from those used in the HCRC Map Task by having a coastline and other landscape features such as a creek and beaches. The items on the maps were shown as drawings rather than symbols, as some of the participants would not have been familiar with map conventions.

This task was conducted six times with adult Iwaidja language consultants, with three pairs of participants who each had a turn at directing. The sessions were videoed with an external microphone. The first pair used matching maps where the only difference was that one had a route marked and the other did not. The other two pairs were given different maps, so that some of the items on one map either did not appear on the other or were in different locations. The Director's map still had a route marked on it. The intention was that more complex language would be generated as the participants encountered the differences in their maps. Participants in the sessions where the maps differed were informed that the maps might be different. The task allowed participants to choose what types of spatial language they used to solve it.

The task elicited a rich variety of route descriptions using motion verbs. The current paper focuses on only a few features of Iwaidja that were used in the task – the serial verb construction, the directional distinction and a set of specific motion verbs to describe ways of passing. These features are of interest because of the ways in which they combine or separate mathematically meaningful components as compared to more well-known languages such as English. Other features such as the use of verbs to describe circling, as in Mi'kmaq, are described in Edmonds-Wathen (2013).

Like some North American languages such as Navajo and Mi'kmaq, Iwaidja is a verb-rich language. Many aspects of life are described as processes rather than things. Kin relations, for example, may be expressed using inflected verbs, so that one says "she sisters me" or "he uncles you" (Evans & Birch, 2007). Verbs often take coverbs or adverbs, many adjectives inflect for number, and it is not always immediately clear whether words are verbs, adjectives or adverbs. Iwaidja is a 'head-marking' language, in which affixes, both prefixes and suffixes, provide information including subject, object, direction and tense with regard to a stem.

In general, spatial verbs consist of a stem with a prefix indicating either the subject (in the case of intransitive verbs) or both subject and object (in the case of transitive verbs). Past tense is indicated by suffixes. Future tense is indicated via a separate prefix. In addition, there is an optional prefix indicating directionality, either AWAY from a deictic centre or TOWARDS it (glossed TO). Without this prefix the directionality can be considered neutral. These directions are with respect to the deictic location, which may or may not be the speaker's location. This prefix sometimes combines with subject and object prefixes as well as the future tense prefix to form a single morpheme (Pym & Larrimore, 1979). Examples include *jan-ara,* glossed AWAY.I.FUT-go, 'I will go', and nyan-ara, glossed TO.I.FUT-go, 'I will come'. An example of a prefix which combines subject and object is *r-*, glossed he.to.it, which means 'he (third person singular masculine subject) acts upon it (third person singular object)'.

Examples in Iwaidja are shown in four lines. The first line shows the sentence or phrase in the standard orthography. The second line shows each word. The Iwaidja words have hyphens separating morphemes (meaningful word parts).The third line shows an aligned morpheme by morpheme English gloss. Where the Iwaidja word is translated by more than one English word, but these cannot be separated morphemically in the original, the English words are separated by a period. For example, *artirran* 'he came back' can be separated into *art-* 'towards; he/she/it', *irra* 'come back' and *–n*, which marks the past tense. The third person singular pronoun and the towards direction marker cannot be separated in the morpheme *art-*, nor can the 'come' and 'back' in *irra*. Hence, *art-irra-n* is glossed 'TO.he-come.back-PST'. The final line shows a free English translation of the sentence or phrase. Translations and transcriptions were done with the assistance of a fluent native speaker.

The predominant approach of the six participants was to use specific verbs of motion. Example (1) illustrates many typical characteristics of Iwaidja motion description.

(1) Artirran ararlarrngbung abulakuny awaran. Yabulakuny wardad ba ajbud. Yartirran yarnukbun jumung murrhala ari. Yartirran yarnukbun wuka jumung narrhardi bani. Yartirran barakbarda yariman ba alan ba yawaran, barakbarda jumung birtbani, arrarnarn lda arrayi.

AWAY.he-come.back-PST

barakbarda	*yari-ma-n*
that.one	AWAY.he.to.it-take-PST

ba	*alan*	*ba*	*yaw-ara-n*
the	track	the	AWAY.he-come-PST

barakbarda *jumung* *birt-bani*

that.one	REL	they-sit
arrarnarn	*lda*	*arrayi*
milky.oyster	and	black.lip.oyster

'He came back, he turned, he came down, he came. He went down to one beach. He turned back to where the pandanus tree is. He turned back to where the goose was sitting. He went back there and he took that road, he went along where that thing is, milky oysters and black lip oysters.'

This example includes several uses of the TOWARDS and AWAY prefixes. The basic movement verb *ara* which means 'go' or 'come' depending on the context is seen in the past third person singular forms *awaran* 'he came' and *yawaran* 'he went'. We also see the verb *irra* which means 'go back' or 'come back' depending on the direction, in the forms *artirran* 'he came back' and *yartirran* 'he went back'. *Irra* thus refers to a change of direction. The example also contains both TOWARDS and AWAY forms of *wulaku* 'go down', in *abulakuny* 'he came down' and *yabulakuny* 'he went down'. Hence the use of the directional contrast enriches the semantic scope of the verbs to which it is applied.

We can also see the serial verb construction which is frequent in Iwaidja. The first sentence consists only of four verbs, all taking the TOWARDS prefix: *Artirran ararlarrngbung abulakuny awaran* 'He came back, he turned, he came down, he came.' A colloquial English translation might be something along the lines of 'he turned and came straight back down'. The use of a series of verbs in this context does not necessarily represent a series of actions that follow each other. Rather, the protagonist's single, if complex, act of turning, returning and descending are conceptually packaged together despite each being expressed as independent verbs which could each stand as a sentence themselves in Iwaidja.

In any language, you would expect the language of motion to involve the use of verbs. However, in 'verb-framed' languages, according to Talmy's (1985) classification, manner of motion is expressed outside the verb, for example as an adverb. In 'satellite-framed' languages the path is expressed outside the verb, for example with a prepositional phrase, as in English. The serial verb construction of Iwaidja frequently combines both manner and path in a series of verbs, as was seen in example (1).

Iwaidja encodes specific spatial information into distinct, although related verbs. The range of verbs elicited to refer to passing objects on the map is a good example of this. The most general of these is *marraywung* 'pass.' It is a transitive verb, requiring the specification of what is passed, but does not provide any more detailed information about how the object is passed. Its use is shown in example (2).

(2) Rimarraywung yawarang mangawala ajbud jumung kabala ari.

ri-marraywung		*yaw-ara-ng*
he.to.it.pass		away.he-go-NPST
mangawala	*ajbud*	*jumung*
fast	beach	REL
kabala	*ari*	
boat	it.stand	

'He goes past them and runs along the beach where boat is.'

There are also verbs derived from marraywung for passing in front, behind or to the side of objects. Their use depends upon those objects having an intrinsic front, back or side. The verbs are *marlmarraywung* 'pass behind' (example 3), *wudbarraywung* 'pass in front' (example 4), and *ngunyunmarraywung* 'pass beside' (example 5).

(3) Artirran ararnukbung rimarlmarraywung wuka jumung mudika wulurr.

art-irra-n		*ar-arnukbu-ng*
TO.he-come.back-PST		TO.he-turn.off-PST
ri-marlmarraywung		*wuka*
he.to.it-pass.behind		LOC
jumung	*mudika*	*wulurr*
REL	car	back

'He came back, turned off and passed behind the back of the car.'

(4) Kirrimul warrkarrk aju riwudbarraywung.

kirrimul	*warrkarrk*	*aju*
like	goanna it.lies	he.to.it-pass.

ri-wudbarraywung
in.front

'He passes in front of where the goanna is.'

(5) Kabanangunyunmarraywun baraka dinghy.

kabana-ngunyunmarraywu-n	*baraka*
you.to.it.FUT-pass.beside-NPST	DEM

dinghy
dinghy

'You will pass beside the dinghy.'

Ngunyunmarraywung 'pass beside' contains the body part stem *ngunyuni* 'waist' which also occurs in words such as *mangunyuni* 'beside' and *angunyulunmin* 'side by side'. The derivational origins of *marlmarraywung* 'pass behind' and *wudbarraywung* 'pass in front' are not so transparent.

In addition to the adverb *mangunyuni* 'beside', Iwaidja has *warrwak* 'behind' (an adverb) and *wurdaka* 'in front' (a verb). *Warrwak* and *wurdaka* are common words and were used by the Iwaidja speakers frequently in activities involving description of static location (Edmonds-Wathen, 2014). The examples here of the various verbs of passing indicate more than just choices in the expression of 'beside', 'behind' and 'in front'. Rather, there are differences in their expression depending on whether one is talking about static location or about motion. Similarly, Iwaidja has adverbs *yurrngud* 'on top, above' and *wurrrwud* 'below', which are often used to describe static locations. However, the verbs *bulaku* 'go down, descend' and the opposite *wurti* 'go up, ascend' are used to describe motion up or down.

DISCUSSION AND CONCLUSIONS

Most Australian Indigenous language speaking children are taught mathematics in English by English-speaking teachers. Their mathematics learning is assessed in English. When English speaking teachers talk and think about how to teach the language of mathematics, they tend to package concepts such as spatial concepts in the way that English packages them. They are likely to think of a concept of "down-ness" which applies in the same way to being down and going down, as this is how the English grammar of "down-ness" works. However, it is far from certain that speakers of languages such as Iwaidja link the location of *wurrrwud* 'below' with the motion of *bulaku* 'go down, descend'. Similarly, an English speaker may conflate the "behind-ness" and "in front-ness" conceptualised in the verbs *marlmarraywung* 'pass behind' and *wudbarraywung* 'pass in front', with that in *warrwak* 'behind' and *wurdaka* 'in front' to a greater extent than an Iwaidja speaker. Kriol, a creole language with an English lexicon spoken by over 4000 Indigenous Australian people, and learnt by many Indigenous children as their first language, also expresses path in basic motion verbs. Examples include *guwap* 'go up, ascend' and *gudan* 'go down, descend'.

Educationally, a possible response to this would be for teachers of Indigenous language speaking students to try to use the discourse patterns of their students in teaching the language of location and motion in English (Lunney Borden, 2011). While the spatial prepositions may be emphasised in describing static location, when describing motion the path should not be separated or emphasised: rather than "down, down, go down", the whole verb phrase "go down, go down, go down" could be repeated.

Grammatical structures provide clues to how speakers of different languages structure their understanding of events and to what they are likely to pay attention. Finding out about these grammatical structures can help mathematics education researchers to design investigations cognitive differences between speakers of different languages. The cognitive effects of using a serial verb construction as in Iwaidja could be investigated to add to comparisons between path- and satellite-framed languages. These types of structures are relevant when considering the design of mathematics questions in different languages. Questions that focus attention to one part of the information in one language and to another part of the information in another language may promote different problem solving strategies.

Finally, investigations such as that reported in this paper, into the grammar of basic mathematical concepts, can also provide us with the opportunity to look more deeply into our assumptions about these concepts. This in turn may inspire mathematicians to think creatively beyond the grammatical constraints of their own languages.

ACKNOWLEDGEMENT

This research was supported by a grant from the Australian Institute of Aboriginal and Torres Strait Islanders Studies and an Australian Postgraduate Award scholarship at RMIT University, Melbourne. The author wishes to acknowledge the assistance of Bruce Birch in collecting and analysing the data, and of Joy Malwagag Williams in translating the data.

How communicative teaching strategies create opportunities for mathematics learning

Margareta Engvall, Joakim Samuelsson and Karin Forslund Frykedal

Linköping University, Department of Behavioural Sciences and Learning, Linköping, Sweden, margareta.engvall@liu.se

The overall interest in this study is actions of the diverse participants in the mathematics primary classroom. More specifically, attention is put on typical communication strategies that teachers and students, in our research context, use during mathematics lessons. We present some examples with classroom data to illustrate how the strategies are used and what opportunities to learn mathematics are offered as an outcome from the implemented actions by teachers and students.

Keywords: Mathematics education, communication strategies, primary classroom.

INTRODUCTION

The language and how it is used is of significant importance for what is possible to learn in all education (Säljö, 2000). The way the teacher manages to direct the communication in the classroom and how students and the teacher talk to each other is crucial for students' learning in terms of mathematical content as well as how they view themselves as mathematical performers (Franke, Kazemi, & Battey, 2007). The main interest in this study is communicative teaching strategies that are used in the mathematics classroom and what these strategies can offer in terms of students' opportunity to learn mathematics.

The findings in this paper extend the results of a larger study by Engvall (2013), to which Samuelsson and Forslund Frykedal contributed importantly. That study discusses teachers' and students' actions in the mathematics classroom in primary school when written calculation methods are in focus. The theoretical framework is built on activity theory (AT), which here refers to Engeström's (1987) model of the activity system. According to Rezat and Sträßer (2012) this theory is one among other socio-cultural or semiotic theories that has been shown to be successful in mathematics education research. In AT, the theory about tool mediation is a mainstay (Cole & Engeström, 1993). It is pointed out that any meeting with mathematics is mediated through either material tools as for example textbooks and rulers or non-physical tools such as language, visual representations and gestures (Rezat & Sträßer, 2012). A major feature in Engeström's model is that the context has been extended with some additional mediating factors such as rules, community and division of labour in order to allow better analysis (Engeström; 1987; Goodchild, 2001; Rezat & Sträßer, 2012). Yet, in this paper, we focus on verbal language as it is used by teachers and students in some classes during mathematics lessons in primary school, or in other words communication strategies. There are two main questions to be elaborated here:

(1) What kind of communication strategies do teachers and students use in the mathematics classroom?

(2) What do different communicative teaching strategies have to offer the students in terms of opportunity to learn mathematics?

Communicative teaching strategies in the mathematics classroom

In this paragraph some characteristic communicative teaching strategies in mathematics classrooms will be presented. In particular, we pay attention to the language used for teaching, i.e. the kind of language used to demonstrate, explain and exemplify mathematical connections, drawing from Löwing's (2000) instrument for analysis of communication in the mathematics classroom. Löwing makes a distinction between formal and informal language for teaching, where the latter is used e.g. together with manipulatives or when an everyday situation is taken as a starting point for explaining a calculation. In this presentation we focus on the formal language since, according to Setati and

Adler (2000), one of the challenges in mathematics education is to get the students to gradually change from informal to the formal language, which is characteristic for mathematical activities.

According to Löwing (2000), two main categories of spoken language strategies can be distinguished within the formal teaching language, namely *descriptive language* and *conceptual language*. By using descriptive language, teacher and students put attention on procedures, as e.g. when teacher and students together are performing calculations like 53+25 on the board and somebody describes adding the tens by saying "five plus two", which means that the tens are treated verbally as if they were ones. In this case the language is representing the calculation procedure. Conceptual language, on the other hand, is visible when mathematical words with a specific meaning, e.g. "five tens plus two tens" are used in order to explain and not only describe a step of a calculation like this.

The following strategies, presented in the community of international researchers in mathematics education (Mercer, 1995; O'Connor & Michaels, 1993), can be associated with the category of conceptual language. Our first strategy to be presented here is *key questions*. Researchers have demonstrated that teachers use key questions or certain phrases to create structures for supporting students' learning (e.g., Mercer, 1995). Some students pick up these questions or other common phrases from the teacher's spoken language and use them as a kind of support when performing his or her tasks.

Another distinctive strategy connected to the second category is *revoicing*, since revoicing directs the attention towards thinking and conceptual understanding (O'Connor & Michaels, 1993). Revoicing can actually be defined as at least three communicative teaching strategies: (a) *repeating*, (b) *rephrasing* and (c) *recasting*.

With reference to Mercer (1995), repeating can be used for directing the students' attention towards something specific in a student's answer/expression/utterance so this can support the students' learning. When a teacher instead rephrases a student's utterance the class will get another chance to grip what just has been said but in a version that is more consistent with what the teacher wants to point out. Finally, if a student has expressed something almost non understandable in class, this can be further developed by the teacher's recasting so the meaning thereby can be explained for the students (Mercer, 1995; O'Connor & Michaels, 1993).

The content in this section is interwoven with our first research question regarding the use of communication strategies in the mathematics classroom. Our second question is aimed at paying attention to the idea of possible learning, which therefore will be followed up in the next section. This theoretical overview will be concluded by a short presentation concerning different aspects of mathematical knowledge.

Opportunities to learn and mathematical knowledge

One of the most firmly established links between teaching and learning is the idea of "opportunity to learn" (Hiebert & Grouws, 2007). This means that "the students learn best what they have the most opportunity to learn" (p. 378). Although it is impossible to predict learning outcomes in mathematics based on the use of a specific teaching strategy it is still likely to reason about students' opportunity to learn with regard to teachers' and students' strategies during mathematics lessons (Hiebert & Grouws, 2007). Further, this means that it is possible to discuss what teachers' and students' verbal action can offer when it comes to opportunity to learn during mathematics lessons. This is a core message in this paper.

In various frameworks (Kilpatrick et al., 2001; Niss, 2003) mathematical knowledge is presented as something multifaceted which comprises different types of "tightly interwoven" competences. Procedural knowledge, conceptual understanding, communication, reasoning and strategic competence are some examples. In Sweden, as in other countries, this approach has influenced the curriculum in mathematics education. This means that students during mathematics lessons will get more opportunities to be involved in activities of communicating together with thinking and understanding instead of putting big efforts into skill practice and remembering procedures (Anghileri, 2001; Clarke, 2006). For more than 20 years, this approach has also given rise to a common trend for the teaching of arithmetic, which is an essential part of the mathematics content in primary school. Before the students get any instructions on traditional algorithms they will focus on strategies for mental calculation. From a Swedish point of view this means that traditional algorithms gradually have been replaced in the textbooks by other written calculation methods. For example the addition 56 + 28 can be calculated as follows, 56 + 28 = 70 + 14 = 84. The “intermediate” 70 + 14 is written down in order to facilitate the mental work.

In this paper, we focus on teachers’ and students’ communication strategies with respect to procedural knowledge and conceptual understanding when the content is written calculation methods for addition and subtraction.

METHOD

The collected data in this observation study consisted of video-recorded mathematics lessons in five different classrooms. Besides, an audio recorder has been used together with the video camera in order to get a more complete sound reproduction. In addition to the recorded material there were also field notes. The participating classes belonged to four schools with students from areas with comparable socioeconomic status. The number of students in each class was 24–25. Every teacher had the primary responsibility for the mathematics education in her/his class. Most of the teachers did also teach all lessons in almost every subject in the class. Collection of data started during the spring when the students were in second grade and continued during the autumn, when the students were in third grade. The video-recorded material comprises a total of 24 lessons. In all the lessons one and the same content has been in focus, i.e. written calculating methods for addition and subtraction with numbers exceeding 20.

The collected research material has been analysed in two steps. The first step, with inspiration from Braun and Clarke (2006), can be described as empirically oriented and thematic. This part of the analysis has been carried out in order to discern phenomena that form patterns in the material and thus point to the characteristic actions in mathematics classrooms. The result derived from the first step of the analysis has then been used as the basis for the second step, where the analysing tool, inspired by Engeström (1987), has guided the analysing process. Engeström’s model for activity system gives the researcher opportunity to analyse not only actions mediated by tools, but also by other mediating factors such as rules, community and division of labour. Yet, the focus in this paper is on the outcome of the analysis regarding a non-physical tool, spoken language, or more generally, communicative teaching strategies in the mathematics classroom.

ANALYSIS AND FINDINGS

In the following presentation we will report some typical communicative teaching strategies that have appeared in the empirical material. These will be presented in relation to descriptive and conceptual language. Thus, here we put attention to just two aspects of mathematical knowledge, procedural and conceptual knowledge.

The content taught in the classrooms in the study is, as already mentioned, written calculation strategies for subtraction. In the first example below, initially, the teacher invites a student to tell how to calculate the subtraction 55−21. Almost at the same moment the teacher clarifies that the goal is to tell how to write the intermediate but the outcome of the subtraction is not going to be emphasized.

Transcript 1

Teacher	[WRITES 55-21= ON THE BOARD] I don’t want to hear the outcome. I want to hear the intermediate...Peter!
Peter (stud.)	Fifty minus twenty makes thirty.
Teacher	[WRITES 30 AFTER =]
Peter	And the plus.
Teacher	[WRITES +]
Peter	And then it is five minus ten...four ... four...forty... [ADDRESSING THE TEACHER WHO WAITS A MOMENT BEFORE WRITING THE NEXT DIGIT], a four.
Teacher	[WRITES 4 =] And that makes??
Peter	Err, thirty-four.
Teacher	[WRITES 34] Thirty-four. Exactly! Yes, it’s important to keep track of whether you have to use the tens or the ones.

From this sequence we notice that the dialogue is dominated by the number words together with some words which are representing other symbols. Thus, the student’s communication strategy can be defined as descriptive language, since it is mainly used for representing the different steps in the calculation which is performed by the student while the teacher is writing on the board. The student’s third reply indicates some uncertainty regarding the value of the digit one in 21. The teacher’s comments are very limited.

However, in the last lines the teacher mentions some fundamental concepts concerning number value but this does not seem to be aimed at clarifying the meaning of these concepts, rather to give the student an advice. Accordingly, in this example attention is directed towards the procedure.

The next transcript illustrates the first steps of a teacher's instruction to the whole class on how to calculate the subtraction 58–34. Together with the written subtraction on the board, the teacher uses manipulatives, especially adapted for putting on the board, representing the number of tens and ones.

Transcript 2

Teacher /.../ If we are going to calculate fifty-eight minus thirty-four, which numbers are we going to begin with? ... Jenny!

Jenny (stud.) The tens.

Teacher We begin with the tens. In fifty-eight there are five tens [MAKES A RED MARK RIGHT BELOW THE DIGIT 5], In thirty-four there are three tens [MAKES A RED MARK BELOW THE DIGIT 3]. Five tens minus three tens [POINTS AT THE DIGIT 5 AND THE DIGIT 3]... yes, here we have five [POINTS AT THE FIVE MANIPULATIVE TENS ON THE BOARD] and then we take away one, two, three [TAKES AWAY THREE TENS]. How many tens do we have left? ...Mika!

Mika (stud.) Twenty.

Teacher We have twenty left. Two tens or twenty. It's the same thing just different ways to say it. [WRITES 20 AFTER =]....Mm. Which numbers are we going to continue with now?

We can observe that the teacher clarifies the number of tens in each term, e.g. "in fifty-eight there are five tens". By that, the ten's names and the number names synonymous with each other appear at the same time, e.g. two tens and twenty. Here, the strategy of conceptual language is prominent.

In both sequences above there are examples illustrating how teachers use *revoicing* although they do it differently. This is particularly evident in the last teacher sentence in each transcript.

Excerpt from Transcript 1

Teacher [WRITES 4 =] And that makes??

Peter Err, thirty-four.

Teacher [WRITES 34] Thirty-four. Exactly! Yes, it's important to keep track of whether you have to use the tens or the ones.

Excerpt from Transcript 2

Teacher /.../ How many tens do we have left? ... Mika!

Mika (stud.) Twenty.

Teacher We have twenty left. Two tens or twenty. It's the same thing just different ways to say it. [WRITES 20 AFTER =]....Mm. Which numbers are we going to continue with now?

What these last teacher sentences have in common is that the teacher is *repeating the student's reply*. On the other hand, a clear distinction is visible when we compare the teachers' actions in the two examples. In the first example, besides repeating the student's reply, the teacher makes a comment without any further explanation while the teacher in the second example makes a typical rephrasing. This rephrasing, "Two tens or twenty. It's the same thing just different ways to say it", offers the possibility for the class to take part in what has been said, but in a version that is more in harmony with what the teacher wants to point out. In this situation attention is put on the meaning of tens and ones and what the digits are representing in terms of place value. Thus, in the second example conceptual knowledge is focused while that is not really the case in the first one.

In transcript 2 it is also illustrated that the teacher puts attention to the tens and ones, each in turn, by asking questions like "Which numbers are we going to begin with?" and "Which numbers are we going to continue with now?" We recognize this from research as *key questions*. These are typified by a seemingly procedural course of action. However, depending on how these questions are formulated, the repeating character offers opportunity to develop not only procedural but also conceptual knowledge. We can notice that the student in this example uses a place value word to reply on a key question. Therefore, this kind of questions has an important function in that they can help the students to make structures. It is not unusual that the students pick up the teacher's phrases and use them later on when performing similar tasks.

Finally, the following transcript represents the final part of a session when a class is performing the subtraction 45–22 together with their teacher. They have already jointly agreed that the result of the performed subtraction of the tens is twenty. 45–22 = 20 is now written on the board and when students are invited to perform the subtraction by the ones, the teacher gets two different suggestions from students about what to write next, either plus five or minus three. The teacher then repeats the question about how many ones there are left, which is the opening sentence in the transcript below. The way this question is formulated together with the teacher's illustrating the calculation by fingers, makes it almost impossible for the students to give anything else than a correct reply. The teacher's utterance in line four "Now you said minus three" is a comment to the student who just recently suggested that the teacher should write minus three to complete the intermediate.

Transcript 3

Teacher	How many ones have you left then? ... If you have five [SHOWS FIVE FINGERS], and you are going to take away two?
Student	Three.
Teacher	You have three ones left. Now you said minus three, but if you have something left, what sign do you think you should use, when you have something left?
Student	Plus.
Teacher	Plus [WRITES + TO THE RIGHT OF 20]. It sounds like plus is a very suitable word when you have something left, doesn't it? ...If something was missing you shouldn't use it, should you?

This transcript makes visible how the teacher uses a specific expression "have left" in order to put the students on the right track about which sign they are supposed to use when writing the intermediate in performing written subtraction calculations. In the bottom line we can also notice that the teacher makes a contrast by using the word "missing" in order to demonstrate an association with the minus sign. This strategy we call *key words*. This strategy resembles other strategies where focus is on remembering rules, which makes it closely related to *descriptive language* and consequently, attention is put on procedural knowledge.

CONCLUSION

Even if mathematical knowledge is multifaceted, our concern in this paper has been concerned with opportunities to learn in terms of conceptual and procedural knowledge. We have presented a number of communicative teaching strategies that teachers and students use in the mathematics classroom. The two categories, descriptive and conceptual language, are represented to various extents in the five classrooms in the study. Depending on which verbal strategies teachers and students are using, different opportunities to learn are offered to students.

With this paper we want to illustrate teachers' and students' actions when they use these communication strategies. The result indicates that strategies that direct attention to procedures are also focusing on conceptual knowledge and vice versa. As an example, when the teacher repeats a student's reply more or less attention can be directed to concepts depending on what type of formal language the students used. In a classroom where descriptive language is frequent, it is more likely that the strategy repeating a student's reply will put emphasis on procedures. However, this is in conflict with O'Connor & Michaels (1993) who claim that revoicing directs the attention towards concepts and thinking. Furthermore, using another strategy such as key words can be characterized as procedural. On the other hand, the key words carry some meaning and thereby this strategy might offer opportunities to develop conceptual understanding.

What has been presented above can also be illustrated in the following figure. The horizontal line expresses the communicative teaching strategies and the vertical line symbolizes opportunities for developing either procedural or conceptual language. The two bigger crosses illustrate that descriptive language offers possibilities to develop procedural knowledge while a similar relationship can be described regarding conceptual language and conceptual knowledge. Also, conceptual language strategies offer possibilities to develop procedural knowledge but to a lesser degree than from descriptive language strategies. A similar reasoning can be applied to the relationship between descriptive language and conceptual knowledge.

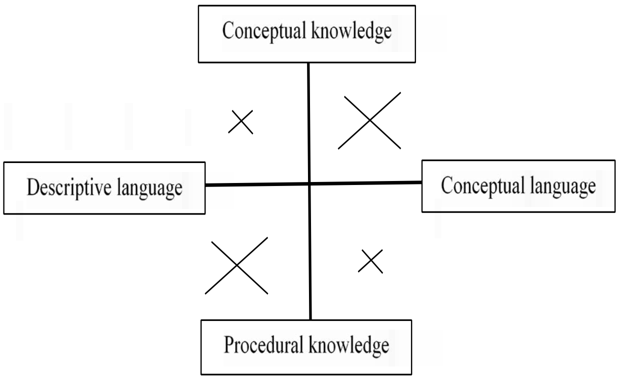

Figure 1: Communication strategies and opportunities for learning mathematics

This paper illuminates how teachers' and students' use of communication strategies influence opportunities to learn with respect to procedural and conceptual language in the mathematics classroom. It can be used for further discussions on pedagogical implications in teacher training programmes as well as in in-service teacher training.

Diverse epistemic participation profiles in socially established explaining practices

Kirstin Erath and Susanne Prediger

TU Dortmund University, Institute for Development and Research in Mathematics Education (IEEM), Dortmund, Germany, kirstin.erath@math.uni-dortmund.de

Same classroom, same learning opportunity? Although learning to explain takes place while participating in the classroom microculture's practices of explaining, this interactionist conceptualization must be widened in order to account for students' diversity. For analysing not only quantitative, but also qualitative differences between students' participation in explaining practices, we present the construct 'epistemic participation profile' and illustrate how it allows to account for the diversity within a classroom.

Keywords: Explaining practices, interaction, epistemic participation profiles.

DIVERSITY IN PARTICIPATION IN CLASSROOM PRACTICES

Many researchers with social, socio-cultural or socio-constructivist perspectives describe mathematics learning *as an increasing participation in interactively constituted classroom practices*. We join this view by adopting an *interactionist perspective* and account for students' learning processes in explaining practices of classroom microcultures (Prediger & Erath, 2014). These practices are regulated by shared sociomathematical and social norms (Cobb, Stephan, McClain, & Gravemeijer, 2001). Whereas early interactionist approaches assumed the class to be a coherent body in which the mentioned aspects can be "taken-as-shared" by all members (cf. critique in Cobb et al., 2001), later approaches acknowledged diversity among students: students usually participate in diverse ways, and the individual participation shapes the individual learning opportunities which are preconditions for learning achievement (Greeno & Gresalfi, 2008). Learning was then described as increasing from the "legitimate peripheral participation" (Lave & Wenger, 1991) to more acknowledged central participation, hence limited participation was seen as an intermediate state. However, many (especially underprivileged) students seem to stay in a peripheral position (DIME, 2007). In order to deepen this idea of *diverse individual learning opportunities depending on students' ways of participation*, these ways must be described *quantitatively*, but also with respect to their *quality*. Greeno and Gresalfi (2008) give hints for this qualification by describing conceptual practices as crucial for mathematics learning in contrast to purely procedural ones. We present a framework for qualifying students' diverse profiles of participation as one key to understand the reproduction of inequality in classroom interaction where all students have the same formal and curricular learning opportunities (DIME, 2007). This paper deals with *three research questions* from which the first one had to be solved by developing an analysing tool: (Q1) How can we distinguish between students' diverse ways of participating in classroom explaining practices with respect to the epistemic processes of knowledge construction? (Q2) Are there patterns of ways of participating which allow speaking about a consistent participation profile? (Q3) How does students' participation develop over half a year?

We address two points relevant to the TWG as raised by Morgan (2013): First, bilingual learners in mathematics and second, the question what linguistic competences and knowledge are required for participation in mathematical practices.

EXPLAINING PRACTICES IN MATHEMATICS CLASSROOMS

Our case study is embedded in our large research project INTERPASS in which we investigate whole class interactions with joint explaining activities and different research questions. For investigating the mathematical core of explanations and their functions in the process of knowledge constitution, we combine the interactionist perspective on explaining with an epistemic perspective. In the *epistemic perspective*, explaining is defined as aiming at building and connecting knowledge in a systematic, structured way by linking an *explanandum* (the issue that needs to be explained) to an *explanans* (by which the issue is explained). This distinction structured the tool developed for analysing contributions with respect to their epistemic character, the so-called epistemic matrix (Prediger & Erath, 2014), which led to observe the phenomenon presented below.

In the rows of the epistemic matrix (in Figure 1), contributions to a joint explaining activity are distinguished with respect to the *explanandum*. For this, we refine the conceptual/procedural distinction (raised as relevant for participation profiles by Greeno & Gresalfi, 2008) into *seven logical levels*: The four conceptual levels comprise concepts (categories such as maximum), semiotic representations (e.g., a diagram itself), mathematical models (addressing relations between reality and mathematical objects/statements), and propositions (mathematical patterns, statements, or theorems); the three procedural levels comprise procedures (e.g. a general way of drawing a diagram), conventional rules (e.g., "frequencies always on vertical axis"), and concrete solutions (e.g., individual solutions of a mathematical task). In the columns of the epistemic matrix, the *explanans* is distinguished in *six epistemic modes*: ||labelling & naming|| is the only mode that can be addressed by a single word (e.g., "maximum"). The mode ||explicit formulation|| includes definitions and theorems and is a linguistically elaborate way to treat an *explanandum*, it is usually also epistemically more elaborate than the mode ||exemplification|| which addresses examples and counterexamples. The mode ||meaning & connection|| comprises all semantic aspects of an explanandum and those that bridge to another level or mode, for example pre-existing knowledge (e.g., meanings, arguments, reasons), it can have different epistemic degrees of elaboration. The mode ||purpose|| belongs to a pragmatic approach (e.g., "in diagrams, we see pattern more clearly"). The mode ||evaluation|| often appears in context of evaluating solutions.

In our empirical approach, each (complete or partial) explanation that is demanded and given in a classroom interaction is characterized by the navigation through the addressed *epistemic fields* (=the combination of addressed logical level and epistemic mode). Figure 1 contains an exemplary *navigation pathway* of Episode 1 (signs as '#17' refer to the lines in the transcript, circles stand for the teacher, rectangles for the students). In this navigation pathway, the teacher addresses the fields --concrete solutions / models-- ||meaning & connection|| by asking if anybody has a cat at home and knows its weight. Afterwards, he navigates to --models-- ||explicit formulation|| by asking for a complete modelling, thus he navigates from children's concrete experiences to explicit formulations and hence, to consolidated mathematical knowledge.

Whereas two preceding papers investigated by the epistemic matrix the epistemic core of common interactive practices (Prediger & Erath, 2014) and a teachers' profiles setting different implemented curricula (Erath & Prediger, 2014), this paper applies the analysing tool to specifying diverse students' epistemic participation profiles. By focusing on the students, we investigate how different individual students contribute on their own ways within an interactively established social practice.

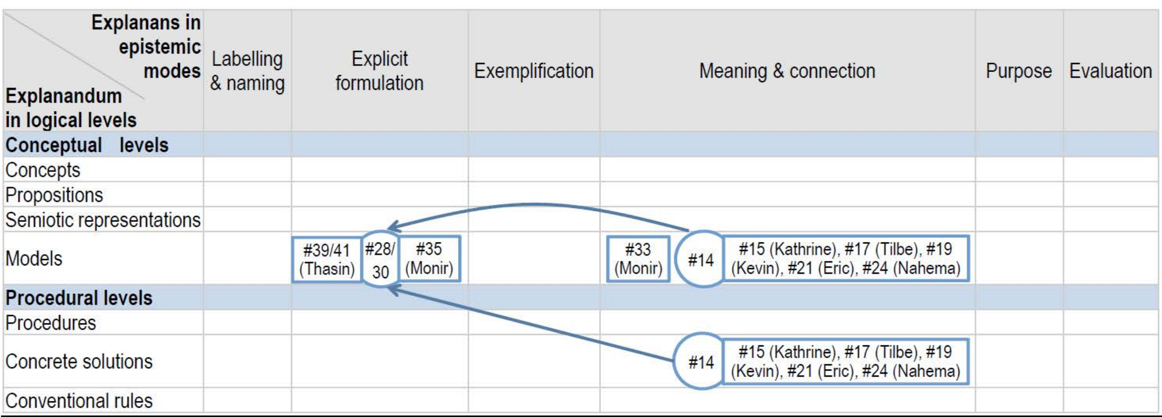

Figure 1: Epistemic matrix for distinguishing explanans and explanandum

We construct a *student's epistemic participation profile* by analysing all her/his contributions in oral classroom explaining practices. The epistemic participation profile is characterized by taking into account (1) the *quantity* of the student's contributions, (2) their *epistemic character*, and (3) their *epistemic potential* for consolidating mathematical knowledge which is determined (3a) by the required level of the epistemic field demanded by the teacher and (3b) by the level of compliance by the individual students. This definition builds upon two assumptions: the epistemic fields play different roles in the collective and individual process of knowledge construction (Vollrath, 2001, pp. 52f), and the individual opportunities to learn also depend on the individual's compliance for contributing to consolidating the knowledge (Greeno & Gresalfi, 2008).

METHODOLOGY OF THE STUDY

Larger data corpus. In the larger project InterPass video data was gathered in 10 times 12 math and language lessons (each 45–60 min.) in five different grade 5 classes (age 10–11 years). The data corpus also comprises all class materials and written products.

Sampling for the case study of this paper. The small comparative case study focuses on 12 math lessons in one higher tracked class (German "Gymnasium", German as language of instruction) in which we compare three students' participation profiles. The students Nahema, Monir, and Thasin were selected due to their similar social and language background (all boys of 10–11 years, second language German learners, living in an underprivileged urban quarter), but contrasting participation profiles. The video corpus for this case study is formed by all episodes of whole class interactions in which one of the three boys was involved in joint explaining activities.

Data analysis. First, the selected video data were transcribed and analysed by means of the epistemic matrix. Second, in order to reconstruct the boys' epistemic participation profiles over time, (1) all contributions above the sentence level of the three boys during classroom interactions of joint explaining were collected, and the *quantity* was determined by counting, (2) their *epistemic character* was operationalized by locating them in the epistemic matrix, and (3) the *epistemic potential* of the contributions (consisting of the required level and the level of students' complying) was identified by an analysis of teachers' navigation pathway and the criterion how the utterance contributed to consolidating mathematical knowledge in the classroom interaction. (For example, explaining algorithms and describing mathematical ways of acting or connecting procedures and concepts demands a high required linguistic and epistemic level of consolidation, whereas naming result or stating everyday experience without connecting it to mathematics is of lower difficulty.) And third, considering the course of the participation during the 12 lessons allowed analysing their stability. The fact that we conceptualize "participation profile" not as dynamic is justified by the empirical outcome that each of the three students' individual way of participation is quite stable over time.

THREE STUDENTS' EPISTEMIC PARTICIPATION PROFILES

The participation of the three boys differs in quantity: Monir and Nahema have 8 and 7 contributions above sentence level (i.e. longer than one sentence) to joint explaining activities in whole class interaction within the 12 lessons (and of course many shorter contributions of one to three words not considered here). Thasin shows a more active participation with 12 contributions above sentence level. The relations are similar for the cases in which the boys raise their hand but are not selected to contribute (Monir 15, Nahema 13, Thasin 32). However, this quantitative information cannot account for unequal learning opportunities in active participation. Only the qualitative analysis of transcripts allows to categorize the differences in the epistemic character and to reconstruct their epistemic potential. We illustrate our analysis procedure by two episodes before describing the results of all analysed episodes.

Episode 1: The meaning of rounded zero in the dot plot

Episode 1 is extracted from a discussion in the class about interpretations for the dot plot in Figure 2, after two students have given opposed interpretations for the 0 kg for cats in Figure 2 ('nothing written' versus 'under ten kilogram, maybe one and a half or two'). The transcript starts when the teacher collects several weights of cats in #14 in order to evaluate the solutions (the translated transcripts use [...] for missing parts, (.), (-) and (--) for breaks of increasing length, CAPITALS for emphasized words):

14 Teacher [...] Does anybody have a cat at HOME, [...] Can you tell how much it WEIGHS, [...]
15 Kathrine um (.) I have now um (.) a little KITTEN at home, well it‘s weighing (.) nearly two KILO;
16 Teacher HM_hm, um (–) TILBE;
...
21 Eric I have a (.) at my grandma's I have a CAT, I once weighed it, (.) it was very THIN, it think its weight was (--) two KILO, and a (.) bigger tomcat I think even SIX kilo;
22 Elif WOW;
23 Teacher HM_hm; NAHEMA;
24 Nahema from my friend who is called KEVIN, (.) the ca (.) um the the cat is like THIS, ((*shows the size with his hands*)) this weighs NINE kilo;
25 Elif NINE; ((*many students expressing scepticism about cats of nine kilo*))
32 Teacher MONIR, (.) THASIN, (.) what do YOU think;
33 Monir well um (-) the um (.) these (.) SCALES of um how much they weigh, is always only (.) after the TENS (.) so (.) always 10, 10 20 30 40;
...
35 Monir but the cat weighs UNDER ten; so (–) um (-) the (.) it does not weigh like (-) um; (–) well it has (-) it has no um (-) it two-digit- ((*indicates digits in the air with his fingers*))
36 Teacher HM_hm; a two-digit NUMBER; or no two-digit WEIGHT;
37 Monir YES;
38 Teacher HM_hm, (.) THASIN;
39 Thasin If a cat would weigh nine KILO on average, one would round it up on TEN;
...
42 Teacher BOTH can be correct by the way; (.) THASIN Monir; [...]

Kathrine (#15), Tilbe and Kevin (in unprinted #17 and #19), Eric (#21) and Nahema (#24) are stating their experiences with the weight of cats, hence they are staying in the epistemic fields for which the teacher asked (#14): the epistemic mode ||meaning & connection|| on the logical levels --concrete solution-- and --models--. After Eric's six kilos were already commented by 'WOW' (#22), Nahema's suggestion of nine kilo (#24) is rejected by other students Nahema's contribution is linguistically correct, but not concise due to superfluous information.

Having collected these concrete values for cats' weights, the teacher moves back to the mathematical core with the next question (#28/30). As the navigation pathway in Figure 1 shows, he navigates into the epistemic field --models-- ||explicit formulation||. He takes on the weight stated by Nahema and calls on Monir and Thasin for giving their suggestions how to model the situation:

30 Teacher one WEIGHT symbolizes about ten ki (.) well symbolizes ten kilo; Now, if a cat REGULARLY, right, (.) well if cats would weigh regularly around nine kilo; would one DRAW a weight symbol there, (.) or rather NOT; [...]
31 class ((*murmuring*))

Monir (#33) first refers to the meaning of the weight symbols in the dot plot and hence addresses the epistemic field --models-- ||meaning & connection||. Then he shifts the mode to ||explicit formulation|| in #35 by stating that since the weight of a cat has not two digits one would not print a weight symbol (see navigation pathway in Figure 1). Monir is struggling linguistically; the multiple breaks indicate how he is searching for suitable words. In #36, the teacher supports him in closing his utterance by translating Monir's gestures into words. Thasin directly addresses the epistemic field to which the teacher referred in his initiating question and models by using the concept of rounding on tens (#39/41). He uses an if-then-clause which is not trivial for second language learners of this age. The teacher evaluates both utterances (#42) by reformulating them and stating that both ways are plausible and not decidable from the dot plot alone.

All three focus boys, Nahema, Monir and Thasin, participate in the whole class explaining activity for the dot plot with a similar length of utterances (Nahema's being slightly shorter). All three contributions are valued in the interaction since the teacher (who is concerned of including everybody) builds upon them in the further interaction. However, we identify a typical difference between Nahema on the one hand and Monir and Thasin on the other hand: Nahema (as all five students in the beginning) only contributes some facts from his everyday knowledge. Although the compliance level is very good, the required epistemic mode of ||meaning & connection|| in this case had only a minor epistemic potential, here reduced to being sensitized for plausible weights. The epistemically deeper work on consolidating students' more general mathematical knowledge comes later in the navigation pathway. In this step, Thasin and Monir are involved (by explicitly formulating how to translate the real life situation of 9 kilo into a diagram). This later step in the pathway has a higher required epistemic level. As Monir's compliance level is not ideal in the beginning, he gets a scaffold with more opportunities to develop his thoughts than Nahema. We will show that the distribution of students on different steps of the navigation pathway has persistent pattern, e.g. the epistemic mode of ||explicit formulation|| seems to be addressed only by some of the (non-focus) students whereas others consistently take more peripheral roles. The epistemic matrix allows describing the peripheral parts of a whole class explaining activity with respect to the epistemic potential for knowledge construction and consolidation.

Episode 2: Multiplication of decimal numbers

Episode 2 took place half a year later in the same class. At the beginning of a lesson, the teacher initiates a recapitulation of the last lesson one week ago. After the girl Tasnim (#10) does not succeed in reporting properly, she calls on Monir to support her.

1 Teacher [...] I would like to know from you, [...] WHAT did we do an eternity ago,

...

10 Tasnim well (.) well three KIDS (.) I believe, were, have (–) on the blackboard (–) well have calculated TASKS? [...] Oh, I can't EXPLAIN it [...]

...

20 Monir [...] so (.) we calculated with (.) DECIMAL numbers, (.) calculated DIVIDING, (.) so um we have (.) at the moment (.) the TOPIC so to speak; (-) um DIVISION and multiplication, (--) with DECIMAL numbers, (-) and we did um (–) um CALCULATIONS, um when to INSERT um the (.) point when dividing (.) um at the result; for EXAMPLE- (.) if you (.) HAVE a number with point, like (-) um ((*2.5 sec break*)) twelve (-) po- um (.) twelve point ((*1.5 sec break*)) seventy-EIGHT, (.) then um you mus- (.) and you have to divide it by (-) um FOUR, (–) um (.) then (.) um (.) it is that are THREE; ((*1.9 sec break*)) um three times four equals TWELVE, (.) then you are calculating twelve MINUS twelve; that equals ZERO; (.) and then you are immediately with the POINT, (--) and um (--) you have this three (–) written DOWN at the result, (-) then you must insert the POINT immediately next to it; because you are (.) NEXT to, (.) um well because you are UNDER the point; with the NUMBER;

21 Teacher HM_hm;

22 Monir you immediately have to put a POINT into (.) the result;

...

25 Teacher THAT was already a bit more DETAILED; right, [...]

After some stumbling, Monir (#20) names the mathematical topic 'division and multiplication of decimal numbers' (i.e. complies the demanded field of --procedures-- ||labelling & naming||), a task of low required level. He immediately continues with a shift to the epistemic mode ||exemplification|| with a potential for later ||explicit formulation|| and explains by an example how the division algorithm works (even though some facts are missing, the idea becomes clear). The teacher evaluates this extensive contribution positively.

Later in the same lesson, after working on tasks in individual seatwork, the second part of Episode 2 starts after discussing the calculation of $19.8 \cdot 0.708 = 14.0184$. Thasin mentions his confusion because his rough estimation $19 \cdot 0 = 0$ does not fit to the result. The class helps him by offering the handier estimation $20 \cdot 1 = 20$. Afterwards the teacher shortly repeats how to put the decimal point at the right place in the result. But Thasin is still troubled and after a classmate points the teacher's attention to Thasin's confusion the conversation starts with him stating what seems strange to him:

2 Thasin um (.) because (.) now if you (.) um (.) MULTIPLY a number, apart from ZERO, (-) the number gets BIGGER (-) ((*silently*)) actually; fourteen is SMALLER than the nineteen;

3 Sina oh yes;

4 Teacher yes (.) to REVEAL that once more; (-) THASIN says; MAN, usually, multiplication means I make something BIGGER [...] EXCELLENTLY seen Thasin; (---) take on (-) one two people who should search an EXPLANATION for that;

Thasin (#2) states his problem by connecting the result of the task to his conceptual understanding of multiplication as an operation that always increases the original numbers. He connects several logical levels in the epistemic mode ||meaning & connection||, namely --concrete solutions / procedures / concepts--. The teacher marks this observation as important by reformulating and positively evaluating it. Several students are asked for an explanation in order to help.

6 Tilbe so (.) um (.) I GUESS so; (--) because it is zero point seven (.) HUNDRED; and if you (.) MULTIPLY the seven hundred times nineteen - so approximately MULTIPLY times twenty, then (.) it becomes FOURTEEN;

...

15 Larissa ((*walks to the blackboard*)) so HERE there are; (-) here there are only three NUMBERS; ((*points to 0.708*)) and here suddenly FOUR ((*points to 14.0184*))

16 Teacher (---) this makes the NUMBER; (--) thereby thus AFTER the point (.) after the point bigger, (.) and in FRONT of smaller; right, (--) does anybody have ANOTHER explanation [...] (---) Thasin, you yourSELF

Tilbe (#6) addresses the epistemic field --concrete solutions-- ||meaning & connection||, here by estimated calculation. Larissa (#15) describes an observation without offering an explanation. The teacher (#16) asks for further different explanations which can be interpreted as implicit mismatch for both. Thasin wants to explain himself:

19 Thasin (--) so- ((*2.6 sec break, walks to blackboard*)) ZERO times nineteen equals zero; (-) but we do have a POINT here, (-) and that makes the zero BIGGER; (.) and AFTER it there is also something written; ((*2.0 sec break*)) and (-) ZERO is always that it gets smaller, (-) and because it's not times ONE, (.) but LESS; ((*1.3 sec break*)) it is SMALLER than nineteen; (--)

20 Tom I didn't understand anything;

21 Teacher try it AGAIN; (-) but one MOMENT; (.) before Thasin (.) starts the EXPLANATION again, (-) I'm putting THIS here; ((*changes 20 · 1 = 20 to 19 · 1=19 at the blackboard*)) maybe you can use THIS Thasin;

22 Thasin Okay; (-) NINETEEN times zero (-) equals zero; (-) and NINETEEN, (.) nineteen times ONE equals nineteen; ((*1.2 sec break*)) and here we got (.) zero point seven hundred and eight ; (-) this is LOCATED (.) um- (-) it's not times ONE, but also not times ZERO; (.) that's why it must be located between the NINETEEN and the zero; (--) it's SMALLER than nineteen, but bigger than ZERO; (.) that's kind of ABOUT,

23 Tom I UNDERSTAND;

24 Teacher YES;

Thasin (#19 and #22) needs two trials to formulate his explanation so that others understand him. The teacher supports him by giving useful referent calculations on the backboard. Thasin takes on this help and explains by connecting logical levels: If $19 \cdot 0 = 0$ and $19 \cdot 1 = 19$ and $0 < 0.708 < 1$, then $0 <$ result < 19. This explanation is marked as understandable by the peers (#23) and positively evaluated by the teacher.

Again, both students, Thasin and Monir, contribute with epistemic potential to the interactive process of mathematical knowledge consolidation. However, we see differences: Whereas Monir stays on the procedural level, Thasin even initiates the connection of the learnt procedure with the prior conceptual knowledge and connects different levels.

Three students' epistemic participation profiles

As Table 1 shows, Episodes 1 and 2 are prototypic for the three students' epistemic profiles that could be reconstructed from the complete material, lessons 1.1 to 1.8 from the beginning of year 5, and from lessons 2.1 to 2.4 six months later (the last number in '1.2.4' indicates a running number for the students' contribution above sentence level). Within the limits of taking only 12 lessons over six months, Table 1 allows first answers to Q3: Students' epistemic participation profiles show certain stability over the time of half a year, visible tendencies in the first episodes can be detectedas persistent pattern.

Explanans in epistemic modes	Labelling & naming			Explicit formulation			Exemplification			Meaning & connection			Purpose			Evaluation

Table 1: Students' epistemic profiles (Monir in blue, Thasin in violet, Nahema in green, ***bold italics*** indicate potential for mathematical learning opportunities)

Thasin comparatively often refers to conceptual levels, the mode ||meaning & connection|| and within it the connection across levels. In the second period, he gives conceptual explanations as in Episode 2. As reconstructed for Prediger and Erath (2014), these explaining practices are highly valued in this classroom microculture. The classification of their epistemic potential (Table 1) detected nearly 9 out of 12 contributions as productive for consolidating knowledge since raising meanings is crucial for consolidation.

Monir with limited linguistic resources is specialised on the procedural levels and on the mode ||exemplification|| and the combination of several modes on one logical level. This specialisation allows his contributions to be mostly classified as having epistemic potential for consolidating (mainly procedural) knowledge. Hence, both boys significantly contribute to the individuals' opportunity to learn mathematics according to the microculture's sociomathematical norms. Nahema's seven contributions are mainly procedural and focus on the mode ||purpose|| in which he refers to mostly initial and concrete issues in the teacher's navigation pathways. This concreteness allows activating deictic means and compensating limited linguistic resources. However, in later steps of the classroom's navigation pathways when it comes to knowledge consolidation on epistemically higher levels, he usually keeps silent. This does not mean that he does not profit from passive participation, but he does not contribute actively to consolidating knowledge. Instead of the often assumed participation trajectory of increasing participation, Nahema's participation decreases to one explanation six months later (he raises his hand four times but is not selected to speak). Hence, Nahema's restricted linguistic resources in the language of instruction limit his active participation and due to the limited epistemic potential, seem to strengthen the inequality of his learning opportunities.

DISCUSSION AND OUTLOOK

From our case study for three second language learners with unequal German linguistic resources, we conclude: Students show different ways of participation which can be grasped by means of the epistemic matrix. The location in the fields of the epistemic matrix and within the steps of a navigation pathway makes the unequal individual epistemic potential for consolidating the mathematical knowledge visible.

The developed framework enables us to observe a new phenomenon: The reconstructed patterns show certain stability over time. Rather than talking about naturally increasing participation, we must therefore talk about participation profiles being connected to unequal German resources and learning opportunities within the same class. The relation between the visibly unequal linguistic resources of the three boys and their participation profiles will be the issue for further research since this seems to be one key for understanding the reproduction of inequality in classroom interaction.

ACKNOWLEDGEMENT

INTERPASS ("Interactive procedures of establishing matches and divergences for linguistic and microcultural practices") is funded by the German ministry BMBF (grant 01JC1112). We thank A.-M. Vogler, U. Quasthoff and V. Heller for the collaboration.

Deictic gestures as amplifiers in conveying aspects of mathematics register

Danyal Farsani

Universidad de Chile, Center for Mathematical Modelling-Education, Santiago, Chile, dfarsani@dim.uchile.cl

This paper investigates communication (verbal and nonverbal) in the bilingual (Farsi-English) mathematics classroom. The study examines the communicative repertoire that interlocutors employed in lessons enabling them to construct meaning and mediate understanding. That is, the ways in which language and gesture can be seen as resources in supporting and conveying mathematical ideas is described. It appeared that the pointing gestures that were produced by the classroom teachers served as a mnemonic device to help remembering the key mathematics register.

Keywords: Mathematics register, code-switching, multimodality, gestures, pointing.

THE ROLE OF POINTING GESTURES IN MATHEMATICAL DISCOURSE

This paper focuses on the communicative functions of gestures in a bilingual mathematical discourse. The term 'gesture' is used in a wide sense, as a physical movement of a part of the body (e.g., hands, arms, eyes and face) (Kendon, 1983; Maschietto & Bartolini-Bussi, 2005) in communicative situations (Streeck, 1988). McNeill (1992, p. 11) used the term gesture to mean "movements of the arm and hands … closely synchronized with the flow of speech". In this paper, I refer to gestures to denote the movements of hands or arms that are synchronously produced in the act of speaking. Along similar lines, Sfard (2009, p. 194) defines gesture as a "body movement fulfilling communicational function" that is co-produced with speech.

Gestures have been categorised into four different groups (see McNeill, 1992). Each gesture category has a different form and function in communication. There are 'deictic', 'beat', 'iconic' and 'metaphorical' gestures. McNeill's (1992) gesture category takes an account of gestures that are dependently produced with their corresponding speech units. Of course, individual gestures can incorporate elements of multiple categories. For example, often pointing gestures trace the outline of the shape that is being pointed at. Therefore in this example, there are indexical and iconic components of a single gesture. In this paper, I will primarily focus on pointing gestures (or deictic gestures). Deictic gestures mostly occur in synchrony with speech. They are employed when interlocutors connect from verbal to visual, in order to index objects, locations, inscriptions that are either present or non-present in the environment. Due to the fact that pointing gestures are so ubiquitous and we interpret them with such ease, pointing can come into view as a trivial phenomenon (Kita, 2003). Pointing often draws on different modalities; for example, a speaker can connect from auditory to visual representation as they point to objects or inscription. Similarly in a classroom when a teacher can point to objects or inscriptions as s/he speaks, those pointing gestures link his/her verbal stream to its physical referents in the environment (Alibali & Nathan, 2012).

Index-finger pointing is the most common deictic gesture but it is interesting to note that there are different variations in index-finger pointing that are correlated with certain discourse factors. For example, the degree of finger closure or openness among the little finger, ring finger and mid-finger while pointing with the index finger is correlated with certain discourse factors. It has been observed that emphatic or first mentions of events tend to be regularly accompanied by the canonical (tightly bunched) index-finger point. In follow-up anaphoric mentions, once the location and the identity of the object have been established, a looser hand is used and the action is executed more quickly (Wilkins, 2003). The forms and functions of index pointing with a looser/tighter degree of closure and its corresponding pedagogical implications within a mathematics lesson have also been explored (see Farsani, 2015).

THE RESEARCH SITE

For part of my PhD research, I carried out an ethnographic-style approach to examine communication in a bilingual British-Iranian mathematics classroom. The students in this study were first and second generations of bilingual (Farsi-English) speakers from a Persian heritage. In this school, the medium of instruction was bilingual and learners were encouraged to value both languages equally. What seemed to be at the heart of the school was creating multilingual spaces (Creese et al., 2006), about using languages flexibly (Blackledge & Creese, 2010), and using a full range of young learners' linguistic repertoires (Creese & Blackledge, 2010). This bilingual school welcomed strategies that supported learning both the content and language simultaneously. I conducted audio-visual recordings of a number of mathematics lessons in order to capture verbal, vocal and visual elements of language to investigate how these modes of communication play a role in making mathematical meaning.

DATA ANALYSIS AND DISCUSSION

This particular interactional recording emerged from a lesson where the classroom teacher (T2) engaged in solving an unknown angle in a regular pentagon. T2 was explaining the solution to how he finds an angle of x which lies inside of a regular pentagon. T2 has divided the regular pentagon into five equal isosceles triangles as a starting point (see *Figure 1*).

I find this extract particularly interesting because T2's instructional talk, gesture and speech convey overlapping information in lines 15–19.

In this transcription, the left-hand – throughout column illustrates the verbal interactions only. The middle and the right-hand - throughout columns signify the multi-modal nature of the classroom and add richness to the verbal discourse. For example, the middle and right column include mathematical notations, Algebraic notations and diagrammatical representations. Based on the idea of what is 'Given' and what is 'New', Kress and van Leeuwen (1996, p. 187) believe that "[t]he elements placed on the left are presented as Given, the elements placed on the right

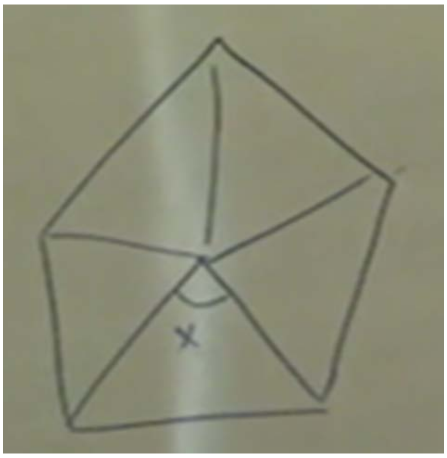

Figure 1: Drawing of pentagon

as New. What is given is what the viewers are already familiar with and agree upon but what is New, on the other hand, is not yet known and viewers must pay special attention to it". Therefore unlike many of the ordinary transcripts, the middle and right hand column are 'new', in that they add clarity and complement the left hand column by bringing visual elements into the verbal transcription.

The multi-modal transcript convention I have used is as follows:

T	Teacher
B	Boy
[ ]	Non-verbal communication
{ }	My translation
Italics	Farsi transliterated into English
Normal font	English language
Dots	Each dot represents one second of silence
Change in font size	Change in volume of an utterance: the bigger the font is, the louder the pronunciation. The smaller the font is, the quieter the pronunciation of the term.

Transcript number 1

T2: divided by five

I find this extract of particular interest firstly because of the geometrical transformation that has been made into the regular pentagon; it has been converted into five equal isosceles triangles as a way to proceed. It emphasises the fact that a particular geometrical shape with a specific property can be turned into a number of shapes with a different identity (see Pimm, 1995).

There are different modalities that play a role in this short transcription of a video recording. T2 conveys his instructional message not only in speech but also in the gestures and a number of different modes that he uses as resources in teaching. For example, notice the way in which T2 directs attention by drawing and tapping (see lines 24–29) on the whiteboard. He taps twice on the angle x and moves on pointing to the other remaining four inner angles as he utters his statement “is equal to angle of x equal to angle of x and so on”. Furthermore, code-switching is evident within the technical forms of register. In lines 20–23, both B1 and T2 emphasised key terminology ‘*motasavi-al-saghain*’ in Farsi. In these lines, not only did they showed awareness of other languages (Farsi) in the class but they drew upon their full range of linguistic repertoire ensuring that the equivalent Farsi mathematics register is known and recognised by all students. By doing so, T2 provided an opportunity that acknowledges the linguistic resources that bilingual learners have at their disposal by demonstrating their knowledge and understanding of mathematics in Farsi. It appears that T2 ensures that bilingualism is foregrounded and is at the centre of the teaching and learning that takes place as he develops awareness of the Farsi mathematics register.

What I am more interested to examine in this particular transcript lies on 15–19 where T2 incorporated a form of deictic gesture (with his index and mid finger) indexing his eyes as he uttered 'isosceles' in his speech (see Figure 5). At this stage there could be two possible interpretations of T2's gesticulation; depending on whether the focus of attention is on his fingers or to the eyes which I will now discuss. It is possible that T2's gesticulation could be read as a visual similarity of the two fingers representing two equal sides. Even where the index and the mid finger are not exactly the same size in length, the gesture could serve as a primitive tool to convey the idea of two equal sides of an isosceles triangle. Hence T2's gesticulation represents not only the geometric representation but also conveys its mathematical definition visually.

Alternatively, if T2's gesticulation was indicating his eyes, then the gesture and the accompanying speech (isosceles) did not appear to have/convey any shared semantic meaning. Semantically there is no overlapping information but phonologically there is a strong connection. The relation between T2's verbal message and his deictic gesture is of homophony. Homophonous words are terms that have the same pronunciation as another but different in meaning, origin or spelling[1]. The way isosceles is pronounced is very similar to what can be thought of as 'eyesosceles'. The pronunciation of the term 'eyesosceles' possibly explains the reason as to why T2's gestural representation was directed at his eyes. Isosceles generated a deictic gesture, by means of indexing an object that was phonologically similar to the accompanying speech.

I find it interesting to see how a mathematics register activated a particular gestural representation in teacher's instructional talk. An interpretation of T2's gestural representation of the term 'eyesosceles' in conveying the instructional information reveals that there was no mathematical understanding or meaning assigned to property of isoscelesness. At the same time, T2's gestural enactment shows a great linguistic awareness that helps the remembrance and recollection of an English mathematics register. The enactment of such gesture also increases the emphasis of its verbal counterpart.

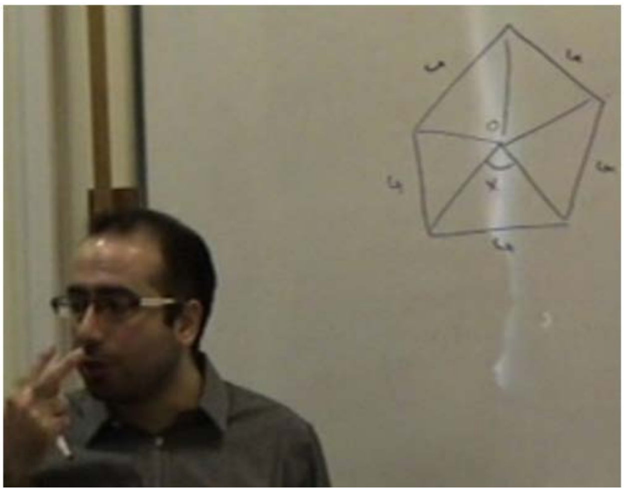

Figure 5: "Eyesosceles" I

Figure 6: "Eyesosceles" II

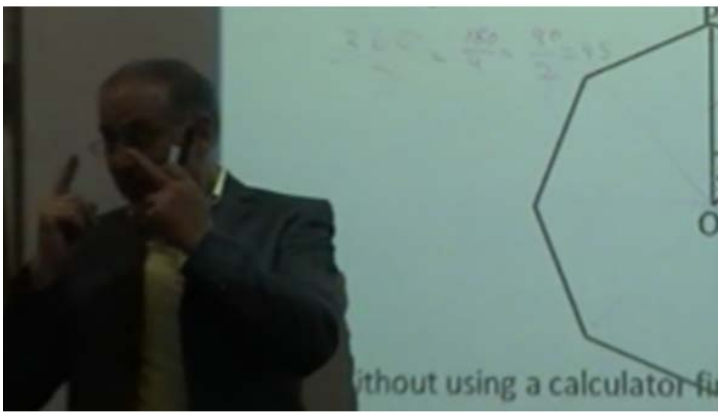

Figure 7: "Eyesosceles" III

The gesticulation for 'eyesosceles' is also evident by another mathematics teacher (see Figures 6 and 7). I would only present a snapshot for each of these gestural representations enacted by mathematics teachers.

In these examples, mathematics teachers' gestural representation for 'isosceles' was beyond deictic because their gestures served more than just indexing as there were also phonological connections to their gestural enactment. There are issues of phonetic and prosodic aspects of language involved in gestural enactment. Both teachers' deictic gestures served to emphasise the verbal language by indexing a visual object that carried a similar sound. Therefore their gestures served as a pedagogic tool to help memorising/remembering 'technical' mathematical words. In other words, teachers' nonverbal message served as a mnemonic device to help remember the terminology and the concept. Therefore, the employment of deictic gestures in instructional talk not only added clarification and richness to the spoken discourse but promoted the remembrance of an English mathematics register.

CONCLUDING THOUGHTS

This paper gave an account of the symbiotic nature of deictic gestures and their accompanying speech, as well as how these two modalities were temporally and phonologically coordinated. I offered examples supporting this symbiotic and the embodied nature of mathematical communication as speakers were engaged in speaking mathematically. The teachers' deictic gestures served beyond 'pointing' as they were not merely used for indexing but played a pertinent role in communication and facilitated phonological purposes.

A question might arise as to what extent deictic gestures facilitate language production in a mathematics classroom. Also, other questions emerge from the bilingual situation of mathematics teaching and learning in my study. Similarly to what was found for the case of homonymy and homophony and their potential confusion in a bilingual mathematics lesson (see Zagorianakos & Farsani, 2012), the reported data points to the relevance of having more than one language of reference.

The interplay of language and objects in the mathematics classroom

Marei Fetzer[1] and Kerstin Tiedemann[2]

1 Goethe-University of Frankfurt, Frankfurt, Germany, fetzer@math.uni-frankfurt.de
2 University of Cologne, Cologne, Germany

Language appears to be a crucial aspect in mathematical learning processes. At the same time, objects like artefacts or other didactical tools play an important role in those processes. For that reason, we are interested in the interplay of both: We focus on the association of mathematical language and objects in classroom interaction. How does mathematical language vary in relation to objects and their participating in mathematical learning processes? Based on empirical examples, three different forms of interplay are presented.

Keywords: Objects, association, orality, literality.

INTRODUCTION

There is no doubt that mathematics teaching and learning are closely connected to aspects of language. Language is a central learning medium in every class and a content of learning, too. In some cases, it turns out to be a barrier to learning. Empirical research in mathematics education is familiar with research projects about language and mathematics learning (see TWG "Mathematics and language" at CERME over the past years). However, our picture of interactions in mathematics classrooms will be incomplete if we solely focus on oral or written language and, thereby, solely on human beings. There are not only students and teachers who contribute to classroom interaction. Material objects like manipulatives, rulers or diagrams influence the course of action as well. They make a difference in mathematical learning processes. Meanwhile, a sociological perspective that accepts objects as actors in the course of classroom interaction is only on the rise (see Fetzer, 2013, 2015; Kalthoff & Röhl, 2011). Latour introduces a sociology of objects that accepts objects as well as human beings as actors and participants in the emergence of social reality. His actor network theory offers us a new perspective on the interplay of language and objects in the mathematics classrooms (Latour, 2005).

LANGUAGE BETWEEN ORALITY AND LITERALITY

When talking about language in classrooms, researchers often need to specify what kind of language they actually mean. In this regard, Koch and Oesterreicher (1985) offer a helpful distinction that focuses on two fundamental aspects of language: on the form of language and on its function. Firstly, they differentiate the medium of language. Thus, an utterance can be phonic or graphic. For the context of this paper, we only focus on phonic language on face-to-face interactions in mathematics classrooms. Secondly, they identify two different conceptions that an utterance can have. It can be conceptually oral or conceptually written. This affects the question of communication strategies used. More precisely, conceptually oral language is often used when interlocutors are directly related and can refer to a given situation. This is what, consequently, gives a specific form to the language. For example, at any time, the interlocutors can ask questions of understanding, show emotions and influence the course of the interaction. For that reason, sentences may be short and even incomplete. Referring to the given situation, the speakers use deictic expressions and gestures. Thus, orality is characterized by interlocutors who spontaneously negotiate their roles and the course of their interaction. Koch and Oesterreicher call this a language of nearness. Examples are a conversation in the family (medially oral) or a chat among friends (medially written). In contrast, conceptually written language is used when the interlocutors are not necessarily in direct relation and the processes of speech production and speech reception might be separated from each other. Thus, aspects of the situational and cultural context have to be made explicit. As a consequence, sentences are longer and more complex. For example, the writer forms main clauses, but also subordinate clauses to express the relations he wants to inform about. Moreover, he uses more specific terms, e.g. mathematical terms, to be precise and explicit. Koch and Oesterreicher call this a language of distance. Examples are a text of law (medially written) or a scientific lecture (medially oral).

Against this background, one can classify the registers of everyday language and academic or technical language (see Cummins, 2008; Duarte, 2011; Gogolin 2009). Halliday (1985, p. 29) describes a register as "a variety of language, corresponding to a variety of situation". According to Halliday, the use of the term 'register' points to the assumption that individuals usually adapt their use of language to a given situation. Thus, the register of everyday language is rather conceptually oral, irrespective of its medium. It has to fulfil the function of a fast and unproblematic communication in our everyday life. As such, the oral language may be, at any time, supported by gestures or by reference to a context. Words do not have to be clearly defined, sentences may be short or even incomplete. In contrast, the register of academic language is conceptually written, again irrespective of its medium. In academic contexts, language should be as explicit and precise as possible and intelligible without any reference to a specific situation. For that reason, words have to be well defined; sentences might be complex in order to reflect the relations that the author wants to talk about.

REASSEMBLING THE SOCIAL

Latour goes beyond the traditional understanding of the social. His Actor Network Theory (ANT) is a radical change of perspectives proposing a sociology of objects (Latour, 2005). Latour extends the list of actors assembled as participants fundamentally. He does not only accept humans as participants in the course of action. Instead, he integrates and gathers all sorts of actors. "Any thing that does modify a state of affairs by making a difference is an actor" (2005, p. 71). Following Latour, objects participate in the emergence of social reality. Consequentially, Latour recommends a broader understanding of agency. "Objects too have agency" (2005, p. 63), and appear associable with one another, but only momentarily. They "assemble" (2005, p. 12) as actor entities one moment and combine in new associations the next minute. Accepting objects as participants in the course of action, Latour gives up the idea of stable and pre-defined associations and actor-entities. He reassembles the social.

Looking through Latour's sociological lenses, not only the traditional understanding of agency has to be re-defined, but also the notion of action. Objects participate in the course of action and take effect. However, it can be noticed that their mode of action is different from the way human participants contribute to the social interaction.

Mathematics education has to deal with all sorts of (material) objects, didactical tools, artefacts and manipulatives, diagrams and signs. All those objects leave their traces in the emergence of mathematical learning processes and take part in the course of action. Mathematical learning appears to be closely connected to objects and non-human things. Even if Latour himself does not suggest any methods of empirical analysis, Latour's approach proves to be a fruitful background theory for empirical research in mathematics education (see Fetzer, 2013, 2014). Accepting objects as participants in the course of action and following the idea of objects having agency helps us to get a better understanding of mathematical learning processes.

METHODOLOGICAL BASES

The goal of our research is to analyse the relationship between language and objects in everyday mathematics lessons. Probably in every classroom, you can gain insights referring to that topic. To start, we have focused on primary classrooms. However, it was not important to us to observe specific lessons, but rather a wide range of occurring mathematics lessons. Therefore, we observed several mathematics lessons in three different German primary schools. On the bases of videos of the whole lessons, we filtered out those scenes in which humans as well as objects participated. Those scenes were transcribed and became objects of analysis. In order to include a wide spectrum of scenes, we distinguished episodes with and without a teacher.

To get access to interaction processes in mathematics classrooms, our analyses are of a reconstructive manner. They are analyses of interaction (see Cobb & Bauersfeld, 1995). This method refers to the interactional theory of learning and is based on the ethnomethodological conversation analysis (see Sacks, 1996). This method was devised by a working group directed by Bauersfeld. In contrast to conversation analysis, it focuses on the thematic development of a given face-to-face interaction rather than on its structural development. For that reason, it is especially suitable for our research because it allows us to analyse the relationship between language and objects while teachers and students negotiate mathematical meaning. However, reconstructing empirically the way objects participate in learning processes remains unaccustomed. Objects' contributions to classroom interaction become accountable in the process of interweaving. As soon as object-actors become associated with other actors they enter the course of action. Their traces render perceivable and can be captured by a turn by turn analysis (see Fetzer, 2013; Sacks, 1996).

To illustrate our results, we selected four strongly contrasting scenes. 'Diagonal' is a teacher-orientated scene. In contrast, both '1000 dots' scenes are group work situations without a teacher and show an interesting change in the relationship between language and objects. In addition, we chose the very short example 'party hat' in which the object is not present at all, but still a point of reference.

EMPIRICAL EXAMPLE I: 'Diagonal'

The following scene is taken from a lesson about the hundred field. The teacher and the students start by repeating what they already know about the hundred field. Thus, a student says that a column „goes from top to bottom or from bottom to top". This utterance is confirmed by the teacher. Then, another student (Danis) puts up his hand and is asked, but the teacher does not pay attention to him. The scene starts when the teacher turns back to Danis. On the mentioned hundred field, no numbers can be seen. They are all covered by coloured squares, the upper half is red, the lower one is blue. In the transcript, the squares are named by the corresponding numbers in order to facilitate the reading.

26 Teacher: [...] How does the diagonal run?

27 Danis and 100 field: *[going to the blackboard:]* Well, like this.
[on the 100-field from the 60 to the 96] Here for example. Then, I move like this.

Figure 1: Material of the hundred field

28 Teacher: Can you also explain that with words? Now, you have already shown that to us.

29 Danis: *[sits down again]* Well, that works for example like this. .. that I am atthe ten and the 91. I can because the corner and the diagogal runs simply *[moving his finger in front of himself from top right to bottom left]* like this. .. Dialogal. .. But it can't go up and it can't go down or right or left.
[Comment: In German, Danis says "diagogal" and "dialogal" which are, like in English, not the correct words.]

In this scene, Danis and the teacher pick out the diagonal as a central theme. As the teacher is talking about "the" diagonal, one could think that there is only *one*. In contrast, Danis shows two different diagonals, one from 60 to 96 and another one from 10 to 91. One can only guess what his definition of a diagonal might be, but one can see that he identifies more than one diagonal on the hundred field. His two references to a diagonal show a difference concerning our research question. In the first one, Danis points at the hundred field with his finger and, thereby, integrates it into the discourse as a participant. In connection with the object, Danis' utterance gets intelligible. Thus, one can say that the object changes its status and becomes an active participant in the discourse. Danis and the hundred field get interwoven. With the object completing Danis' utterance, the boy's language gets reduced and deictic ("like this", "here", 27). Taking over the turn, the hundred field allows Danis to use an easier, more oral language. He only forms main clauses that are not clear without reference to the concrete situation including the hundred field.

In the second part of the scene, we can reconstruct the opposite. The teacher explicitly asks Danis to give his description in words. Thus, he is confronted with the task to describe the same mathematical phenomenon, but without any direct reference to the object (and maybe even without gestures which do not belong to the category of words either). This interpretation is confirmed when Danis goes back to his chair, sits down again and, thereby, distances himself from the hundred field. Now, the object is no longer a participant of the discourse. Instead, Danis develops a second description of a diagonal solely by the use of words and a gesture. One can see that excluding the object from the course of action means to exclude its actions. Now, Danis has to take over again: He has to compensate the missing object by being more specific in his language. For example, he now names the two "corners" of the figure whose diagonal he is talking about. Furthermore, he starts forming more complex sentences ("because the corner...", "... and...", 29). In summary, one can state that the language is more orientated towards written language.

EMPIRICAL EXAMPLE II: '1000 dots'

In contrast to the first scene, there is no teacher participating in the scene '1000 dots'. Two girls, Martina and Sonja, are sitting at a table. On the table, there is a sheet with the task 'Share 1000 dots fair-mindedly between three children', a pair of scissors and a box containing 100-dots-cards (small cards with each showing 100 dots arranged in lines of ten). First, the two girls try to figure out the task on their own. Once they get a leftover of ten dots they get stuck. This is when the selected scene starts.

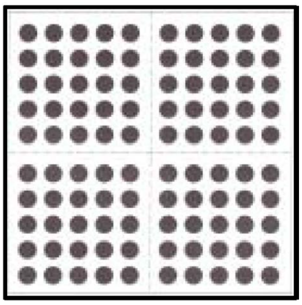

Figure 2: Material of dots-cards

167 Martina and cards: *[reaches with her left hand for the box with the 100-dots-cards]* Shall we make use of them?

Figure 3: Box with the dots-cards

168 Sonja: *[looking at the cards in Martina's hand]* Yes.

169 Martina, box, cards: *[takes the pile of cards out of the box and pushes the box away]*

Figure 4: Student in interaction with the material

170 Sonja: Cause it's difficult, isn't it?

171 Martina and cards: OK. *[puts cards from her hand down on the table like sharing out a deck of cards]* One, two, three.

As soon as the girls get stuck in their solving process, they invite the 100-dots-cards to participate ('cause it's difficult' <170>). These object participants breathe new life into the solving process. Assembling with the girls and the table, the cards embody (at least) one fundamental intermediate step in the solving process: instead of just representing the situation, they *are* the 1000 dots that have to be shared between three children. Their lasting quality contributes to a better orientation within the social solving process. Being arranged in a pile of ten cards they take over the part of a reliable basis. Thus, one can see that objects are not only useful for expressing one's own ideas, but also for developing new ideas that can push the solution process forward. The girls' language changes once the object-actors enter the stage as participants. The association of cards and girls can be reconstructed in the reduced character of the chosen language: short utterances like "of them" <167> or "one, two three" <171> intertwine with the objects and their manifest and structuring message.

Some minutes later, the girls approach a mathematical result: 999 dots lie there separated on three piles. While Martina is cutting the last dot in pieces, Sonja is worrying about the correct result.

917 Sonja Yes, but how much *do* the little ones *count?* How *much?*

918 Martina, pieces, scissors *[laying a little piece of her last cutting action on the middle pile]* A fourth, half of a fourth. *[laying another little piece on the right pile]*

While the solving process is coming to an end on the level of objects, Sonja is worrying about an appropriate language for what the girls can see in front of them (917). The non-human participant was irreplaceable in the solving process. But, subsequently, in order to fix the result and present it to others, mathematical language gets relevant. The girls obviously do not regard the task as completed until they can express their result by means of language, too. Thus, mathematics as a social practice needs a precise language to fix, to communicate and to discuss its results. While the language was relieved during the intensive search for a solution by means of the available object-participants, it now gets more demanding again. Martina forms a description of what the "little ones" count which is comprehensible regardless of the concrete objects. Her language develops from conceptually oral to conceptually written forms. She expresses a mathematically *new idea*, the idea of fraction. By this step in their work, the girls facilitate a precise mathematical communication with others, e.g. their classmates.

Considering both succeeding scenes, they illustrate the development from an orally orientated language in the first scene and the beginning of scene two towards a rather written conception of language including mathematical terms ("a fourth, half of a fourth"). In both examples the object-actors can be reconstructed to be participants. However, their mode of action varies within the emergence of the solving process. At the beginning, they contribute their structuring and lasting quality to the course of interaction. They invite the girls to share the dots out right to the end. Thus, the cards and dots prompt Sonja and Martina to cut the last dot into bits and pieces. Later lying on the table, the mini-objects release the strong requirement for a precise term to label them. They call for language, they demand for mathematical description on a rather written level.

EMPIRICAL EXAMPLE III: 'Party hat'

In the last scene, there is actually no object participating at all. It is only present in the mind of the human participants. In the lesson, the students have worked on their own around the following task:

> Which of the two flatplans fits the three-dimensional figure?
> Why does one of the flatplans match and the other one does not?

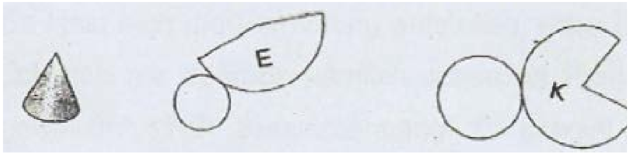

Figure 5: Two flatplans and a three-dimensional figure

Later the students compare their results in the whole class. In the selected scene, it is Dominik's turn to present his findings.

1	Dominik:	K works because the gap is smaller. Cause I have already made myself a party hat of that, you know.
2	Some pupils	*[whisper and nod]*

Dominik puts forward an empirical argument that relies on (his own) experience. He creates the context for his argument exclusively on a phonic level with spoken words. By talking about the party hat, Dominik includes the hat as an actor within the course of action. As such the party hat seems to have the power to convince the other children of the verbally presented decision 'K works'. The party hat is not present at all, but it is replaced by language. In other words, the party hat solely takes part in the interaction in form of its linguistic representative.

EMPIRICAL RESULTS AND CONCLUSION

Objects do play an important role in mathematical learning processes. They may become participants in the course of action and contribute to the emergence of social classroom reality. In our research, we basically differ between two learning situations: Those situations, when objects are to be seen as participants in the course of classroom interaction, and those, when human participants act without reference to objects. In the context of our study the first case might be called 'Language and objects' and the second case can be characterised as 'Language without objects'.

Concerning situations we call 'Language and objects', there are two cases to be observed. Sometimes, object participants and human actors *assemble in their actions*. In these cases, *objects take over part of the turn*. Action is no longer attributed to one single actor but to actor entities, actions are experienced as combined actions. If objects and students assemble in their actions and humans have to take over only part of the turn, language proves to be rather conceptually oral (compare the scene 'Diagonal'). However, the assembled action appears to be 'complete'. Other participants can reconstruct the meaning that emerges. This is the crucial point. If objects participate in the course of mathematical action and take over part of the turn, they thus relieve students on the level of language. This might be an initial opportunity for children with poor language performance to act mathematically.

In other situations, *human actors and objects interact in turns*. In these cases, objects take over whole turns, and students react to those turns. If human actors invite the objects to be a part of the discourse, objects can challenge the students to find a new language (compare the second part of the scene '1000 dots'). We could observe that in these situations language tends to be rather conceptually written. This aspect is of special interest from a didactical point of view. Objects cannot only relieve students on the language level, but also challenge them. They can be 'supporters' in the development of mathematical thinking and of a precise mathematical language.

When looking at situations that we call 'Language without objects', we observe that associations between objects and humans dissolve. Students are obliged to take over each turn on their own. Accordingly, they become responsible for the idea and for the formulation of the intended utterance (see the second part of the scene 'Diagonal'). For that reason, students have to be as explicit as possible in their language. They might use well-defined mathematical terms and rather complex sentences. They might give many explanations about the context of culture and of content in order to be clear about the given topic. Language turns out to be conceptually written.

Summing up, we see conceptually oral language when students and objects assemble in their actions. In contrast, we find conceptually written language, when associations between human and non-human actors dissolve. Finally, we observe a development of language from conceptually oral to rather conceptually written forms, when human actors and objects interact in turns. These situations of language development can be seen as the situations of mathematical learning. Maybe, further research can show how the interplay of language and objects depends on the kind of material that is part of the discourse.

Using gaze tracking technology to study student visual attention during teacher's presentation on board

Enrique García Moreno-Esteva and Markku S. Hannula

University of Helsinki, Department of Teacher Education, Helsinki, Finland, Enrique.garciamoreno-esteva@helsinki.fi

We present some initial findings obtained from a study on student attention in class using mobile gaze tracking technology. In this descriptive case study, we use a teacher's verbal, gaze, and gestural cues to identify the area on the board she wants her students to focus on, and analyse how one student's gaze location is shifting in relation to this. We found out that the student was actively following the cues during most of the time. However, we also observed moments when the student's gaze location was not in synchrony with the teacher's cues. The gaze tracking methodology seems to be a promising tool for a fine grained analysis of classroom communication and student attention.

Keywords: Mobile gaze tracking, student attention in mathematics classes, teacher gestures and indications.

INTRODUCTION

An important aspect of teaching is the multimodal communication (Radford, 2009; Arzarello, Paola, Robutti, & Sabena, 2009) between teachers and their students. Using mobile gaze tracking technology we will take a close look at the way a student's visual attention responds to cues from the teacher when the teacher is presenting new content on the board.

The teaching act is twofold. There is a pre-planned element of what the teacher does, which may be well planned and rehearsed several times over the years. There is also an improvisational element, reaction to unexpected student questions or comments, which requires the teacher to think 'on her feet'. Both of these modes of action include consciously chosen words, prosody, gestures, and facial expressions. However, some of the visible and audible messages are not consciously chosen, but are enacted more or less automatically, or even unconsciously.

Roth (2012) gives an example of a university professor whose dis-fluency he sees as an indication of the communicative act not being completed 'in mind' beforehand. Rather, it is "an unfolding event of communicating and thinking, which are not ready-made but develop in real time" (p. 237). Radford (2009) claims that "thinking [...] does not occur solely *in* the head but *in* and *through* language, body and tools" (p. 114).

The student side of classroom interaction is more complex than the simple receiving of messages from the teacher. Student behaviour in class is based on the student's personal agency, which is determined by his or her needs, goals, and identity. At the same time, student behaviour is largely reactive to changes in the environment, especially to what the teacher and the student's peers do. There is no research method that can provide a full account of meanings of this behaviour and reasons for it. Clinical interviews and think-aloud protocols distort the social interaction in class and thus lack ecological validity. Interviews done afterwards (including stimulated recall) can only have access to the student's post hoc reconstructions. Moreover, all self-reports are subject to be biased towards socially acceptable responses. Observations of facial expressions, brain imaging, and other physiological measures fail to capture the meanings students associate with their behaviour. Yet, each new methodology has shed light on some new aspects of the complexity of student cognition.

In this research report we shall present results from a pilot study using a mobile gaze tracking device to record students' visual attention during mathematics lessons. Gaze tracking is an established method for the study of attention at the automatic level of processing, in which the person is not consciously aware of fixations and shifts of attention. However, until recently, the technology had only been applicable in laboratory settings. Only now is it becoming available for use in ecologically valid situations such as outdoors (Baschnagel, 2013; Foulsham, Walker, & Kingstone, 2011) or in classes (Yang, Chang, Chien, Chien, & Tseng, 2013; Rosengrant, 2013).

THEORETICAL FRAMEWORK

Human communication consists of more than just words and diagrams; gestures, glances, body movement, prosody are also important aspects of it. Roth (2012) and Radford (2009) claim that there is a debate on the relationship between different communicative modalities. Some contend that both speech and gesture originate from the same psychological structure, while others claim that speech and gesture originate from different psychological structures. Still others claim that speech and gesture are different communicative channels, and that gesture serves a subordinate function.

Goldin-Meadow (1999) points out that the importance of non-verbal aspects of communication such as gestures has been recognized for a long time, at least two thousand years, in theatre, rhetoric, philosophy, and language. She identifies two different types of gesturing: gestures that substitute speech (e.g., sign language) and gestures that accompany speech, often unconsciously. She also points out that gesture enriches communication by providing a different representational format. For a speaker, gesture reduces cognitive burden, helps retrieval from memory, and is a tool for thinking. Gestures have also been observed to be important in the process of forming new concepts (Goldin-Meadow, 1999; Arzarello et al., 2009; Radford, 2009)

In gesture studies, McNeill's (1992) categorisation has been used frequently. He identified four different types of gestures: 1) beats, that do not have content information, but give rhythm and emphasis for talk, focus attention, and coordinate taking turns; 2) deictic gestures (pointing), that point to something concrete or abstract and typically have a verbal counterpart such as 'here', 'there', 'that', 'me', etc.; 3) iconic gestures that pictorially represent the target, for example, by drawing in the air; and 4) metaphoric gestures, that also create an image, but such that the image refers to an abstract concept metaphorically.

When teachers teach mathematical concepts, gesturing – and especially pointing – is common (Alibali & Nathan, 2012). Pointing gestures reflect the grounding of cognition in the physical environment, and pointing can be used to highlight connections between related representations. This exemplifies the need to interpret communication in context, which considers the material and graphical structure of the interaction (Goodwin, 2003; Arzarello et al., 2009).

Sweller and his colleagues have studied the influence of split attention on cognitive load (Yeung, Jin, & Sweller, 1997). Their studies show that when attention is split between two sources of information, a higher cognitive load may impede learning. This effect can be ameliorated when the sources of information are physically integrated. However, the effect is dependent on the student expertise. For more advanced learners additional information may be nonessential and impede learning.

Our research project will study student attention to mathematical diagrams and script on the board during mathematics lessons. Our focus in this paper is how well teacher talk and gestures direct student attention. In our study, we are specifically interested in student navigation when information is presented in two distinct areas, and in how effective is the teacher use of gesturing to help students integrate two sources of information. To our knowledge, no previous study has analysed students' visual attention in classroom situations using gaze tracking.

METHODOLOGY

In order for the researchers to monitor a student's attention in class, the student wears a gaze tracking device, which consists of a glass frame equipped with miniature cameras which produce a video scene and keep track of the direction that the eyes are pointing at. This device allows the software calculation of the direction of the gaze in class, producing a video scene with a dot indicating the locus of visual attention of the person wearing the glass frame (see Figure 3). The gaze tracking glasses are connected to a laptop with two cords, which prevents the student from getting up, but does not restrict movement while seated. The device was developed at the Finnish Institute of Occupational Health in collaboration with Aalto University (Lukander, Jagadeesan, Chi, & Müller, 2013). The prototype of this device is used in this study (see Figure 1). In addition to gaze tracking, there is another video recording of the class from behind, focusing on the teacher and the board, and there is a third video focussed on the subject student wearing the glass frame.

The data is obtained from a Finnish eighth grade classroom in a school where the language of instruction is English and where our subject student is a native English speaker (in this school, the students are bilingual). The subject wearing the glass frame was chosen on a voluntary basis. Informed consent has been obtained from the teacher, the focus student, all other students seen in any of the pictures, and their legal guardians.

The video recording we analyse shows a teacher explaining the topic of linear equations and relating

Figure 1: The gaze tracking device

them to the geometry of the lines using GeoGebra on a Smartboard. The dynamic functions of GeoGebra are not used, but the teacher draws additional lines and symbols on the Smartboard as shown in Figure 2. Specifically, throughout the approximately five-minute clip, a couple of lines appear on a Cartesian coordinate system. The lines intersect at a point (point P1 in Figure 2). Then the following sequence of events ensues. The teacher explains how to find the y-intercept of the first line (line L1, point P2, equation E2), and then, how to find the gradient of the same line by locating a second point (in this case P1) on the line and identifying the rise (segment S1) and its length (N1) and the run (S2) and its length (N2) from the lower point to the higher point. The gradient is calculated (E1). She then identifies the y-intercept and the gradient of the line in the equation of the line (in region Q). The same procedure is repeated for the second line (L2). The y-intercept (P3) is located and its value noted (E3), and a second point (P4) chosen in order to find the rise (S3) and its value (N3) and the run (S4) and its value (N4). The value of the gradient is calculated (E4). Finally, these values are identified in the equation corresponding to the line in region Q. In Figure 2, we identify all the areas of interest to which the teacher makes reference.

We made two segmentations of the video clip in the following way. First, we segmented the clip according to what we think are the areas of the board to which the teacher wants to bring attention, as indicated by the teacher's verbal cues, hand movements, and gaze. We then segmented the clip according to the student's

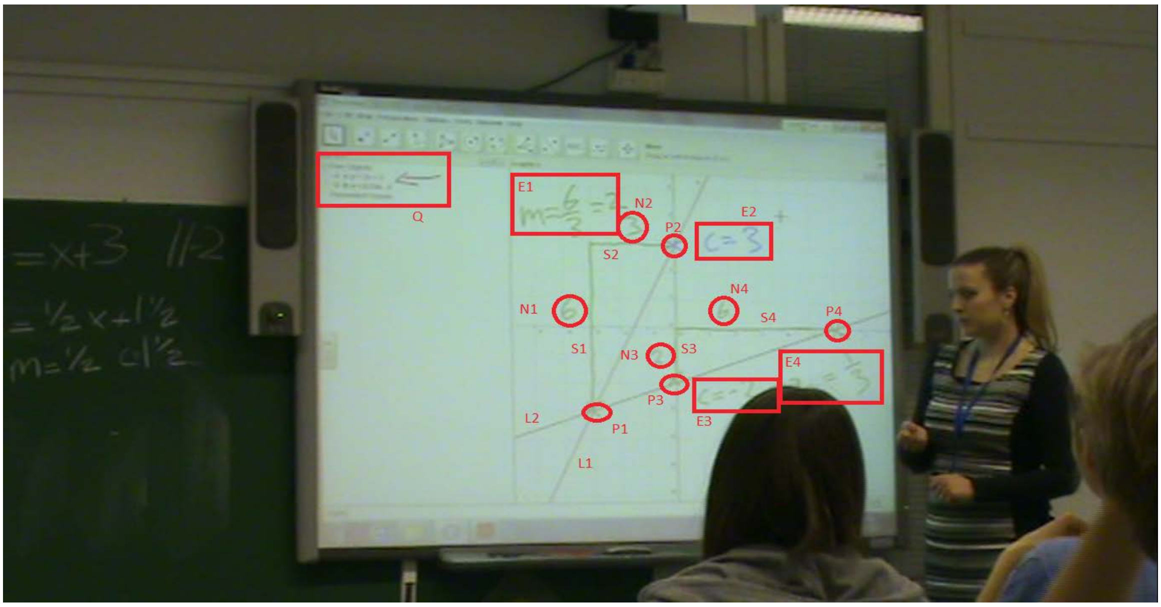

Figure 2: The board with the various regions of attention

gaze location – gaze is typically located for a short period of time at a certain position on the board before moving on to another location. Occasionally, there are glances which move away from a position and back to the original position, or somewhat rapid, but not too rapid shifts back and forth between two spots. We interpret these to indicate that the student attention is split between two areas and in these cases we coded both locations for the gaze. We then analysed the segments in order to find regions where gaze location follows the teacher's cues that direct attention distinctly, and regions where this is not the case.

DESCRIPTION AND ANALYSIS OF DATA

For most of the time during the teacher's presentation, the student gaze location follows teacher's cues quite well. However, there are also moments when this is not the case. We present a detailed analysis of two sections of the clip. Specifically, we shall analyse moments when the student's attention is not matching the intended area of attention. These sections occur after the teacher has finished explaining how to calculate the *y*-intercept and the gradient, and proceeds to link this information to the equations of the lines.

In the first instance (for line 1) the student follows the teacher's indications closely. In the second instance, the student gaze does not follow the pattern indicated by the teacher. The transcriptions follow. We have provided the graphic in Figure 4 to facilitate visualization of the ongoing processes. In the graphic we show how the area of intended attention (AIA) segments interlace in time with the gaze location (GL) segments for each of the two lines discussed by the teacher, line 1 (Line 1) and line 2 (Line 2). The bars representing each segment have been colour-coded according to the area of intended attention or the area where gaze is located: red is the code for the Q area, blue for the teacher's face or hands (T), white for unspecified locations, and other colours for other areas.

For the discussion pertaining to each line we provide the following information. First, we provide the beginning time of the segment and the transcript of what the teacher is saying. We then indicate if there are verbal, hand, or gaze cues that might be used to focus the student's attention onto an intended area of attention and what we perceive to be the intended area of attention. To the right of the transcript of the teacher intervention, we give the same information

Teacher			Student	
Time (ms)	Utterances [actions and non-verbal cues that indicate the area of attention]	Intended area of attention	Time of gaze shift (ms)	Gaze location
742006	and as you can see [glances briefly at equations in area Q]	Not specified	742014	Teacher face
742966	actually [takes another pen]	Not specified	743341	Q
743611	the equation of this line is here [draws an arrow pointing at the equation; gaze and gesture] (Figure 3c)	Q		Q Teacher face Teacher hands Q
748697	you can see that yes, [gaze and gesture]	P2, E2	 749137	P2, E2 Q
	the y-intercept [gaze and gesture]	E2, Q	750496 751959	Teacher face Q
752007	is the number that stands alone [gesture, glance]	Q	753940	Teacher face
754704	and the gradient [gaze and gesture]	E1	755372	E1
756229	is the number [gaze and gesture]	Q	756602	Q
757503	that is the coefficient of x [gesture only]	Q	757743 759268	Teacher face Q
760510	End of sequence		764774	

Table 1: Teacher behaviour and student gaze when the teacher explains the connection between gradient and y-intercept values and the equation for line 1

for the gaze location, except for a transcript. Notice that in some instances, there might be more than one intended area of attention, and in some instances the gaze location information might include two regions if there is a sequence of rapid shifts of gaze location between two spots. First we provide the data that concerns the discussion of line 1.

In the beginning of the segment we see the student focusing on the equation of the line before the teacher gives any explicit indication. Upon closer analysis, we see that when the teacher has finished the previous stage and before she picks a new pen, she casts a brief glance towards the equations. This was very difficult to observe and we noticed it only as we were carefully trying to find the reason why the student moved his gaze into the area where the teacher would move a fraction of a second later. We believe that the student observed the brief glance of the teacher as he was looking at the teacher's face, and therefore was able to react to the teacher's utterance, "as you can see" with a foresight as to where the teacher was likely to focus next.

Next, the teacher is trying to connect the explanation of the *y*-intercept and gradient to the equation of line 1, and the student's gaze location follows the teacher's indications to attend to area Q very distinctly (Figure 3c), and indeed to other areas as well, as can be seen from the top two bars in Figure 4 (in Figure 4, red codes the Q area, and blue codes the teacher's face or hands). What we see in this segment is how the student's gaze shift to the area of intended attention is in slight delay with respect to the teacher's cues. Also note how attention in this section is split between the equations of the line on the left (Q) and the values of *y*-intercept (E2) and gradient (E1) on the left. The teacher uses pointing gestures to successfully guide the student's attention across these two areas of interest.

Now we provide the data that pertains to the discussion of line 2. The student again anticipates the teacher movement to discuss the equations, but he does so substantially earlier (Figure 3a, first red bars in the upper and lower tiers of Line 2 in Figure 4). Moreover, he dismisses the teacher's direction to attend area Q at the end of the intervention (Figure 3b). We speculate as to whether this is partially due to the fact that she moves and turns around and is no longer facing the student; it would seem as if the student wants to see what he thinks the teacher is looking at. In any case, the teacher's pointing gestures are well visible in the student gaze video, but he does not direct his gaze as a reaction to the teacher's actions. This could be an example of self-initiated shifts of attention based on the student's active construction of his own understanding. Also, this might indicate a lack of attention, a blank stare.

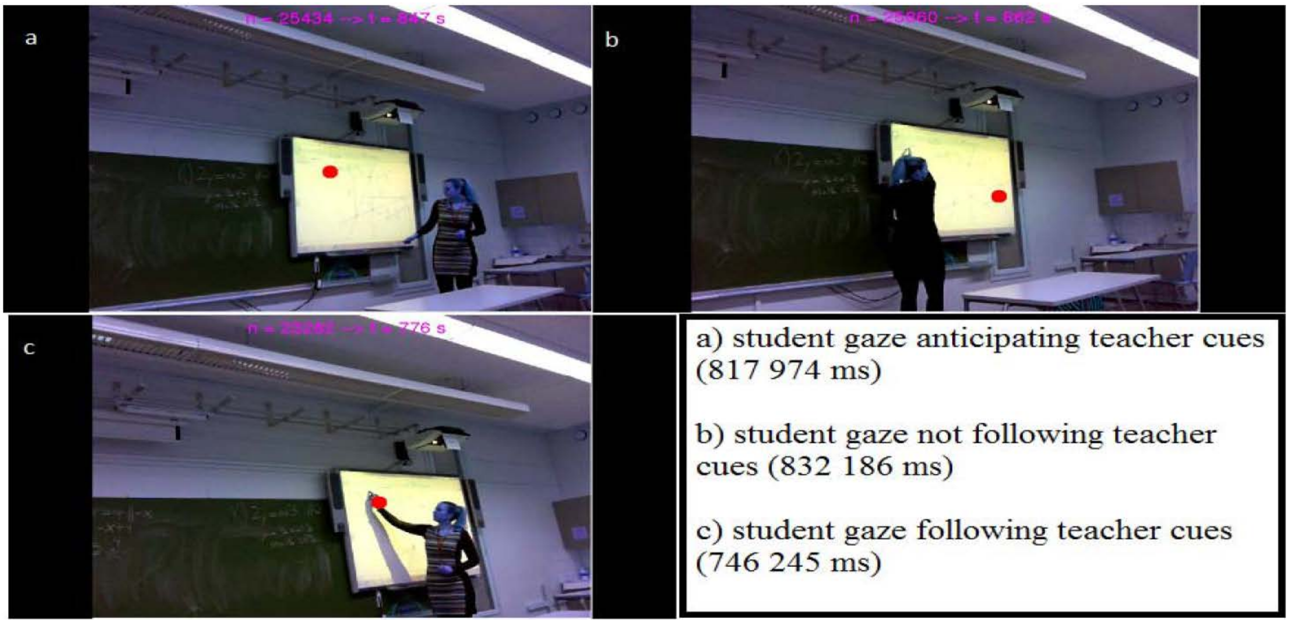

Figure 3: Pictures showing the situations described in the data analysis (Due to calibration error for this distance, the red dot indicating the student gaze location is systematically about 20 cm too much to the right)

Teacher			Student	
Time (ms)	Utterances [actions and non-verbal cues that indicate the area of attention]	Intended area of attention	Time of gaze shift (ms)	Gaze location
817115	pause, changes pen [no gaze, no gesture] (Figure 3a)	not specified	817105 818231	Q teacher hands
818733	this one uses approximate values [gaze, gesture]	Q	819104 819657	teacher face Q
821333	the correct answer there would be one over three (mumble)	Q	821621 822716	teacher face E4
826416	and the same thing again, can I find the [gaze, gesture]	E3		E4
829920	y-intercept [gaze, gesture]	P3	830243	P3
830920	here, the constant [gaze, gesture, teacher turns her back to the student] (Figure 3b)	Q	834352	Not Q, L2
835021	the eeh [gaze, gesture]	E3		Not Q, L2
837102	coefficient of x	Q	837078	S2, N2
838424	is the gradient	Q, E4		S2, N2
840141	End of section		840601

DISCUSSION OF RESULTS

In previous research, the reliability of coding for gestures, speech, and their relationship has typically been high (85%-94%) (Goldin-Meadow, 1999). It seems likely that observing explicit gestures is very natural for human observers, which allows high accuracy. However, when we first watched the video, we did not notice the teacher's glances which, nevertheless, were used as cues by our focus student. This highlights the importance of paying close attention to the teacher's glances in future analysis on student visual attention.

The sections analysed are examples of a well preplanned teacher explanation. Yet, it includes unconscious cues (gaze cues such as glances). The student can follow the explicit cues very well, but is also observing subtle cues. Throughout the whole five minute sequence, the student splits his attention between the board and the teacher's face. In the sequences of closer analysis, there was additional split attention when the teacher connected inscriptions on two separate areas of the board. In both cases of split attention, the student seemed to have no problem following the teacher's cues. In summary, the student seems to be following the teacher's explicit gestural cues and subtle gaze cues quite closely.

However, when the teacher repeats the process for the second line, the student's gaze does not follow the teacher's cues. There are several hypotheses for why this happens. One option is that the student is processing the situation independently and is able to move ahead of the teacher, as indicated by his movement to the equations for the second line well before the teacher's. Another explanation is that the teacher's gaze is such an important cue for the student that when he loses it, his attention begins to drift. There is also the possibility that the student loses interest, due to the repetitive nature of the activity. Although the student's gaze continues to be on the board, it is possible that he is not attending to what he is looking at. We note that just observing the student does not provide information which we gather from gaze tracking data. We see from our data that when the teacher is explaining the first of two examples on the board, the student follows closely, but when she explains the second example, the student is looking towards the board, but is no longer following her explanations closely, lending credence to the usefulness of our technique.

Emotional interactions of high achieving students in mathematical argumentation: The case of Jasmine

Rachel Hess-Green[1], Einat Heyd-Metzuyanim[1,2] and Orit Hazzan[1]

1 Technion, Haifa, Israel, rachely.hg@gmail.com

2 University of Pittsburgh, Pittsburgh, USA

The study of emotional aspects of interaction may tell us much about the social norms and the meta-mathematical rules according to which participants act during their mathematical activity. To illustrate this idea, we present the case of Jasmine, a 16-year-old student participating in a summer camp intended for exceptionally high achieving students in mathematics. Through a commognitive analysis of the interaction between Jasmine and her instructor (the first author), we examine the implicit meta-rules of discourse according to which the two participants acted and that, at a certain point, led to Jasmine's frustrated disengagement from the discussion. Adding the concept of "framing" shows that this episode could be characterized by the student and instructor's "misaligned frames".

Keywords: Emotion, interaction, students, mathematical argumentation.

INTRODUCTION

In past decades, a growing amount of research has been dedicated to the examination of student affect and emotions in mathematical learning (Hannula, 2012). However, most of this research has been concentrated on students' subjective experience, as elicited by self-reports. More recently, researchers have started looking at the effects of emotion on student-student and student-teacher *interactions* (Heyd-Metzuyanim & Sfard, 2012). These studies have been inspired by a sociocultural lens that sees learning as a form of participation in a discourse. Emotional expressions are an important part of any human communication and thus make up an important and indispensable piece of the puzzle when one wishes to understand how learning takes place in real-life situations.

The socio-cultural view has been used in research that attempts to show the marginalization of students who get disengaged from mathematics (Boaler & Greeno, 2000; Heyd-Metzuyanim, 2013). However, rarely has this lens been turned to the learning of students identified as 'mathematically gifted'. In the present study, we employ such a lens to examine the ways in which emotions, social interactions, and mathematical cognition interact in the activity of high-level mathematical problem solving practiced in a summer camp for mathematically gifted students. We do so by using the *communicational* (commognitive) method for examining mathematical discourse as it intertwines with identity construction in mathematical learning (Heyd-Metzuyanim & Sfard, 2012; Sfard, 2008). Our goal is to explore the analytical tools that may shed light on the affective side of teaching-learning interactions in settings where students engage in high level mathematical argumentation.

IDENTITY, GIFTEDNESS, AND MATHEMATICAL ARGUMENTATION

Studies about mathematical giftedness have mainly examined cognitive aspects of learning (Leikin, Berman, & Koichu, 2009). Whenever studies about giftedness examine affective aspects of learning, they do so from an individual perspective, using concepts like self-concept and self-esteem (Zeidner & Schleyer, 1999). Despite the fact that emotions and self-perceptions have been acknowledged as important for understanding gifted students' learning, rarely have they been studied as they take place in these students' mathematical learning. Similarly, the literature about mathematical argumentation rarely deals with the emotional side of argumentation.

In the present study, we focus on *communication*, including its emotional and non-verbal aspects, to integrate the study of mathematical cognition, social interaction and emotions in the activity of mathematical argumentation. We do this by using the communicational (commognitive) framework (Sfard, 2008), whose main tenet is that thinking can be viewed as an intra-personal type of communication, not qualitatively different from inter-personal communication. Within this sociocultural framework, learning is conceptualized as participation in a specific type of discourse (here, the mathematical discourse). Discourses, claims Sfard, are defined by four characteristics: word use, routines, visual mediators and endorsed narratives. In mathematics, all these are used to create discursive objects such as "2", or "prime numbers". Sfard (ibid) defines learning as a *change in discourse* and differentiates between two types of such change: object-level learning, where students learn new routines for dealing with familiar objects, and meta-level learning, in which the *meta-rules* of the discourse change. Meta-rules define patterns in the activity of the discursants trying to produce and substantiate object-level narratives.

Heyd-Metzuyanim and Sfard (2012) pointed to the fact that while learning mathematics, students do not just participate in the mathematical discourse (or mathematize), they also participate in an *identifying* discourse whose main goal is to produce narratives about oneself and others. In line with Sfard and Prusak (2005) they defined identity as a collection of stories that are reifying and significant, told by a person about herself (1st person identity) or by others about her (3rd person identity). Identifying discourse, or discourse that constructs identities, is made up of *subjectifying* utterances, whose object is people (rather than mathematical objects). However, not all subjectifying utterances can be categorized as identifying. Only those utterances that relate to stable, significant attributes of the person (such as "she is mathematically gifted") are considered to be identifying. Subjectifying (and to certain degrees identifying too) can be, and often is, communicated via non-verbal or indirect means. For instance, emotional expressions almost always communicate some sort of subjectifying message (such as "this is embarrassing for me"). Heyd-Metzuyanim (2013) has shown that focusing on the *disruption* of routines can provide useful insights into the meta-discursive rules that often go unnoticed in teaching-learning situations, in particular to the meta-rules of identification. These are implicit rules governing who is supposed to refer to certain actions (e.g. a student giving a correct answer, a teacher challenging a student's claim), what certain actions convey about participants, and what emotional responses are appropriate for certain situations. We incorporate the concept of "framing" to better articulate the discrepancy that can occur between sets of meta-discursive rules (Goffman, 1974; Tannen, 1993). Tannen (1993) explains framing as the participants' sense of "what is going on" in the interaction. Within a communicational framework, we conceptualize this as participants' sense of the meta-rules that are governing the discourse in which they participate. Disruption in routines, and the emotional reactions that accompany such disruptions (Giddens, 1984) may point to *misaligned frames* (Sande & Greeno, 2012) of the interlocutors. In the present study, we ask: what may emotional reactions of participants in a mathematical discussion tell us about misaligned frames, or different meta-discursive rules according to which the interlocutors are acting?

THE STUDY: SETTING AND METHODS

The research was conducted in a mathematical camp for "mathematically gifted" youth (20 participants aged 15–18) that took place during the summer vacation where the first researcher acted both as a researcher and an instructor. It lasted two weeks and included both mathematical and social activities. Throughout the course of the camp, participants engaged in both group and individual study sessions. The group sessions took place with the guidance of an instructor who is a mathematician (holding at least an M.A. in mathematics). The first author was one of these instructors. Every day the students were given a worksheet of problems that progressively increased in their difficulty. Twice a week students were given the opportunity to present problems on the board that they had previously solved and get their solution 'peer reviewed' by their fellow students.

Lessons and social activities were videotaped, in addition to interviews with students during the camp and recordings of episodic happenings such as casual conversations that took place after the study sessions. The first author held a research diary in which she documented the events taking place during the day including her feelings about these events. Based on this diary, we chose for close examination several events, in which it was clear that some emotional interaction was taking place, along with a rich mathematical discussion. These events were transcribed, including interviews and casual conversations that were relevant for understanding the event. The excerpts presented in this report were translated from Hebrew by the authors.

In this report we focus on one event that happened during a "peer-review" session. In it, one of the most active students in the group, Jasmine, volunteered to present her solution to an advanced problem that was given the previous day. The data for this analysis consisted of the recording and transcription of the lesson, as well as recordings of spontaneous conversations about the incident that took place after the lesson and a semi-structured interview with Jasmine at the end of the camp.

The analysis was based on the communicational framework, as presented above. In particular, we focused on three aspects of the communication between participants: a. the mathematical objects being talked about b. the subjectifying/identifying messages of the interlocutors about themselves and about each other; and c. the meta-discursive rules, or framing implied by these subjectifying messages. For instance, Jasmine's expressions of embarrassment or dismay were interpreted as indicative of an incident in which the happenings were misaligned with what she expected to happen or thought should have been appropriate for the situation. The interpretation of emotional expressions was based on the first and second author's view of the videos, in addition to Jasmine's description of the episode later in a casual conversation with other students. In particular, the interpretation of emotional signals and implicit identifying messages was based on our familiarity with the culture where this incident was taking place. Moreover, though we use Jasmine's report as a source of information, we should clarify that our method for analyzing emotional expressions does not necessitate 1st person reports of their emotions (or feelings). Rather, our method focuses on the communicational work that is done by emotional expressions, that is, how they are interpreted by others (see Heyd-Metzuyanim & Sfard, 2012).

FINDINGS – AN EPISODE OF ARGUMENTATION THAT WENT ASTRAY

The given problem was: *Prove that for each number n! + 2, n! + 3, ..., n! + n there is a prime divisor that does not divide any other number from this set.* None of the other students had solved this problem before. Jasmine was the only one who claimed to have solved it. Whilst starting to write her proof on the board, she noticed one of her peers starting to copy it. Alerted, she said "wait, why are you copying it?... what if I do something wrong?"

Figure 1: One of the drawn diagrams

Figure 2: Another drawn diagram

One of her peers responded "no worries, it happens". This instance of subjectifying already indicated that Jasmine was somewhat concerned with her identity as told by the other participants when walking to the board. Yet right after that she went straight to mathematizing. She began her proof by drawing the diagram seen in Figure 1 explaining it by: "So there is a number N! and then one takes it and adds to it all sorts of things, that's my famous diagram" [13–14]. Again, this rather casual remark about her "famous diagram" indicated that Jasmine was thinking about the way her solution is perceived by others. However, this indirect identifying remark went unnoticed within the rest of the proof, the main argument of which was as follows:

Jasmine's proof

"So that... I added 2, so the number won't be divisible by any number that is smaller than N except 2. OK? Good. And then if I added 3, then it (points to N!+3) won't be divisible by any number smaller than N except 3. And then, once we reach four, that's a multiple of two, then this number (points to N!+4) can also be divided by two. Then, wait, but it *must* be divided also by another prime factor that is greater than N" [19–25].

As she was talking, Jasmine was accompanying her explanation by drawing a diagram of N!+2 and N!+4, visually mediating their divisibility by 2 and another prime factor p or q as seen in Figure 2. At that point, the instructor interrupted, asking "why did you say that?"[27]. Here occurred the first failure in communication. While the instructor referred with the "that" to the claim that there are only two primary divisors of N!+4, Jasmine understood it as referring to the signification of the second prime number with q (and not p). She explained "'cause otherwise it would be the same number" [28]. However, since the misunderstanding of the teacher seemed to be related (at least in Jasmine's eyes) to mere signification of numbers by different letters, this interruption did not produce much stress and Jasmine went on in explaining her solution to the group. At this point, other students started getting involved and asking questions. Some asked only clarifying questions. Others' were more challenging, such as the instance below:

52 Yoav: Why do you say that this is prime (Points to p)?
53 Instructor: Wait, are you saying that it (N!+2) is divisible by 2? OK, but why is the other factor a prime?
54 Jasmine: There must be another prime factor

In the above interchange we see more evidence of a communicational breach. While the instructor and Yoav talked about "the other factor" being "a prime", Jasmine talked about the mere existence of "another prime". Therefore, it is not clear that she saw the necessity of the other factor being itself a prime, it might be that she was content with the factor being made up of several primes.

The instructor, together with some of the students, tried to find counter examples to Jasmine's claim that N!+2 is divisible by 2 and another prime. However, the first few numbers that were used for substitution actually confirmed Jasmine's conjecture. Thus, N=4 produced (24+2)/2=13 and N=5 produced (120+2)/2 =61, both prime numbers. The students and instructor did not get to the next N=6 which would have produced a counter-example ((720+2)/2 = 361, 361 is not a prime). Instead, the following interchange occurred:

The instructor's challenge

84 Instructor: So you say that it's always like that
85 Jasmine: I proved it! (Smiling, in a high, anxious voice). I just don't want to start with all the... (mumbles in a high voice, seems embarrassed)
86 Instructor: Are you sure?
87 Jasmine: Yes! I think so.. (tone of voice moves from assertion to a hint of doubt) I proved it. I just don't remember how.
88 Instructor: No, 'cause it's very interesting. 'Cause if you say this, then you are saying it's very easy to find prime numbers. That means I'll take something factorial, I'll divide it by 2, add 2, um.. no, add 2 divide by 2 and then I get a prime number. That means I found an algorithm for finding a prime number. That's why it seems strange to me.

Several points are worth mentioning in this short interchange. The first regards [85–86]. The instructor started by making a claim that combined subjectifying and mathematizing ("*you say* that <u>it always turns out that way</u>") (*subjectifying*, <u>mathematizing</u>). While she expected Jasmine to respond to the mathematical part (for instance by "yes, it always turns out that way") possibly with another justification, Jasmine responded to the subjectifying part. She referred to her *actions* ("I proved it") rather than to her mathematical claims. This divergence from mathematizing to subjectifying could also be seen in her emotional expressions at this point. Giggling and raising her voice were not going to help Jasmine justify her mathematical claims. Rather, they communicated she was mainly interested at this point in her identity (or the 3rd P identity of hers' as told by her classmates).

Another point regarding the above interaction refers to the meta-mathematical rules according to which the two interlocutors were acting, specifically, what "proving" entails and what may be considered as sufficient justification. For Jasmine, the fact that she did something in the past ("proved" the claim or solved the problem) was relevant and even sufficient for putting forward a mathematical claim [85]. Obviously, the instructor, who was an experienced participant in the mathematical community, did not abide by this meta-rule. However, she did give some credit for Jasmine's hypothetical proof by asserting it is "very interesting" and communicating genuine doubt with regard to her own understanding (see also later in [122]).

Another important point in the above excerpt regards the counter argument that the instructor uses [88]. While up to this point, the counter arguments concentrated on finding a numerical counter example that would disprove Jasmine's claim, this counter argument was of a different sort. It drew on some common knowledge of the mathematical community about the feasibility (or unfeasibility) of finding any prime number. However, this knowledge was not necessarily shared by the students. Jasmine showed she did not share it by replying "It's possible to find prime numbers in this way, it's just that for a calculator it's really difficult to do factorials even with small numbers" [98]. The type of meta-mathematical rule for proving that the instructor was following here is a distinct, rather intuitive meta-rule of the mathematical community, not a formal logical routine. According to it, in order to refute a claim, one can draw on the *implications* of this claim to other problems known to be difficult or unsolved in the history of the mathematical community. Any claim that would imply a simple solution for such a difficult problem (such as providing an algorithm for finding prime numbers) would be regarded with high suspicion. Jasmine did not seem to be familiar with this meta-rule. Rather, she concentrated on checking "very big numbers" (or factorials) on her calculator thus resorting to a familiar routine -proving by giving examples.

At this point in the lesson, the instructor moved to explaining the disagreement between Jasmine and herself to the other students. Once the instructor clarified her suspicion about (N!+2)/2 being a prime, Jasmine started backing off:

Jasmine's retreat

117	Jasmine	No, no. It can be 2 times many things but at the end there's a prime number there.
118	Instructor	Of course at the end you have prime factors, but why are they 2, that's what's bothering me.
119	Jasmine	No, you don't have only 2.
120	Instructor	But this is what you drew here... (points to Figure 2) ...OK, but if you have more (than 2) then you do have a problem.
121	Jasmine	Why?
122	Instructor	Because you assumed you have 2 divisors and then you said that because there are 2, then that's exactly N! + 2 divided by 2, if I understood what you said... (Jasmine looks puzzled). If you get to here (implying N! +N) you'll get to (that fact that) the divisor of this is necessarily different than this denominator (pointing to N!+2). That's how I understood your proof, and maybe I didn't understand anything and that's alright.
123	Jasmine	I didn't understand what you understood from my proof (smiles).

The excerpt above marks a transition in the argumentation of Jasmine and the instructor. Instead of checking Jasmine's claims, the instructor moved to an elaborate explanation of the "holes" or gaps in Jasmine's proof. One should notice that Jasmine's difficulty to follow the instructor [123] is understandable. Despite the fact that the instructor claimed to be revoicing Jasmine's proof, she used quite a different language for its expression. Jasmine talked about N!+2, N!+3,... being divisible into a number (2, 3) and a P (where P referred to a prime factor or simply a factor interchangeably). The instructor talked about P and (N!+2)/2 as interchangeable. In Sfard's (2008) words, she "samed" these two realizations into one object. It is probable that Jasmine did not go through the same "saming" process and therefore had difficulty in following the instructor's argument. Indeed, she remained puzzled, giving her fellow classmates an opportunity to voice their opinions. Reuven commented, with a bit of a humorous tone: "so what you proved here is that every number has a prime divisor". Jasmine retorted, quite excited "No! That's not what I proved here. That's totally not what I proved here! I was relying on it" [144].

At this point, it seems that Jasmine was quite frustrated. She was still convinced her proof was correct, but was not able to follow the instructor's counter arguments. The instructor tried explicating a mathematical meta-rule "so look... like, every claim you make here requires clarification". Yet Jasmine did not understand this simply as a meta-rule of mathematical proving. Rather, she interpreted it as a comment undermining her identity as a successful student, as could be seen in her short, high laugh and her retort "you said I think weirdly, so this is my weird thinking" [154].

From this point on, most of the communication in the class revolved around identity issues. The instructor, trying to alleviate Jasmine apparent distress, said "No, I don't have any problem (with it), it could be true and it's possible you'll find a new claim and write a paper about it" [156]. Jasmine replied cynically "yeah, sure... physics maybe, math no" [159]. Other classmates started giggling and immediately Jasmine's attention turned to them (though they claimed not to have laughed at her). The only mathematical claim that Jasmine still tried to make was that 1,814,401 (by using N=10 in (N!+2)/2) is a prime number. She said so quite excitedly, sticking her calculator in the face of her classmates. Here, not only was she not acting according to mathematical meta-rules of proof, Jasmine was also making a wrong assertion about the mathematical object (1,814,401 is not a prime).

There was no resolution to this argument. The instructor tried to encourage Jasmine to re-enter the mathematical discussion and re-state her proof but Jasmine gave up stating that "she's tired" and that she got "totally confused".

Aftermath

After the session was over, during a casual conversation with the instructor and other fellow students, Jasmine remarked: "I think you embarrassed me in front of the whole class, I stood helpless". To explain her discontent with the instructor's conduct she said to another student "I'm standing at the board, proving a problem, and every second she's interfering with it.... But it was true too. I proved it. I proved it completely and you (instructor) didn't believe (it)!" [9]. It is clear from this description that Jasmine's framing of the situation was very different than that of her instructor or of any experienced participant in the mathematical community. While Jasmine saw counter-arguments as "interferences" that unnecessarily "confused" and embarrassed her, such counter-arguments and rigorous search for the veracity of every claim are the hallmark of mathematical argumentation. Expecting the instructor "to believe" her simply because she said she proved it was another signal that Jasmine's framing was misaligned with that of her instructor.

DISCUSSION AND CONCLUSIONS

In this report we took a close look at an episode of high level mathematical argumentation coupled with intense emotional expressions. Our goal was to examine what may be learned from participants' emotional reactions about their framing of the situation, or the meta-rules of mathematical discussion they were following. The analysis revealed that the interaction included three types of communication failures. One was mathematical, at an object level. Jasmine and her instructor talked differently about "prime numbers" and about the objects signified by a "P". Communicational failures resulting from interlocutors referring to different mathematical objects despite using similar visual mediators or words, are a common cause for ineffective teaching-learning interactions (Heyd-Metzuyanim & Sfard, 2012), yet they do not necessarily involve frustration or embarrassment.

Another failure of communication was at the meta-level of mathematical discourse and related to what "proving" was all about. Jasmine saw "proof" as a process where one outlines her reasoning, not necessarily justifies every step. Her instructor followed the mathematical community's meta-rules according to which every claim has to be examined by searching for counter-examples and by following its' implications. Jasmine's difficulties with proof are not unique. Much literature shows that students often do not understand the role of examples and counterexamples in the process of proving. Such misalignments of meta-mathematical rules have a much stronger potential of producing frustration and heightened emotional expressions, if only for the reason that participants usually are not aware of them and therefore do not have access to the reasons that their communication fails.

Finally, we saw here conflict at the level of meta-rules of identification, or what certain actions and re-actions say about the *identity* of interlocutors. While Jasmine saw any disclaiming of her proof as a cause for embarrassment, and disruptions as mistrust in her ability, the instructor saw the process of making arguments and counter-arguments as a purely mathematical activity without any identifying content attached to it. Such discrepancy with regard to the identity stories that should be constructed as a result of a certain activity is, we conjecture, the most potent fuel for intense emotional agitation that may lead to failure in communication.

Yet, despite the distress this particular episode caused for Jasmine, it was probably an important and useful step towards the ultimate goal of initiating her and her fellow classmates into the mathematical community. In this summer camp, such interactions (though usually not so emotionally intense) were quite common. As could be seen here, the instruction in the summer camp was quite different than in school settings and resembled much more the process of apprenticeship (Barab & Hay, 2001). One of the main indications for this could be seen in the role that the instructor took, that of an equal (though somewhat more experienced) participant in the problem solving process. The importance of such a non-authoritative stance has been noted by many. However, in this setting it seems this role was truly authentic, probably because the problems dealt with were far from being trivial even for the instructor.

Finally, we wish to point to the need, which receives only a partial and very preliminary response in our study, to study gifted or extremely high achieving students' learning from a socio-cultural perspective. Such studies might be able to point to the processes that accelerate these students' learning, thus weakening prevalent notions about mathematical giftedness being a purely biological, permanent and individual trait. Furthermore, they can deepen our understanding about how to enhance instruction in schools with normally achieving students.

Interactions in the mathematics classroom affect both the mathematical learning and the identities of those involved. In this paper, we draw upon Discursive Psychology to examine how identities can be developed and altered in whole class interactions. In this sense, identity is not an attribute of a person but is something that is co-constructed through and in interaction. We demonstrate how these identities can shift moment-to-moment within an interaction. Importantly, these identities shift within the same interaction. These changes in identity development have important consequences for mathematical learning and continuing participation and contribute to our understanding of the variance in identities that students self-report.

Keywords: Identity, discourse, classroom interaction, positioning theory.

INTRODUCTION

Identity has become increasingly prominent in mathematics education research and in this paper we build on recent research that focuses on the discursive construction of identity through classroom interaction. We consider understanding and learning mathematics to be an aspect of participating in discourse practices. Furthermore, participating in discourse practices influences, and is influenced by, participants' identities (Esmonde, 2009). In other words, students' mathematical identities are discursively constructed through their interactions and experiences in mathematics classrooms (Grootenboer, Smith, & Lowrie, 2006).

Research has revealed important relationships between students' mathematical identities and their experiences of mathematical practices. For instance, early work by Boaler (1997) showed that students had qualitatively different forms of mathematical knowledge and beliefs about mathematics and the learning of mathematics depending upon the teaching methods they experienced. Her later research then examined how these different teaching methods influenced students developing mathematical identities and their decisions about continuing to study mathematics (Boaler & Greeno, 2000). Cobb, Gresalfi and Hodge (2009) developed this research further by developing an interpretive scheme to explore the relationships between particular classroom norms and sociomathematical norms and the developing identities of the students in those classrooms.

Different conceptions of identity in mathematics education research have arisen since then such as Sfard and Prusak's (2005) narrative work, Solomon's work with figured worlds (2007) and work by Cobb and colleagues (2009) with normative and personal identities. All of these approaches have largely drawn upon data from interviews with students describing their experiences with mathematics. Heyd-Metzuyanim and Sfard (2012) and Wood (2013) have focused on the construction of identity in the moment-to-moment interactions in classrooms. This paper contributes to this body of work.

METHODOLOGY

The conception of identity developed in this paper arises from discursive psychology (DP) (Edwards & Potter, 1992). Discursive psychology is based on the principles of Ethnomethodology (Garfinkel, 1967) and Conversation Analysis (Sacks, 1992). It examines the practical ways in which identity is managed in interaction, which may differ from the narratives or stories individuals may offer in interview situations. The focus here is on how teachers and students discursively co-construct what it means to be a learner of mathematics. From this perspective, identity is something that we 'do', rather than something we 'are'. This is a micro view of identity where identity is conceived as dynamic, complex and situated in the context of the interaction itself. Identities are constructed through these interactions by how the participants orient to each other. Teachers and students construct identities for themselves and for each other through participation in interaction, and also for all the participants and observers of the interactions that occur in the mathematics classroom. This micro approach complements the approaches taken by researchers such as Boaler and Cobb, and those developed from positioning theory (Wood, 2013) which themselves draw from discursive psychology, by giving us a glimpse of *how* these identities are constructed as well as how they shift and change in interaction.

Studies taking this micro approach have illustrated how interactions with different participants within the classroom result in different identities being adopted as the consequences of some of these different identities. For example, Wood (2013) demonstrates how one student's mathematical identity shifts in different classroom interactions with his teacher and his peers within one lesson. Two of the identities constructed, one in interaction with the teacher and one in interaction with a peer, relate to mathematic competence whilst a third, constructed in interaction with another peer, is one of a menial worker needing to be told each step. Yoon's (2008) study also showed that teachers' discursive positioning of non-native speakers affected their participation in lessons but also affected how their peers treated them in the classroom and Turner, Dominguez, Maldonado and Empson's work (2013) offers insight into how teachers can position non-native speakers as mathematically and interactionally competent in a way that supports their peers in positioning them in a similar way. Yet each of these studies examines patterns over time and consistencies in how the different participants orient to each other. In contrast, this study examines moment-to-moment differences in the way identities are constructed in order to contribute to our understanding of the variety of identities that students develop in the mathematics classroom.

The analysis below focuses on three aspects of the talk: the structure of the turns taken by the teacher and his students; and the authorship and ownership of the mathematics (also referred to as the epistemic agency (Ruthven & Hofmann, 2015)). One key feature of talk that is used by teachers related to ownership is revoicing (O'Connor & Michaels, 1993). Revoicing involves repeating students' contributions in a way that attributes the ideas involved to the student. The student is the owner of the ideas involved and capable of offering these ideas. Enyedy and colleagues (2008) emphasise the importance of this attribution in classroom interaction as it "shares the intellectual authority with the students and helps establish their role as one of contributing to the construction of knowledge" (p. 137).

The data discussed in this paper comes from a larger study involving eight mathematics teachers from seven schools in the UK, all working with students aged between 11 and 14 years. Some of the schools serve areas with high levels of social deprivation, whilst others are fee paying independent schools. The teachers all volunteered to be video recorded and the data collected is naturally occurring in that no instructions were given to the teachers about what or how to teach. The transcripts included in this paper are from one of these teachers' lesson with an all-attainment class of 12–13 year old students. The two extracts have been chosen to illustrate how the discursive construction of identity can change within one topic segment within a single lesson. The extracts come from one particular whole class interaction towards the beginning of the lesson where the students are reporting on work they have completed in a previous lesson and at home. The students are preparing for end of year exams and have been working on a worksheet with problems designed by the teacher to support them in their revision. Whilst the majority of studies have focused on small group work in mathematics lessons, whole class interactions are being considered here because the interaction not only positions the students who contribute but also the rest of the class observing and listening to the interaction. Whilst students are generally more agentic in small group discussions than in large whole-class discussions (Turner et al., 2013), the first extract below illustrates an example of where students can be agentic in teacher-led whole class discussions.

IS A MICROCENTURY LONGER THAN A MATHEMATICS LESSON?

In the first extract the students are reporting their work on the question of whether a microcentury is longer than a mathematics lesson. Immediately before this extract there has been some discussion on the meaning of microcentury and the notation associated with the prefix micro.

27 George: well (.) erm (.) I (.) worked it out (.) on erm the calculator and (0.3) it came up as one times (.) ten (1.6) to the power four. and er um (0.9) I times'd it by three hundred and sixty five, to simpl- to make it simpler (.) and um (1.1) and um it still wasn't (0.5) what I wanted so (0.4) I times'd it by twenty four which (0.4) um (1.2) um gave me that nought point eight seven six so it times'd it again by sixty (.) um minutes and it came as fifty two minutes and (1.3) so that's longer than forty minutes so (the answer is it's longer than the lesson) ((teacher is writing down the calculation while it is being said on the whiteboard))

28 Teacher: oh wonderful answer? thank you very much indeed. um you've said it all really haven't you. um this first bit comes up a bit funny on some of the calculators depends what sort of calculator you've got. sometimes when there are numbers that (.) don't fit easily on the display or have lots of noughts in. we represent them in a different way which we'll look at in year nine but um (.) it's basically (.) a ten thousandth. if you um (0.7) press the right button on your calculator and you get ten thousandth. and then with all these timesing what was what was George doing with all this? what was she doing here (1.7) ((turns round to point at a specific part of the calculation on the whiteboard)) yes Lauren

29 Lauren: um she was trying to (re do it) into minutes?

30 Teacher: she was making it into minutes eventually wasn't she I should have written that. (2.8) ((teacher is changing the colour of his whiteboard pen)) she was. so what where- what where the stages she went through. why was she- (0.5) why was she doing each of these steps. Hannah?

31 Hannah: because times three hundred and sixty five is like (.) three hundred and sixty five days in the year, times twenty four because there's twenty four hours in a day, times sixty because there's sixty minutes in an hour,

32 Teacher: but why do you think she stopped when she got to minutes. um I mean she said she got the answer here didn't she but (.) then she carried on and times by sixty Sam?

33 Sam: because it's the same units as what you're comparing it to

34 Teacher: perhaps yes. if you know the lesson is (.) thirty five or forty minutes, then that's what you compare it to...

The extract begins with George explaining her answer to a problem on the worksheet the class had been working on. Her explanation contains multiple pauses and hesitations but she completes her explanation without the teacher or any other student speaking. The teacher, by writing down her explanation on the whiteboard, makes the explanation available to the rest of the class in another representation and also gives weight to the validity of the explanation. This is reinforced further by the teacher's positive evaluation in the next turn.

Several of the pauses in George's turn are longer than the 'standard maximum tolerance' (Jefferson, 1988). Long pauses are often interpreted by the other participants as indicating that there is some trouble in the turn, such as difficulties with the mathematics or difficulties in expressing what the speaker wants to say. It is rare to see pauses of this length in students' turns in teacher-led discussions as the teacher will often step in to speak (Ingram & Elliott, 2014). By the teacher not speaking during these pauses, the student completes the explanation and as such both demonstrates their competence in producing this explanation and their competence in communicating this explanation. This competence is co-constructed with the teacher who neither adds to, rephrases, repeats or revoices the explanation in the following turn. The student is displaying their mathematical knowledge which is structured through the original task and the interaction.

Near the beginning of turn 28 the teacher makes reference to George's comment that the calculator said "one times ten to the power four", which he describes as "a bit funny". He then refers to the different displays produced by different calculators. Whilst George interpreted the calculator display without difficulty, the teacher's comment identifies this as a possible source of difficulty for the other students. This pre-emptive assessment by the teacher constructs the students as not knowing standard form or how calculators deal with large numbers (Barwell, 2013). The difficulty is initially attributed to the way calculators display numbers. The teacher then offers an account for why calculators might do that. The teacher uses 'we' here twice. This emphasises that it's a representation that is used by the general mathematical community (Dooley, 2015) but also accounts for the students not being able to interpret the representation by referring to this idea as something that the students have not yet met, rather than as a deficit in the students themselves. He then minimises the importance of the issue using 'basically' and talking about it as just needing to "press the right button on the calculator". Whilst on the one hand the teacher is constructing the class as lacking the knowledge to work with this representation, the teacher is also treating the difficulty as being outside the responsibility of the students themselves.

The teacher then shifts the focus to the calculation that George was describing in the previous turn. This calculation is attributed to George both by the teacher and by the student that takes the next turn. Lauren phrases her turn hesitantly and answers the question of what George was doing with the calculation as a whole. The teacher partially repeats her response, thereby accepting it, but the addition of the word "eventually" indicates that there was a problem with the response and this is followed by a question that focuses on the stages of the calculation rather than the calculation as a whole. Hannah's subsequent response includes an explanation of what each of the numbers in George's calculation represent. The teacher makes no explicit evaluation or assessment of this explanation but follows Hannah's turn with 'but why' and a reformulation of the question which is answered by Sam. This is then positively evaluated by the teacher, but not in strong terms. "Perhaps yes" indicates that whilst Sam's answer is correct, it is not the answer that the teacher was looking for and the teacher adds additional information in his turn.

In this extract the authority for the mathematics is often given to the students, and they are invited to supply thinking about their peer's strategy for answering the question on the research. The teacher directs each turn to a new student, each of which builds on the explanation offered before and focuses on the calculation initially offered by George. The students are co-constructed as being both mathematically capable and capable of making sense of others' ideas. This also treats the contributions and explanations from the students as important and worthy of consideration. Maintaining the authorship of the explanation with George also implies that she has a mathematical justification for her solution, and therefore evaluates her explanation as valid and treats her as a competent problem solver.

DIVIDING 3.05 BY 2.5

The second extract follows the question 3.05 divided by 2.5 (written as 3.05 as the numerator of a fraction and 2.5 as the denominator) which occurs later on the same worksheet as the earlier question. A student has suggested multiplying the numerator and the denominator by a hundred and the teacher has written 305 over 250 on the board, but the student reported that they had not yet got further with the calculation.

40 Teacher: … I think there's probably an easier number maybe can you see anything to do there Sarah?
41 Sarah: um
42 Teacher: could you use the idea of [a hundred]
43 Sarah: [times by four] yeah
44 Teacher: times by four yep so (0.6) whatever that makes times by four (.) you could probably do that. and then (.) how would you get it finally as a decimal
45 Sarah: um
46 (1.9)
47 Teacher: any ideas. (1.4) if you've got this number here Bella (.) if you got that number d- do you see what's happened here to go from this fraction to this fraction. (1.8) can you see what: (.) um (.) what I've done to convert this into this. what have I done (1.3) I've put a hundred on the bottom and I had twenty five a moment ago
48 Bella: you times'd it by fou[r]
49 Teacher: [ye]s I times'd that by four so I'd have to times the top by four as well and I can do that I just don't know what it is. But whatever it is, how would I get my final answer (0.5) if I wanted it as a decimal. (0.8) this is quite hard actually isn't it. We haven't done much of this …

In this extract the authorship of the calculation shifts and the student contributions are considerably shorter than in the previous extract and often overlap with the teacher's turns. It is a student who first suggests multiplying the denominator by four, though this does follow hints from the teacher in turn 42 and in the turn immediately preceding the extract. The original question invites a range of possible strategies but the hints narrow this range down, so whilst the student has given an appropriate answer of "times by four" (as indicated by the teacher's acceptance of this answer in turn 44) this may not have been a strategy that the student used themselves or would think of themselves without the prompt of "a hundred".

There are several noticeable pauses in this extract in turns 46 and 47. The first two of these pauses offer Sarah the opportunity to answer the teacher's question in turn 44. When no answer is forthcoming, the teacher adapts that questioning towards the calculation that has already been performed. These first two pauses treat Sarah as being able to offer an explanation. However, when these opportunities are not taken up by Sarah, the trouble is treated by the teacher as being with the calculation that has already occurred. The teacher then checks that another student in the class has understood this calculation in turn 47.

The authorship shifts in turn 47 where initially the teacher refers to the numbers involved as belonging to the students, "you've got this number" but then the teacher begins to use 'I' to talk about the calculation that has been performed. The 'you' is used when talking about the strategies that could be used next, the strategies that could be used on the fraction with a denominator of 100. 'I' is used to refer to the calculation that has already been performed when converting between equivalent fractions. This shift from you to I is a further indication that the teacher is treating this calculation as a source of trouble. The teacher is now responsible for the calculation that has been performed and this treats the students as needing to follow his reasoning. The question asked in turn 47 asks a student to explain how the teacher converted the denominator of twenty five to a denominator of a hundred. In Bella's response she also positions the calculation as being the teacher's. In the final turn of the extract, there is another shift in who is doing the calculation that comes next. In turn 44 the teacher asks the students how they would get the final answer and it shifts in turn 49 to how the teacher could get the final answer.

The emphasis in this extract and in the turns that came immediately before has been on the strategies that students can use rather than the final result of the calculation. The teacher is asking for what the students did in turn 40, not what answer they got. In turn 44, the teacher does not perform the calculation involved in changing the numerator once the denominator has been multiplied by four, reducing the importance of the answer to the calculation by referring to it as "whatever this makes". The teacher also positions the students as capable of performing this calculation in this turn before asking for strategies for what could be done next. In turn 49 again the teacher places the emphasis on the strategy but as a response from the students is not forthcoming he then states that "this is quite hard actually" to account for difficulties the students are having in responding to his question. This is then followed by an explanation of "we haven't done much of this" which also accounts for the difficulty by a lack of experiences of working with calculations like this, which locates the issue as outside of the students' competencies.

DISCUSSION

In both extracts the interactional roles of teacher and students are clear. It is the teacher who controls the topic, asks the questions, and decides who can speak when. It is also clear that the teacher has control over assessing the appropriateness of the students' turns. In both extracts the students are treated as capable of explaining and communicating their ideas. They are given opportunities to do so

In this classroom there is a clear focus on the process of doing mathematics. The extracts presented here both focus on calculations but the attention is on the choices made in order to solve the problems and the justification for these choices. Difficulties with the mathematics are also treated in similar ways in both extracts, with the problem being located in the teaching rather than as a deficit in the students. In the first extract the difficulty is attributed to a representation that the students have not yet met and in the second extract the difficulty is attributed to the students not having had enough experience of this type of calculation and to the teacher posing a difficult problem in the first place.

The differences in the treatment of the students in the two extracts arise from the differences in the students' contributions to the discussions. In the first extract the students' responses do not always match what the teacher is looking for but they are accepted as answers to his questions, whilst in the second extract the students' responses are limited in terms of content, length and frequency.

The ownership of the mathematics shifts during the interactions in reaction to the students' contributions. In the first extract the mathematics is attributed to George throughout and this is indicated by both the teacher and the other students. In the second extract the ownership shifts progressively from the students to the teacher. The students position themselves in the first extract as mathematically capable and as capable of inferring George's mathematical reasoning. The teacher could have easily clarified George's answer himself and could also have stepped in when George was hesitating in her turn. By not doing so he enables the students to maintain a position of capability, which is supported further by the teacher in his turns. In the second extract, the students are more hesitant and do not take up the position of being able to suggest a strategy. The teacher initially continues to position the students as capable of suggesting a strategy but as the students do not take up this position the teacher shifts both the ownership of the mathematics and also positions the students as needing to understand the mathematics he is doing rather than as capable of doing it themselves. These different positionings could have consequence for how students come to see themselves as mathematical thinkers (Cobb et al., 2009).

As is evident from the extracts this is a classroom where students are given opportunities to engage in mathematical communication. They are frequently invited to contribute ideas and explanations and to build on other students' contributions. The students also work collaboratively throughout the lessons and for this teacher the majority of time in lessons is spent with the students working in small groups on a variety of tasks. We know from previous research (Boaler & Greeno, 2000; Cobb et al., 2009) that students in classrooms 'like' this are more likely to develop identities associated with mathematical capability and are more likely to continue with their study of mathematics. However, this research does not explain *how* these identities are developed and also it does not explain the variation in students' identities who have similar experiences in their mathematics lessons. The micro approach such as the one taken in this paper and by Wood (2013) begins to give some insight into these two aspects of identity construction. Students are not either positioned as mathematically competent or not according to which teacher they have, but these positionings change and develop moment-to-moment in interaction with all teachers. Students consequently experience different mathematical positionings within each lesson, some of which may be positive but some of which may not. Whilst Wood focuses on the different identities co-constructed in interactions with different participants, teacher and peer, in this paper we have examined extracts from the same topic segment and between the teacher and the whole class.

This paper provides evidence for, and analysis of, the identities enacted by the students and developed by a teacher. The students enact positions where they are mathematically capable and the teacher ratifies and supports these positions. It also demonstrates that identities and positions can change across a short interaction. Paying attention to the influence of minor changes in context may help explain why students may take up different identities within mathematics.

Discourses in kindergarten and how they prepare for future decontextualised learning of mathematics

Judith Jung and Marcus Schütte

Technical University of Dresden, Dresden, Germany, judith.jung1@tu-dresden.de

Abilities in using decontextualised linguistic forms seem to be of great importance for subject-specific learning in school, including the learning of mathematics. However, the basic elements for mastery of these competences are usually not taught in school, but are assumed. Where can young learners gain these abilities? Based on Cloran and Hasan's investigation of mother-child discourses, the ongoing study presented in this paper analyses pre-school learning in kindergarten and compares this with mathematical learning in primary school Year 4. The goal is to investigate to what extent the linguistic discourse in kindergarten and primary school gives children the opportunity to achieve mathematics-specific discursive competences that allow them to participate successfully in the discourse of the mathematics classroom.

Keywords: Academic language, kindergarten, decontextualised discourse, early mathematics learning.

INTRODUCTION

The results of international comparison studies, such as the various PISA studies and the PIRLS (*Progress in International Reading Literacy Study), a* primary school study, show that in Germany there are significant differences in achievement levels and educational opportunities among children with different linguistic-cultural or socio-economic backgrounds (Bos et al., 2003; OECD, 2006). It is assumed that there is great potential for changing this situation if pupils can master the German language, particularly pupils with a multilingual background. According to this view, a strong connection exists between the linguistic abilities of children and their achievements in school, not only in German lessons but also in other subjects – including mathematics (Schütte, 2009). It is important to emphasise here that the current study does not focus only on children with a background of immigration or those who live and learn in several languages; rather, it concentrates on the influence of linguistic abilities on the learning of mathematics for all children.

Studies in migration research and educational science (Gogolin, 2006), as well as recent studies in mathematics education (Schütte, 2009; Schütte & Kaiser, 2011) have consequently concluded that it is not the mastering of general linguistic competences that is significant for successful (mathematical) subject learning, but competences in a subject-specific academic language. With her concept of "academic language" ("Bildungssprache") Gogolin (2006, p. 82) draws on Cummins's (2000, p. 57) concept of "Cognitive Academic Language Proficiency". Cummins makes a distinction between "academic language proficiency" and "conversational language proficiency", on the basis that children quickly gain abilities in their second language which they are able to use in everyday situations. They need significantly longer to achieve competences in the academic language of the classroom. This academic language, following Gogolin (2006), is characterised by its conceptually written form, which allows it to have high density of information and independence from situations; this means there are fundamental characteristics that do not correspond to children's everyday oral communication. However, the question is how to support children in building up sufficient (academic) linguistic competences to enable them to achieve academic success in (German) schools? Furthermore, in what ways should a school, and the teaching staff working there, seek to adapt to a pupil population entering the school system with extremely diverse abilities?

Both international and domestic research in mathematics education has recently begun to include approaches that have taken up this concept of academic language (Gellert, 2011; Schütte, 2009) and applied it to subject-specific learning, in particular to the learning of mathematics. This study aims to make a further contribution to these subject-specific modifications of the concept of academic language for the learning of mathematics. Section 2 will describe the effects of adopting an academic-language-based perspective on the learning of mathematics. The concept of academic language is discussed in the context of academic discourses, mainly on the basis of theories by Moschkovich (2002) and Krummheuer (1992). The fundamental idea is that children need to learn subject-specific discursive practices in order to be academically successful in their future school careers. The third section outlines the studies on decontextualised language use carried out by Hasan (2001) and Cloran (1994), who were able to reconstruct discursive practices of the socialisation of children in the family in early childhood. These forms of discourse used in the family also seem to be fundamental for the development of mathematical abilities. In section 4 the methodological procedure of the investigation is outlined. Section 5 shows the preliminary results.

SIGNIFICANCE FOR THE LANGUAGE-RELATED LEARNING OF MATHEMATICS

Some studies, particularly in the international literature, have begun to improve the concept of a mathematical academic language and move beyond the deficit-oriented approach. Moschkovich (2002), for example, emphasises the discursive element of the learning of mathematics. She links her situated-sociocultural perspective on the learning of mathematics to a paradigm change away from a view of deficits as preventing learners from mastering the academic language of school to focus on the resources and competences of a diverse pupil population. According to this perspective, the learning of mathematics takes place in a social context in which the participants bring with them different ways of looking at situations, which are negotiated interactively. Approaches centred on academic language, which understand the learning of mathematics as "constructing multiple meanings of words" (Moschkovich, 2002, p. 193) and which relate to Halliday's (1975) concept of "register", often focus on the differences between children's abilities to linguistically act in or with different registers. This deficit-oriented approach leads to the idea of a 'target register' –the academic language– and a register of everyday oral communication, which is of less importance in academic discourses. With this perspective only the mastery of the academic language is seen as sufficient for success in school and the achieving of mathematical understanding. In contrast to these approaches, we suggests that the learning of mathematics always takes place in a public, social and cultural context and represents a discursive activity. There is no single correct mathematical discourse that can be achieved. Learners participate in mathematical discourses in different communities and use diverse resources in different registers in order to successfully communicate mathematically.

Interactional and non-language aspects assume a central role in this perspective on the learning of mathematics. Following this idea we can look at various studies of interactionistic approaches of interpretative classroom research in mathematics education. For example, Krummheuer (1992) shows how children are involved in collective argumentation in the learning of mathematics in primary school and that mathematical learning stems from increasingly autonomous participation in mathematics (Krummheuer & Brandt, 2001). Although, according to Moschkovich (2002), there is no single correct discourse, even while moving away from deficit-oriented approaches we must acknowledge that children will still enter school with different conditions for participation in the collective argumentation on account of their extremely differentiated socialisation in the family. Here we can refer to the studies by Cloran (1994, 1999) and Hasan (2001), who investigated the different discursive practices in familial socialisation in mother-child discourses. The central aspect of these studies is the ontogenesis of decontextualised language as a fundamental factor for successful participation in educational discourse in school.

CHARACTERISTICS OF THE DISCOURSE OF SCHOOL EDUCATION: DECONTEXTUALISATION

Diverse authors have seen decontextualisation as an important characteristic of the pedagogical discourse (Bernstein, 1996; Cloran, 1999). However, what exactly are we to understand by this term? What is the difference between context-dependent and context-independent language? In the last 40 years much has been written about decontextualised language use, for example relating to the difference between oral and written language and the question of language development (cf. among others Olson, 1977), the cognitive development of children (cf. among others Donaldson, 1987), and the concept of academic language and the conditions for a successful educational pathway (Cloran, 1994; Hasan, 2001). However, existing approaches offer no clear definition or description of decontextualised language. The concept is given different emphases according to the frame of reference. This can be seen for example in the use of different but basically synonymous terms such as "context-independent", "situation-independent", "autonomous" and "disembedded" (Cloran, 1999, p. 33). The present paper will engage with the sociolinguistic theories and studies of Hasan (1973, 2001) and Cloran (1994, 1999), based on the ideas of Bernstein. These authors seek to forge a link between the language that is learnt in the family in early childhood and the form of language that is prevalent in school. A fundamental definition of decontextualised language use can be found in Hasan (1973, p. 284): "The term 'context dependent' [...] may be paraphrased as follows: language that does not encapsulate explicitly all the features of the relevant immediate situation in which the verbal interaction is embedded". She emphasises the difference between "material immediate situation" and "relevant immediate situation", and notes that the correct decoding of the linguistic message is dependent on knowledge about the relevant immediate situation, although this knowledge is not linguistic in origin. In contrast, context-independent language is language that "encapsulates explicitly all the relevant features of the immediate situation in which the verbal interaction is embedded" (Hasan, 1973, p. 284).

Cloran (1994) makes use of Hasan's (1973) definition and identifies ten different types of rhetorical unit in the conversations between mothers and their preschool-age children, which she places in an order according to the level of decontextualisation. The ten degrees of decontextualised language use move from the least decontextualised, which is based in the material present moment, to the most decontextualised, based in the relations created by language itself. In order, the rhetorical units are: action, commentary, observation, reflection, report, account, plan, conjecture, recount, and generalisation (Cloran, 1999, p. 37). The rhetorical units of generalisation and conjecture play an important role in the learning of decontextualised linguistic abilities.

The idea of revealing a continuum between context-dependent and context-independent is present in Hasan (2001, p. 53). She uses the concepts "actual" and "virtual" for her investigation of mother-child discourses and the ontogenesis of decontextualised language, which refer to the context of the linguistic expression:

> A context is actual if it can be actually, that is physically sensed by the interactants. [...] A context is virtual if no possibility exists for experiencing it physically: the phenomena are, in fact, not available to the senses. (Hasan, 2001, p. 53)

From this she concludes:

> A discourse is decontextualised/disembedded, not because what it refers to is not physically present to the senses here and now, but because it refers to something that is by its very nature incapable of being present in any spatio-temporal location whatever. It is simply not sensible. (Hasan, 2001, p. 53)

Hasan (2001) also draws a distinction between constitutive and ancillary verbal actions: an action is constitutive when it recreates an actual context that is now spatio-temporally displaced. Constitutive verbal action can also bring into existence virtual contexts, which are entirely text-based. An ancillary action seeks to negotiate some physical action that is ongoing within an actual context. This leads to three different classifications for contexts of discourses: immediate (ancillary and actual), displaced (constitutive and actual), and virtual (constitutive and virtual) (Hasan, 2001, p. 54). Hasan concludes from her observations of mother-child discourses that the best learning environments for the use of decontextualised language are situations where continuity is established between actual and virtual contexts. Children thus have the opportunity to gradually move from speaking about concrete things and experiences to speaking about abstract generalisations. Hasan goes on to suggest that school is not an appropriate place for the learning of decontextualised language use because of the structures of discourse that dominate there; however, these abilities are to a great extent made a precondition for later academic success, as they become a factor for selection. Both actual and virtual contexts can certainly be observed in the classroom, but an individual child barely has any opportunity to autonomously change between them. If we agree that the ability to use decontextualised language forms is assumed rather than taught in schools, this ability must then be learnt in pre-school places of learning, or places outside the school environment.

In her investigation of everyday mother-child discourses, Cloran (1994, 1999) discovered that frequency of use of rhetorical units with a high level of decontextualisation in the interaction was dependent on the social class of the respective family. Cloran defines this by the level of autonomy in the occupations of the child's parents. Parents who have jobs that involve a high level of autonomy, for example teacher, doctor, lawyer and so on, usually have a higher level of professional education, and their families too may have a higher level of education. Cloran found that with mothers and pre-school children belonging to this class of family, the rhetorical units generalisation and conjecture appeared significantly more frequently in the interaction than with subjects from families where the parents had a low level of autonomy in their occupation. Cloran speculates that this could be one reason for the differentiated success in school of children with different family backgrounds.

If we focus specifically on mathematics teaching, and the demands placed on children in the mathematics classroom, we can see that the ability to distance oneself from concrete contexts and to express this linguistically assumes a special importance. Particularly in the primary school environment we can conclude that the successful participation in collective argumentation is made easier for children if they have the ability to make assumptions about the contexts of mathematical discoveries, and to take that extra step to generalise these contexts. According to Donaldson (1987), this linguistic distancing from contexts represents an important aspect of the cognitive development of the individual, enabling abstract thought processes and conclusions.

Gellert (2011) also points to the special importance of linguistic decontextualisation for mathematics teaching in primary school. Mathematics in primary school is characterised by the establishing of distance from concrete everyday experiences while moving towards abstract expressions that are applicable in a general sense (i.e. generalisation). Wagner, Dicks and Kristmanson (2015) examine *children's language repertoires relating to conjecture*. It can therefore be assumed that the gaining of decontextualised linguistic discursive abilities –particularly the use of rhetorical units, which, according to Cloran and Hasan, shows a high level of decontextualisation (e.g. conjecture and generalisation) –before entering school will be helpful for mathematical learning in the classroom. With reference to Moschkovich (2002), before abilities in decontextualisation are demanded of children in the mathematical discourse of primary school, it would be helpful if they could be prepared for these demands through discourses in the family or in kindergarten. In the following we will focus on kindergarten, as educational processes are initiated in this environment by professional teachers. From these points, our research questions are:

1) What is pupils' relationship to generalisations in mathematics lessons in primary school?

2) Can we reconstruct in early discourses with pedagogical experts learning situations that promote children's abilities to change between actual and virtual contexts in the interaction?

METHODOLOGICAL PROCEDURE AND CONTEXT

The study presented here is qualitatively oriented and can be categorised under interactionistic approaches of interpretative (classroom) research in mathematics education (Krummheuer & Brandt, 2001). The empirical basis for the study is provided by video recordings of everyday play and discovery situations, each involving a kindergarten teacher and two children (4,7–5,5 years old). The play and discovery situations can be categorised under the mathematical area of space and form, for example classic situations with building-block constructions that follow a model, or situations that principally engage spatial perception. We contrast this with video recordings of whole-class discussion during mathematics lessons in Year 4. Here the focus is on situations where the teacher introduces new mathematical concepts.

Interactions between the participating children and between the children and the attendant adults are analysed. For the investigation of discourse the transcribed video sequences are examined with the help of interactional analysis and an analysis of the used rhetorical units based on Cloran (1994) and Hasan (2001). The analyses presented by Cloran (1994) were carried out on the basis of linguistic categories. Messages of the chosen transcribed scenarios were identified as belonging to one of the ten classes of rhetorical units: action, commentary, observation, reflection, report, account, plan, conjecture, recount, and generalisation. The study focuses here on the units Cloran highlights in relation to decontextualised language, i.e. generalisation. In examining the subject-specific negotiation of meaning within the interactions, Cloran's method of analysis is linked to the interactional analysis.

RESULTS

In the Year 4 mathematics classroom we find multiple situations where children are asked to generalise content linguistically, shifting out of the here and now onto a more general level. The linguistic forms of the expressions the children use seem on multiple occasions not to satisfy teachers' requirements; however, teachers usually offer no explicit linguistic help. The following example illustrates this.

Birkan:	I know what the "cross-sum" (German: Quersumme, "sum of digits") means.
Teacher:	That's oh. Prick up your ears.
Student:	Cross-sum is plus, you know.
Birkan:	Erm the cross-sum means a erm broken line.
Students:	No, oh I know.
Teacher:	That means you make everything erm total.
Students:	No, not total.
Teacher:	No, I don't know if you weren't onto something. You've, maybe you've expressed it a bit wrong.
Birkan:	Yes erm, if you add everything up.
Teacher:	That's there's. Well you're really onto something there. I think I know what you mean. So now I don't want to torture you any longer. [*The teacher writes an addition task on the board.*]

The teacher makes clear that Birkan's answer points in the right direction but that he has incorrectly formulated it linguistically ("maybe you have expressed it a bit wrong"). After this response Birkan attempts a linguistic improvement of his answer, but this, too, seems to fall short of the teacher's expectations. Without explaining this, however, and without helping Birkan to arrive at a correct formulation, the teacher continues with the lesson and writes an addition task on the board.

The analysis of Year 4 mathematics teaching moreover puts into focus that even in primary school certain mathematical concepts, e.g. a straight line, can only be detached from the immediate context and described linguistically in a virtual context, while visual representations neglect their inherent characteristics. Switching between virtual and actual contexts seems barely possible. Here we can refer to Söbbeke (2015), who investigates the dilemma that mathematical knowledge is abstract in most cases, while using means of visualisation is indispensable for speaking with children about these abstract concepts.

In kindergarten we find above all diverse situations where the participants negotiate meanings in relation to immediate contexts and the teacher seldom generates opportunities for switching from immediate to virtual contexts within the conversation. On the one hand this seems determined by the selection of situations in the area of space and form, and on the other hand hardly surprising, given the age of the children. Only at certain points in the situations with a focus on spatial perception do we see potential for switching from an actual to a virtual discourse. However, this is mostly not on the level of mathematical discussion. One example of this can be seen in the following scenario:

Jacob:	She sees the elephant.
Teacher:	Which elephant?
Jacob:	This one. [*Jacob taps on the big elephant.*]
Heike:	[*Heike taps first on the small, then on the big elephant.*] The big one because the small one is too small.
Teacher:	Why doesn't she see it?
Jacob:	Because it's too small. Because it's a baby elephant.
Teacher:	But you can see baby elephants, too. Why doesn't she see it now?
Jacob:	Because there's a wall here.

At this point the adult confirms Jacob's answer and asks a new question, whose content has no connection to his argument. However, from our point of view this situation shows potential. After Jacob's utterance about the wall, the accompanying adult could lead the discussion in a direction where the children are asked to think about the fact that other small animals, plants or objects could not be seen behind the wall either, and, ultimately, that nothing behind a wall that is shorter than the wall can be seen. This could be a first step towards the use of generalisation and switching from an actual to a virtual context.

SUMMARY AND FUTURE PERSPECTIVES

Our results let us assume that conversational situations that contain various individual possibilities for switching between immediate and virtual contexts appear only rarely, and that children are expected to be able to use decontextualised language without receiving help. In addition we might assume that discourses in kindergarten similarly offer only limited points of access for learning such linguistic competences, and that at least play situations in the area of space and form offer limited potential for introduction to decontextualised language use. This could be because this area is introduced above all through immediate, enactive, and visual means, especially in early learning processes. It may therefore be unnecessary for participants to switch into virtual contexts, because the mathematical area provides very good points of access to immediate contexts. Through looking at other context areas that might evoke a greater need for the use of decontextualized language nuance could be added to this hypothesis and the theoretical construct of the typification of contact with decontextualised language in early education could be extended to different kinds of mathematical content. Furthermore, the question needs to be addressed of whether examples can be found of initiation of switching between contextualised and decontextualised forms of language, and of help offered to children to master decontextualised forms of language, at any earlier point in primary education.

Use and development of mathematical language in bilingual learning settings

Rebecca Klose

Justus Liebig University Gießen, Gießen, Germany, rebecca.klose@math.uni-giessen.de

Bilingual forms of teaching and learning have become common practice in Germany. However, the idea of teaching mathematics bilingually has not been totally accepted yet. The on-going study aims to investigate how young learners taught bilingually use and develop mathematical language in both of their target languages, with a focus on the usefulness of the communication tool PriMaPodcast. Parts of the research project and the interactive process of producing mathematical audio podcasts are presented.

Keywords: Bilingual learning, mathematical language, audio podcasts.

LEARNING MATHEMATICS IN BILINGUAL SETTINGS

Content Language Integrated Learning (CLIL) stands for a concept related to teaching and learning in two languages. As such, a combination of subject content learning and foreign language acquisition takes place. The extent to which it puts more emphasis on the subject-based components or the language dimension of learning, may vary from one country to another (European Commission, 2006). Bilingual teaching and learning settings have meanwhile become common practice in Germany, yet they are seen far more in secondary than primary education (Elsner & Keßler, 2013). Internationally, there seems to be no clear preference of any particular subject. Besides the social sciences, Geography, History and Economics, Mathematics is included in official recommendations on CLIL provision (European Commission, 2006).

In Germany however, the idea of teaching Mathematics bilingually has not been greatly accepted (KMK, 2006; Viebrock, 2013), neither in secondary school nor in primary education. Pertaining to primary education, concepts and materials required to facilitate mathematical learning in two languages have not been extensively developed nor become available (Küppers, 2013). As said by Rolka (2004) the exclusion of Mathematics depends on certain attitudes of mathematics teachers in Germany who appear to believe that language use has been reduced in this school subject. Yet the German syllabus of teaching mathematics demands the development and implementation of process and language oriented competences such as reasoning, communication and representation. Many show concern for having to learn a technical language for Mathematics, which other subjects do not require.

All these considerations raise the question whether it is really effective to learn mathematical language in two different languages. If so, how would bilingual learners use and develop mathematical language in order to explain mathematical content in both languages of instruction? In the next section some characteristics of mathematical language will be explained further.

CHARACTERISTICS OF MATHEMATICAL LANGUAGE

The acquisition of mathematical language goes beyond the learning of terms and vocabulary (Maier & Schweiger, 1999; Pimm, 1987). Based on Halliday's (1978) idea of mathematics register, Schleppegrell (2007) outlines some characteristics of mathematical language. First, there are multiple semiotic systems such as symbols, oral and written language and visual representations. These systems combined are necessary for the learner to construct meaning. Moreover, there are linguistic features of mathematical language, which include technical vocabulary as well as grammatical patterns. Technical vocabulary does not only consist of mathematical words (e.g., *sum*), but also of words that are not solely mathematical. The latter refers to words of multiple meanings depending on the context (e.g., *product*). As mathematics uses many words that are part of a child's everyday language, technical vocabulary needs to be used in meaningful grammatical patterns in order to be acquired. It typically comes along with 'dense noun phrases' (e.g., *the length of...)* as well as 'being and having verbs', which construct different kinds of relational processes (attribution and identification). While attributive clauses are non-reversible and refer to objects and events (e.g., *a sphere is a solid shape*), identifying clauses define technical terms and are reversible. Schleppegrell lists 'conjunctions with precise, technical meaning' (e.g., *if, when, therefore*) and points out the differences of their use in mathematical and ordinary everyday language. Moreover, the notion of academic language becomes increasingly more important for teaching and learning mathematics. Interdisciplinary language is characterized by precise and elaborated vocabulary and complex sentence structure, but in a more functional manner: It is this academic language, which affords the participation in teaching activities (Cummins, 1984; Schleppegrell, 2012).

There are multiple discourse practices in a mathematics classroom as learners and teachers bring various perspectives to a situation during interaction. Academic mathematical Discourse practices aim for learners to become mathematically literate and refer to practices that generalize, abstract or make claims (Moschkovich, 2007). Different language activities such as discussing and hypothesising are in accordance with the acquisition of a mathematical language, which is "more broadly conceptualised" (Morgan, 2005, p. 103). A communication tool, which implements different discourse practices, will be presented in the following section.

PRODUCING AUDIO PODCASTS FOR MATHEMATICS

In order to investigate how young learners use mathematical language to express meaning, they get to produce audio podcasts (Klose & Schreiber, 2014). Audio podcasts have been a popular medium for several years now. They can also be used for educational purposes such as in teaching Mathematics. Schreiber (2013) calls mathematical audio podcasts produced by primary school children "PriMaPodcasts". By creating audio podcasts for mathematics, the focus is on oral communication and representation, which means that the learners are not able to use visual aids or gestures to bring their message across. To express meaning accurately to an audience, the speakers need to reflect thoroughly on their topic and speech first. On the one hand, the learners have to discuss, research and accumulate mathematical content in a precise and orderly manner. This may foster their mathematics skills. On the other hand, they have to use language consciously in order to transmit their messages. This might support their communicative competence and skills. By producing PriMaPodcasts the students undergo an interactive process.

1. Unexpected Recording
2. Script I
3. Podcast - First Version
4. Editorial Meeting
5. Script II
6. PriMaPodcast

Table 1: Production Steps

The production steps, as summarised in Table 1, are the following:

1) **Unexpected Recording.** The students split into groups of three and answer a mathematical question unexpectedly, e.g., *'What is symmetry?'* or *'What is so special about a square in comparison to other quadrilaterals?'* A voice recorder records their response. It is interesting to observe the kind of mathematical concepts and mathematical language the learners are able to verbalise in this way.

2) **Script 1.** To plan an audio podcast, the students need to create a script. They are free to decide the format, structure and amount of detail they want to include. At this point, they can gather more information through resources such as the Internet, textbooks and given worksheets.

3) **Podcast- First Version.** Based on their script, the children record their first podcast version.

The procedure, material and media used by the groups are of importance as they have an influence on the quality of the first recording.

4) **Editorial Meeting.** Upon presenting the first podcast version to another group and their instructor, the creators receive feedback. After reflecting on it, they can make amendments to improve the quality in terms of content, style, language and performance. The editorial meeting does not only provide others an insight into the learners' thought process but also enables the instructor to clarify misconceptions.

5) **Script II.** The children revise their script of step 1 and enhance it. Despite receiving feedback and suggestions to improve the podcast in terms of content, language and style, the students themselves decide on the changes they wish to adopt in order to produce the final version that gets presented and published.

6) **PriMaPodcast.** Finally, the students produce the PriMaPodcast based on the second script. It will be published on a blog on the Internet. The advantage of publishing the PriMaPodcast in a blog is the ability to categorize all submitted podcasts into main-topics and sub-topics respectively to provide a clear overview. PriMaPodcasts have been produced in various languages: German, English, Spanish and Turkish. PriMaPodcasts recorded in bilingual learning settings are available in this blog: www.inst.uni-giessen.de/idm/primapodcast-bili

In order to investigate the mathematical conceptualizations of young bilingual learners in Germany, we expect them to produce PriMaPodcasts in both languages of instruction (English and German). The overall research questions of the PhD, which have not been fully addressed up to this point in time, are:

1) How do bilingually taught young learners use mathematical language in both target languages (English and German) if asked to present mathematical content?

2) To what extent does their mathematical language develop throughout the entire procedure of producing PriMaPodcasts?

METHODOLOGY

The following research design (see Table 2) was created to investigate the use and development of mathematical language of young German bilingual learners. Before the study, the communication tool PriMaPodcast and its different steps of production emerged during a pilot study at a bilingual school in Frankfurt a. M. Up to now, two rounds of data collec-

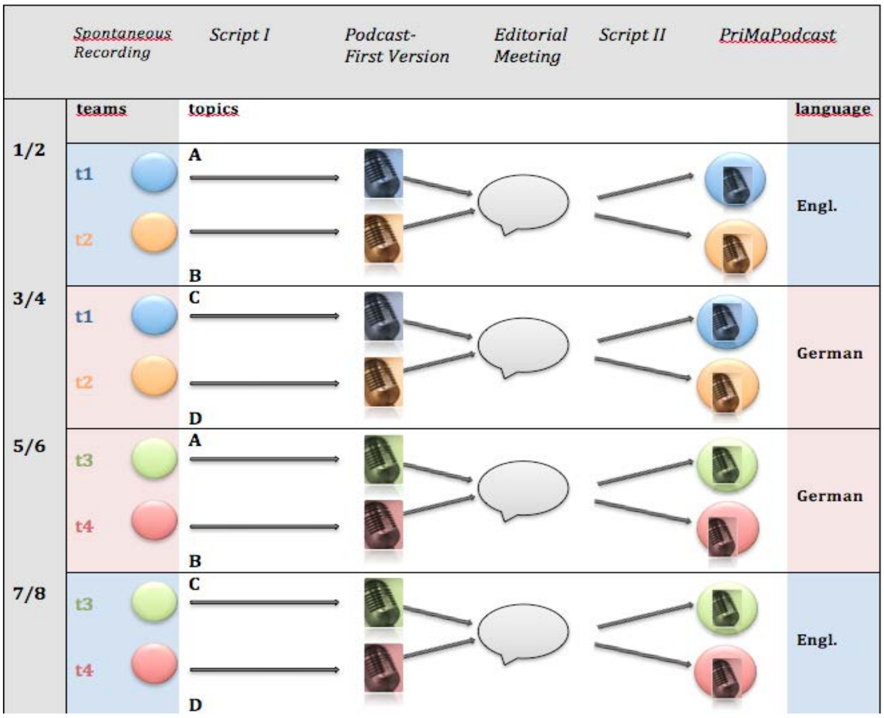

Table 2: Research Design and method of data collection

tion have been carried out. Each time, twelve bilingually taught students of grade 4 were grouped in fours. The groups produced two PriMaPodcasts about two different topics, one in German and one in English. All in all, a total of eight PriMaPodcasts with four different topics in two different languages were developed. In order to capture the different procedures of each team, the entire organisation process was video recorded. The mathematics teachers of both classes did a survey with regards to their personal models of bilingual teaching and learning. The learners' ways of interaction will be examined by the 'interaction analysis' (Krummheuer & Naujok, 1999), which is explained for simplicity by the following English empirical example that depicts the production process.

EMPIRICAL EXAMPLE

The example of the pilot study presented here deals with the question of 'What is symmetry?' Three 4th graders (aged 9 to 10) produced the following PriMaPodcast in a bilingual mathematics classroom in Frankfurt. The transcripts below refer to the following recordings: the unexpected recording, the first podcast version and the final version. All citations of the transcripts are marked in squared brackets <like this>. The following analysis is based on the principles in Schleppegrell (2007) as outlined before. Some of the applied transcription rules are:

. .. ...	Pause: . 1 sec .. 2 sec ... 3 sec
(4sec.)	Pause with given duration from 4 seconds onwards
Text written in *(italics)*	Describes actions for example *(whispering)* or *(incomprehensible expressions)*, ended up with %
Bold	Emphasis
b l o c k e d	Stretched pronunciation
/	Pitch inclination
-	Pitch stays constant
\	Pitch declination
#	One utterance is followed immediately by another

Unexpected Recording

01 Student 1: Explain what is symmetry ... uhm symmetry is w h e n . things are . mh l i k e . mh the same looks like the same on both sides

02 Student 2: Symmetry is uhm l i k e w h e n . it's uh s o m e when it's both the same *(he is mumbling)* be that's what . Kilian said it's . the same

03 Student 3: *(is speaking low)* I don't know what symmetry is\ *(is breathing out)%*

04 Student 2: Yes a symmetry is would be like uhm . a h o u s e and the neighbour has also a house that looks . the same . just the same .. b u t uhm not everything can be symmetry...

05 Student 1: When you draw a picture and . and you wa and you m have a .. mirror it looks symmetric

06 Student 2: Yes like u h m .. m h h how I can say that . symmetry is symmetry *(Student 3 is laughing)*% . like u h like this . like uh a blue order from the same market uhm . yes#

07 Student 3: #the same colour

Student 1 reads out the task and continues giving an answer in <01>. By using an identifying clause combined with the conjunction 'when', he tries to define the technical term 'symmetry'. He talks about things that are the same and emphasizes this fact in the following. Then he reformulates this statement, by saying that something is "the same on both sides". It is difficult to analyse the concept of symmetry he has got in mind because his explanations remain unspecific; technical terms are not used. Moreover, he seems to be uncertain about the topic, which is signalized by having used fillers (mh, l i k e) and pauses. In <02> student 2 alludes "both" to the two things being the same. In doing so, he adopts the grammatical pattern of student 1 and also refers to his answer. In between, his mumbling of words indicates that he has no specific idea yet. Student 3 in <03> answers with a complete sentence and admits to not knowing what symmetry was. Then student 2 makes another attempt by giving an everyday example in <04>. The unknown things are replaced by two houses. He emphasises again that both houses look "the same". Therefore, he begins his statement with an attributive clause. Then he makes a restriction, claiming that "not everything can be symmetry". Being a second language learner he used the noun 'symmetry' instead of 'symmetric'. Student 1 in <05> seems to think of an approach to connect symmetry to mirroring. By using the conjunction 'when' instead of 'if', he tries to describe this procedure. However, he only names two parts of construction, 'drawing a picture' and 'having a mirror'. By having both components, he suggests it would look symmetric. Even though one could understand what he meant, this explanation remains incomplete. Student 2 in <06>

continues with a statement that causes student 3 to laugh. While pondering on an explanation, he simply states "symmetry is symmetry". This attributive clause defines symmetry by itself, which expresses his inability to find a better explanation. Next, he refers to something blue that comes from the same market. This aspect might indicate a translation movement. Student 3 in <07> seems to know what his peer means and puts emphasis on the same colour. At this point the recording ends. The boys seem to have reached a conclusion despite having incomplete statements. They use some grammatical patterns of the mathematical register but they do not use much technical vocabulary and precise explanations. The pupils research their topic and create a script. This serves as basis for their first podcast version.

Podcast – First Version

01 Student 1: Symmetry are things l that look same

02 Student 3: Symmetry means you have a line in the middle and both sides need to are the same like/

03 Student 2: A star has a symmetry . the flag of Great Britain has a symmetry a plane has symmetry - a pentagon a hexagon the White House has symmetry a flower a triangle a guitar a butterfly . uhm . symmetry has also a strawberry a ball . uhm . then underwears has symmetry and p a n t s and the f a c e #

04 Student 3: #and scarfs

05 Student 2: Yes . scarfs and glasses has symmetry .. *(is speaking low)* that's it%

In this version student 1 starts off with a general statement about symmetry by using an attributive clause in <01>. This statement is comparable to the first utterance of the unexpected recording. The emphasis again is on the sameness of things. Student 3 seizes the idea of having "a line in the middle" in <02> which generates two equal sides. This idea, described by a common expression, seems to relate to the line symmetry. In order to express meaning, an identifying clause is used. However, the exact aspect of symmetry and the objects referred to have not been explicitly conveyed yet. Only in statements <03>, student 2 presents some examples concerning line symmetry by using common words as well as technical terms, e.g. "hexagon" and "triangle". It appears that he forgets to mention one example, which student 3 adds in <04>. Student 2 repeats the suggested word and names another example in <05>. In contrast to the unexpected recording, the statements are now better conceived and more structured, except for the rather informal beginning and end. In the editorial meeting the peers praise the chosen examples. The boys receive constructive criticism to improve their script in terms of content, style and language.

PriMaPodcast

01 Student 3: What is symmetry

02 Student 1: Symmetry are things that look same on both sides . when you have a mirror and put it in the middle . of a symmetric thing and it looks same . on both sides it is symmetric ... A mirror is like a line o of symmetry

03 Student 3: These . there are lots of things . that are symmetric\ but not all things are symmetric\ these things are not symmetric\ a radio a door a piano a crane an ocean a sea a river\ these things are symmetric

04 Student 2: Clothes a tie glasses pants and underwears shapes a star the flag of Great Britain a triangle a hexagon a pentagon . nature for example butterflies flowers and strawberries\ . music a guitar/ a violin\ . electricity a plane even words can be symmetric otto

Student 3 reads out the question in <01>. Student 1 gives a definition by using an identifying clause, similar to the beginnings of the other recordings: he equals symmetry with "things that look same on both sides" in <02>. Then he returns to the idea of mirroring which was originally uttered in the unexpected recording. The instruction on how to mirror is more detailed than before. Moreover, the technical term "line of symmetry" is used for the first time. In his explanations student 1 relates to general 'symmetric things'. Before these things are further explained by giving lots of examples in <04>, student 3 emphasizes in <03> that "not all things are symmetric". Having taken up the idea of the unexpected recording, he names seven things, which are not symmetric. He leads over to student 2 who reads out the examples of symmetry in <04>. Some of them, which are presented in the first podcast version, are not mentioned here any more (e.g. the 'White House' or 'a scarf'). Another difference is that the examples are classified into categories like 'clothes', 'shapes' or 'music'. Thus, they are more structured. A new example of symmetry is highlighted in the end: words like 'OTTO' can be symmetric, too.

CONCLUSIONS

As presented in the empirical example, the production of PriMaPodcasts makes it possible to investigate the bilingual learners' use of mathematical language. Each stage of production allows the mathematical language of the group to develop and become more specific as seen in the transcripts. The implementation of mathematical discourse practices, such as explaining and defining, enable the learners to express and discuss their mathematical thought processes. Moreover, the reflection on certain content deepens the students' mathematical understanding. The interactive procedure corresponds with the requirement of a mathematical conceptualization, by going beyond the stringent learning of technical terms and vocabulary. Thus, learners are groomed to become mathematically literate.

In the context of my PhD project, the presented research framework has been implemented twice so far. The analysis of the single stages (audio and video taped) will open up various possibilities to retrack the learners' progress by producing PriMaPodcasts in German and in English. Hoping to get further insights into the learners' understanding of mathematical concepts, the project will continue. As this is an on-going PhD project, further results cannot be disclosed as of yet.

Gestures as part of discourse in reasoning situations: Introducing two epistemic functions of gestures

Christina M. Krause

University of Duisburg-Essen, Essen, Germany, christina.krause@uni-due.de

In this paper, I present how gestures can contribute to reasoning actions in social epistemic processes. In an empirical study, I investigated possible benefits of students' use of gestures in social learning processes. Integrating an analysis of students' gestures in a reconstruction of epistemic processes led to the identification of epistemic functions of gestures as ways in which gestures contribute to the accomplishment of epistemic actions. Two of these epistemic functions appear to be of special interest when students carry out reasoning in social interaction. Therefore, they will be presented in this paper by means of illustrative examples.

Keywords: Gestures, epistemic processes, social reasoning actions, embodiment.

INTRODUCTION

During the last 15 years, the study of gestures as part of the discourse in the mathematics classroom has increasingly gained attention (see Arzarello & Edwards, 2005). Gestures are considered to be a core resource in mathematical learning processes, a resource that can fulfill both a representational as well as an epistemic function in collaborative working processes (Dreyfus, Sabena, Kidron, & Arzarello, 2014; Krause, in press). Gestures have been identified to simplify the communication of ideas that are not yet fully elaborated (e.g. Reynolds & Reeve, 2002), reducing the cognitive effort needed for finding suitable mathematical words. Other studies point out benefits of collaboratively making use of the shared gesture space as mathematical experimental space in social interaction (Yoon, Thomas, & Dreyfus, 2011). Nevertheless, research investigating the use of gestures in mathematical reasoning is still scarce, although reasoning and argumentation are considered an important mathematical activity (Krummheuer, 2007).

This study is related to my PhD-project on the role of gestures in social processes of mathematical knowledge construction (Krause, in press). Although reasoning situations have not been in the focus of the study, they consituted a particular part of these processes. The investigation of gestures' contribution to epistemic processes within an embodied and multimodal framework led to the suggestion that *gestures may support reasoning actions in different ways when mathematical knowledge is constructed*. Evidence of this hypothsis will be presented more in detail in this paper.

THEORETICAL FRAMEWORK

Gestures are considered "idiosyncratic spontaneous movement[s] of the hands and arms accompanying speech" (McNeill, 1992, p. 37), "being done for the purposes of expression rather than in the service of some practical aim" (Kendon, 2004, p. 15). Underlying all the research on gestures is the assumption that gesture and speech are co-expressive, that is, they refer to the same idea: McNeill sees "gesture and the spoken utterances as different sides of a single underlying mental process" (McNeill, 1992, p. 1) and claims that "speech and gesture must cooperate to express the person's meaning" (p. 11), "each can include something that the other leaves out" (p. 79). According to the *Information Packaging Hypothesis (IPH)* (Kita, 2000, p. 163), gestures can help speakers to "package" spatial information into units appropriate for verbalization (Alibali, Kita, & Young, 2000, p. 593). By the use of gestures, information is parsed into entities more convenient to put into words, "consequently, the collaboration between the two modes [gesture and speech] provides speakers with wider possibilities to organize thought in ways suitable for linguistic expression" (Kita, 2000, p. 180).

Mathematical knowledge is considered to be constructed by individuals in social interaction, not arbitrarily but constrained by our bodily experience as humans in the world (Núñez, Edwards, & Matos, 1999, p. 53). While social-constructivism concerns the social-communicative aspects of learning, embodied cognition adds how individual aspects are shared as being based on bodily experience. It grounds the assumption that in social interaction, not only explicit and conventionalized modes of expression like speech are considered for the interpretation of an utterance, but also implicit ones such as gestures. It is due to our shared bodily experience as humans in the physical world that these implicit embodied modes of expression can be processed similarly by distinct individuals. Hence, the social-constructivist and the embodied approach do not oppose each other: While gestures may embody knowledge that is not consciously accessible, they may contribute to the social interaction implicitly. Reconstructing the epistemic processes within social interaction thus requires considering both implicit and explicit modes of expression.

Furthermore, embodied cognition theory states that bodily behaviour influences the way we think, grounding fundamental mathematical concepts in everyday experience through metaphorical thinking (Lakoff & Núñez, 2000). By expressing something in terms of something else, an entire conceptual environment can be understood via a more accessible or more illustrative domain. The domain referred to is called *source domain* and conveys how the relationships in the *target domain* shall be understood.

The social epistemic process was described by an epistemic action model that has been developed by Bikner-Ahsbahs (2006) based on the interpretation of speech acts. It encompasses the three social epistemic actions of (a) *gathering* single mathematical entities like examples or associations, (b) *connecting* a finite number of them, and (c) *seeing structures* such as generalities or patterns *(GCSt-model)*. The latter takes place when a new entity is built or a known entity is re-built in a new context.

A semiotic perspective has been integrated by understanding gestures as signs in a Peircean sense as "something that stand to somebody in some respect or capacity" (Peirce, CP 2.228) and an analysis within the semiotic bundle. The semiotic bundle is a dynamic structure that consists of different semiotic sets (e.g. speech, inscription and gestures) and relationships between them (Arzarello, 2006, pp. 280–282), both evolving in time. Some synchronous relationships can be described by two features of gestures; one concerning gestures' relation to speech, the other concerning its relation to inscription (Krause, in press). Each is considered to frame the interpretation of the utterance as it is shaped by speech, gesture, and inscription in social interaction:

— Gestures can *specify* aspects of the mathematical object referred to and by this, enrich the verbal utterance. They can specify the *where*, the *what*, the *how*, or *relational* aspects of the mathematical object. 'Where' refers to spatial aspects such as *location* or *direction*, 'what' gives information of the *kind* of the object, 'how' concerns the *style* of a mathematical object or activity, *relations* are specified when the gesture represents relations within an object or between objects in addition to what is explicated in speech. The specification reflects a potential non-verbal influence on the interpretation of an utterance within social interaction.

— Gestures are performed on *three referential levels*: *Level 1* is considered the level of the concrete, when the gesture refers directly to something that is already fixed. On this level, the gesture functions as an index in that its meaning solely derives from the meaning of what it refers to. On *level 2*, the level of the potential, gestures are embedded into an existing inscription. That is, something that is not fixed that way is made visible within an existing representation. The interpretation of gestures on level 2 demands for the material and/or contextual background of an inscription. The gestures in the gesture space, which is the space in the air roughly between the shoulders and the hips (McNeill, 1992, p. 86), are performed on *level 3*. They are free in the sense that they are detached from any inscription. Their disengagement from the concrete reveals a state of conceptualization of a mathematical idea.

Adding a semiotic perspective showed that gestures do not only affect which information may be provided

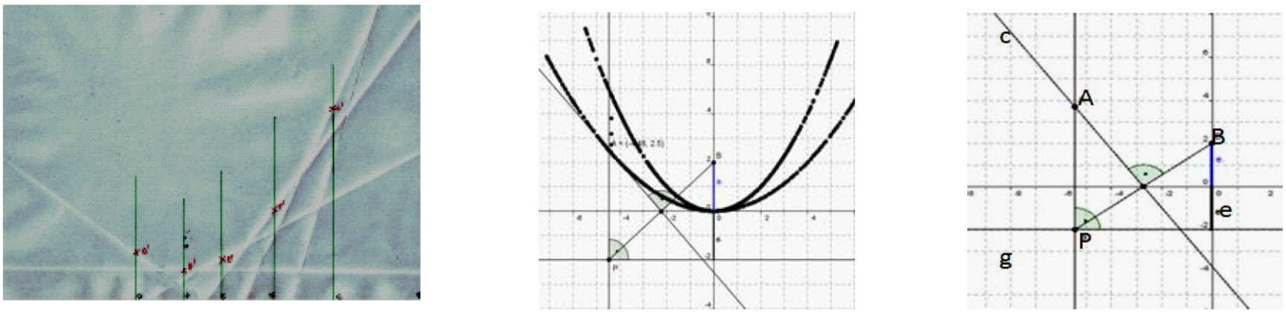

Figure. 1a-c (from left to right): (a) Possible outcome of the folding process, (b) static cut-out of the GeoGebra representation, (c) printout given to the student, representing one possible situation of the GeoGebra environment

by an utterance, but also that gestures can have direct impact on the accomplishment of epistemic actions. They can prepare, support, and also realize epistemic actions in different ways which I call *epistemic functions*. This paper deals with two epistemic functions that I consider to support reasoning actions.

Within the frame of the GCSt-model (Bikner-Ahsbahs, 2006), reasoning actions are a specific kind of connecting actions: Two or more aspects of a mathematical object or idea are linked in order to justify or explain a hypothesis, or the rejection of a hypothesis. This paper focuses on these kinds of connecting actions, providing first suggestions on *how gestures may take part in supporting students' reasoning as epistemic connecting action.*

METHODS

Three pairs of high-achieving students of grade 10 solve three tasks each. The tasks have been constructed to prompt fruitful epistemic processes by initiating epistemic actions. The three tasks deal with different mathematical topics and each provides a different variety of representations to work with in the course of solving the task. The epistemic functions presented in this paper concern a geometric-algebraic task and a task on logical reasoning using the idea of mathematical induction. This choice has been made due to the diversity of mathematical topics and representations provided by the tasks.

The Geometric-Algebraic Task deals with the parabola as geometrical locus. In the course of the task, three different representations are provided to the students: First, they have to construct a folding diagram according to the following instructions. On a given sheet, a point M is marked. They are now asked to (i) mark any point on the lower edge of the sheet, (ii) fold the paper such that the chosen point comes to lie upon the point M, (iii) draw a perpendicular to the lower edge of the sheet running through the point chosen on it, (iv) mark the intersection point of this perpendicular and the folding line with a red cross, (v) keep on proceeding like this by choosing new points on the lower border until they recognize a curve. This process leads to a folding diagram of the envelope curve of a parabola, the folding lines being tangents to the curve and the intersection points being points on the parabola. Figure 1a shows a possible outcome of this process.

Then, a GeoGebra file is introduced that represents a similar situation within a coordinate system. Here, the point corresponding to the one chosen on the lower border is called "P" and can be dragged to the left and to the right. Through dragging, a trace is produced by the points on the curve (Figure 1b). Finally, a printout capturing one possible situation from the GeoGebra environment is given to the students (Figure 1c). A first subtask consists of making conjectures about what can be seen in the folding diagram. Thereupon the folding diagram shall be compared to the GeoGebra diagram before a conjecture about the type of the function shall be stated and justified.

The Task on Logical Reasoning was formulated as a word problem:

An undefined number of persons sit in a circle. Everybody wears a hat. Everybody sees every hat except one's own. Everybody knows that at least one hat is marked. Every five minutes, a bell rings. Everybody who knows that his own hat is marked shall raise his hand with the ring of the bell as soon as he knows. The challenge consists in concluding from the number of hats one sees whether one's own hat is marked or not.

No further representations of the situation have been provided. For the base case of seeing zero marked hats it follows immediately that one's own hat is marked from the condition of knowing that there is at least one marked hat. The induction step can be induced from the reaction of the other persons by reconstructing how many marked hats they see, and then concluding on whether one's own hat is marked from the behaviour of the other's at the n^{th} ring of the bell. Solving the task thus makes use of the idea of mathematical induction and distinguishing cases concerning the reactions of the other consultants at the n^{th} ring of the bell.

The two tasks differ not only in the mathematical topic they deal with but also in the role of representations provided to the students. The rich semiotic variety of the geometric-algebraic environment is suggested to prompt the students to use gestures when reasoning on the kind of function. However, the more important question is *how* gestures may support the reasoning actions when solving this task. The lack of such representations in the task on logical reasoning raises the question whether gestures are used at all, and if so, what these gestures refer to and whether and in which ways they support reasoning as the main mathematical activity of the task.

Data and analysis

The learning processes have been videotaped from three perspectives: One camera filmed from the front to capture the gestures of the students. A second camera was directed to the inscriptions in front of the table. A third perspective was used to record the student's use of GeoGebra visible on a computer screen. Based on these video recordings, transcripts have been written, considering verbal utterances as well as non-verbal actions (see Figure 2 for the transcription key).

For answering the research question stated in this paper, those connecting actions become relevant in which the students justify or explain their conjectures. To reconstruct the role of gestures therein, the gestures are analysed within the semiotic bundle, taking into account also possible metaphorical meaning, grounded in the bodily experience with the physical world.

HOW GESTURES CAN TAKE PART IN REASONING SITUATIONS

In the following section, two examples will be reconstructed. These present the two epistemic functions *contrasting* and *giving visual access to the structure of a reasoning action* as ways in which gestures can support reasoning actions.

Supporting counter argumentation by contrasting to another representation

The two students Mike and Tim work on the task in which the *parabola* is explored and experienced as geometrical locus. They have already constructed the folding diagram and traced the curve in the GeoGebra environment. Preceding the following scene, Mike and Tim have identified the curve to be an exponential function "with some factor in front of it" (235). Prompted by an interviewer, the students are asked

exact.	dropping the voice	exact'	raising the voice
exact	emphasized	,exact	with a new onset
e-x-a-c-t	prolonged	(.), (..), (...)	1, 2 or 3 seconds pause
/S	interrupts the previous speaker	(4sec)	4 seconds pause (for more than 3 seconds)
[squared brackets]	indicate beginning and end of a gesture movement		

Figure 2: Transcription key

Figure 3: GeoGebra diagram as visible on the screen (trace thickened to optimize visibility) and gesture accomplished by Mike in line 288

to make statements about the values of the function represented by the curve for $x = 0$ and $x = -1$. This is when they realise that "it can't be that it is an exponential function' " (284; See Figure 2 for the GeoGebra diagram as visible on the screen at that moment.), explicating the reason in speech and gesture (Figure 1 for transcription key):

284 /Mike: it can't be that it is an exponential function' *(looks at Tim)*
285 Tim: right.
286 Mike: because ,uhm
287 /Tim: then it [would be] (*points towards the screen)* smaller there
288 /Mike: [elsewise the number would be smaller and smaller (*points at the screen from right up to left down)* (.)] the left side normally

Mike's reasoning of the refutation of the curve representing an exponential function consists of three utterances: In line 284, he refutes the conjecture about the type of the function. At this point, the basis of the conclusion he draws after considering the concrete values does not become explicit. In lines 286 and 288 he justifies his conclusion. Although Tim already confirms Mike's statement in line 285, Mike gives an explanation using a counterargument. He starts with "because" (286) but hesitates. This makes Tim start an approach, imprecisely referring to that "it would be smaller there" (287). This mentioning 'something being smaller' in combination with the pointing towards the screen suggests that he has in mind the same reason that in turn is expressed by Mike (288). From Mike's verbal utterance alone, the reasoning is not complete: He uses an undefined reference ("the number") and leaves out aspects that are specified in gesture: The iconic reference to the shape of the curve of an exponential function is combined with the indexical reference to the screen. Through this, two main functions are fulfilled: The gesture allows "the number" to be interpreted as a y-value and the direction of decrease to be from right to left, adding an aspect that is needed to interpret the argument to its full account. Shaping the interpretation frame of the entire utterance, the gesture *specifies* the *where*, the *what,* and the *how* as style of the shape of the curve potentially embedded into the GeoGebra diagram on level 2 in front of the screen. The performance on level 2 superimposes the actual case visible on the screen with the one to exclude as ephemerally shaped in gesture. This depiction of the hypothetical case to be refuted, the shape of the curve of an exponential function, makes apparent the difference in the styles of the two shapes. The curve has been traced in its full extent before and its symmetry is knowledge that is shared between the students. The depiction of the gesture thus represents only that part in which both representations do not fit together, hinting at a difference that is specified and with that, illustrates the counter argument given in speech.

Giving visual access to the structure of the reasoning action

Rosa and Lisa resolve the *task on logical reasoning*. They already hypothesized how to behave after the n^{th} ring of the bell, depending on the number of hats they see and the behaviour of the other consultants. They checked their strategy for some concrete cases and in conclusion, decided it to be valid. In the following excerpt, they investigate whether there may exist another strategy by assuming the case that all consultants wear a marked hat, considering the generic example of five consultants sitting in the circle and consequently seeing n=4 marked hats:

297 Rosa: the at the fourth ring they still see- *(writes: "4th ring: no") (4sec)* none ,oh- *(scratches out "no")* ,there I have always written nobody *(writes "nobody")* (...) *(writes "⇒")* ,that means there have to ,be- *(briefly raises*

Figure 4: Rosa's gesture depicting the path from ***condition*** to ***conclusion***, simultaneous to "more than four"

> *her hand and turns it forward in one fast movement)* [more than four] because they are only five everybody has one. *(writes: "all")*

Rosa concludes on the number of marked hats in the game ("that means there have to ,be [more than four]"), based on the fact that nobody signals at the fourth ring of the bell ("at the fourth ring they still see none"). While this is interpreted as a connecting reasoning action that can be reconstructed from the verbal utterance, Rosa's accompanying gesture metaphorically represents the connection of premise and conclusion as tracing a path from the back forth in an upwards arc by turning the wrist forward once. In this gesture-speech interplay, components of a metaphorical mapping based on the image schema of source-path-goal (Edwards, 2010, pp. 233–234) can be identified: Within this mapping, the "goal" corresponds to the conclusion. The movement of the hand on level 3 metaphorically represents the "path" within the gesture space and embodies what could verbally be expressed by the word "then". The gesture summarizes that the conclusion "there have to ,be- [more than four]" is derived from the condition that nobody signals. It helps understanding how Rosa 'packaged' her utterance into source, path and goal. The metaphorical meaning does not develop within the social interaction such that the gesture is not considered to explicate situated meaning by specifying aspects of a mathematical object. Moreover, it is deeply embodied in the everyday concept of deducing a conclusion from a given premise, not necessarily related to a mathematical topic. The gesture itself implicitly realizes a connection of premise and conclusion and with this, supports the verbal connecting action of logical inference by illustrating it in a more general way. The visual access it provides does not refer to a mathematical object but to the structure of reasoning on a meta-level. This way, it may help to keep the discourse on track by sharing the organization of thought underlying the argument.

SUMMARY AND DISCUSSION

The two epistemic functions of gestures presented in this paper show how gestures may support reasoning as specific kind of connecting action in different ways:

Contrasting-gestures shape a representation of a mathematical object which is reasoned about in comparison to another representation. In this way, the gesture can specify aspects to exclude one of the two possibilities. The contrasting-gesture complements speech and inscription in an *explicit* manner. Without the gesture, it would be left unclear why the verbal utterance justifies the conclusion. Using a gesture this way to support a counter argument becomes possible by the graphical representation of the mathematical object on which is reasoned and the knowledge about it as has been developed within the social interaction.

Gestures can also embody the action of connecting premise and conclusion within an act of reasoning and thereby *give visual access to the structure of a reasoning action.* In this case, the metaphorical character of the gesture is completely detached from the concrete content of the task. The structuring-gesture provides an *implicit* support by not enriching the utterance semantically, but on a meta-level. Using a gesture this way may support the collective act of reasoning as it indicates the logical structure within an argument and may help to keep track. It makes traceable how the argument was organized as logical inference.

Being characterized by a depictive use of gesture and a close and direct relationship to speech and current inscription, *contrasting* can be considered a *situated* function. On the other side, the metaphorical use of gesture while *structuring the verbal discourse* has an implicit meta-relation to speech such that the function may be rather a *universal* one.

This raises the question whether there may be typical ways of using gestures with respect to different types of reasoning actions and about the role of these gestures in learning and in teaching. With regard to the mathematics classroom, Arzarello and Sabena suggest that gestures may foster students' argumentation skills by structuring mathematical arguments (Arzarello & Sabena, 2014, pp. 99–100), similar to what I have presented in this paper. While they adopt an individual approach, the examples presented here indicate how it may also benefit reasoning actions from a social perspective: Adding gestural expression provides visual access to the argument such that it becomes received and processed also in a visual modality, making the understanding of the utterance (and so also of an argument given) more comprehensive.

To test and refine this hypothesis, further individual research on the role of gestures in social reasoning actions is needed, conducted against a more elaborated theoretical background. The epistemic functions of gestures presented in this paper can provide a basis for such an investigation due to their diverse groundings in *graphical aspects* of reasoning on the one hand, and the *logical structure* of discourse as metaphorically *embodied aspect* on the other hand. Furthermore, the presented findings suggest to be aware of the potential of gestures for and in social processes of argumentation.

ACKONOWLEDGEMENT

This project was funded by the Central Research Developmental Fund (ZF) of the University of Bremen (Germany) (grant #03/112/08). The data used in this project is taken from the project "Effective knowledge construction in interest-dense situations", funded by the German Israeli-Foundation (grant #946-357.4/2006).

Ambiguity as a cognitive and didactic resource

Maria Mellone and Roberto Tortora

Università degli Studi Federico II, Naples, Italy, rtortora@unina.it

Mathematics is often perceived and described as a domain of perfection, where polysemy is seen as dangerous and ambiguity is banned. But if that is true for the "final" dressing of official mathematics, in doing mathematics and, as we claim, in understanding it, things run the opposite way. Contrasting usual didactic practices, suitable forms of ambiguity can be seen and used as powerful cognitive resources. We present reflections on a long lasting didactic activity with students of different grades (from primary to university level), and show how to exploit some ambiguities (in particular linguistic ones) related to the notion of consecutive numbers.

Keywords: Language, ambiguity, polysemy, consecutive numbers.

INTRODUCTION

What is the meaning of *ambiguity*? The 2013 online version of the Webster Dictionary states: "Ambiguity: doubtfulness or uncertainty, particularly as to the signification of language, arising from its admitting of more than one meaning; an equivocal word or expression." In these words we perceive something wrong in any occurrence of an ambiguity. According to common sense, ambiguity is a sort of imperfection or a kind of error; and errors should be avoided. This is particularly true within mathematics. One of the main features of mathematicians' activity is the ability to expunge any inconsistency and every uncertainty from their arguments. However, although there is no doubt that the final aspiration of mathematics (and, for that, of all science and knowledge), is total freedom from errors, it is also true that, in the long path towards this goal, errors often play an invaluable role and make a strong contribution. Many authors have stressed this view, in different philosophical and theoretical domains, from gnoseology to epistemology. In the works by Popper, Kuhn or Lakatos, just to mention a few, errors and ambiguities are viewed as powerful stimuli for scientific development.

In the educational domain, the impact of errors as a didactic resource has also been recognized, albeit more recently. For this we essentially refer to the monograph by Borasi (1996) and to the extensive bibliography therein.

Less widely explored, as far as we know, is a possible positive influence on teaching activities of ambiguity and in particular of polysemy, here considered as a form of linguistic ambiguity. Many authors have noticed how and why the confusion that often arises between a naïve and a technical meaning of the same word (*angle*, *continuous*, *square*, *limit*, *increasing*, and so on and so forth) is the source of many students' difficulties (Tall & Vinner, 1981; Ferrari, 2004; Bardelle, 2010). The usual approach to ambiguities is to identify them in order to avoid, as far as possible, their disturbing consequences.

Our approach is quite the opposite. According to the general view by Borasi (1996), we will try to show how ambiguities, in particular linguistic ones, can play a useful role in the development of mathematics learning. To this purpose, we present an example of an educational activity proposed over several years to students of different grades (from primary to university students). Then we will discuss some real and potential developments of the activity and will make comments on its effectiveness. Finally some reflections will be made on the role of the teacher within a general vision of the educational process.

THEORETICAL FRAMEWORK

One cannot assign a positive value to errors and inaccuracies of students if one has a vision of teaching as transmission. Indeed, our claims on ambiguity and its important role in mathematics learning processes require an active role of learners as conceived in the inquiry approach (Borasi, 1992, 1996):

> Whereas in traditional mathematics classes ambiguity, anomalies, and contradictions are carefully eliminated so as to avoid a potential source of confusion, in an inquiry classroom these elements would be highlighted and capitalized on as a motivating force (Borasi, 1996, p. 25)

Starting from this main premise, the research work we are going to present finds its roots in the Vygotskian sociocultural vision of learning. In particular in our work, the language plays a central role: if errors are of several types, ambiguity is a typical linguistic affair. It is therefore necessary to frame our proposal in the context of studies on the importance of language for mathematics and mathematics education. For this, we refer to general studies of functional linguistics (Halliday, 1985) and to the elaboration of these ideas in the domain of mathematics education, especially (Ferrari, 2004). From there we draw some essential constructs, described below.

The pivotal notion connecting texts to contexts is that of *register*, that is, a variety of language depending on usage. Whenever an individual uses the language for a particular purpose, he selects a register which is suitable for that purpose. Of course, the choice is also bounded by the resources that are available for the individual. For further details on this meaning of register (Ferrari, 2004), where the sense is also contrasted with the same term used differently by Duval (2006). In this framework the key distinction is between *literate* and *colloquial* registers. The difference is functional, in the sense that the same people can use a literate register in a context and a colloquial register in a different one. The literate registers are typically used in communications belonging to scientific, legal, political, literary, etc. domains, in most of the narrative and often in speeches among educated people. The colloquial register is typically used in more or less informal speeches. A fully satisfying definition is impossible. For mathematics educators, what is important is to compare or to contrast the literate registers used within formal mathematics with the colloquial ones used in life and also in the everyday discourses in teaching-learning environments. This comparison represents a tool by means of which it is possible to interpret some students' difficulties. In Bardelle (2010) it is used to analyse the behaviour of a sample of university students involved in the study of the monotonicity of a function and of the properties of its graph.

The ambiguity coming from two different uses of the same word or locution in the colloquial and in the literate (mathematical) register is shown as an obstacle for the acquisition of some mathematical notions. This is true, but at the same time, in many mathematical contexts, ambiguity can be viewed and exploited as a resource, acting as a stimulus for a deeper and more critical advancement of knowledge. More generally, we are convinced that it is quite illusory to try to expunge any ambiguity from the mathematical discourse; or, as it may be, from mathematics itself, according with Sfard's (2008) radical identification of mathematics as discourse.

In the history of mathematics, such intricate paths are frequent (see the analysis of Lakatos (1976) of the Euler's theorem for polyhedra). We do not think that the individual cognitive development reproduces faithfully cultural evolution but want to observe that whenever an epistemologically difficult notion is encountered, both in the history and in a learning environment, many attempts have to be made before the notion can be assimilated. Many of these attempts include shifts from a linguistic register to another and changes in the meaning of some key word.

According to a sociocultural vision of learning and teaching, our way of working with students is based on a continuous interplay between the linguistic components of knowledge and an epistemological analysis of the disciplinary concepts involved. For this kind of analysis, we refer mainly to the theoretical construct CAC (*Cultural Analysis of the Content*) by Boero and Guala (2008). Mathematics is seen as an evolving discipline "with different levels of rigor both at a specific moment in history (according to the cultural environment and specific needs), and across history, and as a domain of culture as a set of interrelated cultural tools and social practices, which can be inherited over generations" (ibid, p. 223). This vision of mathematics forces a conception of mathematics education activities that leads teachers and educators "to radically question their beliefs concerning mathematics in general and specific subject matter in particular" (ibid, p. 223).

A CULTURAL-LINGUISTIC ANALYSIS OF CONSECUTIVE(NESS)

In this study we take into account the notion of *consecutiveness*, in particular its occurrence in the locution *consecutive numbers*. We deeply analyse this notion within the solution and discussion of the following arithmetic word problem, submitted, with some variants, to students of different grades.

> Take four consecutive numbers. Multiply the two middle numbers by each other, then multiply the first one by the last one and calculate the difference between the two results obtained. Repeat the exercise several times, using different numbers. Do you observe any regularity?

The consecutiveness notion is not encountered here for the first time as an argument of discussion within mathematics education research (see Boero, Chiappini, Garuti, & Sibilla, 1995). This notion is suitable to trigger various arithmetic explorations, or to develop argumentation and proof activities in arithmetic, guided by careful teaching mediations. Here, we focus on some subtle ambiguity inherent to the notion of "consecutiveness", trying to show how, if handled with care, it can represent a powerful resource for education and knowledge purposes. With this aim, in this section we analyse some cultural and epistemological aspects of that notion, starting from the above problem, and according to the CAC perspective.

First of all the text refers to consecutive numbers without specifying the number domain. That is not a problem. From one side the use of the word "consecutive" in a literate register, like the text of a word problem, should suggest that the correct domain is the set of natural numbers or perhaps of integers; from the other side the common use in a colloquial register of the word 'number' without specifications, always refers to natural numbers. But what is the meaning of consecutive natural numbers? Even in the scientific register we can recognize (at least) two meanings assigned to these words: i) the first one is framed within the order relation; ii) and the second one comes from the additive structure (one might even distinguish this meaning from the one embodied in Peano's successor operator). Let us give a closer look at these two meanings, and at their formal renderings:

i) Probably the most natural meaning of the term "consecutive" corresponds to the idea "to be immediately subsequent to", like, for example, in "Monday and Tuesday are consecutive days". In mathematical words this requires the presence of an order relation (better, a total and discrete one). So to say in a (partially) formalized language that two elements a and b are consecutive, we have to say that "$a < b$ and there is no element c such that $a < c < b$". From the logical point of view, we have the conjunction of two statements, an atomic one and the negation of the existential of a conjunction (there <u>does not exist</u> any c such that $a < c$ <u>and</u> $c < b$). So, we see that the formal translation of a (relatively) simple notion has a logical structure far from simple. Worse, we could even argue that the notion of consecutive is 'symmetric' (that is, if 2 and 3 are consecutive, also 3 and 2 are consecutive), and so its algebraic translation becomes even more complicated.

ii) The other meaning of consecutive can be expressed as: "Two numbers are consecutive if the second one is obtained adding one unity to the first one", which in algebraic language is written as "a and b are consecutive if $b = a + 1$". Unfortunately, this definition is good for natural numbers (and for integers too), but not for other numerical domains, for example the sets of even or of odd numbers. But one can generalize the above notion of consecutiveness by taking into account the more general 'additive' relationship existing between two closest terms of any arithmetical progression, i.e., with obvious meaning of the variables, $a_{n+1} = a_n + d$.

What happens is that the two above meanings of the word consecutive coincide for natural numbers, but they do not for other kind of numbers: either in the sense that the first meaning disappears (for rational numbers a and b it is meaningless to say that they are consecutive while it makes sense to say that $b = a + 1$); or in the sense that the second possibility vanishes (two even numbers a and b can be consecutive but it can never happen that $b = a + 1$); or in the sense that both conditions are acceptable but bear different meanings (e.g., the case of rational numbers truncated to the second decimal place). The two properties keep their own importance.

We focus on how ambiguity can represent an opportunity for mathematics teaching and learning. In the next section we will show and analyse some students' behaviours and the development of their mathematical knowledge coming out in the attempts to manage the situation produced by the ambiguity of the notion of consecutiveness in the problem presented.

SOME EXPERIMENTAL EVIDENCE

We present some critical points of the experiences that we have been living during these years, working with the problem presented in the previous section. We have submitted the above problem or some variants of it for several years to students of different grades (from elementary school up to prospective elementary and secondary school teachers) with slightly different goals, according to the context and to the age of students (Iannece & Romano, 2009; Mellone, 2011).

According with our inquiry approach, as outlined by Borasi (1992), in the management of mathematical activities, rather than packing ready-made solutions and imposing them to students, we prefer to spend most of the time in mathematical discussions, believing that this increases students' opportunities to build a flexible and critical mathematical knowledge. For this reason we often use open tasks, without posing limits to their developments and, most of all, taking seriously all students' reasoning and feedback. This way of working, besides the outcomes concerning students, allows us to grow in our awareness as educators.

We have collected data regarding students' behaviour when dealing with problems of the type above described. Despite their different ages and experiences, we have observed many common points in their answers and reasoning. Here we report some notable behaviours of about 40 students of a mathematics class of prospective elementary school teachers. We comment on students' typical reactions to a specific articulation of the problem that we have proposed several times.

Most students, after the first arithmetic explorations and the discovery/recognition of regularities, are led to express the notion of consecutiveness in a general form. In their attempts to translate the relationship among the four numbers into the algebraic language, the students often propose to use four letters, typically four "consecutive" letters in alphabetic order, like a, b, c, d, for denoting the four consecutive numbers. Such a choice can be labelled as unproductive, since the letters of the alphabet do not support an algebraic structure, and therefore the circumstance that b follows immediately a does not express adequately the analogous relationship between the two numbers. One could be tempted to push directly towards the more effective algebraic translation a, $a + 1$, $a + 2$, $a + 3$, which is, of course, completely faithful and, above all, suitable for the usual algebraic manipulations, including those required in the problem. We too have done this many times, before becoming aware of the fact that by doing so we were losing a great opportunity. Now, we prefer to recognize the value of this choice, where a sort of isomorphism between two order structures (numbers and alphabet) is clearly glimpsed and exploited. After all, the fact that this attempt is not effective is akin to what normally happens to mathematicians when they reach their results by trial and error.

Giving time and confidence to students who choose the four letters a, b, c, d, for representing the four numbers, allows most of them to implement an interesting bridge behaviour between the initial idea of the four consecutive letters and the final four expressions a, $a + 1$, $a + 2$, $a + 3$: they prefer to maintain the four different letters, but accompanying them with the three conditions $b = a + 1$, $c = b + 1$, $d = c + 1$. This behaviour testifies that often a system of equations is easier to be conceived in comparison to the more concise and effective solution a, $a + 1$, $a + 2$, $a + 3$, that requires the quite sophisticated ability to conceive four numbers and simultaneously their relationship. In other words a, $a + 1$, $a + 2$, $a + 3$ appear as the mental result of a transformation applied to the three above equations [1]. The practice of discussion guarantees that the best representation (a, $a + 1$, $a + 2$, $a + 3$) emerges in any case. But the possibility for the students to discuss about the benefits or the disadvantages of using different algebraic translations represents an invaluable way to converge with full awareness towards the best one.

The typical step that follows in our activity is to ask students to consider the problem for four consecutive even numbers. We have experienced that many students propose without hesitation an algebraic representation like a, $a + 2$, $a + 4$, $a + 6$, and this is true especially for those students who had represented the four consecutive natural numbers as a, $a + 1$, $a + 2$, $a + 3$. Of course the use of the additive representation for natural numbers fosters a similar form also in the case of even numbers. The fact that the students do not manifest any hesitation in shifting from the operator "+1" to the operator "+2", shows that the meaning of consecutiveness associated with the order relation prevails over its additive interpretation in the students' perception of this notion. Indeed they have no problem in abandoning the transcription of "consecutive of n" as "$n + 1$". However, their favourite representation is a, $a + 2$, $a + 4$, $a + 6$, in contrast with $2n$, $2n + 2$, $2n + 4$, $2n + 6$, selected by relatively few students, although the second representation is of course the only one that correctly expresses the evenness of the four numbers. This inaccuracy turns out to be useful. It reveals that students prefer to focus on the arithmetic progression as the real nature of the problem, rather than on the kind of numbers involved (in this case, even). When asked, in the next step, to represent four consecutive odd numbers, the students who had represented the even numbers as a, $a + 2$, $a + 3$, $a + 4$ easily realize that their representation also works with odd numbers, while among the students who proposed $2n$, $2n + 2$, $2n + 4$, $2n + 6$ only a few of them succeed in finding the correct representation $2n + 1$, $2n + 3$, $2n + 5$, $2n + 7$ [2]. The discovery that in both cases (even and odd numbers) the searched difference is always 8, moves the mathematical discourse towards the arithmetic progressions with common difference 2.

The last step of our typical way of managing the problem has the goal of addressing the concept of density of the rational numbers. We request to consider four consecutive decimal numbers. The persistence of the *concept image*, in the sense of Tall and Vinner (1981), of the "discrete" order relation as unique prototype of all the possible order relationships, is the trigger element at the base of our proposal. We have experienced that this condition of cognitive break represents a fertile tool to face the epistemological knot of the density of rational numbers. We have observed that the students often propose to consider decimal numbers truncated at the first decimal digit (for example 2.1; 2.2; 2.3; 2.4), or, less frequently, at the second digit.

This answer is a mistake but this error offers to students the opportunity to start new explorations on arithmetic progressions. They easily discover that for decimal numbers truncated as above the difference in the problem is 0.02, and after that, moving to consider decimal numbers cut at the second digit, they realize that the difference is 0.0002. These are good premises to explore and discover the more general rule according to which, given four consecutive numbers a, $a + d$, $a + 2d$, $a + 3d$ of an arithmetic progression, the difference $(a + d)(a + 2d) - a(a + 3d)$ is $2d^2$.

The path shown is an example of how successive generalizations can be exploited to make evident to students the usefulness of the algebraic language for doing manipulations and seeing relationships. We claim that here we have more, namely the possibility of exploiting the ambiguity of a term like "consecutive" for didactic purposes. Two meanings associated to the term coincide in the case of natural numbers, but they split when passing to other domains of numbers. When moving the problem towards the field of rational numbers, the students have the opportunity to become aware of this double meaning, realizing that, according with the first meaning, there cannot be consecutive rational numbers, while according with the second meaning, but enlarging it to sequences of numbers separated to each other by a constant difference, new fascinating arithmetic structures can be glimpsed and explored. The interesting linguistic-epistemological phenomenon of the splitting of a notion into two different ones, when switching from a source domain to new enlarged environments, already studied from several points of view (Lakatos, 1976, and many others) appears here in a new guise as a learning resource.

EDUCATIONAL OUTCOMES AND CONCLUSIVE REMARKS

Several studies in mathematics education have shown that many students' difficulties in mathematics come from their inability to juggle between the daily life use of a word and the formal use of the same word in mathematics (Bardelle, 2010). On the other hand to have a word with different meanings and different uses depending on the needs of the communication is an advantage for people who are in possession of this variety. In this direction, we are convinced that the ambiguity of words used in mathematics rather than to be hidden, as most education practices usually do, should be exploited as resources for mathematics education. At the same time we are convinced that in order to do this in an effective way, it is necessary to develop deep reflections about the epistemological and linguistic features concerning the use of words in mathematics (and not only). A useful framework for this analysis is the CAC construct by Boero and Guala (2008).

The case of the word "consecutive" examined above offers a particularly rich context, but it is just an example (for an analogous investigation on the word "triangle", see Castagnola & Tortora, 2009). In our research we have understood how the polysemy of such a simple word like “consecutive” is something to explore with our students. This also amounts to doing interdisciplinary work between mathematics and language and to including mathematics fully in human sciences.

During these years, our way of organizing mathematical activities has allowed teachers get involved to grow their awareness as educators, but also to gain deeper competence about the mathematical topics explored with students. The inquiry approach that inspires our work requires from teachers a strong ability to give space and attention to every proposal and idea that students might have and to carefully guide them. It also entails that the teachers be involved in the mathematical work in an atmosphere genuinely oriented to discovery, where even the possible lack of a prompt response to students' questions does not appear as a diminution of their authority. As written by Radford (2014, p. 19): “Teachers and students are in the same boat, producing knowledge and learning together. In their joint labour, they sweat, suffer, and find gratification and fulfilment with each other.”

ENDNOTES

1. This cognitive behaviour suggests that the usual curricular hierarchy, according to which equations are treated rigorously before systems should perhaps be partly revised.

2. While in $2n$, $2n + 2$, $2n + 4$, $2n + 6$, the term $2n$ is used as a standard way of representing an even number, and +2, +4 and +6 are standard ways of adding two units at a time, in $2n + 1$, $2n + 3$, $2n + 5$, $2n + 7$, the term $2n + 1$ is a common representation of a generic odd number but $2n + 3$ (and $2n + 5$ and $2n + 7$) has to be obtained from $(2n + 1) + 2$, where the two +'s play different syntactic-semantic roles.

Sharing structures of algebraic expressions through language: A transformation gap

Alexander Meyer

TU Dortmund University, Dortmund, Germany, alexander.meyer@math.tu-dortmund.de

Collaborating in the transformation of algebraic expressions results in a need to share the structures of algebraic expressions with the help of language. However, little is known about how such structures are conveyed through language – and adopted by the other participants of the discourse. This paper uses a functional-pragmatic framework to reconstruct the patterns behind such discourses in which structures are shared. With this framework, a transformation gap between conveying and adopting structures is identified: Where the first speaker can only refer to the original expression to propose a transformation, the other participants are able to refer to both the original and to a transformed expression for seeing structures.

Keywords: Structure sense; language; discourse; algebra.

INTRODUCTION

Algebraic expressions can be flexibly interpreted. Arcavi (2005) shows the different ways for students to make sense of symbols and symbolic expressions. Drouhard and Teppo (2004) argue that an algebraic expression, especially one with a distributive structure, can be interpreted in many different ways according to a specific context that can be flexibly activated, e.g. as a function. Accordingly, the students' transformation of an algebraic expression is not a mechanical activity that is aimed at a predefined result, but an activity that is guided by the students' individual interpretations of the structures of expressions. Furthermore, these structures in an algebraic expression do not solely exist „on their own", but come *into existence* in the activity of transforming an expression (Rüede, 2012). For example, when transforming the expression $5ab + a - 5b - 1$, there are different ways to apply the distributive law; students may either relate $5ab$ to a or to $-5b$. Each relation gives way to a different notion of the structure of the expression and, through this, a different application of the distributive law.

In a collaborative task of transforming an algebraic expression, students coordinate their joint activity to a large part with the help of language. More specifically, they explicate their interpretations of the structures of the expression in the discourse with the help of language to other students. Being able to use language to describe structures in algebraic expressions helps students to see structures, as language provides the means to share perceived structures with the teacher and with others. However, little is known about how students convey a structure in an algebraic expression to other participants of a discourse through language - and how language affects how the latter ones can adopt these structures.

STRUCTURE SEEING AND ITS CONNECTION TO LANGUAGE

In order to conceptualize the transformation of algebraic expressions not as a mechanical activity, but as activity that is guided by the interpretations of structures in algebraic expressions, the model of structure sense was introduced (Linchevski & Livneh, 1999) and used and refined in various studies (Novotná & Hoch, 2008). As structures of algebraic expressions emerge in the activities *with* the expressions, structure sense is here regarded as structure seeing, that is, as an interpretative activity of relating identified parts of an expression to each other and to the whole expression in order to decide for a transformation of this expression (Meyer, 2014).

When translating a text into an algebraic expression, students link the structure of the text with the algebraic expression they are constructing. There is evidence that the translation of a task into an algebraic expression is linked to the understanding of language (Duru

& Koklu, 2011). A sequential translation of the words of a text from left to right might be a way for students to structure an expression also in a sequential way (e.g. Clement, 1982). However, other evidence suggests that students do not usually translate this way, but rather first look into the meanings of the words before translating (Capraro & Joffrion, 2006).

The link between the structure of the text and the algebraic expression, however, is not direct, but mediated by meta-linguistic awareness, that is, by the ability of a student to "reflect on and analyze spoken or written language" (MacGregor & Price, 1999, p. 451). Based on their empirical results, MacGregor and Price conclude that "this conscious awareness of language structures and the ability to manipulate those structures may be a manifestation of deeper cognitive processes that also underlie the understanding of algebraic notation" (1999, p. 462).

Caspi and Sfard (2012) give insight into the elements of language that can be used for expressing structures in algebraic expressions, like compound noun phrases and objectified processes. While they do not look into students' seeing of structure, they conceptualize different levels of how elements of an algebraic expression can be expressed with language and what level of generality this language indicates. The first level is that of processes, where language is used to express a calculation. The calculation is presented in the order in which it is executed. The second is the granular level around the description of a calculation; it still describes a process but also contains compound clauses that make procedural elements into an object, like "the sum of…is". The third is the objectified level where complex calculations and processes can be substituted with objects or objectified descriptions, e.g. "A product of a sum of two numbers". Caspi and Sfard find out that 7th graders are, under certain circumstances, capable of talking about algebraic expressions on the third level. Their argument suggests that when students, at a higher level, can express complex structures in a more condensed way with language, then more complex structures are available to participants.

My study is focused on the language that students use to express the structures of algebraic expressions in order to share them with others, and how this affects which structures are adopted by others or put to the fore in an algebraic expression - and which are disregarded. In order to look into this question, I use a functional-pragmatic framework which is based upon an activity-theoretical notion of linguistics. Within a functional-pragmatic analysis, the genesis and transformation of the propositional content in the discourse can be traced back to the linguistic actions and 'linguistic reality' of participants.

METHODOLOGY: A FUNCTIONAL-PRAGMATIC ANALYSIS

The aim of a functional-pragmatics analysis has been formulated by one of its main representatives as follows:

> In short, the fundamental aim of Functional Pragmatics is to analyze language as a sociohistorically developed action form that mediates between a speaker (S) and a hearer (H), and achieves – with respect to constellations in the actants' action space […] - a transformation of deficiency into sufficiency with respect to a system of societally elaborated needs. (Redder, 2008, p. 136)

Functional Pragmatics regards a communicative act as driven by a purpose. Speaker and hearer equally participate through speaker-actions and hearer-actions in this 'purpose-guided' activity. The inner structure of the speech acts of both speaker and hearer are synchronized with respect to „topics, focus of attention, previous (speech-)actions, etc (p. 138)" between an extralinguistic reality (depicted by P), the mental reality of speaker ($\prod_s$) and hearer ($\prod_h$) and the linguistic reality (p) (Redder, 2008).

In this study, the extralinguistic reality (P) is the structures of algebraic expressions, while the aim of the functional-pragmatic analysis is to reconstruct the linguistic reality (p), in this case, the structures that are actually shared in the discourse. The students' joint action of transforming an algebraic expression is a „transformation of deficiency into sufficiency" in relation to the „extralinguistic reality" of algebraic expressions - it is about the speaker transmitting identified structures of algebraic expressions ($\prod_h$) to the hearer ($\prod_h$), so that speaker and hearer arrive at a mathematically acceptable transformation („sufficiency").

Functional pragmatics provides a tool to analyze how structures of algebraic expressions are made available and are picked up in a communicative act for the purpose of finding a mathematically adequate transformation. This reconstruction involves two steps. The first step is the reconstruction of the *surface progression* of the discourse. The second step is the reconstruction of the *pattern* behind this surface progression. In Functional Pragmatics, the pattern is what guides the participants' actions without them being explicitly aware of it.

Reconstruction of the surface progression of the discourse

The linguistic actions of the speaker and hearer are continually influencing each other; at a given time, both participants' actions have an equal potential to influence the other's actions. There are three qualitatively different categories to distinguish these structures of linguistic actions:

- the *organization of the discourse* (Ehlich, 2007, p. 71), that is, how linguistic actions coordinate each others actions;
- the *action potential*, that is, the potential of the speakers action to bring something about in the hearer or vice versa, e.g. bringing about a deeper understanding (Ehlich, 2007, p. 71), this is connected with the purpose behind a speaker's actions;
- the *propositional content* of the linguistic actions.

A functional-pragmatic analysis starts with separating the parts of the transcript in line with these three categories. First, the organization of the discourse is in focus. It is reconstructed by looking into those parts of the transcripts where speaker and hearer coordinate each other's actions (e.g. by expressing interpersonal relations like „I'm writing, you dictate". This is driven mainly by linguistic categories.). Second, action potentials that are realized in a discourse are carved out. In the activity of transforming an algebraic expression, one can think of a situation where only procedural action potentials are realized. Accordingly, the activity would be about a calculation and about arriving at a result - this would relate to Caspi and Sfard's (2012) processual level. In the analysis of action potentials, both linguistic and didactic categories can be put to use. Third, building upon the previous steps, the propositional structure of the discourse is reconstructed. This includes the reconstruction of the linguistic realities of speaker and hearer ($\prod_s$ and $\prod_h$). For this, didactic categories have to be used, as this is on the plane of the mathematical knowledge that is in focus in the discourse. In this step of the analysis, relations, dependencies, references to previous linguistic actions etc. are in focus.

Reconstruction of the pattern that guides the students' linguistic actions

The reconstruction of the surface progression of the discourse is the starting point for analyzing the elementary propositional basis. The elementary propositional basis is the reconstruction of the knowledge that is independent of the speakers and hearers actions. The reconstruction of this knowledge leads to a notion of the linguistic reality of p. In this case, the linguistic reality p encompasses the structures of an algebraic expression that are shared. The relations between p, P, $\prod_s$ and $\prod_h$ constitute a pattern in the discourse, in this case, the pattern of sharing structures of algebraic expressions in a discourse.

In generalizing such a pattern, an apparatus can be reconstructed. An apparatus describes general patterns in discourses; it is assumed that patterns are generalizable to other discourses of the same kind. In this study, the analysis aims at reconstructing discursive patterns of structure seen in regard to the question how structures are conveyed and adopted in a discourse. The pattern presented here, however, can only be regarded as a first approximation of a general pattern. The pattern has to be tested for its generality in other qualitative and quantitative studies.

Background for the study

The case study of Max and Tim presented here is part of a larger design research study. The larger study aims at promoting the students' structure seeing by providing scaffolds and requiring the students to negotiate structural elements of algebraic expressions (Meyer, 2014). Tim and Max are 8th graders from a German middle school; they were chosen for the teaching intervention based on a previous assessment that showed that they possessed a basic understanding of the transformation of algebraic expressions, but a lack of understanding of the underlying structures of algebraic expressions. The teaching intervention consisted of three tasks with subtasks. It took 1.5h and was supervised by trained interviewers.

In the episode presented here, Tim and Max worked on the second task that required them to transform a sequence of algebraic expressions by applying the distributive law. The episode represents the third expression in this sequence; the students thus already applied the distributive law to the two previous – structurally simpler – algebraic expressions. With each expression, the students are given the original formulation of the distributive law $ab + ac = a(b + c)$ as a structural reference. The students already acquired marking strategies and were able to use them to mark structures and to better communicate about structural elements. In the here presented episode, the students start to work on the expression $ab + ac + bd$.

EMPIRICAL RESULTS: SHARING STRUCTURES THROUGH LANGUAGE

As a first step of a functional-pragmatic analysis, a transcript is divided into segments (letters) and sections (numbers); these segments and sections are heuristically refined during the analysis. The already refined segmented transcript is given here; the later analyses refer back to this transcript.

1	Tim:	[1a][*writes down expression ab+ac+bd that is given in the task*] [1b]Hm, [1c]do you want to do this?
2	Max:	[1d]Mhm [*confirming*]
3	Tim:	[1e]Ah, wait, |[2a][*starts to write down the transformed expression a(b+c)+bd*], [2b]I would do it this way, [2c]simply for the reason, [2d]because of course *a* is there two times [*points at the a's in the original expression*], [2e]thus *ab* and *c* [*points at a, b and c in the transformed expression*]
4	Interviewer:	[2f]Mhm [*confirming*]
5	Tim:	[2g]Just taken times [*german for multiplicating*]. [2h]And there [*points at bd*] just only the *b* times *d* is taken. |
6	Interviewer:	[3]Ok
7	Max:	|[4a]Yes, [4b]I believe that too, [5a]because only there is *a* [*points at ab and ac*], [5b]and there is no *a* in front [*points at bd*]
8	Interviewer:	[5c]Mhm
9	Max:	[5d]This is why one just has to put this in brackets [*points at b+d*] [5e]and this other one [*points at bd*] comes behind the brackets. |

The action potential and the organization of the discourse

The *organization of the discourse* that is established by Tim is oriented at Max and at the Interviewer. At first, Tim organizes his actions in relation to Max. In 1a, he writes down the task while at the same time addressing Max: "Do you want to do this?" (1c). On the one hand, Tim wants Max to participate in the solution of the task. On the other hand, he is delaying the discourse, so that he 'squeezes out' some time to think about the algebraic expression at hand. The invitation to participate is held up in 2b, where Tim explains: "I would do it this way" - this discursive action implies that there might be another way and that Max is expected to propose one. Later on, Max directly relates to Tim's transformation of the expression in 2a, confirming it (4a). With this he indicates, that the propositional core of his speaker actions are related to Tim's reasoning. In addition Max organizes his speaker actions in relation to Tim's actions (2b), by suggesting that *he* "believes that too" (4b).

The *action potential* revolves around transforming the expression in a way that is acceptable to the interviewer/teacher, while making themselves understandable to each other. As Tim's actions are directed at the interviewer, who is regarded as a knowledgeable teacher, he likely wants to give correct reasons and to use "mathematical" language (the literate register). Furthermore, Tim needs Max to understand and approve of his transformation, so that they together can arrive at a common solution. Thus, he has to make himself understandable to Max. On the other hand, the purpose of Max' actions is to confirm Tim's transformation of the expression. As shown above, the discourse is organized in a way that requires Max to give an individual perspective. Accordingly, Max has to relate to Tim's actions but also has to give his own perspective on the transformation.

The propositional content of Tim's linguistic actions

The basis of the *propositional content* is the written expression $a(b + c) + bd$ that Tim writes down in 2a. The following speaker actions all relate to this expression (depicted in Figure 1; relation diagrams are an element of a functional-pragmatic analysis). In his first actions, Tim explains the first part of the expression, namely $a(b + c)$, by saying "because of course *a* is there two times" (2d). The following speaker actions depend on this latter speaker action with "thus" and "just".

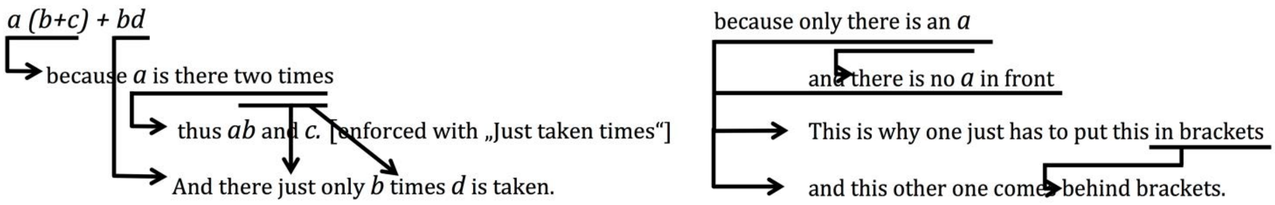

Figure 1: Reconstructed surface progressions of sections 2 and 5

"Thus" refers to the propositional content "*a* is there two times", while "just" is connected to the propositional content "*ab* and *c*" (2g). Tim gives two reasons for the expression $a(b + c)$ that build upon each other. In his later speaker actions, Tim also explains "*bd*". He is connecting this action with "and" to his previous actions, while at the same time he uses deictic gestures/ words ("there") to connect his action to the algebraic expression (2h). The expression "just only" stands in contrast to "two times". In this way, Tim expresses that in case of *bd*, there are no two variables. This is further indicated by using the phrase "taken times" (multiplication) for explaining both $a(b + c)$ and *bd*.

The algebraic expression in Tim's *linguistic reality* has two cornerstones. The first cornerstone is how often a certain variable is there. This is expressed by "*a* is there two times" and "only the *b* times *d*". The second cornerstone is the multiplication; on the one hand, "*ab* and *c* [...][are] just taken times", on the other, "*b* times *d* is taken". Both the first and the second part of the expression rest on this cornerstone. This way it connects the first and second part of the expression.

The relations of the cornerstones show how Tim structures the algebraic expression. "*ab* and *c*" is dependent on "two times". In other words, leaving out one *a* is a result of *a* being there two times, where leaving out *a* is explained by the multiplication. These relations are expressed by Tim as causal relations through "because", "thus" and "just". The second part of the expression *bd* is structured in the same way as the first part. This time, there is only a single variable *b*. The multiplication is not based on leaving out a variable. In summary, Tim structures the expression according to how many times a variable occurs, and how this results in a certain form of multiplication - one time by leaving out a variable (transformation of the first part) and one time by not changing the variables (transformation of the second part).

The propositional content of Max's linguistic actions

The basis of the *propositional content* of Max' linguistic actions is both the original expression and its transformation. In 5a, Max relates deictically to the original expression, pointing at the expressions *ab* and *ac* and referring to them with "there" ([5a]"because only there is a [*points at ab and ac*]"); in 5b, he refers the same way to *bd*. In both 5a and 5b, he argues for the existence/ absence of *a* in the subexpressions of the original expression. In 5d and 5e, Max deictically relates to the transformed expression, but at the same time builds an argument upon the perceived properties of the original expression (indicated by the arrow that encompasses both 5a and 5b in Figure 1), saying "this is why one just has to put this [*points at* (*b*+*d*)] in brackets" (5d). Max uses the same relations in structuring the second part of the expression (5e). Both parts of the expression, $(b + c)$ and *bd* are connected with "and" and by stating the position of *bd* in relation to $(b + d)$ ("behind the brackets").

The structure of the algebraic expression in Max' *linguistic reality* has only one cornerstone. This cornerstone is the (non-)existence of *aa* in the subexpressions of the original expression. However, Max' conclusions that are based on the original expression are, additionally, supported by features of the transformed expression. Thus, his conclusions are circular: Max' justification why one has to transform the original expression into $(b + d)$ requires that $(b + d)$ is already given as a transformation. In this way, Max' justification dissolves the logic *of the process* of transformation. In summary, in Max' notion of the distributive law $ab + ac = a(b + c)$ the two *a*'s on the left side directly result in the bracketed expression $(b + d)$.

Pattern of sharing algebraic structures in a discourse

At first sight, it seems that the linguistic realities of Tim and Max have one element in common, namely the existence of the variable *a*. However, on closer inspection, Max' reasoning is based upon the existence and non-existence of a in the subexpressions, while Tim's reasoning is based on how often a (or b) exists in the original expression. Thus, in the course of this short episode, Max has 'only' picked up one aspect of Tim's structuring of the expression.

At second sight, the linguistic realities of Max and Tim are both based on the original and the transformed expression. However, when comparing the propositional content of Tim's and Max' discursive actions, it becomes apparent that Tim's speaker actions depict a process, in the sense that they relate to his steps of the transformation: Each step relates the transformations to features of the original expression. In other words, the mathematical objects, on which he builds, are located in the original expression, while his deductions are about properties of the transformed expression.

In contrast, Max' speaker actions are abstracted from the process of transformation. While his arguments are based upon objects in the original expression, they require at the same time the existence of the transformed expression. Thus, Max' reasoning is based upon the equation as a whole, that was established by Tim and that links the original expression and the transformed expression. Max' structuring may be a result of the organization of the discourse. As shown above, the discourse requires Max to relate his structuring of the expression to Tim's transformation and reasoning behind this transformation. Perhaps, in the logic of the discourse, Max has no other option as to include the transformed expression into his reasoning.

In a broader perspective, the pattern behind Tim's and Max' negotiation of the structure of the expression can be described as a transformation gap. This transformation gap describes that the one discursive participant who comes up with a first transformation has different means to justify his structuring than the hearer, who can work with both the original expression and the proposed transformed expression. Accordingly, while the speaker needs to connect the original expression with the transformed expression in order to give reasons for his transformation, the hearer can base his reasoning on the original expression *together* with the transformed expression. As a result, at a given point in a discourse about algebraic structures there may exist two different structures of an algebraic expression: One structure that follows the logic of the transformation, and one that disconnects from this logic and focuses on the transformed expression together with the original expression. To the participants, these structures may seem compatible or even equal, while in reality these structures are very different.

DISCUSSION

Although just one case has been discussed in this paper, the reconstructed pattern of conveying and adopting the structures of algebraic expressions in a discourse may yield significant consequences. For example, teaching interventions that focus on promoting students' structure seen by implementing activities of negotiating different structures of algebraic expressions have to account for the transformation gap. One way to do this could be to connect algebraic expressions more strongly to other mathematical objects like functions, so that the different ways of structuring an expression come into light in reference to this object. The possibility of translating the algebraic expression into another representation may further act as a scaffold.

The functional-pragmatic analysis has proven its potential to look into the foundations of the students' ways of conveying and adopting structures in algebraic expressions. The reconstruction of the surface process, resulting in the reconstructed linguistic realities of speaker and hearer, as well as the reconstruction of the pattern behind this, may also be suitable for addressing other research questions, where "deficiency [is transformed] into sufficiency" in students' discourses.

In further studies, the generality of the here presented pattern has to be addressed. It has to be addressed, if it is part of a larger structure-sharing-pattern that is typical for discourses about algebraic expressions. A more systematic view on different discourses of sharing structures may show, if such a pattern is common to discourses about algebraic structures. This might also lead to a deeper understanding of students' resources in regard to structure seeing and of coordinating transformations.

The discursive routine of personifying and its manifestation by two instructors

Talli Nachlieli[1] and Michal Tabach[2]

1 Levinsky College of Education, Tel Aviv, Israel, talli.nachlieli@gmail.com

2 Tel Aviv University, Tel Aviv, Israel

This paper focuses on teaching processes in the mathematics classroom. We adopt Sfard's communicational framework to address the question: What were the teaching actions that seem to promote learning? To address the question, we analyzed four lessons taken from two courses about functions which were studied by elementary-school prospective mathematics teachers. We identified a teaching mechanism that seems to relate teaching to students' learning. This mechanism includes flexible and dynamic transition between mathematizing (talk about mathematical objects), subjectifying (talk about the participants) and personifying (talk about human participants acting upon mathematical objects). We also identified several types of personifying talk.

Keywords: Classroom communication, personifying, teaching routine.

INTRODUCTION

This paper focuses on teaching processes in a mathematics classroom. Teaching and learning processes are interwoven, both enacted concurrently by different participants. Studying both under a similar lens could provide holistic insights about classroom processes. This study is a part of a larger study about teaching and learning, however, here we mainly focus on teaching. Let us look at the following two turns, uttered by an instructor:

> Please look at the board. Ok, here we have a graph that describes a connection between two variables. The question is, what type of questions we could answer using this graph and which questions we cannot answer by this graph.

> The *y*, yes, it is always *y* that changes according to *x*, ok? We have y that changes depending on, or according to, *x*, ok?

It is obvious that both excerpts are from a mathematics lesson. This certainty stems from the words used (graph, variables), and the articulation (*y* changes according to *x*). However *look at the board* is a general classroom saying about participants' actions, not specifically related to mathematics.

Indeed, during mathematics lessons we could expect the participants to talk about the participants of the discourse (about the students and teacher, as in: *take out your books*, or *could you please write it on the board?*), or about mathematical objects (*this is a graph of a constant function*). Looking back at the above excerpts, we find that some parts are compatible with this division: *Please look at the board* is about human participants; whereas *it is always y that changes according to x* is about mathematical objects. However, we have other sayings that do not fall under those two categories. Rather, they are at the intersection between the two sets, and relate to both –human participants and mathematical objects: *here* ***we*** *have a* ***graph*** *that describes…* We suggest that this type of teacher's interwoven talk about both - participants and the mathematics is important for students' learning.

To learn more about this phenomenon, we closely examined 4 lessons out of two cohorts of data: transcribed video-recordings of two courses about functions that were studied by elementary-school prospective mathematics teachers. The question we asked: *What were the teaching actions that seem to promote students' learning?*

TEACHING PRACTICES AND ROUTINES

Sfard (2008) has defined the teaching-learning agreement, which is:

> a situation that arises when the discursants are unanimous, if only tacitly, about at least three basic aspects of the communicational process: about which is the leading discourse, about the discursants' own respective roles as those who learn or those who teach, and about the nature of the expected change. (Sfard, 2008, p. 299).

From this we (Heyd-Metzuyanim, Tabach, & Nachlieli, submitted) derive that a pedagogue (teacher or instructor) is a person who assumes the role of the leading participant in the discourse while the student is a person who assumes the position of the follower in the discourse. Indeed, these definitions fit the Greek etymology of pedagogy which is *a person who leads the child*.

In that sense, pedagogy is a particular form of communication, and communication, in turn, is a particular type of activity (Sfard, 2008, p. 296). Combining this view with Cultural Historical Activity Theory (Engeström, 1987; Roth & Lee, 2007), one realizes that the main distinction that can characterize a particular activity as pedagogical is its motive. Leont'ev, Roth and Radford (2011) write: "The chief difference in activities is to be found in the difference of their objects or motives. An object/motive (fishing, for instance) is what endows the activity with a particular intent. But activities involve also actions and specific contextual methods and means to carry out these operations" (p. 6).

Combining activity theory with the communicational definitions, we arrive at the conclusion that pedagogy can be defined as the communicational activity which motive is to bring a change in the learners' discourse towards a leading discourse. Such a definition of pedagogy includes all communicational actions (verbal, non-verbal, emotional, etc.).

Contrary to the common division between content and pedagogy (see Leinhardt & Steele, 2005) we offer an alternative lens – that of dividing pedagogical activity into subjectifying (talking about human participants) and mathematizing (talking about mathematics). Subjectifying is thus a communicational activity which motive is to produce narratives about people while mathematizing is a communicational activity which motive is to produce mathematical narratives. Since pedagogy includes both mathematizing and subjectifying, it becomes obvious that different (and something conflicting) motives can be enacted within the same activity.

In this paper, the instructors of the course are the pedagogues and the teaching actions are the pedagogy. We focus on specific teaching-routines (exchange routines, Leinhardt & Steele, 2005), that seem to promote students' learning. For that purpose we focus on the instructor's talk during whole-class discussions.

RESEARCH QUESTION AND PARTICIPANTS

The research question of the study reported in this paper is the following: *What were the teaching actions that seem to promote students' learning?*

The data for this paper are taken from a project that focuses on identifying learning and teaching processes. The data for the project include transcribed video recordings of two mandatory first-year courses about functions for elementary-school prospective teachers studying at a college of education in Israel. The two courses were similar in their content and goals, and were taught in consecutive years, by two different instructors. Each course included 18 students. All of the students have already learned functions and graphs in high school algebra. The students were all older than 19. They vary in age and background, as well as in the level of mathematics that they studied in high school. The two course instructors (Ellice and Talli), hold a PhD in mathematics education and have been teaching at the college for over ten years.

All lessons had a similar structure: opened by a whole-class discussion, followed by group-work (of 3–4 students). The students then reconvened for a summarizing whole-class discussion. The groups were formed by the students and remained stable throughout the course. All 12 lessons of each of the course were videotaped and transcribed. During the lessons, field notes were taken and students' written work was collected. During group-work, the work of two specific groups, chosen randomly, was recorded and transcribed.

For the study reported in this paper we chose to closely examine 4 lessons out of the 24, 90 minutes lessons, the first and last in each course (We chose lesson 2 rather than lesson 1, as during the 1st lesson consent forms were distributed, and the study was explained.) The choice to focus on two different courses did not originate in intent to compare the courses, but to allow us to examine whether a certain identified routine is teacher-specific or could be a part of common teaching routines.

OVERVIEW OF ELLICE'S LESSONS

In the 2nd lesson, the students were asked to solve an algebraic task (see Figure 1).

The following is a sequence of the three first structures in a series of structures. How many cubes are needed to build the nth structure?

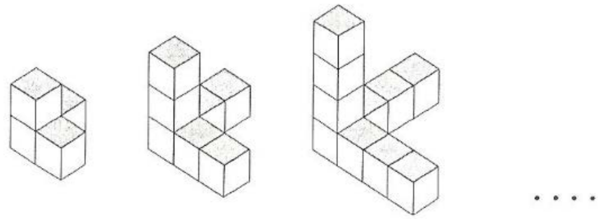

Figure 1: The sequence discussed in class during Ellice's 2nd lesson

While working in small groups, the students were given small cubes to build the structures and answer a sequence of sub-questions aimed at guiding them towards the generalization of the pattern. They then reconvened to discuss the task.

As early as this 2nd lesson, students talked about various representations of the mathematical task: drawing, relation, formula, reversed formula and pattern. These words, although relating to representations of mathematical objects are not the common terms used. A formula and reversed formula were suggested in the form of algebraic expressions (;).

The task given in Ellice's 12th lesson was taken from Friedlander and Tabach (2001). This task included 4 situations each described by a different representation (story, table, graph and algebraic expression). The task included a set of sub-questions that guided the students to first relate to each of the representations alone and then connect between them.

The task given in the 12th lesson was more complex in two aspects: (1) the number of situations described, and (2) the number and type of representations provided. The task in the 2nd lesson included a drawing and tangible representations of one sequence only, whereas that in the 12th lesson included 4 situations described by 4 different representations (story, table, graph and algebraic expression). The students were asked to compare the phenomena. That is, there was a development in terms of the complexity of the given task. The tasks chosen by Ellice in both lessons included various sub-questions that helped students focus on specific representations and relations amongst them.

OVERVIEW OF TALLI'S LESSONS

The task provided in Talli's 2nd lesson included 5 different graphs and 5 verbal situations (e.g. *The amount of fuel in the tank changes according to the distance that the car rides.*) The students were asked to connect between them and support or refute claims by relating to data provided by the graphs.

The task given in Talli's 12th lesson was:

> In your summer job as a salesman, you could choose one of three earning methods: (1) 100 NIS for each working day and 35 NIS for each sale, (2) 80 NIS for each working day and 40 NIS for each sale, (3) 250 NIS for each working day and 5 NIS for each sale. Which would you choose? Explain your choice.

This task includes a verbal description of 3 situations that could be modeled by a function. The students were asked to compare between them. The task did not include reference to any representations. Also, it did not include sub-questions that could guide the students in their attempts to solve the task. This is in contrast with the task given in the 2nd lesson which included a graphic mediator and guiding questions. Also, the task given in lesson 12 asked for comparing alternatives whereas the task in the 2nd lesson asked for describing a situation provided by a graph.

METHOD OF ANALYSIS

To address the research question, we analyzed the entire whole-class discussion in each of the lessons. We focused on the instructors' talk in these discussions. We segmented the instructor's turns into clauses which were then analyzed. Thoroughly examining all the clauses uttered by the instructors, we noticed that they talked either about mathematical objects (mathematizing – y changes according to x) or about the classroom participants (subjectifying – look at the board). However, we identified a third type of communication that is a sub-type of both mathematizing (because it speaks about math objects) and of subjectifying (because it speaks about persons). We call this last type – personifying, and define it as *non-alienated talk about mathematical objects*. Therefore, to analyze the data we categorized the clauses of the instructors' talk according to three categories: mathematize, subjectify and personify. Chi square test was used to determine whether differences are significant.

We further identify types of personification according to what we call *the distance* between the human actor and the mathematical object: one could act upon an object directly (e.g. *what can you say about the interception point?*), could describe her actions upon the object (e.g. *how do we know that the claim is true?*) or talk about how others would or should act upon the objects (e. g. *how do you think a 7th grade student would solve this problem?*). We name these categories as distance 0, 1 or 2.

FINDINGS

In this section we characterize instructors' talk to learn about how the instructor's choice of words promoted students' learning. We refer to three categories, (1) mathematizing, (2) subjectifying, and (3) personifying. Table 1 presents the number of clauses used by each instructor during the whole class discussions which were analyzed, and the (number) and percentages of clauses in each category. This table includes all the analyzed data that is discussed next. From Table 1 we see that both instructors used all three types of talk in each lesson. However, the distribution amongst the three types is significantly different (chi-square test, $p<0.002$).

Moreover, as can be seen from Table 2, in both of Ellice's lessons, the number of personifying clauses

	N	Math	Subject	Person
Ellice lesson 2	316	(53) 17%	(69) 22%	(194) 61%
Ellice lesson 12	157	(48) 31%	(37) 23%	(72) 46%
Talli lesson 2	219	(96) 44%	(28) 13%	(95) 43%
Talli lesson 12	220	(52) 24%	(8) 4%	(160) 73%

Table 1: Categorizing teachers' talk: mathematizing, subjectifying and personifying

(cls.) is significantly higher than that of mathematizing or subjectifying, while there is no significant difference between the number of mathematizing cls. or subjectifying cls. In Talli's 2nd lesson, subjectifying was significantly lower than personifying or mathematizing, while there was no significant difference between mathematizing and personifying. In Talli's 12th lesson, personifying was significantly higher than mathematizing and subjectifying, and mathematizing was significantly higher than subjectifying. In each of Talli's lessons there was significantly more talk about mathematics objects than about participants.

Next, we refer to changes between the two lessons for each instructor. Table 3 presents whether the changes in instructor's talk between her two lessons are significant (chi-square). We find that in Ellice's lessons, mathematizing is significantly higher in lesson 12 than in lesson 2 ($p<0.001$) and personifying is significantly lower ($p<0.001$). In Talli's lessons, subjectifying and mathematizing are significantly lower in lesson 12 than in lesson 2 ($p<0.001$). At the same time, personifying is significantly higher ($p<0.001$).

There is no clear tendency between the two instructors as for the differences in the three types of talk. This will be referred to in the discussion.

Inst.	Lesson	Personifying cls., Mathematizing cls., Chi-square value	Personifying cls. , Subjectifying cls., Chi-square value	Mathematizing cls., Subjectifying cls., Chi-square value

INSTRUCTORS' PERSONIFYING TALK

We identify three types of personifying talk according to the distance between the human actor and the mathematical object. Table 4 presents the number of personifying clauses uttered by each instructor during the whole class discussion and the (number) and percentages of clauses in each category. From Table 4 we see that both instructors used all three types of personifying talk in each lesson. However, the distribution amongst the three types is significantly different (chi-square test, p<0.001). Moreover, as can be seen from Table 5, in both of Ellice's lessons, distance-0 personifying is significantly higher than distance-1 or distance-2, while there is no significant difference between distance-1 and distance-2. In Talli's 2nd lesson, distance-2 personifying was significantly lower than the other distances. In Talli's 12th lesson, distance-0 personifying was significantly higher than distance-1.

Next, we refer to changes between the two lessons for each instructor. Table 6 presents whether the changes in the number of the instructor's personifying cls. between her two lessons are significant (chi-square). We find that in Ellice's lessons, distance 0 personifying is significantly higher in lesson 12 than in lesson 2 (p<0.001), while distances 1 and 2 are significantly lower (p<0.05). In Talli's lessons, the personifying talk remains unchanged related to the three distances.

DISCUSSION

This study is a part of a large-scale study in which teaching and learning processes were analyzed. Here we only refer to the teaching actions and specifically –

Inst.	Lesson	N	Distance-0	Distance-1	Distance-2
Ellice	2	194	(91) 47%	(56) 29%	(47) 24%
Ellice	12	72	(52) 72%	(12) 17%	(8) 11%
Talli	2	95	(55) 58%	(40) 42%	(1) 1%
Talli	12	160	(94) 59%	(64) 40%	(2) 1%

Table 4: Categorizing teachers' personifying cls. according to the distance between the human actor and the mathematical object

Inst.	Les.	Dist. 0, Dist. 1, Chi-square value	Dist. 0, Dist. 2, Chi-square value	Dist. 1, Dist. 2, Chi-square value
Ellice	2	91, 56, 8.33**	91, 47, 14.0***	56, 47, 0.876

Table 6: Chi-square test for comparing lesson 2 and lesson 12 for the same instructor

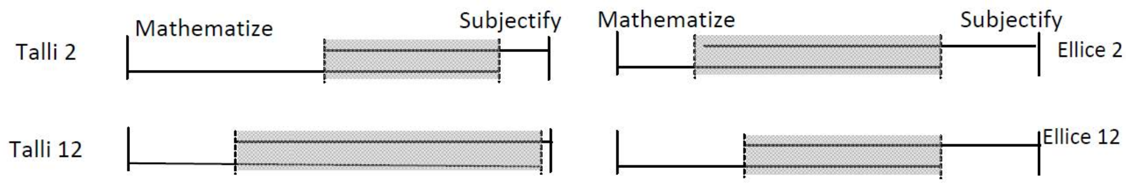

Figure 2: Distribution of mathematizing, personifying (in grey) and subjectifying talk

to teachers' talk due to space limitations. Findings from this study point to phenomena that suggest discursive mechanisms that could connect teaching and learning processes in general.

It seems reasonable to expect that during a lesson in mathematics an instructor would talk either about the participants (e.g., *open your books*, *work in groups*) or about the mathematical objects (e.g., *the function is positive for x<4*). However, from this study it is apparent that there is a third type of talk – about human participants acting upon mathematical objects (e.g., *when we move on the graph*), and that this talk is prevalent. Figure 2 presents personifying as the overlapping between mathematizing and subjectifying.

We did not find a similar pattern in the two courses regarding personifying. In Ellice's lessons, personification was used vastly in lesson 2 whereas in Talli's – in lesson 12. To make sense of this finding, we examined each of the lessons.

In Ellice's 2nd lesson there were several students' sayings that we could relate to Ellice's choice to personify. One is a student's publicly uttered saying of *I got lost*. Several other students joined this statement. Another, is the fact that while working on the task in small groups, at least 2 groups could not find the expression that mediated the given sequence, and therefore felt that they cannot solve the task. That is, the instructor faced a situation in which she had to make the mathematics accessible to her students. The way of doing it included personifying, in general and using distance-2 personifying, in particular. Personifying has the potential to make the mathematics more accessible to the learner as it includes talk about human who acts on mathematical objects. The distance-2 personifying includes others' actions on objects. This could protect the learner as it places someone else in the front, facing the mathematical objects. With that, it provides the learner with a role of judging someone else's actions on the mathematical objects. That is, it has the potential to both empower the student and protect her. Such expressions from the students were not uttered in Ellice's 12th lesson. This is coherent with our finding that Ellice's mathematizing was significantly higher in lesson 12, and her personifying was significantly lower. Likewise, distance-2 personifying was significantly lower in lesson 12.

In Talli's 12th lesson, in which personifying talk was significantly higher, we could not find explicit sayings of students' frustration. However, the students' initial responses to the task given in lesson 12 were local and surprised the instructor at this late stage of the course. Therefore, the instructor had to find a way to help students identify a reasonable strategy with which they could address the task. Thus, make the relevant mathematics accessible to them.

That is, we suggest that the personifying routine enacted by the instructor is strongly related to students' talk, and aims at enabling them to participate in the mathematics discourse by making this discourse more accessible to them.

Earlier, we stated that subjectifying is a communicational activity which motive is to produce narratives about people while mathematizing is a communicational activity which motive is to produce mathematical narratives. What, then, is the motive for personifying talk as a communicational activity? It seems that the motive is related to the activity of participation. That is, it seems that this is a communicational action whose motive is to produce mathematical narratives by first promoting students' participation and engagement in the mathematical discourse.

To substantiate conclusions from this work, larger-scale studies are needed, which will focus on relations between teaching and learning in general, seeking teaching-routines that promote learning. Also, they will focus on the specific discursive-routine of personifying aiming to define the when and the how of this routine.

Bilingual mathematics learners, conceptual mathematical activity and the role of their languages. How best to investigate?

Máire Ní Ríordáin[1] and Aisling McCluskey[2]

The significant role of language in mathematics teaching and learning is not a new phenomenon. Investigating bilingual mathematics learners is complex and research has demonstrated that language switching practices are also complex and involve not only social and cultural aspects, but also cognitive aspects. However, little investigation has been undertaken into the specific role of languages and their influences on conceptual activity at undergraduate level. The framework, and future research directions, presented in this paper aim to investigate further the cognitive aspects of bilingual learners and their use of their languages, when engaged in conceptual mathematical activity.

Keywords: Language, conceptual mathematical activity, bilingualism, framework.

INTRODUCTION

In this paper we will present a theoretical framework to support empirical research investigating bilingual students' use of their two languages as they engage in conceptual mathematical activity at undergraduate level. The need for such a framework has arisen from the authors' previous research findings and development of new research directions within the area of language and mathematics education. Comparisons of the Irish and English languages demonstrates that there are differences between the languages in terms of syntax and semantics and that this may impact on the processing of mathematical text, and advantage those learning through the medium of Irish. However, what is difficult to conclude, without further investigation, is whether differences between the languages, and when/how they are used, have a differential impact upon cognitive processing (Ní Ríordáin, 2013).

Previous studies in the Irish context demonstrate that a significant relationship exists between performance on mathematical word problems and language proficiency, with bilingual students with high proficiency in both languages performing better mathematically (Ní Ríordáin & O'Donoghue 2009). In particular, high proficiency in Irish had a strong correlation with performance in mathematics (through the medium of English) for students in the transition from Irish-medium primary to English-medium second level mathematics education. National testing in mathematics and English at primary level reveals that students in Irish-medium primary education perform the same or better than students in all-English medium education in both mathematics and English (Gilleece, Shiel, Clerkin, & Millar, 2011). Similarly, at third level education, when examining high-ability bilingual students, it was found that some students found it easier to undertake operations and to process ideas in Irish (as opposed to English) and displayed greater comprehension of the mathematics problems, an ability to self-correct, to select appropriate features in the problem and displayed knowledge of their strategies (Ní Ríordáin & McCluskey, 2012).

The significant role of language in mathematics teaching and learning is not a new phenomenon. Given the marked growth of cultural migration, the focus on education for economic development and the emphasis on English as a language for learning, we have become acutely aware of the importance of recognising the significance of language in learning mathematics (Barwell, Barton, & Setati, 2007). However, little investigation has been undertaken in relation to the specific role of learners' different languages when engaged in mathematical learning. There has been a focus more on the social, rather than cognitive functions of code switching/use of languages. In particular, there is a need for the development of a coherent and integrated interpretive framework for investigating whether differences in languages, and their use, by bilingual mathematical learners have a differential impact upon cognitive mathematical processing, while recognising the social aspects of learning. Fundamental to this is the commognitive approach for the study of mathematical learning by Sfard (2008, 2012).

SFARD'S COMMOGNITIVE APPROACH

Sfard's (2008) interpretive framework for examining learning is founded on the premise that thinking is a form of (interpersonal) communication, and that learning mathematics entails extending one's discourse. If assuming the premise that mathematical learning involves initiation into the discourses of mathematics, then learning mathematics involves substantive discursive changes for learners (Sfard, 2008). Accordingly, mathematics teaching involves facilitating such changes. Sfard also emphasises that communication, and being part of a community, is central to facilitating such teaching and learning activities. A discourse is distinctive in terms of a community's practices in relation to *word use*, *visual mediators*, *endorsed narratives* and *routines* (Sfard, 2008, pp. 133–135). Sfard (2012, p. 3) distinguishes between two types of mathematical learning (change in discourse): *object-level learning* (expansion of what is known already, mainly accumulative) and *meta-level learning* (change of meta-discursive rules, more radical and complex kind of change).

Overall, the commognitive framework 'provides a unified set of conceptual tools with which to investigate cognitive, affective and social aspects of mathematics learning.' (Sfard, 2012, p. 1). A key purpose is to help make sense of classroom processes, while being responsive to the intricate nature of complex data generated in a teaching and learning setting. What we aim to do in this paper is to build on this approach within a bilingual university mathematics education context and to potentially assist towards the reification of the framework into tools that can help analyses within such a context.

A FRAMEWORK FOR THE STUDY OF BILINGUAL LEARNERS

The following sections firstly provide an overview of key perspectives and aspects of consideration informing the proposed framework. Key principles of the framework are then presented, taking a commognitive standpoint (Sfard, 2008). The approach, proposed in this paper, is the result of a number of research studies undertaken in the Irish context to comprehend the intricacies of bilingual mathematical learning.

Perspective on discourse

Given the central aspect of discourse to the commognitive approach it is important that we outline our perspective of discourse. We see mathematics as a discourse and a type of communication (Sfard, 2012). Discourse is more than just language. As defined by Gee (1996, p. 131):

> A Discourse is a socially accepted association among ways of using language, other symbolic expressions, and 'artifacts,' of thinking, feeling, believing, valuing and acting that can be used to identify oneself as a member of a socially meaningful group or 'social network,' or to signal (that one is playing) a socially meaningful role.

By employing this definition, Discourses are more than verbal and written language and the use of technical language; Discourses also involve communities, points of view, beliefs and values, and pieces of work. Moschkovich (2012, p. 95) utilises the phrase 'mathematics Discourse practices' to draw attention to the fact that Discourses are embedded in sociocultural practices as they evolve from and involve participation in communities, while also cognitive as they involve thinking, signs, tools and meanings. This concept of Discourse will inform the examination of conceptual mathematical development of bilingual learners, linking both the cognitive and social aspects of use of languages.

Perspective on bilingualism

Our work is with bilingual (Irish and English) mathematics learners and it is essential to incorporate this concept into the proposed framework. Defining bilingualism is difficult, in particular defining whether a person is bilingual or not. Definitions vary between political, social and cognitive perspectives. Grosjean and Moser-Mercer (1997) developed the notion of a "complementarity principle" in which they emphasise that bilinguals use their languages for different purposes and in different domains of life. Dominance in one language over the other is common among bilinguals depending on the use and function of each language. Also, studies involving bilinguals tend to focus on only one language, but due to the complex nature of the issue of bilingualism, aspects of both languages need to be taken into account. For the purpose of the development of a framework for the investigation of bilingual mathematical learners, we utilise Grosjean's (1999) concept of a continuum of modes with monolingual and bilingual at each endpoint. Therefore, by utilising the concept of a continuum of modes (monolingual to bilingual), it facilitates an understanding of bilinguals using their languages independently and together depending on the context/purpose. This is further supported by Cummins' (1980) Common Underlying Proficiency (CUP) model of bilingualism, which is a more apt description of language construction within the mind. Outwardly both languages are different in conversation. However, internally, both languages are merged so that they do not function independently of one another, with a central processing unit that both languages contribute to, access and use. We support a non-deficit view of bilingual learners and view language(s) as a resource and a support for learning.

Language and mathematics

In our research we are primarily concerned with the role of bilingual students' languages in mathematics teaching and learning. We consider mathematical language as a distinct 'register' within a natural language, e.g., Irish or English or French, which is described as "a set of meanings that is appropriate to a particular function of language, together with the words and structures which express these meanings" (Halliday, 1975, p. 65). One aspect of the mathematics register consists of the special vocabulary used in mathematics and it is the language specific to a particular situation type (Gibbs & Orton, 1994). However, the mathematics register is more than just vocabulary and technical terms. It also contains words, phrases and methods of arguing within a given situation, conveyed through the use of natural language (Pimm, 1987). The grammar and vocabulary of the specialist language are not a matter of style but rather methods for expressing very diverse things. Therefore, each language will have its own distinct mathematics register, encompassing ways in which mathematical meaning is expressed in that language. The process of learning mathematics inevitably involves the mastery of the mathematics register (Setati, 2005). Developing a learner's mathematical register provides them with analytical, descriptive and problem solving skills within a language and the communicative competence necessary for successful participation in mathematical discourses.

Conceptual mathematical activity

Given that our research is concerned with undergraduate bilingual students, it is essential to examine the mathematics register and discourse development at this level. The nature of cognitive growth in the development of university-level mathematical thinking has borne considerable scrutiny over the past half-century (Thurston, 1990; Asiala et al., 1997). The associated literature presents a strong case that the maturing over time of the mathematical thinking of professional mathematicians is such that mathematical concepts become distilled and perfectly understood - by them. As a result of such sustained processing, all forms of former struggle or lack of understanding are potentially removed from memory. Thurston (1990) captures eloquently the power and satisfaction of arriving at deep understanding after struggle. In the process, he suggests that "once you really understand it and have the mental perspective to see it as a whole... You can file it away, recall it quickly and completely when you need it, and use it as just one step in some other mental process" (Thurston, 1990, p. 847). At its core, these authors refer to what has been identified and named by Tall and Vinner (1981) as *concept image* for any given mathematical concept such as, for example, function or limit.

It proposes a genetic decomposition for a given mathematical concept. This encompasses knowing what it means to understand such a concept and knowing how such an understanding can be constructed by a student, thus providing a model of cognition for the concept. Such a model plays a key role also in alternative cognitive theories for mathematical thinking and learning such as those due to Tall and Vinner (1981) where it is referred to as *concept image.* A genetic decomposition attempts to identify the layers of meaning, robustness and accuracy that arise as a particular concept is revisited in a variety of contexts. Thus, for example, a student may initially recognize a function only when given a specific (single) formula to compute values. The student restricted to this level will have a narrow range of comprehension. A deeper level will allow the student to appreciate and manipulate the notion that a function can receive inputs, operate on them and return outputs, thus giving greater flexibility. Encapsulation into an object occurs when the student recognizes the process as a whole, namely that a function is a rule between two sets of values with certain properties. Once constructed, objects and processes can be interconnected in various ways. Given that language influences thought and thinking, and that each language will have its way of constructing the concept, insight into the role and effect of bilingualism/languages on conceptual mathematical learning is critical.

Language and learning

Developing a student's mathematics register and participation in discourse is facilitated by language(s). Language is an essential instrument of thought and is necessary for understanding and combining experiences, and is required for organising concepts. The general consensus in cognitive science is to presume that thinking is occurring in some language (Sierpinska, 1994). Vygotsky was one of the earliest theorists to begin researching the area of learning and its association with language. He concluded that language is inextricably linked with thought – "the concept does not attain to individual and independent life until it had found a distinct linguistic embodiment" (Vygotsky, 1962, p. 4). Although a thought comes to life in external speech, in inner speech energy is focused on words to facilitate the generation of a thought. If this is the case, it raises an important question – does the nature of the language used affect the nature of the thought processes themselves? The transition from thought to language is complex as thought has its own structure. Thought is mediated both externally by signs and internally by word meanings (Vygotsky, 1962). It is the use of language as an instrument of thinking that is of importance, as well as its effect on cognitive processing. Therefore, thought is intimately linked with language and ultimately conforms to it. The linguistic relativity hypothesis proposes that the vocabulary and phraseology of a particular language influences the perceptions and thinking of speakers of that language (Whorf, 1956). Accordingly, each language (e.g. Irish or English) will have a different cognitive system that will influence concept formation and development. We support the premise that a language influences our mathematical thinking, but not necessarily to a degree that it determines our entire mathematical thinking (Sternberg, 2003). We propose that there are differences 'between linguistically distinct versions of "the same discourse".' (Kim, Ferrini-Mundy, & Sfard, 2012, p. 2) which correspondingly impact on mathematical learning.

Learning mathematics

Mathematics and learning is arbitrated through mathematical discourse practices, spoken and written language, symbols, gestures, etc. (Forman, 1996). Learning is situated within and involves participation in a community. Within a mathematics classroom, learning involves participation in the discipline of mathematics, in conjunction with the specific type of mathematics associated with the context (e.g. school mathematics, undergraduate mathematics, etc.) (Forman, 1996). When examining bilingual mathematics learners, it is important to address the social use of language within the context, not just its role in cognition. Moschkovich (2012) emphasises the importance of learning being illustrated within the sociocultural practices of a given setting. Importance is placed on describing learners and communities, and seeing culture as a set of practices and actively involving participants (Gutiérrez & Rogoff, 2003). Accordingly, bilingualism is described in terms of participation and use of language(s) by learners for different purposes and particularly in the context of mathematical discourse.

Effective teaching and learning is a complex endeavour. In correlation with a teacher's strategies, the teacher's own philosophical beliefs of instruction are harbored and governed by the student's background knowledge and experience, situation, and environment, as well as the learning goals set by the student and teacher. Moschkovich (2012) emphasises the importance of discerning between the *conditions of* learning and the *processes for* learning, and the importance of describing the curriculum, courses/programmes and teaching and learning approaches utilised that yield successful outcomes for different groups of learners. Therefore, it is important to examine and report on the characteristics of the learning environment such as whether there are opportunities for: speaking, listening, reading and writing; constructing meaning and knowledge; high expectations for all students; rejection of a deficit view of learners (AERA, 2006; García & González, 1995). In particular, we adopt a non-deficit perspective of bilingual learners and focus on the strategies that teachers use in developing conceptual mathematical learning.

Key principles of the proposed framework

Adopting a commognitive approach to research, combined with key concepts discussed in the previous sections, give rise to several key principles and methodological considerations for investigating undergraduate bilingual mathematics learners and their use of their languages. Primarily, the authors' framework is underpinned by a non-deficit view of bilingual learners where languages are viewed as a resource and essential for thinking. Within the framework, thinking can be defined as the activity of communicating with oneself (Sfard, 2012). Accordingly, mathematical thinking can be viewed as a Discourse, which in turn is a form of communication and involves being part of a mathematical community. Taking this view, the language or language(s) in which mathematics is being learned becomes an important issue for consideration. Within the framework, development refers to a change in Discourses (Sfard, 2012). Accordingly, we refer to the development of a student's mathematical Discourse as opposed to the development of the student themselves. Development of Discourses is a product of collective human actions and the context acknowledged. Given that the authors are primarily concerned with conceptual mathematical learning/activity, we are concerned with meta-level developments in Discourses. Since our focus is on bilingual mathematics learners, it is important that an analysis of the language(s) in which the discourse is taking place is conducted. The successive meta-discourses relating to topics of interest, for example functions, need to be documented and compared between languages.

By adopting a commognitive approach (Sfard, 2012), there are a number of key principles that need to be adhered to and which have been adapted to reflect our framework. Firstly, *Operationality*: the purpose of the research is to share useful stories. Therefore, it is important that the researcher's articulation avoids misunderstandings and is unambiguous and clear (p. 9). Second is *Completeness:* the researcher must choose the entire discourse related to the topic as the unit of analysis (p.9). Here, we add to the principle in that when examining bilinguals, we must document this discourse (plausible developmental trajectories) in both languages e.g. the discourse relating to 'limits' or 'functions' in both English and Irish. It should involve an analysis of successive meta-discourses in each language. Third is *Contextuality*: any kind of interaction is an event of learning (p. 9). It is essential that the researcher documents the interactions as fully as possible and analyses utterances within the context of the conversation. We extend this, in the given context, to the need to examine when and how bilingual students/researchers use their language(s). The next principle is that of *Alternating Perspectives*: when analysing data, the researcher alternates between being an insider and an outsider of their own ways of using words (p. 9). This is heightened within a bilingual context in that consideration must be given to both languages, their use in the given context and possibility of significant differences between researcher and participant discourses. Finally, the principle of *Directness*: when describing their study, the researcher presents things said (and done) by the participant first, not their own interpretation of the data (p. 9). It is hoped that these over-arching concepts and principles will foster insights into bilingual mathematics learning and contribute to the development of research.

CONCLUSION AND FUTURE RESEARCH

At the National University of Ireland (NUI) Galway, students have an option to study Mathematics through a bilingual approach (Irish and English) during their first year of undergraduate education. This provides an opportunity to investigate language choices made by undergraduate students and to identify how these choices impact on conceptual mathematical activity. We propose to address the following research questions via an investigation that is supported by the proposed framework.

— In what ways do formal discourses in English and Irish on, for example 'limits', follow different developmental trajectories in undergraduate mathematics education? 'Limits' are chosen as an example given its ubiquitous nature; for example, limits of sequences, of functions at points and at infinity, summation of series, derivatives and integrals. Developmental trajectories refer to identifying all of the discourses related to 'limits' that an Irish-speaking and English-speaking person is likely to encounter (Sfard, 2012). This can be in everyday life or specifically related to a teaching and learning context (e.g. second and third level in this case) – all potential trajectories need to be listed.

- What is the nature of and reasons for meta-level developments of mathematical discourses in bilingual students? Meta-level development refers to a change in the discourse that results in expansion of the discourse relating to a particular topic(s) and is a complex type of change, rather than an 'object-level' change that is more accumulative in nature (Sfard, 2012, p. 3). Therefore, meta-level development is primarily concerned with conceptual mathematical activity.

- How are languages (Irish and English) utilised in, and how do they impact on, meta-level developments in mathematical discourses of, for example 'limits', in undergraduate mathematics education? By detailing the developmental trajectories in each language it is expected to demonstrate how learning can be affected by the characteristics of a language, while also examining when and how bilingual students utilise their languages.

Investigating bilingual mathematics learners is complex and research has demonstrated that language switching practices are also complex and involve not only social and cultural aspects, but also cognitive aspects. The framework, and future research directions presented in this paper, aim to investigate further the cognitive aspects of bilingual learners and their use of their languages, when engaged in conceptual mathematical activity.

Mathematical reasoning through a broad range of communicational resources

Anna-Karin Nordin and Lisa Björklund Boistrup

Stockholm University, Department of Mathematics and Science Education, Stockholm, Sweden, anna-karin.nordin@mnd.su.se

Mathematical reasoning is examined in this paper that investigates student – teacher communication at the front of the classroom where students gave account of their solutions to a mathematical problem. Adopting a multimodal approach we have discerned how students communicate reasoning through a broad range of communicational resources, such as speech, drawing, hand gestures and the like. We adopted Toulmin's (2003) model of argumentation as means to capture different elements of the reasoning given account for in the communication.

Keywords: Reasoning, argument, multimodality, communication.

INTRODUCTION

The importance for students to participate in mathematical reasoning has been highlighted in international frameworks (e.g., Niss & Jensen, 2002). In the ongoing PhD study, of which this paper is a part, the interest of exploring and understanding reasoning concerns reasoning in public, as a communicative act, not as a thinking process. Specifically, we, in this paper, investigate reasoning when students explain solutions to problems while positioned at the front of the classroom. The teacher takes part in the communication as well.

> Reasoning is a collective and human transaction, in which we present ideas or claims to particular sets of people within particular situations or contexts and offer the appropriate "reasons" in their support. (Toulmin, Rieke, & Janik, 1979, p. 9)

An argument is described by Toulmin and colleagues (1979) as a "train" of reasoning. Various works have studied observable reasoning or argumentation in mathematics education, some focusing on collective or collaborative argumentation/reasoning with a focus on peer interaction (e.g., Bjuland, Cestari, & Borgersen, 2008; Mueller, 2009). When analysing students' collaborative reasoning, Bjuland, Cestari and Borgersen (2008) highlighted the need for paying attention to more than writing and speech when analysing arguments. Another example is Meaney (2007), who considered the role of gestures in strengthening arguments when analysing levels of mathematical literacy demonstrated by students.

Within research on mathematical communication, there is a trend to recognise the multimodal nature of communication even though it continues to privilege language as the primary mode (Morgan & Alshwaikh, 2012). In order to analyse and understand communication in mathematics education, a multimodal approach has been adopted (e.g., Björklund Boistrup, 2015; Morgan & Alswaikh, 2009). While taking on a multimodal approach, Morgan and Alswaikh (2009) drew attention to the duality of a mode, the drawing mode: as the process of drawing and as the outcome, the picture itself. By using a multimodal approach when analysing reasoning expressed in student – teacher communications we hope to contribute to the understanding of reasoning as a sequence of communicative acts. In this study we investigate how students display reasoning in student – teacher communications through a variety of communicational resources when giving account of solutions at the front of the classroom.

ANALYTICAL FRAMEWORK

Drawing on Toulmin and colleagues (1979), we view an argumentation as consisting of ways of giving reasons and hence we understand argumentation and reasoning as strongly connected (Krummheuer, 1995). In order to examine reasoning we adopt Toulmin's model of argumentation (2003). When analysing communication, as constituted through a wide range of resources (such as speech, symbols, pictures and the like), we added to the framework a multimodal social semiotic perspective.

TOULMIN'S MODEL OF ARGUMENTATION

In mathematics education, Toulmin's model of argumentation has been used, sometimes in a reduced form (e.g., Krummheuer, 1995, 2007; Meaney, 2007), consisting of four of the six original elements of the model, where three of them represent the "core" of an argument. The elements are the data/ground, the warrant and the claim/conclusion, as well as the forth element, backing. The model that serves as the basis for our analysis of reasoning is presented in Figure 1.

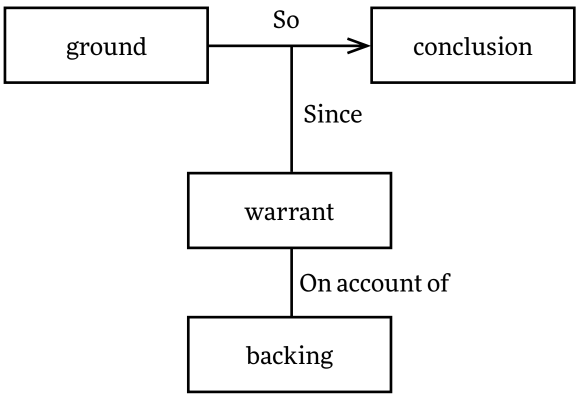

Figure 1: Toulmin's reduced model of argumentation

In a mathematical argument, a *conclusion* (Figure 1 top right), is presented, often in the form of a solution of a solved problem. In order to support a conclusion, some underlying foundation for the conclusion needs to be produced, which is to be seen as the *grounds* (Figure 1 top left), often consisting of facts or information. In order to justify the step between the presented grounds and the asserted conclusion, the *warrant*, can be provided (Figure 1, middle). The warrant is provided to show that starting from the grounds, the step to the given conclusion is appropriate and legitimate. The *backing* (Figure 1, bottom), gives authority to the warrant and can, like the grounds, often be expressed in the form of facts. Toulmin (2003) described the process of argumentation as G because W so C. Participants in a communication do not necessarily structure their contribution clearly according to the elements of the model but they may still be identified through a detailed analysis of interaction (Krummheuer, 1995). We adopted this model as an analytical tool in order to reconstruct reasoning in a situation where students presented solutions to problems while positioned at the front of the class and with the teacher participating in the communication.

Multimodal social semiotics

Focusing on communication, we adopted a multimodal social semiotic perspective (Kress, 2010) in order to describe and understand the mathematical reasoning in classroom communication. Kress (2010) stressed that resources for communication are to be understood as more than writing and speech. They include images, facial expressions, gestures, and the like. The various communicational resources form multimodal ensembles which constitute the communication. In our study we focused on the semiotic resources that communicated mathematical reasoning identified in classroom interaction. Through this perspective we have analysed how the participants used various semiotic resources in their interaction to present reasons in support of a conclusion, which is regarded as the central activity of reasoning when forming an argument (Toulmin, et al., 1979). The multimodal approach affected transcripts as well as analysis and findings, which will be described further on.

METHODOLOGY

The context of this paper is a case study (in the sense of Hammersley & Gomm, 2009) including four classes from grade three to five. In this particular paper we draw on data from two episodes from a grade four class. The episodes are from two presentations at the front of the classroom about solutions to a problem. In order to identify potential reasoning in the presentations we structured and analysed data from the two videorecorded episodes in the following way. The episodes were transcribed taking on a multimodal approach by using the software Videograph. Videograph made it possible to note the semiotic resources the participants were using in terms of our interest in communicated reasoning. With a focus on elements of an argument, the following semiotic resources were identified as being relevant for this study: *speech*, *written text* (including symbolic notions), *drawings*, and *hand gestures* including the use of manipulatives (physical resources). This provided an overview of the communication (see Excerpt 1 as an example), making it possible to identify different elements of an argument according to Toulmin's model and a multimodal approach.

ANALYSIS

The teacher's aim with the lesson which we give account for in this paper, was to involve the students in a problem solving activity, in pairs or small groups, as well as a whole class activity where selected solutions were presented. These presentations incorporated students explaining and justifying their reasoning. The mathematical content of the lesson was fractions and the task was formulated as follows:

> It is a sport/field day and it is sunny and warm. The school will provide food and drinks. Each student is given ¼ of a liter of juice to drink. There are 16 students. How much juice will be needed?

At the end of the lesson the teacher asked some of the groups to present their solutions to the class. We present two episodes from the presentations, including analysis and findings. We chose these episodes since they represent two different solution strategies and, as will be shown, different aspects of student reasoning.

Description of Episode 1: Stina starts with the bottles

In this first episode, Stina and her friend are standing in front of the class in order to present their solution. The teacher asks Stina, who is doing the presentation of her group's work, how she initially was "thinking". Stina tells the teacher that she drew four bottles and then she starts to draw one bottle on the board. Being asked by the teacher regarding the number of bottles, Stina clarifies that they started off with drawing one bottle. Stina continues to talk but is interrupted by the teacher who wants to know what they did with the bottle. Stina starts to explain that they counted (inaudible continuation) and is prompted by the teacher to do that with the bottle on the board. Stina divides the bottle into four parts and clarifies in words what she did. Asked for a clarification as to why they divided the bottle into four parts, Stina responds verbally "For it to be...since everybody could drink one quarter". The follow up by the teacher to Stina's response is yet another question, concerning the meaning of a quarter.

In Excerpt 1 (see Table 1) we give account for the continuation of the interaction. Actions taking places at the same time are beside each other horizontally.

Stina continues to draw a third and a fourth bottle, each time dividing each bottle into four parts, while explaining verbally how many they were enough for, ending up with "and then they were enough for sixteen" with a picture of four bottles each divided into four parts. The student – teacher interaction continues for a while and includes another student as well, ending with a verbal clarification that there are four liters needed for sixteen students.

Analysis of the first part of Episode 1

In Episode 1 we could identify in the analysis the elements of Toulmin's model. Here we give account of our analysis of the first part of Episode 1. Stina's argumentation here is made in relation to the teacher's question regarding how many can drink from the first bottle. The image of the four parts of the bottle visualized how many that could drink from one bottle (Excerpt 1, row 5) and this was also expressed by speech, "four" (row 6). This utterance (picture+speech)

	Speech	Writing/Drawing	Hand gestures	
1	Teacher (T): How many parts should one divide it into then?		T takes a magnetic circle divided into four quarters and puts it on the white board.	Stina (S) points at the parts in the bottle
2	S: Four			
3	T: Four. Ok		T points at the circle	
4	S: It was not enough. We had to do one more	S starts to draw one more bottle next to the first one.		
5	T: How many could drink from the first bottle?	S divides the second bottle into four parts.		
6	S: Four			
7	T: Four. Ok			

Table 1: A multimodal transcript from Episode 1

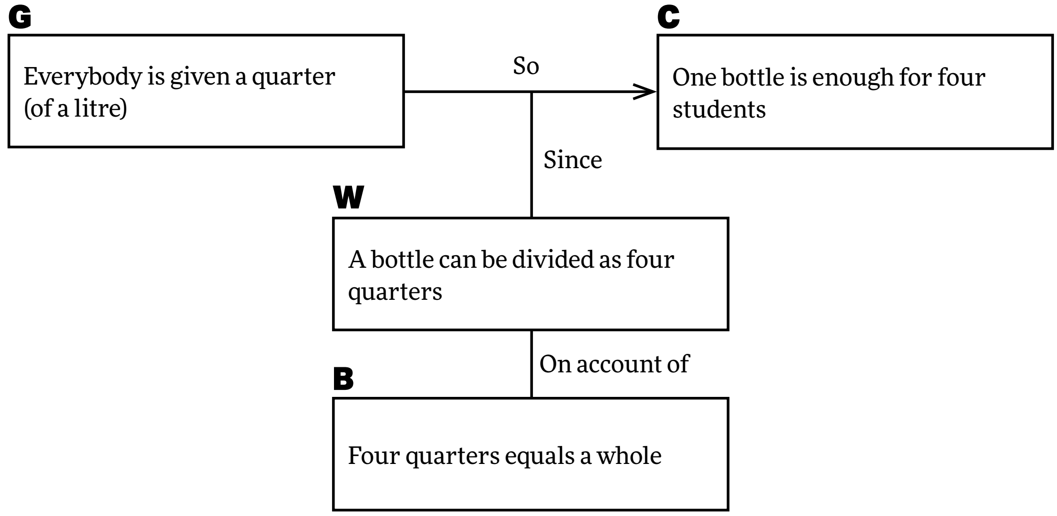

Figure 2: Elements of Stina's argument in Episode 1

has been identified as the first conclusion. In Figure 2 we summarise our analysis according to Toulmin's model.

As we wrote earlier, we could identify a conclusion from Stina's picture of bottle divided into four (row 5) and speech, "four" (row 6). This utterance from Stina was seen as claiming that four students could drink from one bottle. The fact Stina appealed to as the foundation for claiming that four students can drink from one bottle was categorised as the grounds and was identified from her verbal response to why the bottle was divided into four parts "because everybody can drink a quarter".

The warrant in this specific situation has been identified in this argument by taking into account the use of different semiotic resources. The warrant in this case should answer to why one can claim a bottle to be enough to four students (the conclusion) if each person is given a quarter (the grounds). The warrant, which we construed here, was: a whole can be divided as four quarters, which was communicated by Stina through drawing, speech, and hand gesture. More specifically, we construed that she communicated that a whole can be divided into four in her drawing where she divided the bottle (as a whole) into four parts together with her saying "we divided it into four parts". That each part is to be seen as a quarter was stated in her answer to the teacher's question on why they divided the bottle into four parts. Stina also indicated, according to our analysis, that one of the drawn parts of the bottle was to be considered as a quarter when pointing (row 1), a bit vaguely, towards the parts of the bottle when asked by the teacher what a quarter means. The teacher also contributed to the argument by stating, "Four" (row 3) as a verbal reinforcement to Stina's verbal response "Four" (row 2) to her own question regarding how many parts it (the bottle as a whole) can be divided into.

Further evidence, authorizing the warrant, was categorised as backing: a whole equals four quarters, and in this episode was identified in the image of the magnetic circle consisting of four quarters of a circle put at the white board by the teacher (row 1).

Description of Episode 2: Frida starts with the mugs

After two groups had presented their solution, it was time for Frida to present her and her friend's solution. With both Frida and the teacher standing at the whiteboard, the teacher asks Frida to start with how she began to solve the problem. Frida begins to explain how she started off solving the problem by stating "I started to draw each student's mug". While expressing this Frida starts to draw a rectangle on the white board, emphasizing it by also pointing at it. While beginning to draw a second rectangle/mug (from now on referred to as "mug") the teacher asks her how much each mug contains. Frida completes drawing the second mug and writes ¼ in the first mug saying, "There was"... without continuation. The teacher expresses the content in each mug verbally "There was a quarter in each mug" and puts a quarter of a magnetic circle over the first mug drawn by Frida. Frida writes ¼ in the second mug and continues to draw six more mugs on the same row and eight mugs on a row below ending up having drawn sixteen mugs in total (Figure 4)

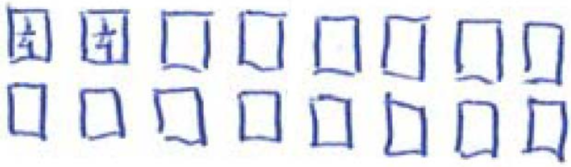

Figure 4: A picture of the way Frida drew the mugs

The teacher asks Frida how many quarters she had but Frida does not respond to that question and continues "I did like this" and shows on her picture of the sixteen mugs how she divided the sixteen mugs into four groups with four mugs in each group by drawing a line after four mugs and after eight mugs in the first row, and after four mugs in the second row and partly after eight mugs in the second row (Figure 5).

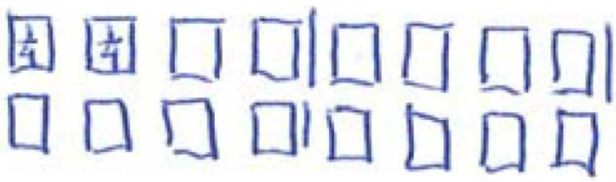

Figure 5: A picture of how Frida divided the mugs

Here Frida is interrupted by the teacher who wants to return to her question regarding the number of quarters. After some elaboration by the teacher regarding the number of quarters, she asks another student how many litres there are and receives the answer "Four litres". As a final contribution in this presentation the teacher is stating. "We do know that in one litre there are four quarters" at the same time as she is putting the four quarters of the magnetic circle into a full circle on the white board.

Analysis of Episode 2

Also in Episode 2 we could, in the analyses, identify the elements of Toulmin's model. We summarise our analysis in Figure 6.

The presentation in Episode 2 ended up with the conclusion that four liters were needed. The conclusion was identified in Frida's final image reflecting the outcome as the four groups of four mugs/quarters in each liter (Figure 5) and was identified in the other student's verbal answer "Four liters" towards the end of the presentation.

In these episodes two grounds, supporting the conclusion that four liters were needed, were identified. These grounds were identified as 1) there are sixteen students, and 2) each student is given a quarter each. The use of the first ground was identified in Frida's drawing of the sixteen rectangles. Each rectangle was explained to illustrate a mug for each student, which is clear in Fridas speech "I draw all students' mugs" when she started to draw the mugs. The number of the mugs/students, sixteen, was expressed in the drawing and the picture of sixteen mugs (as well as by the teacher when elaborating verbally on what Frida was drawing). The second ground – each student is given a quarter – was identified when Frida wrote ¼ in two of the mugs as a response to a question from the teacher regarding how much the mug contained. After Frida had written ¼ in one of the mugs the teacher made this clearer by saying "It was a quarter in each mug". A visual representation of the content was seen in the form of the magnetic quarter of a circle placed over the first mug by the teacher.

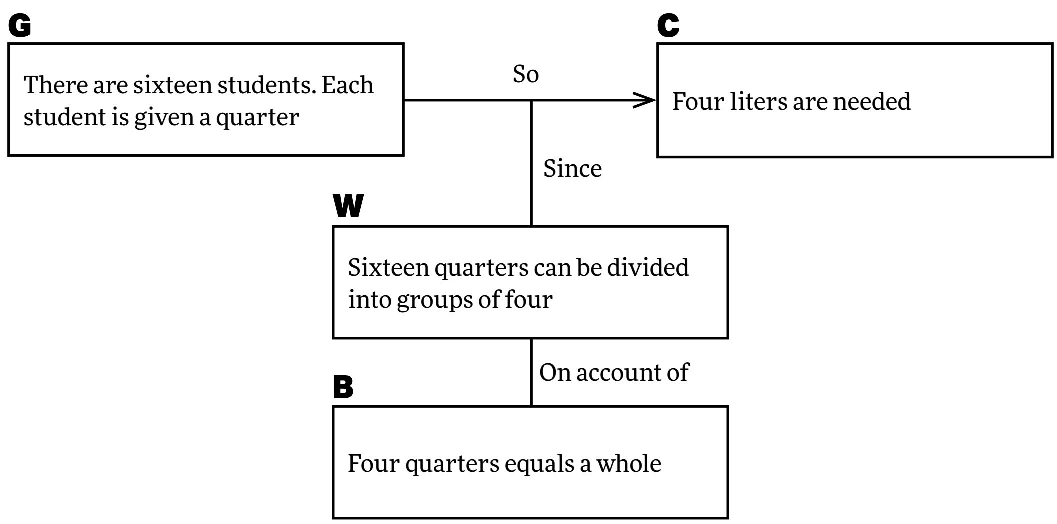

Figure 6: Elements of Frida's argument in Episode 2

Our understanding is that Frida's method, to divide the sixteen quarters into groups of four, leading to the conclusion of four litres, indicates the warrant, justifying the step from grounds to conclusion. We construed the warrant to be: sixteen quarters can be divided into groups of four. The grouping of quarters was indicated by the process of drawing a line after the fourth mug in the first row, after the eighth mug in the first row and after the fourth mug in the second row.

In our analysis we identified that the teacher provided the backing by putting the four quarters of a circle, into a whole circle, showing: four quarters equals a whole. This was also identified in the teacher's, less formal, verbal expression "We do know that in one liter there are four quarters".

CONCLUDING DISCUSSION

The aim of the study was to identify reasoning in student – teacher communication, interpreted by us as presenting support, (that is, reasons) for a conclusion, showing how these reasons can be seen as giving strength to the claim (Krummheuer, 1995; Toulmin, 2003). By using Toulmin's model as an analytical tool together with a multimodal approach we have been able to discern aspects of reasoning.

We investigated how students display reasoning through a variety of communicational resources when giving account of solutions at the front of the classroom. In our findings we discerned how both students in the episodes presented here displayed reasoning through several communicational resources but in different ways. An example of this is how the girls displayed a ground they both referred their argument to: each student is given a quarter. In the first episode we could see Stina displaying the use of this ground by picture and speech whereas in Frida's case we could see how three different resources were identified as being used, interplaying with each other. In the second episode Frida displayed the ground by writing ¼ in a drawn rectangle (she had previously in speech communicated it to represent a mug to one of the students). Another example was when they were justifying the step from ground to conclusion, the warrant in Toulmin's model. Stina communicated this both through drawing, speech and gesture and Frida only through drawing. This illuminates how essential it is for teachers, as well as researchers, to pay attention to what is displayed in various communicative resources in order to capture and illuminate the reasons, mathematical justifications, and to make them accessible for all students in classroom communication.

By taking a broad range of communicative resources into account, this study opened up for capturing students' silent and non-symbolic display of reasoning which would have passed unnoticed if we had only been looking for verbal or written expressions. One example was our identification of Frida's process of drawing lines, which we construed as her justification, providing warrant for the conclusion considering the grounds she provided. Expressed verbally, such as in "A number of quarters can be divided into groups of four in order to get the number of wholes", it would be likely to receive a response from a teacher as a "proper" justification. If it was only expressed in drawing it might go unnoticed. If the warrants, such as Frida's in this case, are not noticed and elaborated upon, they might pass as unnoticed by other students in the classroom as well. Hence, an opportunity for the teacher to highlight and generalize mathematical ideas may be lost.

We want to clarify that as researchers adopting a multimodal approach, we always need to make choices of what resources to pay attention to in the analysis. In this paper we focused on reasoning and the resources identified as being relevant to this. If we had chosen to focus more broadly on the interaction itself, for example on feedback, other resources, such as voice, facial expression etcetera, would have been part of the transcripts and analysis as well.

Mathematics education in bilingual contexts: Irish-English, Breton-French

Caroline Poisard[1], Máire Ní Ríordáin[2] and Erwan Le Pipec[1]

1 UBO, ESPE de Bretagne, Bretagne, France, caroline.poisard@espe-bretagne.fr

2 National University of Ireland, Galway, Ireland

Irish and Breton are both Celtic languages but unity has vanished resulting in deep linguistic differences. But the common heritage is still at hand when one considers the lexicon, grammatical peculiarities and number. The concept of the structure of a language impacting on thought processes is referred to as the linguistic-relativity hypothesis, which proposes that the vocabulary and phraseology of a particular language influences the thinking and perception of speakers of this language, and that each language will have a different cognitive system. This paper examines the Irish and Breton languages in their bilingual context, their linguistic characteristics and impact on mathematics learning in comparison to English and French, while identifying future research requirements.

Keywords: Bilingual contexts, Irish-English, Breton-French, linguistic differences.

INTRODUCTION

Irish and Breton are both Celtic languages, spoken in the western ends of Europe, namely in Ireland and in the western half of Brittany (France). The Celtic languages are divided into two branches: the *gaelic* one (the native languages of Ireland, Scotland and the Isle of Man) and the *brythonic* one (comprising Welsh, Cornish and Breton). Accordingly, these languages might have once been the same language or at least, two dialects of the same language. Nevertheless, centuries have passed by and unity has vanished, resulting in deep linguistic differences. However, the common heritage is still at hand when one considers the lexicon (roughly 5 000 shared words, those expressing very old notions such as a house: *teach/ti*; weather: *aimsir/amzer*; good: *maith/mat*, etc.) and grammatical peculiarities (mutations of initial consonants to distinguish word gender; mutations in syntactical context; 'declined' prepositions; word order, etc.). Numbers are also a domain where a very old continuity can be traced, as will be shown in this paper. These two languages are spoken in a bilingual context, involving either a Germanic language: English, or a Romance one: French. This is the first investigation of its nature into the Irish and Breton languages and given the rise in Irish-and Breton-medium education it is timely and can contribute to the development of policy in this area.

In this paper we present a preliminary study which builds on two previous research studies in the two commented contexts (Ní Ríordáin, 2013; Poisard et al., 2014), with the aim of identifying future comparative studies. We focus here on languages features and the potential of language as a resource for teaching (Adler, 2001), while examining fundamental questions about relationships between mathematics and language (Barton, 2008). Taking into account that language reflects the way we see the world and that mathematics is a modelisation of the world, our questions are: What are the features of languages that may be of importance for mathematics teaching and learning? How can language be a potential resource for teaching? How to identify mathematical particularities in linguistic expression?

LANGUAGE CONTEXTS

The history of Irish and Breton is marred by stories of decline and persecution. However, both languages have experienced parallel revivals at various times. Since the 90's on, there is more and more concern in both populations to revitalize their languages and avoid complete extinction (Le Pipec, 2013). Strategies have been and are being designed at state or near-state level to revitalize them, primarily by supporting them as medium of education. Table 1 provides a summary

	Type of schools	Number of primary and secondary students	Total of students
Breton-medium education	Bilingual public schools	6 662	15 338
	Bilingual catholic schools	4 971	
	Diwan schools	3 705	
Irish-medium education	Maintenance heritage language	15 546	56 974
	Immersion	41 428	

Table 1: A comparison between Irish and Breton educational contexts

of the number of students learning through the medium of Breton and Irish.

Breton schools are part of the centralised educational system of France and the teaching of Breton is optional. There are over 15,000 pupils learning through the medium of Breton (with an average growth of 4 to 5% per year), ranging from pre-school to secondary level (OPLB, 2014). There are three types of Breton-medium schools that pupils can attend, distinguishable by two ways of utilising the languages. The 'bilingual schools' (Public or Catholic) devote the same amount of time to each language. On the other hand, *Diwan* schools claim to be 'immersive' schools since Breton is only in use during the first four years of schooling. French is then introduced by the age of 7 to 8 and takes up to half of school time by age 11.

Irish-medium education is the norm for those growing up in the Gaeltacht regions in Ireland (maintenance heritage language education). The rise in popularity of primary (Gaelscoileanna) and second level (Gaelcholáistí) immersion education (Irish-medium education outside of Gaeltacht regions) is significant and has seen an increase in excess of 60% over the past decade. Currently, approximately 8% of the primary level population and 4% of the second level population are learning through the medium of Irish (Gaelscoileanna Teo, 2014). In Ireland, there is an adequate supply of suitably qualified teachers at the primary level due to incentives and a strong history of native speakers pursuing a career in primary teaching. However, at second level education there is a shortage of suitably qualified teachers to deliver the specific subject areas of mathematics, science and foreign languages through the medium of Irish. Similar problems arise in Brittany. However, at primary level a shortage of skilled speakers willing to become teachers can be observed. Moreover, no *specific* qualification is required for teaching through the medium of Irish/Breton at primary or second level education, although some specific teacher education programmes exist. Accordingly, teachers in Irish- and Breton- medium schools may not have high standard of Irish/Breton themselves, nor have an understanding of the complexities of teaching and learning mathematics in a bilingual context. Therefore, it is not surprising that teachers report difficulty in supporting the language development element of mathematics teaching and learning and a lack of suitable resources and textbooks to support their work (Poisard et al., 2014).

THEORETICAL FRAMEWORK

Bilingual education research shows that using two or more languages to learn and teach is not a simple addition of languages that enable someone to use one language or another (Cummins, 1984). Indeed, linguistic competencies and learning strategies are involved simultaneously and bi-/multilingualism is seen as a "language-sensitive approach of content" (Bernaus et al., 2012). In our work we see bilingualism as a particular form of multilingualism.

The concept of the structure of a language impacting on thought processes is referred to as the linguistic-relativity hypothesis (Whorf, 1956). The basic premise of this hypothesis is that the vocabulary and phraseology of a particular language influences the thinking and perception of speakers of this language, and that conceptions not encoded in their language will not be available to them. Hence, they are proposing that each language will have a different cognitive system and that this cognitive system will influence the speaker's perception of concepts (Whorf, 1956). Whorf emphasises also that we act according to how we describe things, and accordingly different languages may classify experience in different ways. Therefore, in theory, an Irish speaker/learner should have a different cognitive system to that of an English speaker/learner, influence our actions and accordingly may influence mathematical understanding. For example, Miura and colleagues (1994, p. 410) contend that 'numerical language characteristics (East-Asian languages) may have a significant effect on cognitive representation of number'. However, other researchers have questioned argued for the difficulty in applying the linguistic-relativity hypothesis and the difficulty in testing such claims in relation to mathematical thinking (Towse & Saxton, 1997). We acknowledge that this may be too strong of a way of viewing the influence of language on the mathematical thinking and less severe forms of this hypothesis have been proposed. We support the premise that language may not shape and determine our entire mathematical thinking, but that it may influence it to a certain degree and facilitates our thinking and perception (Sternberg, 2003). Moreover, we are acutely aware of the importance of other factors such as exposure to mathematics, teaching strategies employed and culture as influencing attainment in mathematics, not just language (Towse & Saxton, 1997).

Some research shows the positive effect of teaching and learning mathematics in bilingual and multilingual classrooms. In particular, Adler (2001) considers linguistic plurality as a possible resource for mathematics teaching. Three types of resources are distinguished: material, cultural (including language) and human resources. Adler's work is set in the post-apartheid context in South Africa where multilingual classrooms and lack of material resources are common. She shows how linguistic diversity can gradually constitute a resource for mathematics teachers. At primary level, Setati (2005) explored the language practices in primary multilingual mathematics classroom in South Africa where the complex relationships between English language and home language and mathematics education is confirmed.

In Australia, Edmonds-Wathen (2015) has studied the grammar and conceptualisation of motion in Iwaidja, an Indigenous language. In her paper she discusses how understanding grammatical features to express spatial concepts in Iwaidja can help teachers of Indigenous students in their activity of teaching mathematics.

Moschkovich's (2002) research in the United States demonstrates that language can be a resource if a teacher's focus is not only on acquiring mathematical vocabulary, but also on constructing multiple meanings across registers and on developing participation in mathematical practices. This is possible only if teachers are aware of cultural and mathematical needs to teach mathematics.

The example of New Zealand is also of interest to us (Barton, Fairhall, & Trinick, 1998). In the 1980's mathematical vocabulary was developed in Maori. Several general principles were adopted in making vocabulary decisions and "metaphors were a common method of vocabulary development in both formal and informal settings. [...] An example was the development of *rere* and *arawhata* as early translations of *continuous* and *discrete* as applied to statistical data, the methaphor being that of a flowing stream or one proceeding in a sequence of waterfalls" (Barton, Fairhall, & Trinick, 1998, p. 5).

In the Welsh context, Jones (1993) concluded that there are benefits to studying mathematics in a minority language due to it being developed relatively recently as a language of learning and accordingly the terminology established tends to avoid linguistic complexity and employs a more self-explanatory mode. Furthermore, Dowker (2005) found an advantage for students learning through the medium of Welsh, in comparison to English, in terms of how numbers and arithmetical relationships are expressed in Welsh.

Our work in the Breton context (Poisard et al., 2014) shows that the particularities of the Breton language can be a resource for the teaching of mathematics, for example in the teaching of geometrical concepts and oral numeration. Teachers in this study also identified a lack of suitable resources as a significant issue. In particular, many of the material resources used in class are a direct translation from French to Breton, with no consideration of linguistic and cultural specificities. Mathematical and linguistic competencies are interrelated and these competencies need to be jointly developed by students and teachers.

Research in the Irish context demonstrates that students with high ability in Irish and English perform better mathematically (Ní Ríordáin & O' Donoghue, 2009) and that a significant relationship exists between their performance on English mathematical word problems and their Irish language proficiency at the primary to second level education transition (Ní Ríordáin, 2011). A comparison of the English and Irish languages demonstrates that there are differences between the two languages in relation syntax, semantics and access to meaning. However, what is difficult to conclude, without further investigation, is whether differences between the languages have a differential impact upon cognitive processing (Ní Ríordáin, 2013).

In this paper we discuss such questions in Irish and Breton mathematical vocabulary and the structure of the languages, while demonstrating how bilingual students' languages can be a resource for them in mathematics learning. We examine fundamental questions about relationships between mathematics and language.

LANGUAGES: A RESOURCE TO TEACH MATHEMATICS

Some linguistic peculiarities of Breton and Irish may influence the teaching of mathematics. The facilitating aspects and combinations of key features of Breton and Irish are presented here, and where appropriate comparisons are made with English and French. The findings presented here are hypothesis and further investigation (class observations, interviews, questionnaires, etc.) would be helpful to give some more precise conclusions of the influence of the use of these languages on bilingual learners of mathematics. We will not discuss dialects in this section, but Breton and Irish codification as united languages leave much space for dialect variation. In many places, it may happen that the language of books differs from oral use. General features of the languages (sentence length, topic prominence, mutations) are presented initially, followed by a focus on mathematical aspects (transparent lexicons, oral numerations and numbers). The six aspects we develop here are linked to our previous individual research (Ní Ríordáin, 2013; Poisard et al., 2014) and demonstrate commonalities between both languages.

Sentence length

Short sentences are generally more common in Breton and Irish than in French and English, which demands less concentration for pupils and short-time memory is devoted to side-information. Shorter sentences lend to an easier understanding of mathematical text and are a desirable feature (Austin & Howson, 1979). English and French readers may have a greater cognitive processing load, and this suggests a difference in mathematical processing.

Topic prominence

Breton and Irish are strongly oriented topic-prominence languages, in comparison to French and English. In Irish, the first word is usually the verb, while in Breton, it may be any word (rarely the verb). Indeed, in Breton, words expressing new information should come first in a sentence, no matter of their grammatical status or function. In problem solving, this gives pupils clues about relevant mathematic information, emphasised by their position in texts (Galligan, 2001) in comparison to English and French. Topic prominence may alter the complexity of semantic structures and have an effect on mathematical processing.

Mutations

They are an important feature of Celtic languages, either to indicate word gender or in syntactical constructions. As an example, in Breton after the word *tri* (three), any *p-* standing at the beginning of a word goes to *f-*. When combined with *poent* (point), *three points* is thus expressed as *tri foent*. The permanence of words through surface changes may help to understand the permanence of mathematical relations. Although mutations would cause difficulties for pupils with good language skills, recognising mutated words (especially when there are many of them) may be problematic for those insufficiently familiar with the language. Such mutations are not evident in English and French.

Transparent lexicon

A large part of the mathematical vocabulary is coined out of autochthonous word-roots. The meanings of many words have become easier to understand. For example, to say *parallel* in Breton is *kenstur* (same direction) and in Irish is *comhthreomhar* (equal directionality). Many of the Breton/Irish words describe concepts/objects as opposed to just labelling them. Given that the more easily and quickly the meaning of words is activated, the simpler it is to process mathematical text. It may help to retrieve all the words associated with the concept thus enhancing the total cognitive structure (Galligan, 2001). However, Celtic-made vocabulary has been criticised for various reasons: some words might have been coined too quickly by *amateur* linguists; often these words are not encountered outside of the classroom; in some cases, they were promoted not in an effort to facilitate understanding, but to wash brains of a foreign language; concern lies with if pupils must leave and should adapt to a dominant-language school. This is why an international mathematical lexicon has also been developed in Breton (Kergoat, 2012). Instead of *kenstur*, the teaching authority now recommends to express *parallel* as *parallelenn*. Further investigation is needed in terms of student learning and accessing meaning in more common languages/lexicon of English/French.

Oral numerations and counting

In this area Guitel (1975) gives an historical view of written numeration. One of the particularities of Celtic languages is the use of vigesimal system (base 20) to say numbers. Some groupings by 20 are evident in French also. In old Irish, we find traces of 20 groupings in all tens: 30, 40, 50, 60, 70, 80, and 90. For example 90 is *ceithre fhichead a deich* (four-twenty and ten, 4×20+10). We find traces in French for 80 (quatre-vingts four-twenty, 4×20+10) and 90 (quatre-vingt-dix, four-twenty-and-ten, 4×20+10) where it is literally the same expression as old Irish. Breton refers also to 20 for 40, 60, 70, 80, and 90. Indeed 40 is *daou-ugent* (two-twenty, 2×20), 60 is *tri-ugent* (three-twenty, 3×20)... 90 is *dek ha pevar-ugen*t (ten-and-four-twenty, 10+4×20), etc. In Breton the word order is not the same: +10 is mentioned before and not after as in French and English. We have the equality (the model) 90=4×20+10= 10+4×20 that is shown in a comparison of languages. If we make a link with topic prominence (above), we could argue that old Irish emphasises the grouping by 20 (coming first) and Breton the addition on this grouping (+10 coming first). These characteristics are clearly different from the numerations/counting systems of English and French (base 10). We think that the comparison of number names could be a rich resource for teaching oral numeration, written numeration and the associated mathematical meaning. Oral numerations have been studied concerning other contexts. For example, number words in "other" languages is explored by Chronaki, Mountzouri, Zahakari and Planas (2015) in the Greek context to experiment a mathematical learning activity with young children, and shows that the creation of a culturally responsive context.

Word order to say numbers

In Breton, *32 <u>pupils</u>* is said *daou <u>skoliad</u> ha tregont* (two <u>pupil</u> and thirty, 2 <u>pupil</u> and 30). The common name expressed by the number is in-between tens and units. One can notice that the name is here in singular form (*skoliad*) and not plural (*skolidi*). Indeed plurality is not attached to nouns but it is expressed by the adjunction of a number. For large numbers, the word order refers also to this rule. For example, 32 000 <u>pupils</u> (*daou vil <u>skoliad</u> ha tregont, 2* thousand <u>pupil</u> and 30 (thousands not mentioned), coming from 2 000+30 000) and 3 020 <u>pupils</u> is (*tri mil ugent <u>skoliad</u>*, 3 thousand 20 <u>pupil</u>, 3 000+20). Irish is similar to Breton when using ordinal numbers in that the common name is positioned in-between tens and units. For example, 53 <u>pens</u> is *trí <u>pheann</u> is caoga* (three pens and fifty, 3 pens and 50). Large numbers generally preserve this order also. This can be seen as a difficulty for students, but we also argue that this is a good opportunity to work on number sense and the place of each digit in a number. In Irish, different words are used for counting people: two, three, four etc. is expressed by *beirt, triúr, ceathrar*, to signify that the numbers relates specifically to counting people. The comparison between the languages is a good resource to understand the grouping by three of large numbers.

DISCUSSION AND CONCLUSION

This paper explored specific aspects of language concerned with mathematics teaching and learning in relation to the bilingual contexts of Irish-English and Breton-French. But why does this matter? The importance of language for the teaching, learning, understanding and communication of mathematics cannot be ignored. Features of the Irish and Breton languages presented in this paper demonstrate the importance of investigating languages and their potential impact on mathematical learning. For example, some Breton and Irish words assist in conveying meaning and/or permit the concept to be formed more readily. Similarly the sentence structure allows access to key information. Some promising insights are emerging, suggesting that students who learn through the medium of Irish or Breton may experience advantages in terms of mathematical learning. Further investigation is needed into how a particular language and its syntactical structure may impact on mathematical activity and reasoning.

When investigating the Irish and Breton languages we are cognisant of the fact that we are investigating bilingual learners (Irish-English, Breton-French). The relationship between mathematics learning and a student's language is complex, and further complicated when working with bilingual learners. Moreover, we need to consider mathematics as a discourse and that this is not a singular or homogenous discourse (Adler, 2001). Accordingly, mathematical learners use multiple resources and languages from their experiences (both in and outside of the learning context) and we need to be cognisant of multiple registers co-existing in the learning environment. Bilingual learners should not be viewed in a deficit mode, but rather view their language(s) as a resource for learning mathematics. However, as demonstrated in this research paper, this area is under-researched and under-theorised. Research practices/findings generated from participants from a dominant group (e.g., monolingual speakers) assumes these to be the norm for all learners. We endorse a call for more research in relation to the role of bilingual learners' different languages when engaged in mathematical learning (Barwell, Barton, & Setati, 2007). There has been a focus more on the social, rather than cognitive functions of code switching (Ní Ríordáin, 2013). The authors of this paper purpose that there is a need for a coherent and integrated framework to investigate whether differences in languages, and their use, by bilingual mathematical learners, have a differential impact upon cognitive mathematical processing. The authors also stress the importance of recognising and integrating the social aspect of learning into the framework and seeing language as a resource for mathematics teaching and learning.

Capturing learning in classroom interaction in mathematics: Methodological considerations

Jorunn Reinhardtsen, Martin Carlsen and Roger Säljö

University of Agder, Kristiansand, Norway, jorunn.reinhardtsen@uia.no

This paper discusses issues of how to transcribe and analyze video-recordings when studying learning in small group work in mathematics. Since bodily features of interaction and the use of artefacts play important roles in mathematical reasoning, a multimodal approach to transcribing is necessary. Thus, the theoretical grounding for transcriptions has to be in accord with the perspective on learning adopted in the analysis. In the paper, the principles for studying what Radford (2000) refers to as knowledge objectification processes when learning mathematics will be discussed.

Keywords: Analytical approaches, knowledge objectification, multimodality.

INTRODUCTION

This paper discusses ways of doing video analyses that are relevant for understanding mathematics learning. Thus, this is a methodological paper. Our particular focus is on multimodality as a resource for learning but also as a methodological challenge for research. Analytical approaches, selection of episodes and a multimodal transcription will be discussed in light of recent developments in the field.

The background of this study is an international, comparative project called VIDEOMAT (Kilhamn & Röj-Lindberg, 2013), which studies teaching and learning of introductory algebra in four countries: Finland, Norway, Sweden and the USA. Students are between 11 and 13 years old. Data include video-recordings of lessons, written materials from student activity, teacher interviews etc. Five consecutive lessons when algebra was introduced[1] in classrooms in the four countries were documented. A group work session with a pattern task with matchsticks was selected for further investigation. This task resulted in a multitude of problem-solving strategies among students, all the way from counting to sophisticated forms of mathematical reasoning (multiplicative/generalizing).

In the literature there are many attempts to make use of multimodal analyses to understand learning processes in the context of mathematics. We will comment on some of these below. Considering that we are at an early stage of advancing knowledge through the use of multimodal approaches, we have formulated the following question for this paper: *In what ways can video recordings be transcribed and analyzed in order to study student's learning processes?*

BACKGROUND

The methodical reflections in this paper focus on classroom interaction in a problem-solving, small-group setting. A particular aim is to understand the knowledge objectification process (Radford, 2000, 2002). The object of activity in the classroom, as the students work with the matchstick task, is to develop algebraic thinking; more specifically to perceive the general nature of a pattern, and to use this insight when solving a problem. The ability to generalize is viewed as one of the most important developments in mathematical thinking.

Our analysis will follow a socio-cultural, Vygotskian view on learning and development. A central idea is that learning results from participation in social and interactional processes. Equally important is that this perspective stresses that learning and knowing are cultural phenomena.

Approaching group work in mathematics classrooms with an interest in the contributions of multimodality, the cultural-semiotic theory of learning, developed by Radford (2000), provides a promising route ahead. Radford (2002) suggests that knowledge objectification happens through semiotic activity, that is through "objects, artifacts, linguistic devices and signs that are intentionally used by individuals in social processes of meaning production, in order to achieve a stable form of awareness, to make apparent their intentions and to carry out their actions" (p. 14). The process of knowledge objectification is understood as the process of placing something at the center of someone's attention. In this study, knowledge objectification thus refers to the process of perceiving generality; the knowledge of the general nature of the pattern having a genesis and a development, and, as a further step, knowing how to express the generality mathematically and to solve the problem.

METHODOLOGICAL DEVELOPMENT IN THE STUDY OF LEARNING

The methodological deliberations by different researchers have been scrutinized. The studies analyzed all rely on naturalistic data and interpretive approaches to method, and they represent different choices in terms of data collection and analysis.

Bjuland (2002) focused on small group problem-solving in mathematics by student teachers. Data were collected by audio recordings, and the theoretical perspective utilized was dialogical, situated and socio-cognitive. The unit of analysis, referred to as an episode, was "conceived as a sequence of verbalizations focused on a special mathematical topic or idea" (p. 64), relevant to the research questions. These were then categorized according to five features of problem solving processes: sense-making, conjecturing, convincing, reflecting and generalizing.

Carlsen (2009), working in a sociocultural tradition, analyzed the appropriation of mathematical tools by students attending the final year of high school. Video recordings were used. The aim was to trace development of the student's mathematical reasoning. Relevant parts of the entire audio recorded material were transcribed in detail and subjected to in-depth analysis. The transcripts included multimodal elements in order to investigate the role of inscriptions in the appropriation process.

Radford (2000, 2002, 2012) reported on longitudinal studies involving students' group work with algebra and more specifically with patterns. This work involves methodological and theoretical developments that are interesting. Radford's research is based in a semiotic-cultural perspective on learning building on Vygotsky's view of signs as linked to and affecting our cognition. In Radford (2012), researchers took part in the process of designing the lesson material and students were organized in small groups. These sections were video recorded and student works were collected.

In his early work, Radford (2000) uses concepts from discourse analysis. He follows a three-step analysis of transcripts, a) valuing each utterance as equally important, b) contextualizing utterances, and c) including pauses and hesitations. This approach Radford (2000, p. 244) terms *situated discourse analysis*. The unit of analysis was conceived through a process of refining salient episodes through data managing by indexing and theorizing. Radford emphasizes the importance of natural language in the development of algebraic thinking and the use of algebraic symbols.

Radford, Demers, Guzmán, and Cerulli (2003) introduce the concept of *semiotic node*. This was a response to findings in many studies on the importance of gestures and artifacts in the production of graphs and algebraic expressions. Semiotic nodes are "pieces of the students' semiotic activity where action, gesture, and words work together to achieve knowledge objectification" (p. 56). The transcripts include description of gestures and the analytical tool of semiotic nodes was applied in the analysis. In Radford, Bardini, and Sabena (2007), the analysis was done in greater detail. A slow-motion, frame-by-frame, fine-grained video micro-analysis was carried out and complemented with a voice-analysis. The same kind of micro-analysis was carried out in Radford (2012), except for the voice analysis, where a multi-semiotic analysis (spoken words, written text, gestures, drawing, and symbols) was done.

Arzarello (2006) outlines a theoretical frame emphasizing the role of multimodality and embodiment in cognition. He argues for a multi-semiotic analysis of objectification processes and claims that the present semiotic frameworks cannot capture didactical processes in a satisfactory manner. Therefore, he introduced the idea of the *semiotic bundle*. In the semiotic bundle, which includes semiotic sets such as gestures, speech, written representations, as well as more formal systems, the distinctions between the sets are only made for analytical purposes while interpreted as a unitary system. The semiotic bundle is dynamic and can shift to include more or less semiotic sets as the event unfolds. The meaning of the mathematical object may not be the same in the different sets. Moreover, even if the transformation from one set to another is accomplished, the meaning the object had in the prior set may linger, and so it can take time before the concept is formalized. By looking at the data synchronically and diachronically, the genesis and evolution of the semiotic objectification process can be traced. The semiotic node introduced by Radford (2003) is similar to looking at the semiotic bundle synchronically.

Arzarello (2006) used the semiotic bundle to analyze the work of one group of five fifth-graders. Video recordings and student work were collected as part of a longitudinal research design. However, the episodes presented were chosen from a 30 minute session on problem solving. The selection process was not commented on, except by saying that four main episodes were chosen. The episodes were subjected to different analytical methods; (episode 1) synchronic analysis; (episode 2) diachronic analysis; (episode 3) synchronic + diachronic analysis; and (episode 4) diachronic analysis. The transcriptions include descriptions of gestures and pictures are presented in the analysis.

Roth and Thom (2009) looked at multimodality and learning from a phenomenological perspective. The aim of the study was to propose a new way of understanding mathematical concepts grounded in a case study. Data were collected in a second grade classroom during group work sessions in geometry. In addition, artifacts used and all work by the teacher and the students were photographed. One episode from a whole class session, lasting 69 seconds, which is called exemplary, was chosen for analysis. The episode is presented in the context of what happened before. The transcript includes details (length of pauses, pitch etc.). The episode is presented over 6 pages and several drawings depicting movements are part of the description. The authors argue that "conceptions can be understood as networks of experiences that indeterminately emerge from lived (rather than intellectual) reorganizations of embodied bodily experiences" (op. cit., p. 188).

The studies presented above are all conducted within the paradigm of interpretivism. They are ethnographic and researchers spend time observing, making field notes, and collecting students' work; the researchers are concerned with the context in which the events take place. The video and/or audio recordings are done in classrooms and are naturalistic in the sense that students are in their everyday environment engaging with mathematical activities. The studies also share a common focus on the multimodal aspects of learning, except Bjuland (2002) and Radford (2000).

METHODOLOGICAL CONSIDERATIONS

In spite of the commonalities of the studies presented, the transcripts look very different and include different features of interaction. Bezemer and Mavers (2011), investigating multimodal transcripts in research, point out that "transcripts should be judged in terms of the 'gains and losses' involved in remaking video data" (p. 204). The focus should not be on attempting to achieve representational accuracy, rather the approach should be transparent.

The studies use different analytical approaches to dialogue. Bjuland and Carlsen use the *dialogical approach* elaborated by Linell (1998), while Radford uses *situated discourse analysis*. Consequently, the process of analysis is different. Radford's first step is to look at each utterance in its own right and categorize it. As a second step, he contextualizes them. In contrast, sequentiality is central to the dialogical approach as each contribution in a dialogue gets its meaning from both prior and subsequent turns. Arzarello (2006) and Roth and Thom (2009) do not fully reveal their approach for analyzing dialogue.

An important aspect is the selection of salient episodes. Bjuland (2002) transcribed all verbalizations and then identified relevant episodes according to the analytical interest. Carlsen (2009) worked with video recordings. After several viewings, he chose 14 sessions which were roughly transcribed. Following this, relevant episodes were identified and transcribed in detail. From this sample salient episodes were chosen. Radford (2000) used *situated discourse analyses* as a first approach to the data set, which was transcribed in its entirety. The studies by Arzarello (2006) and Roth and Thom (2009) do not fully comment on the selection process.

These studies show that multimodality is an essential part of understanding how students learn mathematics. Thus, it becomes important for this branch of research to enter into a discussion on how to advance the use of multimodal methods of analysis.

CAPTURING LEARNING: SUGGESTED METHODS

The aim of this paper is to describe ways of doing video analysis that focus specifically on learning processes and which include attention to multimodality. The approach will be discussed in three sections: *video analysis*; *multimodal transcription*; *learning processes and video analysis*. Our discussion will be twofold as it a) provides arguments for the methodological choices and b) is practically oriented in that an excerpt of a multimodal transcript is included and analytical approaches are briefly exemplified.

Video analysis

The video analysis follows an interpretivist paradigm. The aim is to understand learning processes by closely following how participants engage in meaning making. Applying the notion of knowledge objectification through semiotic activity implies analyzing multimodal aspects of interaction. According to Knoblauch (2012), one has to apply two types of interpretation in order to preserve the essence of multimodal elements of interaction. The first is to interpret what is seen and heard as it appears from an everyday understanding and from the actors' point of view. The second level is the professional interpretation of the interaction.

The ethnographical aspect of this research is important in terms of the validity of interpretations. Observation of lessons, interviews with the teachers and the written materials collected improve the ability to interpret the situation. The validity of the interpretations will depend on the assumption that "people are existent and, that they have been conducting (acting) in ways that are open for reconstruction (capture) by video data" (Knoblauch, 2012, p. 73). This allows *subjective adequacy*, which means that there is a correspondence between what the researchers say and the statements by the participants. Psychological studies have shown that people often "see events similarly in terms of causal, behavioral, and thematic structures" (Derry et al., 2010, p. 7), which supports the validity of an *everyday* interpretation of interaction.

The empirical material in this study is considered to be *naturally occurring data*. We recognize that the presence of three cameras, two professionals operating them, and one to three researchers observing exert some influence on the situation. However, students today are familiar with cameras, and in consultations with the teachers after lessons they expressed that students behaved as usual.

In order to approach the complexity of the interaction in the groups, the discourse is separated into two main parts: dialogue and multimodal elements. However the two parts are interpreted as belonging to a unified system of communication and therefore seen as integral parts of meaning making. Two methodological concepts will be considered when analyzing the multimodal elements (Knoblauch, 2012, pp. 74–75): *sequentiality*, considering any action as motivated by prior actions and motivating future actions; *reflexivity*, actors do not only act but also indicate, frame or contextualize how their action is to be understood and how they have interpreted a prior action to which they are responding. These concepts correspond well with the dialogical approach which also emphasizes sequentiality.

The issue of multimodal transcription

In attempting to transcribe visual data of video recordings there is a challenge in doing adequate data reduction. The focus of our research is the interaction in the groups. Luckmann (2012, p. 32) argues that "the elements of the interaction which the analyst, based on his knowledge of social life, must assume were relevant to the participants in the original interaction, must be noted in the transcript". Knoblauch (2012, p. 75) argues that video analysis is a hermeneutic activity. "[T]he task set is not to only describe and explain non-verbal behavior". As a researcher one has to decide what knowledge is needed to make sense of a situation and to identify visible conducts constituting the situation. Therefore, multimodal transcribing is not only a preliminary stage to the analysis; the activity forms an essential part of the analysis.

The video material and the written works of students have been examined in order to understand the problem solving process through the dialogue and the semiotic actions that appear both by each individual student and as part of the joint group activities. Several multimodal elements of the interaction have been identified. These fall into three categories of use of mediating resources: *inscriptions* such as drawings, tables, texts, numbers, arithmetic, algebraic (including variable/s); *concretes* i.e. matchsticks; *gestures*

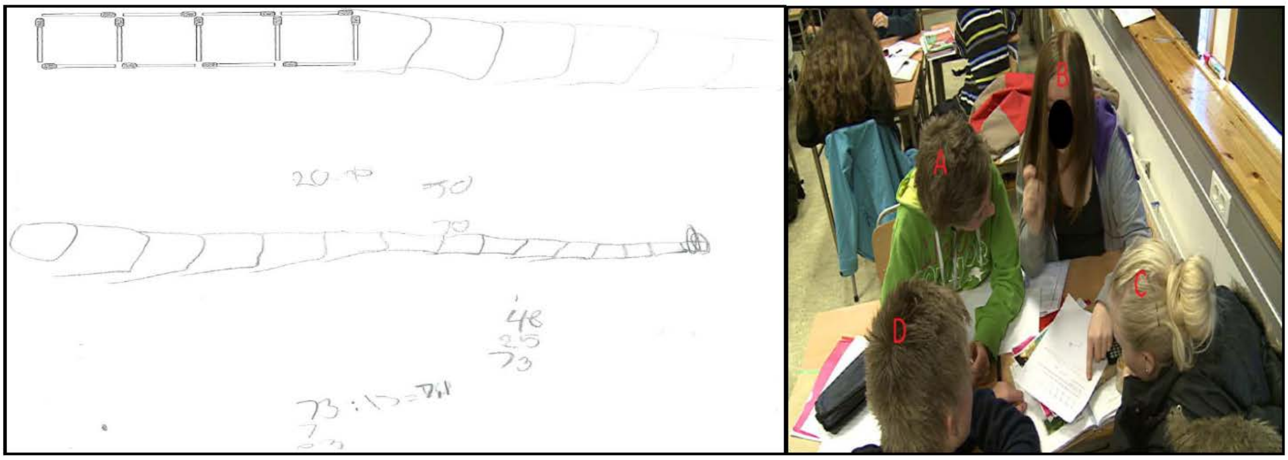

Figure 1: Representation of part of the multimodal transcription

such as pointing, tracing in air/figure/table, glance, rhythmic hand movement, raising hand.

The learning processes and video analysis

Derry and colleagues (2010) stress the importance of being systematic when selecting salient episodes. Schoenfeld (1985) parceled the dialogue according to the mode of reasoning (i.e. planning, exploration) as he expected strategic decisions to be located at the junctures between such episodes. In this study, the dialogue will also be parceled according to the mathematical strategy the students are working with. This is done in order to explore how the students' discourse on the problem evolves during the problem solving process and to reveal mechanisms which drives it. In light of these explorations, fragments of the text which show the first traceable step and its successors in the objectification process will be identified.

An excerpt from a multimodal transcription of a Norwegian group is presented below. A group of 8th grade students, Ben (A), Ann (B), Trish (C) and Sam (D), are given an algebra task (adapted from TIMSS 2007) involving matchsticks and patterns. The teacher hands out toothpicks as a material to use in order to solve the problem. Only Ann writes on the task paper. Marks indicating if the students are in the process of conjecturing (Cj) or convincing (Co) and also specifying the mathematical strategy used such as additive (A) or multiplicative (M) have been inserted into the transcript in order to show the analytical approaches to the text.

8 Trish: We can make them [*squares*] on the table. But should we just use these or? [*Trish shakes the can of toothpicks she is holding in her hand*].

9 Ann: But see, we get 7.1 [*Ann points to the division, 73 divided by 13, she has been working on*], then if you have taken ( ) then you get 7.1 squares. 1, 2, 3, 4, 5, 6, 7 [*Ann points at the squares in the task paper as she counts them and continues by pointing at imaginary squares until she reaches 7*]. So then you get less than sev...then we get, if we make 7 squares. Ok, 4.

The girls try to add a square to the figure using the toothpicks. They give it up quickly as they notice that the dimensions are different.

10 Trish: Ha..ha

11 Ann: You, this didn't work

12 Trish: We'll draw it.

13 Ann: [*She adds a square to the figure by drawing three sides in one motion, she then points at each square as she counts them*] 1, 2, 3, 4...[*adds another square in the same manner*], 5. [*starts counting the matchsticks making up the squares*] 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14... 17, 18. Ok, but see...ah...I got a good idea...look [*Now she only counts the horizontal matchsticks*] 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12...[*adds more squares using the same motion*] 13, 14...15, 16...17, 18...19, 20 [*There are now 10 squares altogether*]. So if we take [*She now counts the squares*] 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. When we have 20 rows we have [*writes 20 and then counts the vertical matchsticks silently*]...((then we have...then we have)) =

14 Sam: ((But what are we going to do with them...Ann?)).

15 Ann: = When we have 20 we have 50 pieces [*writes 50*]. Or, when we have 20, when

we have 20 such things... [*she points or taps repeatedly at the figure*].

16 Sam: It is those [*Sam holds up a toothpick*].

17 Ann: Yes, matchsticks, then we have 50 altogether [*points to the number written*], used 50 such matchsticks [*points back at the figure*] and we are going to use 73, right? =

18 Sam: Just make...

19 Ann: = So then...

20 Trish: ((really one more will be 53 and then 56))

21 Ben: ((We are going to use...))

22 Ann: No, if we have one more with 10 in it, then it becomes... =

23 Sam: ((Yes because it is four in one)).

24 Ann: = So, then we get 20 more and it becomes 70 [*writes 70*]. ((It is 1, 2, 3...so then we get 70... No, now there is too much here)) =

25 Ben: [looks at Sam and responds to his comment] ((No, it is 3, it is 4 in one and 3...1, 2, 3, 4, 5, 6, 7, 8, 9))

26 Ann: = I think I sort of lost count of it.

27 Trish: No, 70, and then you should have 1 thing more and then it becomes exactly 73.

28 Ann: Ah, but see, oh yes because 20...

29 Trish: It is really only three in each, it is only the first there is four in, and then there is only three in each the whole time [*points at the figure while she explains*].

30 Ann: But see...

31 Trish: If you do like that then...4 [*she holds her finger over the first square*]

32 Ann: 1, 2, 3. [*counts three matchsticks in the first square, then pushes away Trish's finger and starts counting in the pattern she has developed, horizontal matchsticks first and then the vertical ones*] Ok, 1, 2, 3, 4, 5, 6, 7, 8, 9 ( ) 18, 19. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20. 20. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11. 11.

While Ann is counting, Ben and Sam start paying attention to something that is going on in the classroom which is not relevant for the mathematical discussion. When the teacher approaches the group, the boys attend to solving the task again.

33 Trish: [*traces the matchsticks in the squares using the same motion as Ann used earlier when drawing new squares*] Oh, you! 73 divided by 3 and then just add 1! [*she picks up her calculator*]

34 Ann: There you said one. [While Trish is working on the calculator, Ann traces first the four matchsticks in the first square and then the 3 matchsticks in each of the following squares. She is using the same motion as earlier when drawing the squares].

35 Trish: No. [*The teacher comes over to the group, but Trish only looks at the calculator while she speaks*] 73 divided ((by 3, plus 1, 25)).

36 Ann: [*Ann looks at the teacher*] ((divided by...3. Is that right?))

In turn (9) Ann suggests a solution to the task based on a multiplicative strategy. In order to make sense of the answer she found, she turns back to the task paper and applies an additive strategy.

The marks in the text indicate important events in the problem solving process. If we focus the attention on the objectification process, we see in (20) the first verbalization of the *3+3* pattern, which is discussed and developed by Sam (23), Ben (25) and Trish (29), and finally expressed as *4+3+3*. However, in (33) we see that Trish traces the matchsticks with the same motion used by Ann that appears early in the text (13), immediately before she expresses a new conjecture for how to solve the task (33). Ann is not taking part in the discussion of the *4+3+3* pattern but seems to drive it with the gestures and the drawing she is making.

CONCLUSION

The video recordings available of 16 groups working with the same task offer an opportunity to study the role of features of thinking in the objectification process. These features, as elaborated through the empirical materials and the theoretical perspective, have been identified as: *elements of reasoning* (sense-making, conjecturing, convincing, reflecting, generalizing), *mathematical strategies* (additive, multiplicative, equations, functional), *semiotic resources* (use of language, inscriptions, concretes, gestures) and indicators of the *culture of collaboration*.

The analytical methods described are developed in order to understand how these different features of thinking are incorporated in learning processes. The ambition is to shed light on a) what role mediating tools play as students decide on mathematical strategies, b) what features of the knowledge objectification process that can be discerned, and c) what are the differences, if any, between classrooms and cultures of work in the different countries.

A case study of epistemic order in mathematics classroom discourse

Kenneth Ruthven and Riikka Hofmann

University of Cambridge, Cambridge, UK, kr18@cam.ac.uk

This exploratory study analyses the discursive frames through which ideas are developed and evaluated during one section of an early secondary lesson. The study employs a refined version of the classic IRF framework to analyse the interaction structure of classroom dialogue, linking this to semantic analysis of the ideological stance conveyed by participants' utterances and actions. The epistemic order which emerges emphasises the evaluation of ideas primarily in terms of whether they are understandable and make sense. The predominant discourse pattern is one in which the teacher exercises epistemic initiative but offers little overt epistemic appraisal. Occasionally, however, the teacher passes the epistemic initiative to a pupil and provides some form of supporting or concluding epistemic appraisal.

Keywords: Classroom dialogue, discourse analysis, school mathematics, IRF.

MOTIVATION FOR THE STUDY AND THEORETICAL FRAME

In this paper we report an analysis of how classroom dialogue functions to create what we will term an *epistemic order*. By this term we refer to the system of discursive frames within which ideas are developed and evaluated in the classroom. Recent theorisation of classroom discourse has distinguished two crucial dimensions, one concerned with *discourse structure* – the forms of talk and patterns of interaction in play – and the other concerned with *ideological stance* – the degree to which knowledge and ideas are taken as fixed and given as opposed to fluid and open (O'Connor & Michaels, 2007). Such theorisation has also challenged the assumption that these aspects are necessarily aligned; as fostered by the archetypical Initiation-Reply-Evaluation (IRE) structure of classroom recitation in which the opening Initiation move accords the teacher the *epistemic initiative* in posing the question, just as the closing Evaluation move makes the teacher the agent of *epistemic appraisal*.

However, within linguistic research, the limitations of the IRE template – even in representing the structure of conventional classroom dialogue – have long been known, and a broader and more flexible Initiation-Response-FollowUp (IRF) model has been preferred (Sinclair & Coulthard, 1992). Linguistic scholarship has also suggested modifications to the original IRF framework to better model the nuances of classroom dialogue (Coulthard & Brazil, 1992). In particular, the modified version of the IRF framework that we employ is designed to acknowledge the uncoupling of two aspects of the teacher's management of classroom dialogue which typically takes place as that dialogue moves away from an IRE pattern: management of the taking of turns by speakers in interaction slots, and of the substantive exchange of ideas through communicative acts. Thus, our adapted IRF approach introduces a distinction between the *interactional initiative* of launching an exchange, and the *epistemic initiative* of introducing the idea on which an exchange focuses. While one move often combines both types of initiative – as in the classic teacher I within IRE – this is not always so. In the transcript analysis which follows, for example, see E4 where the teacher simply initiates interaction by inviting a pupil to speak, followed by E5 where, by making a substantive contribution in response, that pupil initiates the idea to be discussed.

More recently, pedagogically motivated research on classroom dialogue has shown that triadic IRF interaction patterns continue to play an important part even in more enquiry-oriented classrooms, but fulfil a wider range of functions (Nassaji & Wells, 2000; Truxaw & DeFranco, 2008). This literature has identified markers of what is termed 'dialogic activity' in which classroom talk is more varied in its forms of interaction and more open to exploring differing perspectives.

Such markers include the extent to which questions are posed by pupils, the types of question posed by the teacher, and the kinds of teacher follow-up to pupil responses, including the extent to which responses are not explicitly evaluated and/or are taken up in further exchanges.

DESIGN OF THE STUDY AND ANALYTIC METHODS

In this paper we analyse one section of a video-recorded lesson. Our purpose is to employ an IRF system, adapted for analysis of epistemic order, to establish a baseline against which a later section of the same lesson will (in future) be compared. This later section is of particular interest because it appears to offer a strong example of 'dialogic activity' displaying a distinctive epistemic order. Our adapted system aims to underpin deeper analysis to provide a more rigorous basis for such judgements.

Coding in particular, and analysis more generally, were undertaken against a transcript of the classroom dialogue but involved referring also to the original video-recording. We employed an approach to transcription in which the emphasis was on capturing both the taking of speech turns and the development of substantive ideas (so, for example, excluding exchanges only concerned with classroom management, and omitting repetitions, stumbles or repairs in spoken expression which proved to have no analytic significance). This produces more accessible transcripts while ensuring that all analytic judgements are backed by the source video-record.

One of the reasons that we chose to update the classic IRF system is that it is very rigorously specified. Here, however, space permits us only to set out the essentials of the modifications we made to the original IRF analytic framework. First, a prefix is added to the coding of each move to indicate whether it was undertaken by teacher or pupil. Second, recognising the way in which interaction slots are sometimes linked in practice, the familiar repertoire of I, R and F slots was extended through the addition of two composite types: the R/I type (in which a Response consists of, or develops into, a further Initiation) and the F/I type (in which a Follow-up consists of, or develops into, a fresh Initiation). All moves are given a speaker prefix and slot code.

Next, to distinguish the interaction slot that a move occupies from the communicative acts that it accomplishes, a further code string indicates the character of such acts. Moves which convey some substantive idea about the operative topic (typically I or R moves) are coded either as a solicitation (s) or as a contribution (c), depending on whether they explicitly seek to elicit a response or not. Equally moves (typically F moves) receive a code if they provide an explicit evaluation indicating approval (a) or disapproval (d) of a prior contribution; and if they repeat, restate or revoice (all or a salient part of) a prior contribution (v). Thus in an archetypical IRE exchange the initiating teacher question would be coded tIs, the pupil reply pRc, and the teacher evaluation something like tFav or tFd. The purpose of refinement, however, is not just to enhance the information carried in the code string but to better model moves in dialogue. So, for example, a teacher move which simply nominates a pupil to speak would be coded tI; and the ensuing move in which the pupil poses a question pR/Is.

When italics are used this indicates a part of the code that has had to be inferred.

Finally, as well as recognising the basic interactional unit of the IRF *exchange*, we acknowledge two larger units. A *transaction* is a higher level unit consisting of one or more exchanges, grouped because there is linkage between these exchanges through uptake of ideas (often signalled by the presence of F/I moves). We refer to one particular type of transaction as a *duologue:* where interaction extends over more than one exchange and is restricted to the teacher and a single pupil. An *episode* is a still higher level unit consisting of one or more transactions forming a recognisable structural component of the lesson as marked out by participants and/or resources.

The lesson involved an experienced teacher with a class (aged 11/12) in their first year of secondary education in England. The lesson material came from a module on probability, making connections between mathematics and science (Ruthven & Hofmann, 2013). For reasons of space, we confine ourselves to five episodes making up a lesson section in which the whole class addressed a series of related questions. These questions appeared on two slides about the genetic model of the inheritance of the characteristic of attached/detached earlobes which had also supported a

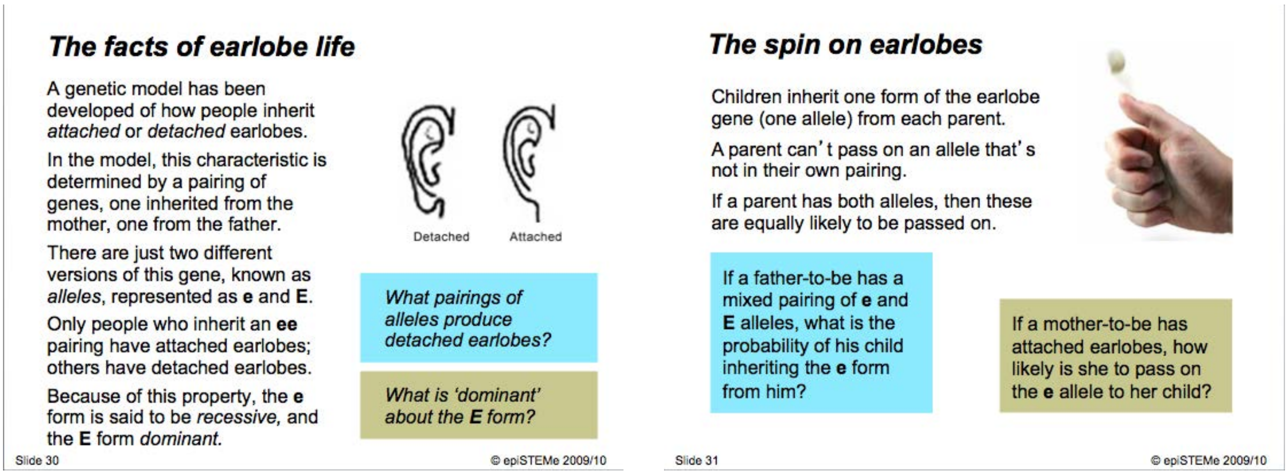

Figure 1: The slides supporting the section of the lesson under analysis

shorter introductory exposition by the teacher. These two slides are shown in Figure 1.

PRESENTATION AND ANALYSIS OF THE INDIVIDUAL EPISODES

Episode A

The first episode takes place when the teacher brings the whole class together after they have independently tackled the first question posed on Slide 30.

A1 T: Dan, what pairings have you got, because I think you look like you've finished? So for detached earlobes. tIs
A2 P: Two large ees.pRc
A3 T: Two large ees. *[Records on board]* tFv
A4 Ps: A big ee and a little ee. pRc
A5 T: A big ee and a little ee. *[Records on board]* tFv
A6 P: A small ee and a big ee. pRc
A7 T: A little ee and a big ee. *[Records on board]* tFv

Rather than repeating the scientific question about pairings posed on the slide, the teacher invokes it at one remove, asking a pupil to report the pairings that he had found (A1). The teacher follow-up (A3, A5, A7) to the pupil responses (A2, A4, A6) (which adequately answer the scientific question) repeats them in a neutral tone and records them on the board without offering any explicit evaluation.

A8 T: Everybody happy so far? tIs
A9 P [Hal]: No I don't get it. pRc
A10 T: What don't you understand, Hal? tF/Is
A11 P [Hal]: The big ees and the little ees. pRc
A12 T: What about the big ee and little ee don't you understand? tF/Is
A13 P [Hal]: How that represents anything. pRc

The transition to a new transaction is marked by the teacher's next solicitation (A8). She asks pupils whether they are "happy" with what has been presented (A8) (rather than, for example, whether it is correct). In response, Hal expresses unhappiness (A9) in terms of his "not getting it". This framing is taken up by the teacher in her subsequent solicitations (A10, A12) about what he "doesn't understand". This co-construction of the situation underpins the reflexive and diagnostic duologue which takes place, in which the teacher's probes serve to elicit Hal's thinking.

A14 T: Can anybody help him? Hal says he doesn't understand about the big ee and the little ee, and he doesn't understand what they represent. Can anybody help him? tIs
A15 Ps: *[Inaudible. Many pupils speaking over each other.]* pRc
A16 T: Not necessarily. No. No no no no. No no. Forget about X and Y. Forget about boys and girls. Just think earlobes please. tFd/Ic

A17	P:	A little ee and a big ee are detached, and a big ee and a little ee are detached, so [inaudible].	pRc
A18	Ps:	*[Inaudible. Many pupils speaking over each other.]*	pRc
A19	T:	All right. I'm not sure that Hal's getting the answer to his question. Hal, are you?	tFd/Is
A20	P [Hal]:	Yeah.	pRa

Opening the final transaction, the teacher invites pupils to help Hal (A14). However, this solicitation (A14) elicits a tangential line of thinking in response (A15; inferred from A16) which the teacher follows up with strong disapproval and a steer back towards the issue at hand (A16). This elicits further pupil responses (A17, A18). It is ambiguous whether the follow-up to these (A19) alludes to the breakdown of orderly talk or to the substance of the help being offered. The teacher solicits Hal's evaluation (A19), positioning him as the arbiter of whether his difficulties have been resolved. His positive response (A20) is allowed to conclude the episode.

In this episode, then, all solicitations are made by the teacher, and so epistemic initiative remains firmly with the teacher. However she exercises little overt epistemic appraisal. In this epistemic order, the teacher directs the unfolding of ideas which are to be evaluated by pupils according to whether they make sense to them. To this end, the teacher employs discursive strategies such as eliciting pupils' ideas and self-assessments, as well as avoiding evaluative follow-up to their responses. Where such follow-up does become evaluative, it relates to redirecting pupil contributions to the matter at hand or establishing their helpfulness to other pupils.

Episode B

B1	T:	Bet, you had a question.	tI
B2	P [Bet]:	Oh yeah. *[Referring to question on slide]* Like what is dominant about the ee then?	pR/Is
B3	T:	*[Reading question from slide]* What is dominant about the ee form? So if you've got a big ee, what is dominant? What are you going to see?	tR/Is
B4	P [Bet]:	If you, the little ee, you have to have two of them to have attached, but you only need one big ee and one small ee to have detached, so there's more ways you can have big ee than little ee.	pRc
B5	T:	Yes.	tFa

The next episode begins with the teacher inviting a pupil to speak (B1). Bet draws attention to the second question on Slide 30 by restating it (B2). Rather than responding by answering this question, the teacher restates it to create a fresh solicitation (B3). Through this discursive manoeuvre the teacher leads Bet to answer the question that she herself raised. When Bet responds with a broadly well conceived answer (B4) the teacher approves it (B5).

B6	P [Tia]:	Surely if you have a big ee then you're going to have detached earlobes.	pIs
B7	T:	Yes. Yes. So if you've got at least one big ee, then you are going to have detached earlobes.	tRav

The final exchange starts with a solicitation from another pupil seeking validation of a variant of the same answer (B6). The teacher approves and slightly refines it (B7).

In this episode, then, the opening solicitation for each transaction comes from a pupil. In both, the pupil puts forward her answer to the question under consideration in a rhetorical form which invites endorsement. The answer is duly approved (and in one case restated) by the teacher. Here, the discursive frame is one in which the teacher cedes epistemic initiative to the pupil but becomes the agent of epistemic appraisal.

Episode C

The next episode relates to the first question on Slide 31.

C1	T:	*[Reading question on slide]* If a father to be has a mixed pairing of ees, so a little ee and a big ee, what is the probability that the child will inherit the little ee. Tia?	tIs
C2	P [Tia]:	Surely it's quite low, because like	pR/Is
C3	T:	Can we put a figure on it?	tR/Is
C4	P [Tia]:	Zero.	pRc

C5	T:	So he's got one of each. He's got a big ee and a little ee. What is the probability that the baby will have a little ee, from their dad?	tF/Is
C6	P [Tia]:	Zero. I think it is.	pRc
C7	T:	Zero. You think it's impossible?	tFv/Is
C8	P [Tia]:	Surely if you have a big ee, somewhere... you're going to have detached?	pR/Is
C9	T:	Yes, but this question isn't about what sort of earlobes the child will have. It's about which of those two alleles the child will inherit.	tRc

The first transaction in the episode consists of a duologue between the teacher and Tia. It opens with the teacher reading the scientific question posed on the slide, restating some elements of it, and then nominating Tia to respond (C1). Tia's emergent answer to the question is ill conceived (C2, C4, C6) and is taken up by the teacher through a series of follow-up and solicitation moves which successively press for greater precision (C3), restate the question (C5), and draw attention to an implication (which would be incompatible with the question situation) (C7). In response to this last probe, Tia finally articulates the reasoning behind her answer (C8), allowing the teacher to pinpoint the misinterpretation of the question that underlies Tia's responses (C9). While the teacher makes no explicit evaluation of these responses, the direction and persistence of her questioning does imply dissatisfaction with them. This duologue, then, has a more dialectic quality.

C10	T:	So he's got one big ee and one little ee, the father. What is the probability that any baby he makes will inherit the little ee. Lea?	tIs
C11	P [Lea]:	[Inaudible] make it a half. [*Pause*] Yeah fifty per cent.	pRc
C12	T:	Lea says it is a half. Tia, you're now saying that makes sense.	tF/Is
C13	P [Tia]:	Yeah.	pRa
C14	T:	Could somebody just confirm why. Why does that make sense? Kit?	tF/Is
C15	P [Kit]:	It says up on the board, if a parent has both alleles, whatever, then there is equal chance, and if it goes up to one there's a half chance.	pRc
C16	T:	So it does indeed. [*Reading from slide*] Equally likely to be passed on. So that makes sense doesn't it. So the probability of a little ee is going to be a half.	tFva

The teacher then restates the question and nominates another pupil to answer (C10). Lea does so (C11). The teacher does not evaluate but, acknowledging a signal from Tia, refers Lea's answer to her (C12), eliciting Tia's agreement that it "makes sense" (C13). The teacher then solicits explanation of "why" from another pupil (C14). Kit's response refers to the key piece of information on the slide and pinpoints how it leads to the answer (C15). The teacher's concluding follow-up endorses this contribution, and reiterates the key point as the basis for the answer "making sense" (C16).

In the opening duologue of this episode, epistemic initiative remains firmly with the teacher, exercised through a series of questions probing the pupil's ideas. While the pupil also makes solicitations, these are by way of response, and in a rhetorical form which insists on a point and appeals for its endorsement. It is the absence of such endorsement from the teacher, accompanied by her probing of the point, that tacitly implies epistemic appraisal. This probing by the teacher leading to the diagnosis which concludes the transaction could, however, be viewed as compatible with the epistemic order enunciated in the ensuing transaction: that ideas should be appraised in terms of whether they make sense and are consistent with the institutionally approved knowledge available. In this transaction, while the teacher retains the epistemic initiative through a series of solicitations, she designates pupils as the primary agents of appraisal, only exercising such a role herself in the final move.

Episode D

The fourth episode comprises a short duologue on the second question on Slide 31.

D1	T:	[*Reading from slide*] If the mother to be has attached earlobes, so the mummy has attached earlobes, how likely is she to pass on a little ee? Tom.	tIs
D2	P [Tom]:	Certain.	pRc

D3 T: Certain. Hundred per cent. Why is that? tFv/tIs
D4 P [Tom]: Because if she's got attached earlobes, then she's got ee ee. pRc
D5 T: She's got two little ees. tFv

The opening teacher solicitation restates the question and nominates a pupil to respond (D1). Tom does so succinctly and correctly (D2). The teacher follows up by repeating and elaborating Tom's answer, and then solicits an explanation of it (D3). Tom highlights the key idea (D4) which the teacher follows up by refining it (D5).

Here, the teacher takes the initiative in posing questions but offers no explicit evaluation of pupil answers. Unlike previous episodes, the notion of appraisal by other pupils in terms of whether an idea makes sense is neither articulated nor enacted here. Indeed, by not subjecting the ideas put forward to such scrutiny, the teacher might be taken to be signalling her own approval of them, so employing a tacit form of appraisal within a more conventionally authoritative epistemic order.

Episode E

The final episode develops from public exploratory talk by two pupils which raises the question of whether both questions on the projected slide are intended to refer to the same situation (E1, E2), a suggestion rebuffed at this stage by the teacher (E3).

E1 P: But, if the mother to be and the father to be, like, are the same mother and father, and they both make, like pIs
E2 P: Yeah, does it matter? Is it like the same child, like, that they're talking about, or not? pR/Is
E3 T: I don't think it's a particular child. [*Pause*] tRc

However, after a short period during which the teacher consults teaching notes and pupils talk amongst themselves, the teacher gives Bet the floor (E4).

E4 T [*In response to indication from Bet*] Yes. tI
E5 P [Bet]: About the question that we've just said. The baby might not definitely have attached earlobes but it would definitely have a little ee because she has two little ees so she you'll definitely have one of them. But depending on what the father might have, detached ears he might have. pRc
E6 T: [*Intervening*] So if we actually join this mother and this father together to make a child. [*Gestures to Bet to speak*]tF/Is
E7 P [Bet]: It could have two little ees or one big ee and one little ee. So he's got one big ee. It's definitely going to have a little ee. pRc
E8 T: Definitely going to have a little ee. tFv
E9 P [Bet]: But it could get a big ee from the father, it could get a little ee. pIc

Bet starts to put forward her ideas (E5). The teacher intervenes by commencing a statement that explicitly restates the hybrid situation, inviting Bet to complete it (E6). Bet does so (E7), the teacher repeats a key phrase (E8), and Bet expands further (E9).

E10 T: [*Turning away from Bet towards class*] So which sort of earlobes is it more likely to have? [*Pause*] If these two parents get together which sort of earlobes is it more likely to have? Hyp, any thoughts? tIs
E11 P [Hyp]: Detached. pRc
E12 T: Bet was just saying that it's guaranteed to have one little ee but it could get a big ee, and I'm saying, what sort of earlobes is it most likely to have. Yes Jay. tF/Is
E13 P [Jay]: Half and half because, because of the father, because if you then get a big ee then it will be dominant, and so it'll be detached. pRc
E14 P: Yeah. pFa

In the final transaction of this episode, the teacher puts a new question to the class and nominates a pupil (E10). Hyp gives an incorrect answer (E11) which the teacher follows up without evaluation. Rather, she recapitulates part of Bet's earlier exposition, restates her own question, and accepts another pupil's bid to speak (E12). Jay's response provides both correct answer and supporting reasoning (E13), which appears to be approved by another pupil (E14). Again, by allowing the transaction to conclude in this way, the teacher might be taken to be tacitly signalling approval.

The teacher's rebuff to the idea proposed in the opening transaction, serves to reclaim the epistemic initiative in the face of an apparent digression. But, in the second transaction, she passes the initiative to another pupil who productively develops the idea. The teacher now changes her position, lending support to the idea, and eventually appropriating it in formulating the question to be pursued in the final transaction. The duologue is launched by Bet, punctuated by shorter contributions from the teacher which extend and revoice key points. In the final transaction, the teacher reclaims the initiative, and dialogue returns to interaction around teacher questions. The teacher makes no explicit evaluation of responses, but she follows up the incorrect answer to her first solicitation by restating the question. She then allows the episode to conclude without following up the sound answer to this second solicitation (or an apparent pupil endorsement of it). This pattern could be interpreted as one of tacit appraisal within a more conventionally authoritative epistemic order.

SYNTHESIS AND DISCUSSION

The epistemic order which emerges from these episodes is one in which initiative is generally exercised by the teacher. The predominant discourse structure involves a tIs>pRc>tF move sequence, where the tF component takes a tFv or tF/Is or tFv/Is form. It is notable that in such an interaction pattern, the teacher does not exercise any overt epistemic appraisal, at least not in the form of an explicit evaluation. Rather she probes the pupil response (C3, C5, C7, D3) or refers it to other pupils for approval and/or explanation (A8, C12, C14). The ideological stance guiding this approach is conveyed by the teacher's references to evaluating ideas in terms of whether they are understandable and make sense (A10, C10), and also whether they are consistent with institutionally accepted knowledge (C16). In particular, in the opening episode, this stance is articulated and enacted through the reflexive duologue concerning Hal's understanding (A8–13) and the ensuing transaction in which the teacher moderates the provision of help by other pupils (A14–21); although when she doubts whether the lines of explanation being put forward by pupils are appropriate, she does make an explicit evaluation (A16 and possibly A19). However, in later episodes (D, E) the referral of responses to other pupils falls away, leading to their ending as soon as a pupil has enunciated an institutionally accepted resolution of the issue of the matter under discussion. This could be interpreted in terms of the teacher exercising – and conveying to those alert to this scheme – tacit epistemic appraisal within a more conventionally authoritative epistemic order.

Beyond this predominant pattern are two occasions when the teacher passes epistemic initiative to a pupil (B1–7, E1–9). With few examples, all that be confidently said is that substantive development of ideas originates from a pI move. On the first occasion, the teacher exercises epistemic appraisal by concluding her exchange with each pupil with an explicit evaluation (B5, B7). On the second occasion, the teacher exercises a supportive, if tacit, epistemic appraisal through expanding on (E6) and echoing (E8) the ideas put forward by a pupil over a series of moves.

Both these discursive frames, then, grant pupils a degree of epistemic agency: over appraisal in the first type, and initiative in the second. In maintaining such frames, of course, the teacher exercises a more fundamental epistemic authority. Indeed, all five of the episodes conform to a pattern in which, once an institutionally accepted resolution of the topic has been enunciated, the teacher directs any further discussion towards elucidating that resolution. Such authority is apparent too on those occasions where the teacher judges it necessary to explicitly evaluate and steer pupils' exercise of agency. Such interventions show devolution of agency to pupils as conditional.

Writing in mathematics lessons in Sweden

Cecilia Segerby

Malmö University, Malmö, Sweden, cecilia.segerby@mah.se

Previous research has shown benefits for both the students and the teachers in letting students write in different ways in mathematics. Consequently, communicating their understanding is emphasised in the current Swedish curriculum. In this paper, Swedish students' perceptions are examined of their writing during mathematics lessons and their assumptions about the purpose of keeping notes. The results come from a questionnaire answered by 136 randomly selected students in Years 3, 4 and 5 and show that writing is not extensively used during mathematics lessons with calculations being the dominant kind of writing. As well, half of the students considered their notes to be worthless.

Keywords: Mathematics education, primary school, communication, writing.

INTRODUCTION

Research has previously shown advantages from having students write more than numbers and symbols during mathematics lessons. This is because writing helps clarify and organize students' ideas, which then contributes to making sense of mathematics; in this way, students' thoughts become visible and provide opportunities for reflection (Freitag, 1997). In contrast to orally communicating ideas, writing allows students to develop a deeper understanding of concepts (Johanning, 2000). Consequently, writing contributes to documenting students' knowledge and experiences to others. Writing can also be an effective communicative tool as both students and teachers become aware of the student´s understanding, feelings and misconceptions about the content being learnt (Meaney, Trinick, & Fairhall, 2012).

There has been some research which has documented the kind of notes the students write during their mathematics education. Britton, Burgess, Martin, McLeod and Rosen (1975) examined the writing in mathematics of students between the ages of 11 to 18 years and found three categories: transactional, expressive and poetic. Transactional writing focuses on the final product as its purpose is to inform, advice, persuade and/or instruct. These authors found this to be the most common writing. Expressive writing is more personal and has been called "thinking aloud on paper", like a diary. Less than ten percent of the writing collected in Britton and colleagues (1975) research was of this kind. The last category, poetic writing, encourages imagination such as constructing your own exercises, drama and poetry and was about twenty percent of the collected writing.

Meaney, Trinick, & Fairhall (2012) examined the writing in mathematics lessons of students in Years 1 to 11. They divided what Britton and colleagues (1975) categorised as transactional writing into three different genres: description, explanation and justification. Descriptions were of mathematical situations or objects, such as definitions. Explanations showed how mathematical phenomena and events came to be, often through a series of steps showing the working out of a problem. Justifications involved providing information about why something is done and included reflections. In their study, Meaney and colleagues found that calculations were the students´ privileged of writing.

The current Swedish curriculum (Skolverket, 2011) emphasises developing students' communication skills in mathematics to support their understanding. However, there is limited research on the kinds of students' notes used in mathematics lessons and it cannot be found previous research in Sweden on students' opinion about their writing in mathematics.

The aim of this paper is to examine students' perceptions of the writing they do in Year 3 (when they are about nine years old), 4 (when they are about ten years old) and 5 (when they are about eleven years old) during their mathematical lessons. The research questions for the study reported in this paper are:

- What kinds of writing do Year 3, 4 and 5 students perceive that they write down during their mathematics lessons?
- What do these students consider to be the functions of that writing?

A questionnaire study was conducted with 136 students. The result of this study will be the baseline for an intervention study. Before discussing the methodology, next section discusses research connected to writing in mathematics education.

WRITING IN MATHEMATICS IN YEARS 3, 4 AND 5

Writing in mathematics is often considered as useful for developing students' vocabulary knowledge. For example, Lundberg and Sterner (2006) stress the fact that students should have possibilities to build up a dictionary in mathematics. These authors considered some vocabulary to be difficult to comprehend as there are terms (concepts and words) that only can be found in mathematics. Some words, such as odd, can have a different mathematical meaning to their meaning in natural language (Lee, 2006). Having different meanings for the same word can be confusing for students. This may be the case in Year 4 in Sweden as it is at this point that mathematical textbooks are considered to become more challenging with many new concepts and the quantity and complexity of the text increasing, thus putting higher demands on students' reading skills (Myndigheten för skolutveckling, 2008).

The importance of understanding the vocabulary in mathematics is also shown in Vilenius-Touhimaa, Aunola and Nurmi´s (2008) study with students in Year 4 and in Möllehed's (2001) study in Years 4 to 9 where a relationship appeared between students' mathematics problem solving performance and understanding the mathematical vocabulary in the exercises. Yet, according to Misono and Takeda's (2012) study in a fifth-grade class in Japan many of the students did not use mathematical terms and they found it difficult to write descriptions about mathematical operations. As a consequence these authors suggested that teachers need to train the students to describe each step using mathematical terms and not only let the students write down why they were able to get the correct answer by only using numbers.

In Sweden, Ebbelind and Segerby (2015) and Segerby (2014) found that few of the exercises in the textbook require the students to describe, explain and evaluate their understanding, so there are limited opportunities to develop this skill in the textbook. This is problematic since working in the textbook is the dominant practice in mathematics in Sweden (Johansson, 2006; Myndigheten för skolutveckling, 2008).

It has also been suggested that teachers should provide students with instructions about how to structure mathematical arguments, such as justifications and explanations, and to construct narratives, which support mathematical thinking (Meaney et al., 2012). In the research by Hensberry and Jacobbe (2012) with seven students, aged between 5 and 11, a problem solving model was used to structure students´ writing, which led to improvements in problem solving achievement.

Another positive aspect of keeping notes in mathematics was found in Johanning´s (2000) research about problem solving in groups. It indicated that writing helped students to find their mistakes and understand, remember and solve the problem better, when they first wrote in isolation before they met and discussed the problem in groups. However, this study was conducted among Years 7 and 8 students and it is not clear how relevant the results are for younger students.

There are several benefits of letting students write different kinds of texts in mathematics, but it is also essential that teachers explain the aim for the writing and for whom they write so they understand the purpose of doing that (Meaney et al., 2012; Morgan, 1998). In next section, the method for the reported study is described.

METHOD

To examine students' perceptions of their writing in mathematics, a quantitative study was conducted with 300 randomly selected students from Years 3, 4 and 5 (100 in each Year) throughout Sweden during spring 2012. A total of 136 students responded; 50 students from Year 3, 40 students from Year 4 and 46 from Year 5. When randomly selected samples are used, every unit in the target population has the same possibility to participate and it is reasonable to generalize the result. In this study, the selection of the students was

Britton et al.´s categories	Questions in the questionnaire
Transactional involving informing, such as calculations	1a, 1b, 1c, 1e, 1g, 3a, 3b, 3c, 3e, 3f, 4a, 4b, 4c, 4e
Expressive, such as evaluation	1d, 1f, 3d and 3e, 4d
Poetics, such as original mathematical exercises (stories)	2

Table 1: Categories connected to the questions in the questionnaire

done by the Swedish Tax Agency, who has information on all Swedish residents. By using this approach 136 different classroom contexts from across Sweden could be examined to reveal the context of culture involving writing in mathematics. Context of culture refers to what occurs outside language, such as the events and conditions of the world (Halliday & Matthiessen, 2004). For example, context of culture can involve how the mathematic education is designed in Sweden such as the reliance on the textbook and how that affects the teacher´s and the student´s roles.

As mentioned earlier, it is considered that mathematics becomes more difficult in Year 4 with texts becoming longer and many new concepts being introduced (Myndigheten för skolverket, 2008). This is why it was decided to investigate the writing in Years 3, 4 and 5 to see if there were differences in the writing.

Pre-testing the questions in the questionnaire is crucial to its success. Therefore, a pilot study was conducted involving 15 students in Year 3 to examine how the youngest students were likely to reply to the questions. The students answered the questionnaire individually before talking in groups of three or four students. This led to that question four was reformulated from "How does your understanding in mathematics being accessed?" to "How does your mathematics teacher find out about your understanding in mathematics?" With other questions, the numbers of alternative responses were expanded.

The questionnaire contains four questions and all of them, except for question 2, contain closed-response answers where the students could choose one or more alternatives. In question 2 the students could only choose one alternative since it involves students making decision of how often they write down mathematical exercises (stories) of their own. The alternatives in the questions contain limited amounts of texts in respect to the youngest students´ reading ability in this study.

Questions 1 and 2 of the questionnaire examine the first research question concerning what the students perceive that they write down during their mathematics lessons, while questions 3 and 4 examine the second research question involving what the students consider to be the functions of keeping these notes in mathematics.

In order to answer the research questions the categories by Britton and colleagues (1975), *transactional, expressive and poetic*, are used to structure the questions in the questionnaire to visualize the students´ different kinds of writing (see Table 1).

However, what differs between previous studies (Britton et al., 1975; Meaney et al., 2012) and this study is that is does not examine examples of students´ texts. Instead it focuses on students´ opinions and feelings about what they write down during mathematics lessons and what the purpose of keeping those notes are. This approach has previously not been used in Swedish mathematics education research.

In the next section each of the questions responses are presented and discussed.

RESULTS AND ANALYSIS

Question 1: "What do you write down during mathematics lessons?"

The results are presented in Table 2 and in the text that follows they are interpreted regarding the categories of transactional and expressive writing.

Transactional writing: The most common kind of writing, which the students perceived that they did, was writing calculations. This is a similar result to that of Britton and colleagues (1975) which was conducted 40 years ago in USA and suggests that writing in mathematics may have not developed much since then, at least from the perspective of how students refer to it.

What do you write down during mathematics lessons?	Year 3	Year 4	Year 5	Total
a) My operations (calculation)	100%	100%	100%	100%
b) Knowledge goals for the different areas in mathematics	10%	5%	4%	7%
c) Mathematical words with explanations	22%	5%	26%	18%
d) Thoughts about what I think is easy and/or difficult in mathematics (evaluation)	10%	2%	2%	5%
e) How to solve mathematical problems	30%	18%	37%	29%
f) Thoughts as preparation for group exercises in mathematics, such as problem solving exercises	12%	4%	9%	9%
g) Results from practical exercises	12%	11%	11%	12%

Table 2: Summary of results from question 1

The second most common kind of writing was keeping notes on different strategies connected to problem solving. Although this kind of mathematical writing has been connected to improve problem solving (Hensberry & Jacobbe, 2012; Johanning, 2000), only 29 percent of the students considered that they had been involved in producing this kind of writing.

Less than 20 percent of students had written definitions of mathematical words. In Year 4, only 5 percent of the students considered that they had written definitions in their mathematics lessons. Given that previous research has suggested that this is important for students in making sense of what they are learning (Lee, 2006; Lundberg & Sterner, 2006), there is some concern that so few students recognise this as part of the writing that they do in mathematics. As a correlation has been found between Year 4 students' knowledge of mathematical vocabulary and the problem solving performance (Möllehed, 2001; Vilenius-Touhimaa et al., 2008), this result suggests that an intervention study would be most beneficial for students in this Year level. The students, independently of the Year, considered that they rarely wrote about the knowledge goals that they were to achieve in different areas.

Expressive writing: Research has also shown benefits by letting the students write down thoughts as preparation for group exercises (Johanning, 2000), but very few students had done this in this study. Evaluation is another kind of expressive writing and as discussed in the part about the responses to question 4, evaluation in mathematics was said to be done by teachers. This would explain why students rarely wrote their own evaluations of their mathematics learning.

Question 2: "I create own exercises (stories) in mathematics"

This question is the only one in the questionnaire that examines the poetic writing. There is a summary of results in Table 3.

This table shows that in Year 3 approximately 70 percent of the students consider that they sometimes or often create exercises of their own but that number decreases to approximately 30 percent in both Years 4 and 5. The poetic writing seems to occur rather often in Year 3 but is barely used in Year 4 and 5. This kind of writing can contribute to reveal the students´ understanding and misconceptions about the content being taught (Meaney et al., 2012) so this

I create exercises (stories) in mathematics by myself	Never	Rarely	Sometimes	Often
Year 3	8%	26%	56%	10%
Year 4	29%	42%	22%	7%
Year 5	33%	33%	27%	7%
Total	23%	33%	36%	8%

Table 3: Summary of results from question 2

What do you use your notes in mathematics for?	Year 3	Year 4	Year 5	Totally
a) To correct my calculations	28%	38%	24%	29%
b) To practice and look at before tests	8%	15%	28%	17%
c) To look up explanations for different mathematical words	4%	7%	4%	5%
d) To follow my development in mathematics	20%	13%	9%	14%
e) To communicate with the teacher	4%	0%	2%	2%
f) As a help when I solve different exercises	24%	30%	19%	24%
g) Nothing (for my learning in mathematics)	48%	40%	52%	47%

Table 4: Summary of results from question 3

kind of exercises seems to be relevant regardless the students´ age.

Question 3: "What do you use your notes in mathematics for?"

Table 4 shows the results in relation to the students' responses to question 3 in the questionnaire. It is argued that the reported writing can be divided into transactional and expressive writing.

Transactional writing: The results show that approximately 30 percent of the students' used their notes in mathematics to correct their calculations. Notes as a help to solve different exercises were used by approximately 25 percent of them. Less than 20 percent used notes as a preparation before tests. In question 4 (see Table 5) students considered that tests were the most common method that teachers used to determine their understanding. Therefore to find that very few students considered their notes as helpful to study for these tests suggest that students are not seeing writing in mathematics valuable for their learning. As well, very few students considered that they used their notes to communicate with the teacher. Given that it has been found that writing as a communication tool between the teacher and the students can contribute to exposing the students misconceptions, feelings and understanding (Meaney et al., 2012), and both the transactional and the expressive writing are involved. This seems to be an area to focus on in an intervention study.

Expressive writing: It is also interesting to note that older students considered that they used their notes less for following their own development. This is related to responses to question 1 about determining whether what they were learning was difficult or easy. A higher percentage of students in Year 3 considered that they wrote about this in mathematics in comparison to students in Years 4 and 5.

Almost half of the students considered that their notes in mathematics lessons were not important for their understanding in mathematics. This suggests that the students are unclear about the aim of writing in mathematics. If students are unclear about the purpose of their writing, it may be that they do not perceive that they engage in different kinds of writing. The same might concern the use of explaining mathematical words. In question 1 approximately 20 percent considered that they wrote down explanation of mathematical words but according to the result of this question very few of the students used their notes as a dictionary. This might show that they know the words but it can also refer to students understanding of the usefulness in this kind of writing. Therefor it is essential that the aim for the writing is explicit

How does your mathematics teacher find out about your understanding in mathematics?	Year 3	Year 4	Year 5	Totally
a) Test and diagnoses	86%	90%	100%	90%
b) By the number of exercises I have done	28%	20%	17%	23%
c) Through the operations in my counting book/textbook	50%	38%	54%	48%
d) Through what I have written in my evaluation what I think is easy and difficult in mathematics	20%	18%	11%	16%
e) Other ways, such as homework	4%	5%	2%	4%

Table 5: Summary of results from question 4

articulated by the teacher (Meaney et al., 2012; Morgan, 1998).

Question 4: "How does your mathematics teacher find out about your understanding in mathematics?"

Transactional writing: The main sources for the teachers to evaluate the students' understandings are tests and diagnoses (90%). About 20% of the students also indicated that the teacher could work out how much they understood by counting the number of exercises they had done. Approximately 50% of students considered that the teachers looked at the calculations that they had done in their notebooks. The students' perceptions that the teachers focused on their calculations may contribute to them considering that writing mostly concerns doing calculations.

Expressive writing: Less than 20 percent of the students thought that their teachers used what they had written in their evaluations. This indicates that evaluation is not important for the students´ development in mathematics. However, letting the students evaluate their learning visualize their thoughts (Freitag, 1997) and thereby provide opportunities to make the teacher aware of the students´ understanding, misconceptions and feelings about the content being taught (Meaney et al., 2012).

CONCLUSION

According to the results of this study, it can be inferred that few classes in Years 3, 4 and 5 in Sweden use writing in mathematics extensively. Calculations are the dominant type of writing that appears, independently of the Year, and these notes are the main source for the teachers to evaluate understanding in mathematics.

However, in Year 3 it is more common for the students to use different kinds of writing connected to transactional, expressive and poetic functions, but that progressively decreases in Years 4 and 5. With older students the production and use of notes is less thought of as a way to follow their development in mathematics and to communicate with the teacher to expose misconceptions, feelings and understanding in mathematics. This is critical since Year 4 mathematics is considered to be more complex than in earlier Years and correlation between students' knowledge of mathematical vocabulary and problem solving performance has been found.

Further research is suggested where different kinds of writing activities are implemented into a Year 4 class in mathematics to examine how these can contribute to developing communication skills and thereby support the students' mathematical understanding. The purpose for the writing then needs to be explicitly explained for the students so the notes can become valuable for them and not, as approximately half of the students in the reported study say to think, worthless for their understanding in mathematics.

Language use, mathematical visualizations, and children with language impairments

Elke Söbbeke

University of Paderborn, Paderborn, Germany, elke.soebbeke@math.upb.de

This article presents a first approach and theoretical foundation for a new research project. It focuses on the role of language in the process of communication about structures and relations in mathematical visualizations. Mathematical knowledge is abstract in most cases. Using means of visualization is indispensable for speaking with children about the abstract mathematical concepts. Against this background language is seen as an important tool in the construction of knowledge. But this raises the question, which features of language in children with specific language impairments (SLI) pose a challenge for verbalizing abstract structures. The interest in research relates to the question how students with SLI manage to communicate about the embodied structures in mathematical means of visualization.

Keywords: Means of visualization, communication, structures, language impairments.

EPISTEMOLOGICAL VIEW ON MATHEMATICAL KNOWLEDGE

For a better understanding of the focus on means of visualization in this paper, it is useful to think at first about the special character of mathematical knowledge and the special epistemological conditions involved in processes of learning mathematics.

Mathematics as a science of pattern, structures and relations deals with essentially abstract concepts. From the beginning of the learning of mathematics the young child is confronted with this challenge: Even dealing with elementary mathematical objects like numbers, operations and later the concept of the place value system the child is confronted in a first way with the abstract ideas of mathematical knowledge. Therefore the child has to develop awareness that mathematical concepts are not empirical objects. For example the child has to learn that numbers represent more than only an amount of objects. Rather, it is the theoretical relation between these objects that constitutes the mathematical concept of number.

> In the \`world of objects\`, \`0\`(zero or null) means \`no object\`: and in this world there is no principal difference between the removal of \`5 apples and 5 pears\` or of \`5 black and red chips\`. If, in the model with black and red chips, the same number of black and red chips is given to mean \`0\`, this theoretical relation has to be established \`by one's own and independent activities of thinking\` and, only in this way, a difference is constructed between the chips configurations, which symbolizes a number aspect, and the pears and apples, which belong to the world of things. (Steinbring, 2005, p. 20).

This example points out, that an *amount of ten chips* (five black ones and five grey ones) - that could be seen, counted and manipulated by the child - can also represent the *number zero* (see Figure 1). But this interpretation is only possible if the learning child does not only focus on the real objects, the concrete properties of the objects (the colour for example) but focuses on the *relations that are represented by the different coloured objects*. This particularity is an important basis of the understanding of numbers in general.

In his reflection about the character of numbers, Benacerraf (1983) points out:

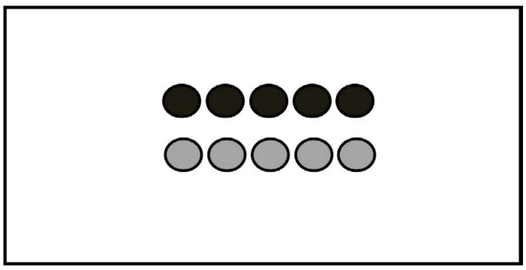

Figure 1: Number 'zero' as a relation between two amounts of five

> Therefore, numbers are not objects at all, because in giving the properties (that is, necessary and sufficient) of numbers you merely characterize an abstract structure - and the distinction lies in the fact that the elements of the structure have no properties other than those relating them to other elements of the same structure. (...) To be the number 3 is no more and no less than to be preceded by 2, 1, and possibly 0, and to be followed by 4, 5, and so forth. And to be the number 4 is no more and no less than to be preceded by 3, 2, 1, and possibly 0, and to be followed by (....). Any object can play the role of 3; that is, any object can be the third element in some progression. What is peculiar to 3 is that it defines that role - not by being a paradigm of any object which plays it, but by representing the relation that any third member of a progression bears to the rest of the progression. (Benacerraf, 1983, p. 291)

This means that even the numbers which often seem to be understood in everyday experience as an amount of concrete objects, or as objects with concrete properties have to be understood in the progression and relation to the preceding and following objects. More generally:

> So what matters, really, is not any condition on the objects (...) but rather in the relation under which they form a progression. To put the point differently - and that is the crux of the matter - that any recursive sequence whatever would do suggests that what is important is in not the individuality of each element but the structure which they jointly exhibit. This is an extremely striking feature. (Benacerraf, 1983, p. 290)

Mathematics is thus as shown above a science, whose concepts are used to describe and analyse abstract patterns and structures. But in contrast to this, in „non-mathematical" everyday experiences mathematics is often understood as a collection of rules, procedures and algorithms. Against this background, the mathematical signs and symbols are often used and (mis-)understood as important „anchor points", which have to be memorized and which are often confused with the underlying mathematical concept. However, the peculiarity about mathematics is - which Duval (2000, p. 61) describes as the "*paradoxical character of mathematical knowledge*" - that just these signs and symbols are not the mathematical concept in itself, they only refer to it, they represent it. Presmeg (2008) describes *signs* as *interpreted relationships* between a *representative* and an *object*.

> I shall take a sign to be the interpreted relationship between some representamen or signifier called the sign vehicle and an object that it represents or stands for in some way. In mathematics, the objects we talk about cannot be apprehended directly through the senses: for instance, "point", "line", and "plane" in Euclidean geometry refer to abstract entities that we can never see, strictly speaking, as in Sfard's (2000) virtual reality. We apprehend these objects, "see" them, and communicate with others about them, in a mediated way through their sign vehicles, which may be drawn or written by hand or through dynamic geometry software, labeled in conventional ways, moved and manipulated for multiple purposes. We work with these sign vehicles as though we were working with their objects. (...) It is this interpreted relationship between a sign vehicle and its object that constitutes the sign. (Presmeg, 2008, p. 3)

The result is a particular challenge for the development and insight of mathematical concepts: If mathematical signs are not the mathematical concept, but only a symbol of a relationship, and if mathematical concepts have to be understood as abstract relations, how is it possible to speak and to reflect about them at all - especially with young children in elementary school?

EPISTEMOLOGICAL VIEW ON MEANS OF VISUALIZATION

For these processes of thinking about abstract structures and teaching mathematics, the use of means of visualization is an important foundation to help young students in building adequate internal representations of mathematical ideas. The mathematical ideas, as

> theoretical ideas, are not things which could be conveyed as completed products. The mathematical subjects consist of relations between things and not in the objects and properties. Therefore, mathematical thinking (...) has to be visualized, in order to represent such relations. (Otte, 1983, p. 190, translated by author)

Goldin and Shteingold describe "the development of efficient (internal) systems of representation in students, that correspond coherently to, and interact well with, the (external) conventionally established systems of mathematics" as a fundamental aim for the process of mathematics teaching (Goldin & Shteingold, 2001, p. 3). But this aim implies a difficult and challenging task for the teacher: As different studies in mathematics education have shown, the intended way from external to internal representations is not straight, easy or clear (Söbbeke, 2005a, 2005b).

For a better understanding of this difficult requirement, it is helpful to consider the elementary learning processes in mathematics education in a more detailed way. For this purpose we will look at the use of means of visualization from different perspectives. In German mathematics lessons chips are a common means of visualization. In the following, the example chips illustrates in which way the interpretation of the material must be differentiated: an interpretation of the chips as concrete to an interpretation of the chips in a first systemic and relational way.

First Perspective: Especially in teaching processes with young learners the counting of concrete objects is an essential activity to develop a first concept of numbers. With this background, objects like "chips" have to be understood as an explanatory background for the understanding of the new number symbols and number words. The concrete materials seem to deliver an explanation for the new mathematical symbols (Steinbring, 2014). The material-based and concrete interpretation of each single object („one chip means '1'") is helpful and important.

2nd Perspective: The interpretation of the ten chips undergoes a first conversion / change if they are sorted in the place value system. A new interpretation of the material is necessary (see Figure 3).

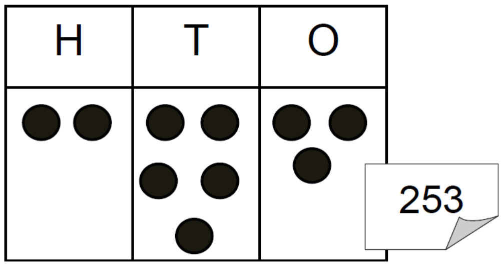

Figure 3: Ten chips in the place value table

The 10 coloured chips should be seen in their structural relationship to each other and to the whole system: Sorted in the place value table, each single chip is given a new meaning: It no longer represents „one", but also „10" and „100" (Söbbeke, 2005).

3rd Perspective: We continue the consideration of the 10 chips a bit further. The 10 chips are arranged now in a rectangular shape (Steinbring, 2014). The relationship of each single element to the overall structure is important. The learning child has to be aware of the "new" structure(-units): e.g. "twos" and "fives". This is an important modification and at the same time a more sophisticated approach to the material: for mathematics learning, the child has to see that the collection of these 10 chips does not only stand for the amount of ten, but also represents essential arithmetical ideas: e.g. "two times five" (2×5) or "five times two" (5×2). This view has to become even more differentiated, for example to see the possibility of a distributive decomposition of the "chips field" like "1×5+1×5=2×5" (see Figure 4).

These examples show that the first perspective on the material, using it to count objects ("one chip means '1' "), successively undergoes a major evolution. By putting the chips into the place value table or in the shape of the rectangle, the children can be encouraged to think about the first *systemic aspects* of the mean of visualization.

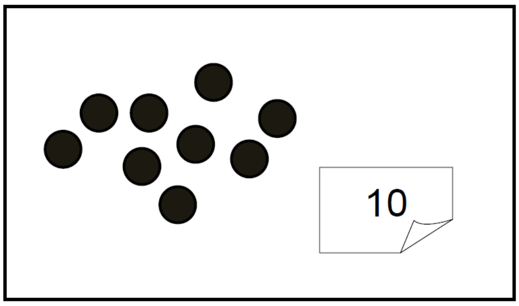

Figure 2: Counting ten chips to develop a first concept of numbers

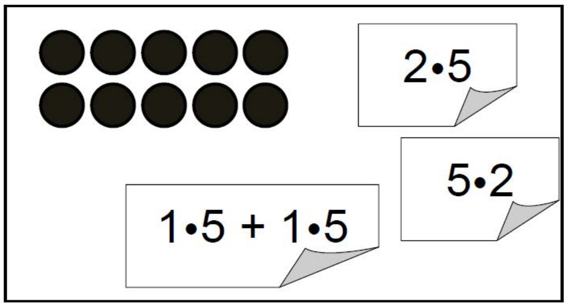

Figure 4: Ten chips structured in a rectangular shape

Against this background, it becomes clear that the children have to learn a new approach to the use and interpretation of means of visualizations (Söbbeke, 2005a): To build new mathematical knowledge it is necessary to disregard the concrete properties of the objects and to understand these objects as elements of the overall system. Therefore the child has to learn to examine the relations, structures and the theoretical ambivalence, which the means of visualization contain. The author's main interest in research belongs to this difficult and challenging requirement for the learning child (Söbbeke, 2005a, 2005b). For further research, it seems relevant to investigate, in how far it is possible for elementary learners not only to develop this systemic view on mathematical visualizations, but also to *communicate about* it.

THE ROLE OF LANGUAGE IN EXPLORING STRUCTURES IN MEANS OF VISUALIZATION

Language and the learning of mathematics

Language is important for the learning of mathematics in two ways: on the one hand language has a communicative function that serves the exchange among the children and with the teacher. On the other hand, it has a cognitive function that advances an increase of new mathematical knowledge (Maier & Schweiger, 1999).

The communicative function of language

The importance of language is highlighted in German mathematics curricula and the German "Bildungsstandards" (educational standards) by emphasizing the activities and processes of "communication" and "reasoning" as prominent skills for mathematics learning. The guiding principle on "patterns & structures" requests the children to describe mathematical relations and structures in general to all mathematical topics. Against this background the communicative exchange can be seen as a necessary component of a stimulating and challenging teaching and learning culture.

The cognitive function of language

Regarding different research traditions, today the learning of mathematics is no longer seen as a purely individual, mental process of the single child, but as a learning process in which the social interaction and communication with others is an essential basis for the development of new mathematical concepts. In this context, the sociologist Miller (2006, p. 200) distinguishes different types of knowledge (cumulative knowledge versus structural or fundamental knowledge) and justifies the importance of social discourse as an important factor for learning.

While cumulative knowledge can be developed quite individually on the basis of experiences by a subject on its own (e.g. a poem or foreign language vocabulary), structural or fundamental knowledge can only increase in the social debate and reasoning of learners with others (Miller, 2006, p. 200). As shown above, mathematical concepts are assigned to the structural knowledge. They arose historically and therefore they require cultural processes -processes of communication and interaction - to be developed and learned. Miller also highlights that new knowledge cannot be completely derived from existing knowledge, because new knowledge exceeds the acquired knowledge. That is, in processes of collective argumentation new findings, beliefs and concepts can be developed.

But children in elementary school are still on their way to become mathematically communicating people and thus „autonomous learners" of new structural knowledge. They still have to learn to derive new structural knowledge from their empirical experiences or activities with concrete materials or means of visualization (Steinbring, 2014). Finally it becomes clear, that the communicative function of language strongly supports and requires the cognitive function. This point shows the reference for the presented interest in research: The teacher has to *reveal an (seemingly) empirical world* to the children, in which they have to make *theoretically significant experiences* and in which they *learn to verbalize* them.

Mathematical communication with children with language impairments

At least in the German discussion about mathematics and language, it is quite popular to discuss primarily the influence of language impairments on performance in mathematics or to develop concrete actions (or aids) to support the learners (e.g., Donlan, 2007; Fazio, 1999; Jordan, Levine, & Huttenlocher, 1995). In contrast to that, the aim of the author's research interest is to better understand the theoretical and epistemological conditions of language use, and analyse the special features of language in the context of the interpretation of means of visualization. As shown above means of visualization deliver an important access to the theoretical and abstract "world" of mathematics.

The language plays a fundamental role to this access: Children learn to derive the theoretical and systemic aspects from their empirical experiences with the concrete materials *only by a special communication about the structures and relations in these means of visualization.* This aspect fits the author's main interest in research: Which kind of linguistic particularities affect the communication about mathematical means of visualization, especially the conceptual and systemic interpretation of the means of visualization? In the following, two essential aspects are described which seem to be relevant for a deeper understanding of the described research interest.

Symbol competence

Studies in cognitive sciences emphasize the importance of an „image and symbol competence" (DeLoache & Burns, 1994) for the cognitive development and learning of young children. They also show that this competence is a challenging skill, which has to be developed: "There are several reasons to suspect that recognition of a depicted object is not equivalent to understanding the nature of pictures or the relation between a picture and its referent" (DeLoache & Burns, 1994, p. 85).

Other studies point out that images are iconic symbols that are associated with a specific content. This "association" is based on structural similarities either on a concrete or abstract level (Elia, Gagatsis, & Demetriou, 2007). In processes of mathematical communication the children have to develop this understanding of symbols, and furthermore the competence to verbalize this. Several observations indicate that children with SLI show a delayed development of such a symbol understanding competence: Understanding signs which establish a relationship between signifier and signified is delayed. This delay can have an effect on the symbol competence in the context of interpretation and verbalisation of means of visualization in primary school education (Lorenz, 2005, p. 4).

Linguistic means to describe relations and generality

In the German discussion about language impairments and learning mathematics, different technical terms have been described, that affect the communication about mathematics: For example problems of seriality include difficulties to verbalize linguistic sequences, to differentiate and interpret them. An example is the major effects that arise in number words by interchanging the individual positions of the digits: 163, 631, 316, etc. (Lorenz, 2005). It is clear that difficulties in the context of seriality not only exchange the names of the numbers (factual knowledge) but can lead to problems for the *structural concept* of numbers.

It is important to understand the spatial relations in diagrams. The use of prepositions, which describe such spatial relationships, are important linguistic means for the development of a concept. In addition, the children have to verbalize relational concepts which combine different objects in a comparative sense and be aware of causal constructions (Nolte, 2000). These linguistic expressions are a key basis to describe first ideas of generalization; they are technical terms that need to be learned.

However, taking into account the epistemological perspective shown in the previous sections, *more* seems to be important than to examine the use of these *technical* terms. My current research aim is to develop a first theoretical framework to analyze the *children's linguistic means to express relations and generality*. The epistemological framework clarifies the special *content* of communication. But it does not clarify *in which way* the language use of children with SLI should be theoretically described. It is necessary to integrate certain theoretical concepts into the epistemological framework in order to describe the linguistic means of children with SLI adequately. A first approach to this could be the distinction of different levels and linguistic means by Akinwunmi (2012).

Mathematicians use algebraic expressions such as variables, terms or equations to express generality. But primary learners have no knowledge about variables to describe mathematical patterns and something universal. Akinwunmi (2012) examined processes of generalization. Through the analysis of clinical interviews with fourth graders, she reconstructed different types of verbal means, which the children (in this context without SLI) used to discover and describe mathematical patterns. Akinwunmi worked out five categories for generalization that could deliver a first access to the presented interest and further work: use of *a representative example*; use of *several examples*, development of *quasi-variables*, *conditionals* and *variables*. These categories embrace a range of linguistic expressions from relating to concrete objects and examples to describing generality.

CONCLUSION FOR RESEARCH

This paper is a first theoretical foundation of a research project. Based on an epistemologically oriented view of mathematical knowledge and the role of means of visualisation, the importance of communication about structures in mathematical representations had been worked out. In the following process of research a solid framework has to be developed. This work includes to integrate certain theoretical concepts (in the field of communication and language) into the epistemological framework in order to describe the linguistic means of children with SLI.

The communication with children with SLI about means of visualisation is of current interest. For mathematics teaching in Germany this requirement constitutes currently a special challenge. Because of a new law on inclusion, children with and without SLI have to be taught together. In order to develop for this kind of teaching not merely superficial recipes, it is important to investigate processes of challenging communication.

Linguistic norms in mathematics lessons

Kerstin Tiedemann

University of Cologne, Cologne, Germany, kerstin.tiedemann@uni-koeln.de

The present paper reports on a qualitative study that focuses on linguistic norms in everyday mathematics lessons. The central question is what kind of norms students and teachers establish for their language use when talking about mathematics. The underlying data contains videos from two second grade classes. Two short examples from that corpus illustrate the empirical results and show two fundamentally different kinds of linguistic norms.

Keywords: Norm, form of language, function of language.

INTRODUCTION

In Germany, approximately one fifth of all students has a migration background. As a consequence, representatives from politics and science focus more and more on this special group. But international comparative studies like PISA 2000 or IGLU 2001, to mention the earliest, show that learners with a migration background are less successful in the German education system than other students of the same age. Another important result from those studies is that also the group of learners coming from families with a low socioeconomic status performs below average. What these students might have in common with those from migration families is that their language skills tend to be below average. Thus, with regard to both of these student groups, it is important to note that the proficiency in German academic language turned out to be more relevant than other background factors, such as multilinguism, socioeconomic status or immigrant status (see Prediger, Renk, Büchter, Gürsoy, & Benholz, 2013). For that reason, German mathematics educators pay increasing attention to the topic of language in mathematics classrooms.

Language is often seen from a normative point of view. Researchers use categories, such as those of everyday language and academic language (see Gogolin, 2009), and try to assess to what extent the language used in classrooms meets these categories. Having a slightly different focus, some other researchers use this helpful differentiation in order to describe everyday discourses in mathematics classrooms (see Riesbeck, 2010). Thus, although these categories can help us to describe the language which is used, they do not explain which rules or norms the interlocutors themselves establish when they talk about mathematics. One might expect that each learning group establishes its own norms for using language. But which norm could that be? What might be their point of orientation?

To answer these questions, my empirical analyses are focused on the negotiation of linguistic norms in everyday mathematics lessons. These norms are relevant in regard to mathematics learning because they can create or constrain learning opportunities for students. For that reason, the linguistic norms seem to be a good starting point for changes in mathematics classrooms.

LINGUISTIC NORMS

If a student talks about mathematics with the teacher or with other students in class, he will have to coordinate two levels in one utterance: First, there is the content level and, second, there is the language level. The student has to find an accepted and understandable way of expressing his mathematical idea. According to these two levels of an utterance, Sfard (2008) distinguishes between object-level rules and metadiscursive rules. Object-level rules are narratives about "regularities in the behavior of objects of the discourse" (p. 201). Sfard provides the example of the sum of angles in a polygon: "The sum of the angles in a polygon with n sides equals $(n-2)\times180°$". One can imagine that this narrative guides the content level of an utterance in a mathematics lesson. But, by that rule, nothing is said about when and how to say something about the sum of angles. This metadiscursive level is governed by another kind of rules: the metadiscursive rules. They offer orientation concerning the question of "when to do what and how do to it" (Bauersfeld, 1993, quoted in Sfard, 2000, p. 167). Sfard (2008, p. 201) clarifies that these rules "define patterns in the activity of the discursants trying to produce and substantiate object-level narratives."

Yackel, Cobb and Wood (1991), Yackel and Cobb (1996), and Voigt (1994) give further examples of metadiscursive rules which they name as norms. One of these examples is that of social norms. They are related to classroom interactions in general and are not necessarily unique to mathematics, e.g. teachers do not only expect their students to give answers, but also to explain and to justify them (Yackel & Cobb, 1996, p. 178). In contrast, sociomathematical norms are not object-level rules in Sfard's sense, but they have a component that focuses on the content level. For example, a sociomathematical norm guides the understanding of what counts as an acceptable mathematical explanation in a specific learning group (see Yackel & Cobb, 1996, p. 461). On closer inspection, one can see that these sociomathematical norms combine the content level and the language level. For example, in order to produce a good explanation you have to meet the established object level rules, but your utterance has to be appropriate to the recipient as well. To meet the latter requirement, you have to use a specific language. For the moment, I would like to push the focus even more on the language level than it has been done in the work of Yackel and Cobb or Voigt. As it is known the language is for some students a barrier to learning, it is necessary to understand the language use in detail. That is what my focus is on. One might expect that, similar to social or sociomathematical norms, teachers and students also negotiate norms for their use of language. This is what I refer to as *linguistic norms* in the following. Thereby, we have to keep in mind that these linguistic norms affect the content level and the development of mathematical learning processes because they determine the medium of learning, the language.

To supplement the preceding ideas, I would like to clarify the difference between rules and norms. Both terms refer to regularities that one can reconstruct in a given interaction. But, according to Sfard (2008, p. 204), not every rule is a norm. But to be a norm, a rule has to fulfill two conditions. First, it must be "widely enacted within that community." Second, it must be "endorsed by almost everybody." The first condition might be regarded as fulfilled if a norm is enacted in a situation where almost all the students are listening. We can think of an interaction between one student and the teacher in front of the board with everyone else listening and looking in their direction. Then, we can say that this norm is enacted in that specific learning group. In contrast, it is often impossible to decide whether the students really endorse the established rule, thus, to decide whether the second condition is fulfilled. But, as Sfard (2008) remarks, a norm does not necessarily have to be accepted by really all the members of a community to be considered as such. She stresses that in order to be a norm the rule has to be endorsed especially by those within the community who count as experts. Similarly Tatsis (2013) shows that a student might violate a norm to protect her or his face. Nevertheless, the considered rule might be a norm. To put it methodologically, the violation of a norm does not automatically mean that this rule was not a norm. What can help us in this regard is Sfard's (2008, p. 204) clue that a norm becomes explicit and most visible when it is violated. Then, this violation evokes "spontaneous attempts at correction". To sum up, a norm distinguishes itself from a rule by its obligation. While rules guide an interaction towards observable regularities, norms do the same, but are treated as a requirement by most of the interlocutors, in particular by the teacher.

LANGUAGE BETWEEN NEARNESS AND DISTANCE

Koch and Oesterreicher (1985) offer a distinction that has proved to be helpful in the context of linguistic norms. These authors differentiate the medium of language. Thus, an utterance can be phonic (oral) or graphic (written). For the context of this paper, I focus on phonic language in face-to-face interactions in everyday mathematics classrooms. Secondly, Koch and Osterreicher identify two conceptions that an utterance may have. It can be conceptually oral or conceptually written. This affects the question of communication strategies used. As an example, it is easy to recognize that we use different communication strategies when talking informally to our mother compared to when we are giving a lecture at the university. Conceptually oral language is often used when interlocutors are directly related and can refer to a given situation, e.g. an informal conversation with one's mother. This is what, consequently, gives a specific form to the language. For example, at any time, the interlocutors can ask questions of understanding, show emotions and influence the course of the interaction. For that reason, sentences may be short and even incomplete. Referring to the given situation, the speakers use deictic expressions and gestures. Thus, orality is characterized by interlocutors who spontaneously negotiate their roles and the course of their interaction. Koch and Oesterreicher call this a language of nearness. Examples are a conversation in the family (medially oral) or a chat among friends (medially written). In contrast, conceptually written language is used when the interlocutors are not necessarily in direct relation and processes of language production and language reception might be separated from each other. Thus, aspects of the situational and cultural context have to be made explicit. As a consequence, sentences are longer and more complex. The writer forms main clauses, but also subordinate clauses in order to express the relations he wants to inform about. And s/he uses more specific terms, e.g. mathematical terms, to be precise and explicit. Koch and Oesterreicher call this a language of distance. Examples are a text of law (medially written) or a scientific lecture (medially oral).

What we can learn from Koch and Oesterreicher's concept is that the language we use is not only characterized by its form, but also by its function. We have different purposes when talking to our mother or when giving a lecture at the university. The form of language changes according to these functions. To say it with Halliday (1994), we use different language registers in different situations. In the concept of registers, Halliday combines the aspects of form and function.

METHODOLOGICAL BASES

The goal of my research is to describe which kind of linguistic norms teachers and students establish for their language use in mathematics lessons. I have focused on primary classrooms and on conversations in which both students and teachers are involved. The reason for the latter decision is that the teacher plays a special role in the negotiation of (linguistic) norms. Because of his position in the social situation of a classroom, his norms might be accepted as such in almost every case. Thus, if the teacher introduces a norm and no student disagrees explicitly, we might assume that the rule is enacted in that learning group. By reconstructing linguistic norms in this way, we should keep in mind two issues. First, there might be other norms which are enacted only by a few students and which do not come to light in a class conversation at all. In this regard, Tatsis (2013, p. 1632) talks about "'minor' norms". But, for an individual, these norms can be as important as those confirmed by the teacher. Second, not all linguistic norms that are established in the classroom have to be desirable ones, some might even hinder mathematics learning (see Tatsis, 2013, p. 1629). My research goal is to describe types of linguistic norms which are established in the mathematics lessons and which are an important (although not the only and maybe not even the best) part of the learners' linguistic environment.

I filmed everyday mathematics lessons in two German classes of second grade for several weeks. The data contains both one unit about arithmetic (orientation on the hundred field) and one unit about geometry (characteristics of geometrical bodies). In all cases, I filmed the whole lesson and decided afterwards which scenes might be interesting with regard to my research aim. Those scenes were transcribed and became objects of analyses. In the process of selecting scenes, analysing them and describing the results, I revised the selection of scenes several times.

To get access to occurring negotiation processes in mathematics classrooms my analyses have to be of a reconstructive manner. Thus, they are analyses of interaction (see Cobb & Bauersfeld, 1995). This method refers to the interactional theory of learning, is based on ethnomethodological conversation analysis (see Sacks, 1996), and was devised by a working group directed by Bauersfeld. This method is especially suitable for my research focus because it is aimed at the thematic development of a given face-to-face interaction and allows to integrate both perspectives: the mathematical and the linguistic one.

EMPIRICAL EXAMPLES

To illustrate my results, I have selected two short scenes from the different learning groups. These examples allow reconstruct different types of linguistic norms, although they are very similar concerning the content. In both cases, the teacher and the students deal with the hundred field. According to the teachers who usually plan their mathematics lessons together, the goal of those lessons is the orientation on the hundred field. The students should find numbers quickly and describe their positions exactly. From other lessons, the students know already what rows and columns are. For that reason, both teachers start their lessons with a repetition.

1	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	23	24	25	26	27	28	29	30
31	32	33	34	35	36	37	38	39	40
41	42	43	44	45	46	47	48	49	50
51	52	53	54	55	56	57	58	59	60
61	62	63	64	65	66	67	68	69	70
71	72	73	74	75	76	77	78	79	80
81	82	83	84	85	86	87	88	89	90
91	92	93	94	95	96	97	98	99	100

Figure 1: Diagram of the hundred field

Example I: Ozan's number puzzle

At the beginning, the teacher, Ms. Kunz, and the students talk about rows and columns on the hundred field. They repeat that rows "go from left to right" and that columns "go from top to bottom". After that, Ms. Kunz starts to give number puzzles of the following form: "The number is in the third row and in the fifth column." When having given a puzzle, Ms. Kunz always asks one child to solve it. The following scene starts when the course of action changes. Now, one student is allowed to give a number puzzle on his/her own. It is Ozan, a young boy with a Turkish migration background.

47 Ozan: The number is in the fourth column and... in the third r-
48 Ms. Kunz: No, first the *row*.
49 Ozan Err... The number is in the third row and in the fourth column.
50 Ms. Kunz: Okay. Choose a child, Ozan.

If we assume that Ozan would have finished his number puzzle by saying "row", we can state that he has given a correct number puzzle (47). With respect to the content and the language, he has formed an appropriate sentence. However, he deviates from those examples that Ms. Kunz has given before. The difference is that he refers to the column first and then to the row, not vice versa. Ms. Kunz insists on her order and therefore on a specific sentence structure (48). The structure that she demands cannot be derived from general object-level rules or general meta-discursive rules. Instead, she starts to establish a new norm that only applies for this specific learning group. In his following turn, Ozan accepts the proposed norm. He restructures his number puzzle according to Ms. Kunz' example without change of content (49). He describes the position of the 24 again. Thus, in this example, it is evident that the linguistic norm which Ozan and Ms. Kunz establish does not focus on the mathematical content at all, but on the grammar. The interlocutors develop their own grammar for number puzzles which can be described as follows: When giving a number puzzle with regard to the hundred field, you have to refer to the row first and to the column thereafter. Ms. Kunz confirms that norm explicitly in the end: "Okay." (50) Finally, by asking Ozan to choose a child that may solve his puzzle, she leads back to the course of the discourse. The negotiation of the linguistic norm has come to an end.

In this process of negotiation, we can see that the teacher's language use is conceptually oral. Thus, Ms. Kunz forms an incomplete sentence in order to ask Ozan for a correction (48). That makes her utterance short and allows a rapid progression of the discourse. This kind of language use is typical for face-to-face interactions in our everyday life (see Koch & Oesterreicher, 1985). When looking at Ozan's language use in comparison, we can note that his utterances are rather conceptually written. He is asked to form a complete sentence with a given subject ("the number") and with two indications of location that should be linked by an "and". Thus, his sentence is rather complex and more explicit.

An interesting point about the reconstructed norm is its potential influence on the content level. On closer inspection, Ozan and Ms. Kunz establish a linguistic norm that might be relevant to mathematical learning processes. When you always name the row first, you allow an early and quick estimation of the size of the specified number. Thus, the row indicates the ten, the columns indicates the one. So when you know in which row the number is, you know approximately how big the number is. From that example, we can see that linguistic norms can create (or constrain) mathematical learning opportunities.

Example II: Zeynep's number puzzle

The second scene is taken from the corresponding lesson in the other learning group. The initial situation is quite similar. Ms. Yilmaz and her students talk about rows and columns and repeat that rows "go from left to right or from right to left" and that columns "go from top to bottom or from bottom to top". Thus, there is a small difference in defining the row and the column compared to Ms. Kunz' class. While Ms. Kunz and her students only mention one direction, Ms. Yilmaz draws attention to two possible directions in each case. After that, Ms. Yilmaz also starts to give number puzzles: "My number is in the sixth row and in the second column." Then, she always asks one child to solve the puzzle. In the following scene, Zeynep, a young girl with a Turkish migration background, is the first student who is allowed to give her own number puzzle.

16	Zeynep:	In the ninth colow-
		[In German, Zeynep says "Speile" which is a mixture of the two words "Spalte" (column) and "Zeile" (row). Accordingly, "colow" should be a mixture of the two words "colums" and "row".]
17	Ms. Yilmaz:	Err, either column or row.
18	Zeynep:	*Row*. Row nine and column four.
19	Ms. Yilmaz:	Yes, *good*. We can also say it like that, like Zeynep has done it. Who
20		can *say* to Zeynep now, which number is in the *fourth* column and in
21		the *ninth* row?

While giving a number puzzle to her class, Zeynep uses a word that does not exist in German (16). But it is easy to recognize its components. It is a hybrid of the German words for column and row. For that reason, one cannot decide whether Zeynep is talking about the ninth column or about the ninth row. Ms. Yilmaz interrupts her, shows a little bit of irritation by hesitating ("err") and asks Zeynep for a decision: column or row (17). In the following, Zeynep seems to be quite clear about that point and stresses her answer: "*Row.*" (18) Then, she gives her number puzzle in a new form: "Row nine and column four." In contrast to her first try (16), she does not use ordinal numbers any longer to appoint a specific column or row. Instead, she uses the numerals like names which do not necessarily have a mathematical meaning. Ms. Yilmaz accepts and values this new way of formulating a number puzzle and leads back to the course of interaction. She asks the class who can solve Zeynep's puzzle (19–21). In this short scene, Zeynep and Ms. Yilmaz establish a norm for the formulation of a number puzzle. From now on, it seems to be allowed to waive ordinal numbers and to choose from different linguistic possibilities. What remains the same through these different linguistic forms is the content. Zeynep and Ms. Yilmaz describe exactly the same position on the hundred field by their different sentences; they are both talking about the number 84. Thus, we can see that the linguistic norm which Zeynep and Ms. Yilmaz establish rather focuses on the function of language. They do not seem to be interested in a specific form of language, but in a precise description of a position.

In that process of negotiation, Zeynep's language is essentially characterized by orality. She uses mathematical terms (row, column), but does not form any complete sentence. Instead, her utterances are rather short and understandable in the context of that specific situation. In contrast, Ms. Yilmaz uses different registers. Parts of her language are conceptually oral, too. When pointing to Zeynep's word mistake, she forms an incomplete sentence, reduced to the necessary (17). Like in the scene before, that makes the utterance short and allows a rapid progression. But in the end, when Zeynep has given a correct number puzzle, Ms. Yilmaz offers a grammatically complete sentence (19–21). That way, Zeynep and all the other students who listen to the discourse can learn two different versions of number puzzles, one is conceptually oral (Zeynep) and the other one is conceptually written (Ms. Yilmaz). As both versions are valued, the learners are obviously free to choose one of them.

By negotiating the reconstructed norm, Zeynep and Ms. Yilmaz do not only touch a matter of language, but a matter of content, too. When a student who listens to the discourse recognizes that there are different ways of formulating a number puzzle, he may ask himself what the invariant through the different forms of representation might be and, thereby, he gets to a mathematically interesting question: What is necessary to describe a position on the hundred field clearly? Thus, one can see again that linguistic norms refer to the content level and cannot be separated from them.

CONCLUSION

The two examples do not only allow me to reconstruct two different linguistic norms, but two different types of such norms as well. Thus, they focus on different aspects of language. In both cases the interlocutors negotiate how one might talk about mathematics, in this specific case about a position on the hundred field. In the first example, the focus is on the form of language.

Thus, everyone is asked to always refer to the row first and to the column second. One could say that the interlocutors establish their own kind of grammar for number puzzles. In the second example, the focus is on the function of language. While the interlocutors obviously accept different linguistic forms of giving a number puzzle, they check whether an utterance fulfills its function: "We can also say it like that." (19)

When reconstructing these different types of linguistic norms, one can note that the belonging processes of negotiation are linked to different language registers. Thus, the negotiation of linguistic norms which are orientated to the structure or form of language rather need a conceptually written language (Example I). This assumption seems plausible because it is necessary that someone produces the whole linguistic form when you want to talk about it. Only then, it is clear what the topic of the discourse is. In situations like that, short clues or incomplete sentences might not be enough. In contrast, the negotiation of linguistic norms which are orientated to the function of language does not necessarily need a specific register (Example II). According to the situation, both a conceptually oral and a conceptually written language obviously might meet the given requirements. One can assume that the use of a certain register depends on the mathematical content. Thus, difficult mathematical contents possibly require a more written conception of language so that complex relations and processes can be described accurately, whereas rather simple contents might be expressed in a conceptually oral language, too.

Embedding the two empirical examples in the wider field of my data, it can be stated that it is not possible to assign one linguistic norm to one learning group. Instead, both types of norms can be observed in both classes from time to time. But when students and teachers negotiate how to speak about mathematics, there is a clear emphasis on one of the two types of norms. Obviously, it is not helpful or even possible to negotiate the form and the function of language at the same time. Furthermore, the differentiation between these two types of linguistic norms in mathematics classrooms can help us to be clear about the learning goals that we have as teachers and also to be clear about the perspective that we have as researchers. First, as a mathematics teacher, we cannot support the language development of our students in all respects at any time. Instead, we can decide where to put the focus on, so that we can offer situationally suitable exercises and materials to our students. While we work on some kind of grammar in one lesson, it might be more important to work on the function of language (e.g., a precise description, a convincing argumentation) in another lesson. And of course, there are lessons where our focus is not on the language at all. Second, as researchers, we possibly like to know more about the language development of learners in mathematics classrooms, about good materials and learning arrangements that help teachers to support their students' language development, but we should distinguish what the main focus is in each case. Depending on the linguistic norms which are established in a certain mathematics lesson at a certain time, the interlocutors have different needs of support and we might see fundamentally different ways of using language.

The two examples show that linguistic norms are related to the content level. By defining norms for their language use, interlocutors define their medium for teaching and learning. Thereby, they create or constrain learning opportunities. We can conclude that Sfard's (2008) distinction between object-level rules and meta-discursive rules is an analytic one. We can distinguish between the content and the language when we look at everyday interactions as researchers, but in the classroom, these levels always belong together and might interact with each other.

Reconstruction of teachers' professional vision concerning important aspects of classroom interaction

Anna-Marietha Vogler

TU Dortmund University, Dortmund, Germany, anna.vogler@math.uni-dortmund.de

Participation in classroom interactions gives students the opportunity to learn subject-specific topics and to acquire discourse competences. Hence, there is a multitude of research concerning arrangements which enable learners to successfully participate. But what counts as an adequate contribution, enabling students to successfully participate in mathematical classroom interactions and, especially, what counts from the teachers' perspective? Based on the fact that the teachers' perspective on adequacy of considerations in interactions highly influences the teachers' acting and support in the classroom, the study INTERPASS investigates the teachers' perspective within video stimulated group discussions. One of the identified motives of the teachers' perspectives is presented in detail in the following.

Keywords: Group discussion, professional vision, participation in classroom interactions, documentary method.

INTRODUCTION

Acquisition of mathematical knowledge takes place in classroom interactions and through the opportunity to participate in the process of negotiation of meaning involved (Cobb & Yackel, 1998; Sfard, 2008). To be able to participate, content-specific comprehension and linguistic abilities of students as well as the teachers' efficiency in producing interactive scopes for participation are important.

On the one hand, based on a constructivist interactionist view, a lot of research has been done to empirically examine different aspects of influence on opportunities to participate by analysing classroom interactions. On the other hand, teacher education programmes have been created to establish eligible acting repertoires of teachers to foster interactive support. The so-called 'mistake-handling' concerning students' contributions thereby plays an important role in creating these programmes (Heinze, 2005). Two examples of professional demands on teachers on the basis of these acting repertoires are (1) to provide explicit feedback on the adequacy of students' contributions and (2) to form discursive competences. But, also ideas of students should be embedded in the interactive process in the mathematics classroom to foster participation. More or less successful teaching experiments often serve as examples of the implementation of professional demands into classroom interactions. This form of training is mostly based on the idea that one prototypical conceptual situation can be established in the classroom situation. Hence, most of the time the perspective of protagonists on such more or less supportive interactions was not conceptually considered in detail and realisation in every day classroom failed (Prediger, Quasthoff, Vogler, & Heller, 2015).

Furthermore, Sherin (2007) describes that the teachers' perspective and especially their conceptions and perceptions concerning linguistic and content-specific aspects of classroom interactions are strongly related to the way they give support. Thus, the teachers' expectations of students' contributions provide an insight into the teacher's supportive behaviour and their way of establishing opportunities to participate. But what counts as an adequate contribution for teachers in mathematics? What do teachers define as aspects of successful classroom interactions?

To answer these questions I will draw upon the constructs 'selective intention' and 'knowledge-based reasoning' developed by Sherin (2007) to investigate conceptions and perceptions of teachers empirically.

In this paper, I therefore analyse thematic motives of negotiation processes within video-stimulated group discussions of teachers. Here, Sherin's approach allows me to focus on recurrent motives of teachers concerning supportive or non-supportive interactions shown in the videos. What kind of linguistic, content-specific and interactive aspects of the shown classroom situations do they partake? Pursuant to the analysis, possible insights into the teachers' perspective on what counts as a successful interaction are delivered. Furthermore, corresponding to the presented empirical data I present one of the major negotiation themes and pick up the question, whether there are differences amongst the eligible repertoires of action between interactionally relieved or stressed teachers.

PARTICIPATION IN CLASSROOM INTERACTIONS

The theoretical principle for the following explanation is a constructivist view on learning as considered in cultural historical elaborations by Sfard (2008) and interactionist articles referring to approaches of Cobb and Bauersfeld (1995).

Participation in mathematics classroom interaction gives students the opportunity to learn linguistic, content-specific and interactive aspects of the discourse. However, to participate in these interactions puts great demands on students, because negotiation processes of mathematical meaning have their own alternating dynamic (Krummheuer 2011). To participate in classroom interaction, students have to interpret what topic is negotiated as well as how and when an adequate contribution can be presented. Thereby, mathematical meanings and linguistic demands of the discourse can be perceived and interpreted differently by all participants, students and teachers, depending on their definitions of the situation. Students' ability to comprehend the ongoing interactive process and its demands as well as the competence to produce matching contributions within the classroom interplay are important for participating and thus for learning. If students are not able to produce these matches, they can be excluded from the classroom discussion over time (Jablonka & Gellert, 2011). But who decides and controls what counts as an adequate contribution? Different studies have shown that in most classroom interactions the teacher is central to this controlling process (Lee, 2007). "Teachers' verbal utterances trigger, encourage, discourage, 'delete' students' verbal contributions and allocate evaluations accordingly" (Prediger et al., in press). These evaluations and feedbacks give accessory advice for expectations concerning content-related conceptions and conventions that are substantial for the specific discourse (O'Connor & Michaels, 1993). However, research on classroom interaction shows that mostly the 'rescuing' of an interactive fluency or a communicative order is more relevant than progress in the development of content-related aspects of the communication (for description of the characteristic funnel pattern: Bauersfeld, 1995). The phenomenon is justified by the assumption that teachers, stressed by the pressure to act in time in classroom interaction (henceforth: 'interactionally stressed teachers'), have to react on students' considerations in time and have to spontaneously manage the negotiation of meaning towards the content-related goals of learning and the communicative order within the polyadic interaction. The way in which teachers take up learners' contributions is crucial for their opportunity to participate in classroom interaction and to learn both mathematical and discursive competences.

TEACHERS' PROFESSIONAL VISIONS

A lot of classroom studies have described how the support of teachers enables students to participate, and what kind of support is particularly conducive for learning and participation. Some of the studies also give advice on how to fulfil certain conditions to help students to participate. Nevertheless, teachers' enacted strategies often do not match these demands in spite of different professional development programmes. An explanation of the mismatch between requested acting repertoires of teachers and everyday classroom interactions (of course) could be the pressure affecting teachers to act in time. Anyhow, there is a lack of comprehensive teachers' perspective regarding considerations about the improvement of classroom support. Relating to this, Sherin (2007) pointed out that every teacher has a professional vision, meaning the way she or he makes sense of issues happening in the classroom and that is shared in the professional community of teachers. This professional vision influences the way teacher act and also support in the classroom. For teacher training programmes it is necessary to conceptually comprise these perspectives of teachers and to improve the teacher trainings. But how can the teachers' professional visions towards the support in classroom interactions be observed?

To this end Sherin (2007) reconstructed the teachers' professional visions on classroom interactions in so-called 'video clubs' over time. She proposes to distinguish analytically between the process of 'selective attention' (of aspects from classroom interactions) and 'knowledge-based reasoning' wherein teachers link their perceptions with own experiences and knowledge. Especially the selective attention is taken into account in this paper to reconstruct recurrent motives of teachers in such discussions. These motives represent specific pattern of perception, evaluation, and interpretation. Hence, through these motives it should be possible to draw conclusions from the teachers' active repertoires of acting that are characteristic for them. Concerning the selective attention, Sherin (2007) observes that in the first meetings of the video clubs, when all participants were stimulated by videos for the first time, teachers exclusively focused on pedagogical aspects of the contributions of the other teacher. The students' acting was for the first time mentioned in the third meeting. Therefore, I will also pick up in details the process of knowledge-based reasoning in the exemplary analysis.

RESEARCH DESIGN AND EMPIRICAL DATA

The study presented in this paper is part of the larger project *INTERPASS*, an interdisciplinary study of linguists and mathematics educators, being led by Uta Quasthoff and Susanne Prediger at TU Dortmund University. The study combines a classroom video study and group discussions of mathematics and German teachers while they are relieved from any pressure of classroom action. Within the classroom video study 10x12 mathematics and language lessons (each 45–60 min.) in five grade five classes were recorded during the first inquiry. By means of comprehensive sequential analysis five sequences were selected for the group discussions.

The following three comparative categories were selected: 'lessons of mathematics and German', 'matches and divergences in micro-cultural practice' and 'German native speakers and speakers of German as a second language'. Also, only sequences showing emergences of subject-specific matches and divergences, i.e. sequences containing the formerly introduced structure and are therefore particularly substantial for the process of socialization in the discourse, were selected. The group discussions are based on video presentations of different sequences of interaction lasting an average of two minutes. To create the possibility of a detailed discussion based on the video data, the sequences were additionally transliterated and shown at the end of each unit of interaction via beamer. This paper focuses on group discussions with teachers. Four discussions with five to ten teachers, each lasting 1.5–2.5 hours, were recorded. The group discussions, based on this paradigmatic analysis, were held with German and mathematics teachers at different German secondary schools (Gymnasien). Each group only met once. After a short introductory round, the teachers were asked to observe a video of a short interactive sequence and to comment on it. This was the only impulse for the group discussions.

METHODICAL APPROACH FOR DATA ANALYSIS

The focus of analysis is exclusively limited to video clips from mathematics classrooms. In order to analyse the teachers' selective attention, parts of coherent negotiation processes concerning thematic motives of the teachers within the group discussion were identified. According to this, there is a short overview over all relevant categories of motives the teachers mentioned in their discussion. To select these parts of the group discussion, the methodical approach of the documentary method of Bohnsack (2009) is applied. The first step of this analysis is to organise the transcribed video material in interactional units, which are interpretatively described in categories. These categories are developed with respect to the content interpreted from the ongoing process of negotiation within the group discussion. Based on the sequential interpretation of 'turns' within these interactional units the negotiation of meaning, respectively the thematic development, is reconstructed. Therefore, (1) the categories describe the topics of all negotiated taken-as-shared themes, respectively all motives of the teachers. After the development of these *descriptive* (sub-) categories they are (2) summed up to the following seven main categories from the discussion of the teachers: participation aspects, acting and turn aspects, classroom management, teaching aspects, social aspects, aspects of professional identity, and subject specific aspects.

In the following sections, I will summarise aspects from the categorisation and present a detailed interpretation of a scene that is exemplary for two topics discussed, delivering first insight into teachers' motives.

ANALYSES OF TEACHERS' PROFESSIONAL VISIONS

A discussion between five teachers is analysed: two German teachers (Mrs. Nachbar, Mrs. Fuchs-Focke) and three mathematics teachers (Mr. Neumann, Mrs. Jacobi, and Mr. Klein) from different German Gymnasiums in urban areas. Background for the discussion in the following scene is the video "Explaining the procedure of rounding" from a mathematics classroom interaction on how to round 63 to 60 (see Prediger & Erath, 2014, for a more extensive transcript and analysis of the episode), wherein one teacher (Mr. Maler), a male student (Kostas) and a female student (Katja) in grade five interact. After the teacher had asked for a solution of rounding 63 to the nearest tens, the boy Kostas answered: "And then ... when you ... take away three and write down a zero, well ... you could do it now but actually it is wrong, you have to round down and wr ... write down the number closer to zero". Kostas describes the rounding rule based on the basic concept of geometrical representation of proximity and distance for a particular tenner on the number line by his answer. Thereby he marked that rounding is not only changing the last number to zero, but even more: one has to identify whether the last number is closer to the previous or subsequent tenner. But also Katja gives a solution: "You round down with zero, one, two, three, four and with five, six, seven, eight, nine, you, ... you round up". She termed the mathematical concept. While the teacher Mr. Maler does not evaluate Kostas' utterances positively, he comments on Katja's considerations with the phrase "Did everybody get that?"

In the group discussion presented below, the two mathematics teachers Mr. Neumann and Mr. Klein discuss the explanation of Kostas. Flashpoint for the discussion was the difference between the reaction of the teacher to Kostas' and Katja's contributions. Mr. Klein pointed out that Katja gave a "perfectly clear" answer.

1 Mr. Klein: Well, he did not1 name the rule. She has defined exactly...
2 What happens with each digit? When? This actually is the criterion.
3 When to round up or down he said eventually in the last sentence?
4 Closer number to zero. Well, he probably meant...
5 Because sixty-three is closer to sixty? Could you now...
6 This is highly interpreted. But...
7 Mr. Neumann: Yes sixty. Or seventy. Right?
8 Mr. Klein: Yes sixty or...
9 Mr. Neumann: The question is...
10 Why does he always have the same seventy...
11 Because sixty is the closer number.
12 Mr. Klein: That is a bit the... What is behind? Without being just the dull rule?
13 But that is difficult already! Also, to understand something at this
14 sound level. What he meant and...it was not really phrased clearly.
15 But...
16 Mr. Neumann: Now it is too... Because the five solution is not there.
17 That is important.
18 Mr. Klein: Well, anyways it was not clear.
19 Because he was not even counting the digits...
20 Mr. Neumann: Yes. Closer number to zero.
21 Mr. Klein: Logically... You can say...
22 Mr Neumann: It is certainly more general now he has to well count the
23 numbers, right?
24 Mr. Klein: Yes, exactly.
25 Mr. Neumann: That is already...
26 There is already an achievement.
27 Mr. Klein: Well, probably he tried to think it through!
28 Without possible understanding... Maybe ...
29 Mr. Neumann: But he has not phrased it by a rule, right?
30 Well, that is what is missing... and that is...
31 Mr. Klein: Exactly!
32 Mr. Neumann: But basically they hear....
33 And Kostas has not given it to him.
34 Mrs. Now it is named...
35 Fuchs-Focke: Wonderful.

ASPECTS OF THE RECONSTRUCTION OF THE INTERACTION PROCESS

Acting and turn aspects (with emphasis on students' concepts)

After 30 minutes of discussion, the teachers explicitly deal with the content of Kostas' solution for the first time. At this point of time, the presented sequence starts. Mr. Klein describes the central idea of the geometrical representation (proximity and distance on the mental number line) on which Kostas' answer is based for the first time (line 4–5). Mr. Klein and Mr. Neumann both highlight several positive aspects of Kostas' solution concerning his mental number line. These aspects are: creativity ("without being just the dull rule" – line 12), universal validity ("it is certainly general" – line 22) and cognitive performance of finding a solution ("There is already an achievement. Well, probably he tried to think it through!" – line 26–27). But also Katja's answer to the teacher's question is regarded to be sophisticated. Mrs. Fuchs-Focke gives a particularly positive evaluation of Katja's contribution in the last sentence (line 34–35), when she refers to Katja terming the rule discussed in the previous scene. Also Mr. Klein refers to this answer as "defined exactly" in his first sentence (line 1). The descriptive (sub-)category in this interactional unit can be summed up as 'rating of students' contributions within classroom discussion'. Thus, the category for the analysed sequence is marked as 'acting and turn aspects'.

Teaching aspects

Already in previous scenes, not being covered in this paper, the aspects of the teacher's acting concerning the didactical goal of the lesson are very prominent. The five teachers broadly discuss Mr. Maler's goal of the lesson and his methods to reach this goal. During the presented interaction several aspects of the students' utterances are named. The teacher Mr. Klein refers to the missing match between initiation of the teacher and Kostas' answer: Kostas does not phrase a rule (which is demanded by the teacher) (line 29–30). Also Mr. Neumann agrees with this negative evaluation of Kostas' answer (line 31). He names the high degree of the implicitness of Kostas' solution as reason for the teacher's evaluation (line 13–14). Although the student's contribution is evaluated positively towards aspects of subject-specific content, both teachers put the quality of the contents of the students' statements in another perspective as it is not matching the interpreted goals of Mr. Maler. In this case, the loudness within the classroom (as a additional context caused problem) (line 14), the absence of a solving strategy in case of the five (as a content regarding problem) (line 16) and the lack of comprehension are identified as a communicative problem of the student's statement, letting the rejection of Kostas' statement seem to be 'reasonable'. The subcategory that is found here is described by the phrase: 'description and rating of teachers' acting concerning didactical goals of the lesson'. Concerning the utterances of Kostas, the teachers share the opinion that it is legitimate to reject the solution because of a mismatch regarding the didactical goals of the teacher Mr. Maler. They agree that a rule is required to complete the lesson's goal Therefore, the category 'teaching aspects" can be summed up.

Acting and turn aspects (with emphasis on comparison of students' contributions)

Mr. Neumann's contributions at the end of the scene completed the process of comparing both students' utterances and the teacher's reaction to them (line 29–30 and 33). All three teachers agree on the crucial reason for Mr. Maler to reject Kostas' statement in the process of classroom interaction. The absence of a rule description is more important than the high quality of Kostas' described concept. They argue for the rejection of Kostas' contribution with his lack of linguistic standard. Mr. Klein, for example, points out that Kostas' solution is not phrased clearly (line 14). The teachers discuss that Katja's rule is the appropriate answer to the given task of justifying the solution 60. Furthermore, the way she presents it can be seen as a socially accepted practice of the rounding rule. In line with that, Kostas' solution is not accepted because his answer does not fit into the interactive fluency to reach the goal of the lesson. Therefore, the rejection of Kostas' solution is legitimated several times by the teachers referring to Mr. Maler's need to reach educational goals. The high degree of implicitness of the rejection Mr. Maler shows in the video is not mentioned within this short discussion. But while Mr. Neumann interprets Mr. Maler's rejection another time, he positively remarks that the teacher avoids face-threatening reactions towards Kostas. Besides the negotiation about the contributions of the students Katja and Kostas, also the comparison of both students' considerations result in the category for the analysed sequence as "acting and turning aspects". The interactive process is not mentioned in the presented sequence.

Reconstructed professional visions

The reconstructed aspects of the discussion process show that two major motives of teachers' selective attention can be identified: namely (1) keeping track of teachers' goals (Prediger et al., in press) and (2) rating of students' considerations. Concerning the first motive, the group-discussion teachers interpret easily that the favoured reaction of Mr. Maler is to give just positive evaluation on contributions that match lesson goals (for details, see Prediger & Erath, 2014). For these teachers the alignment of feedback with goals of lessons is a natural process of classroom interaction as well as legitimation for reaching educational goals. In comparison to the reactions given by the discussion group towards the different contributions of Katja and Kostas, it can be assumed that the saving of the fluency of the interactional process in classroom interplay is one of the major demands. Both Katja's and Kostas' utterances could be the starting point to develop a description for the rule for rounding. Nevertheless, the teacher only pays little attention to Kostas' solution, even though it is possible to evolve the rounding rule by his geometrical approach. The problem for students to achieve a high degree of discourse competence to manage the demands of an accepted participation in mathematical classroom is not mentioned within the discussion. These findings are confirmed by other scenes and through the clusters of recurrent combinations of (sub-) categories. Hence, aspects of legitimation are mostly motives that are mentioned while teachers discuss methodical aspects.

CONCLUSION

With this short insight into a complex group discussion it becomes evident that some non-supportive findings from classroom studies, like the implicitness of demands for presentation and content, are also judged as adequate from the teachers' perspective. However, there is a gap between the normative professional demands, which result from research on classroom interactions, and the professional visions of teachers (for details, see Prediger et al., in press). Especially motive (1) is of particular importance for teachers. While the teachers discuss pedagogical motives in detail, the content specific quality of students' utterances is picked up for the first time after 30 minutes of the discussion. This phenomenon could also be confirmed (with few exceptions) in other reconstructions of interaction units in different group discussions. These findings confirm results from Sherin (2007). Participants from Sherin's research as well as the teachers in our first video-stimulated group discussion of classroom interaction focus on the pedagogical behaviour of the videotaped teacher. In future, these qualitative findings shall be triangulated by quantitative analyses of the categories of the interaction units.

Despite the presented motives of the discussion group, it is remarkable that there is no stress on the interactive process and the negotiation of mathematical meaning. Considerations of the students' statements are only given in form of their matching with regard to the didactic ambitions of the teacher. From that perspective, the *interactionist* demand for support, enabling students to participate in classroom interactions, can be seen as contrary to the motives reconstructed here. Therefore, the process of negotiation of meaning, giving particular attention to learners' ideas, is opposed to the focus of keeping track of the teachers' goals. Also, the lack of Mr. Maler's acting to not provide explicit feedback on the adequacy of the contribution is not mentioned in our discussion group. Although the feedback is an important turn within the structure of the process of the negotiation of meaning, it seems to be adequate to the teachers that this turn is absent in the case of the interaction between Kostas and Mr. Maler.

Comparing the results from this illustrated analysis with reconstructions from research in classroom interactions, one can assume that also *interactionally relieved* teachers prioritise actions that are contradictory to normative professional demands. This is an unexpected result for research on group discussions. One consequence of this finding is to adjust approaches of teacher training programmes. Hence, the teachers' perspective on classroom interactions and supportive situations should be integrated into the process of forming professional demands and eligible acting repertoires. The inclusion of empirically based approaches concerning teachers' motives makes it thus possible to mention also meaningful motives of teachers instead of substituting them through the idea of one prototypical conceptual situation or new techniques.

ACKNOWLEDGEMENT

The research project INTERPASS ("Interactive procedures of establishing matches and divergences for linguistic and micro-cultural practices") is funded by the German ministry BMBF (grant 01JC1112) under the guidance of Susanne Prediger and Uta Quasthoff. I thank them, Kirstin Erath and Vivien Heller for the collaboration.

Students’ language repertoires for prediction

David Wagner, Joseph Dicks and Paula Kristmanson

University of New Brunswick, Fredericton, Canada, dwagner@unb.ca

For communication about prediction (both relating to probability and to conjecture), language is by nature recursive – language is an indicator of meaning as well as a force that shapes meaning. We describe how this recursive nature of language impacted the choices we made in a cross-sectional longitudinal study aimed at gaining insight into children’s language repertoires relating to conjecture. We then use some of the data from the project to identify issues relating to interpreting data in such a context. Finally, we raise questions about implications for educators.

Keywords: Language, mathematics education, prediction, conjecture.

INTRODUCTION

The understanding of possibility, risk, and certainty, like the understanding of any mathematics, is mediated by language. Certain language repertoires are necessary to convey the ideas. At the same time, the language used to describe risk shapes the way people conceptualize it. This recursive nature of language compelled us to develop a research project to investigate children’s language repertoires in relation to conjecture. Having noted similarities in the language of conjecture and of prediction, we structured classroom and interview prompts to encourage students to make predictions and we talked with them about the meaning of the things they said. In this paper, we focus on research choices in relation to this endeavour. First, we describe choices we made to gain insight into children’s language repertoires. Second, we use some data from the project to identify issues relating to interpreting data in the characteristically mathematical contexts of conjecture and prediction.

Moving beyond our academic interest in mathematics education, we will argue that the issues we identify may be significant for understanding everyday experience. In particular, we will raise questions about the impact of mathematics class experiences with uncertainty. We will also raise questions about the impact of intertextuality between uniquely mathematical ways of communicating about conjecture and everyday ways of interacting about authority.

COMMUNICATING ABOUT UNCERTAINTY

The investigation of conjectures (hypotheses) is one of the most important mathematical processes. Much mathematics teaching focuses on enabling students to perform particular mathematical procedures, such as adding fractions, factoring polynomials, and calculating probability. These skills appear as standards in curriculum documents and frameworks (e.g., CCSSO, 2010) that are used by curriculum planners and teachers. Research and professional literature, including curricula (e.g., New Brunswick Department of Education, 2010) and curriculum frameworks, point to the necessity of students learning these intended outcomes through the exploration of mathematical problems.

When people explore a mathematical problem together, as with mathematical investigations in classrooms, it is necessary to have a way of suggesting an idea before knowing it is true. Rowland (2000) noted the centrality of such conjecture to mathematics, and coined this “space between what we believe and what we are willing to assert” (p. 142) as the Zone of Conjectural Neutrality (ZCN). Because of the recursive relationship between language and experience, the language resources available affect the possibilities for making conjectures.

Our theoretical perspective for this research draws on the work of Vygotsky and Wertsch related to the connections between thought and language, and, in particular, the central role that language as social interaction plays in the process of learning. Nevertheless, we have found it a challenge to avoid deficit framing because of the shaping force of one’s language repertoire. Deficit framing suggests that one's own way of speaking or thinking is superior by evaluating whether or not others have acquired the same skills. In the study of linguistic variation for numbers, the one area of mathematics register variation that has been documented significantly, Swetz (2009) pointed out how cultures have been rated on the extent of their number systems. In our research we are more interested in the potential for linguistic variation to open up opportunities to understand mathematics differently – for example, how does thinking of numbers as verbs (e.g., Lunney Borden, 2010) change one's conception of counting and arithmetic operations? In our case, how does linguistic variation express itself in relation to understanding probability? Because linguistic variation in mathematics (besides the area of number) has not been researched significantly, the discussion requires careful research to move forward.

Our focus in the article is on participants' repertoires for expressing modality. Modality refers to linguistic tools for expressing degrees of certainty, for example the use of modal verbs like *must* and *could*. "It must be six" is stronger, and thus has higher modality than "It could be six." Some modal verbs—e.g., 'can'—are ambiguous. "You can be excused from the table" indicates a degree of obligation; "You can finish the race" indicates ability; "I can help you" indicates inclination; and "It can be a six (because one of the remaining cards in the deck is a six)" indicates probability. When students hear the word *can*, what does it mean to them?

In an example of research that may appear deficit framed, Shaffer (2006) explained how deaf children with hearing parents did not develop what she called "The Theory of Mind" because of the absence of modality in their vocabulary. Theory of Mind relates to the understanding that different points of view are possible. Linguists Martin and Rose (2005) described the effects of modality (sometimes called 'modulation') this way: "it opens up a space for negotiation, in which different points of view can circulate around an issue" (p. 50) – a description that bears close resemblance to Rowland's ZCN. Shaffer reported that once the children developed vocabulary for modality (in American Sign Language) it became clear that these tools facilitated their quick development of this Theory of Mind.

We are especially interested in the way children use language to express modality in mathematics contexts (and beyond) because modality is important in conjecture (Rowland, 2000), to describe uncertainty, and to understand other points of view (Shaffer, 2006). In our research, we did not aim to look for holes in children's language repertoires. Rather, we focused on attending to the ways they talked about their understanding, to help us see a range of ways to talk about and understand conjecture and uncertainty.

METHODOLOGICAL CHOICES

The data for our cross-sectional longitudinal study comprise audio- and video-recordings from English-medium and French Immersion instructional contexts in an Anglophone region in Canada. Students worked in groups in class and were subsequently interviewed, extending the group work. At the end of the interviews we asked students about the meaning of words they used to describe degrees of certainty.

For each mathematical context we tried to avoid using specialized mathematical language ourselves. We know from second language acquisition literature that learners are generally good at noticing and, subsequently, using the language used in interactions with more able speakers (Long, 1996). We wanted to hear what language skills the children in our research used to communicate their ideas without setting them up with the specialist language to build on. As we struggled to construct problems without use of specialist language, we found that larger narrative contexts made this possible. Other strategies we considered became grammatically awkward. These narratives also made the problems accessible to very young children, perhaps partially because of the lack of specialty language, but mostly, we think, because they connect to children's experience. In addition to embedding our questions in a narrative context, we attempted to avoid specialized uncertainty language when we interviewed participants about their predictions in contexts based on uncertainty. We agreed it would be acceptable to use a language strategy after the participant did, but not before. This proved very difficult; indeed, in the interviews we often used words we intended to avoid, and sometimes used incorrect or awkward structures in attempts to avoid this. After completing most of the first year's classroom and interview interactions, we agreed amongst our team that we should be less paranoid about avoiding specialty language, but knew that this issue would plague interpretation of the data (from before and after our decision to loosen up.)

The first year's participants were in Grades 3, 6, and 9. We had them play a modified version of skunk, which is a game often used in the teaching of probability (e.g., Brutlag, 1994; Neller & Presser, 2004). We had them play in pairs so that they would be more likely to talk with each other about their ideas and strategies. We introduced the game with a narrative like this, varying slightly between contexts because we did not script the narrative: "I was picking strawberries in the forest. After a while, when my basket was quite full, a skunk wandered into the berry patch. I ran away so the skunk would not spray me. I lost the berries in my basket when I ran off." (This narrative also gave a reason for calling the game *skunk*.) Participants had a pile of beans (representing the berries), a cup (the basket), and a bowl (home). When the researcher rolled the die and called out the number, participants put that number of berries in their basket. A six represented the skunk. When it was rolled, everyone would lose the berries in their baskets. On the other hand, if they "went home" (dumping their beans into their bowl) before the appearance of the skunk, their berries were safe. We played seven rounds – one berry-picking expedition for each day of the week. We played the game with participants in their classrooms first. The following day we interviewed groups of students and played again but with six cards bearing the numbers one to six instead of the die. The interviewer would not replace the cards into the deck until the deck was completely played out, at which time it would be reshuffled. Thus the participants experienced the difference between independent and mutually exclusive events in probabilistic situations. During the game, the interviewer would ask the participants to say why they made their choices about when to "go home." After the game, the interviewer would ask participants about specific things they said, asking for clarification on meaning. The camera operator was helpful in this regard, acting as a second interviewer. She or he could make notes on what participants said, which was relatively difficult for the primary interviewer who was busy with the cards and interaction.

In the second year, participants from Grades 4, 7, and 10 (catching some of the same students as the previous year, one grade earlier) predicted the 50th car on different trains based on the first seven cars. The narrative context of this situation had the researcher tell a story about waiting with a friend for a train at a level crossing, and deciding to predict what kind of car the fiftieth car would be. Trains were then shown using presentation software, with an engine and the first six or seven cars, each labelled with their number. After students made their predictions about the 50th car, we had the train accelerate and then decelerate to settle on the 50th car. As with the game of skunk, we had students work in groups to draw out communication.

The sequences presented to students varied considerably to defy expectations of certain kinds of patterns. The cars were distinguishable by colour and shape – Yellow (Y) cars were rectangular boxcars, green (G) cars were tankers, and blue (B) cars were flatbeds carrying big triangles. Train 1 showed Y,G,B,Y,G,B,Y and continued with a pattern of threes (YGB). Train 2 showed Y,G,Y,Y,G,Y and continued with a pattern that increased the number of Ys before each G – i.e., Y,G,Y,Y,G,Y,Y,Y,G, etc. Of course, the initial seven cars could have suggested a pattern of threes (YGY) similar to the previous train – i.e., Y,G,Y,Y,G,Y,Y,G,Y, etc. For this train, we stopped the train at around the 25th car to let students reconsider their predictions. Of course, we invited students to tell us their reasoning whenever possible. Train 3 showed B,G,B,B,G,G, etc. and continued with B, B, B, G, G, G, etc. with increasing groups of B and G. The interviews on the following day started with Train 4 showing Y,B,G,Y,Y,B,G. It continued with groups of four (YBGY) – i.e., Y,B,G,Y,Y,B,G,Y etc. Train 5 started with Y,B,G,B,P,B,Y and continued with a random collection of cars, in which the colours started to misalign with the shapes and new kinds of cars appeared. As with Train 2, we stopped train 5 at around the 25th car so we could hear the students reconsider their predictions. In addition to the confounding randomness of the fifth train, there was no 50th car – it had only had 42 cars. As with skunk, we ended these interviews with questions about distinctions among various language choices we heard the students use.

For this paper, we focus on one interview with four Grade 6 students playing the game of skunk. However, we make some references to other data within the project to illuminate certain findings through comparison. This group of students was not identified by their teacher as exceptional in any way. The school is in an area that has relatively low socio-economic indicators. As noted above, these four students played skunk in class the day before, and subsequently one of our research team interviewed them – first playing skunk with cards instead of a die, and then asking them about some language meanings. We asked them to play skunk in pairs, and they somehow came to an implied agreement that the pairs were competing against each other.

LANGUAGE USED TO EXPRESS UNCERTAINTY

These four 11- and 12-year olds show considerable language repertoires, which we found to be the case for even the most mathematically and linguistically novice students in this project. We were the most careful about and attentive to modal verbs because of our earlier research and teaching work.

The modal verb *have* expresses high modality because it refers to events that must occur. The interviewer used it first (though trying to avoid doing so) in turn 111 and it was used again in turn 229 when Chris talked about the difference between playing skunk with cards and with the die: "It's easier this way because when the skunk first came you just don't have to worry." It wasn't used again until the interviewer asked questions about its meaning. Here is a short version of that discussion.

319 Interviewer: [Yesterday] I heard Terry say when you're working in your groups, "Do we both have to write this down?" So what's the difference between "it has to be the skunk" and "she has to write this down"? Is the "has to" the same? "This has to be the skunk." "She has to write it down." Do you notice a difference between them? ...
346 Terry: Do we both need to, like, do we both need to write it down?
347 Interviewer: No, but it's a proper use of the word. But is it the same as "this has to be the skunk"?
348 Terry: No.
349 Interviewer: No? Why not?
350 Terry: Because you know it has to be.
351 Dale: It absolutely has to be.
352 Interviewer: It absolutely has to be.
353 Terry: Yeah
354 Interviewer: But when asking "do you have to" it's not absolutely
355 Terry: No, yeah
356 Interviewer: Okay
357 Dale: Because the fire bell or something could ring or something and you all go outside and you don't have to write it down.
358 Interviewer: Don't have to write it down but if the fire bell rung this would still be the skunk.
359 Dale: It would still be the skunk.

We note that, to clarify meaning, the students introduce new vocabulary that was not part of the interview up to this point. Terry used the modal verb structure "need to" to emphasize the necessity of "have to." Dale introduced the adverb *absolutely* to further emphasize this sense. The students distinguished between instances of 'have to' depending on context.

We had a similar conversation about the modal verb *can* which had been used in its various forms, including *can't*, by the students in the interview. We started this part of the conversation by referencing Dale's writing in class earlier. When asked what is the most number of berries they could get in a day, Dale wrote, "You can get any number because it could just keep going." (This was with playing skunk with a die) The researcher referred to Dale saying in the interview that it is different with the cards because "we can't keep going." What follows is again a short version.

391 Interviewer: That *can't* – If you're wanting to go visit your friend, and your mother or father says that you can't go over to your friend's house, is it the same kind of *can't*?
392 Terry: No, that means you're not allowed. ...
395 Interviewer: You're not allowed to
396 Terry: Yeah.
397 Interviewer: Or how do you know it's not the kind of can't that Dale said? Where it just can't possibly happen? How can you tell the difference?
398 Terry: By the way she says it.
399 Chris: Yeah. ...
418 Interviewer: When you said earlier "you can't win", which one is that closest to? Remember, when you looked at your basket and you said, "Oh, we can't win." Is that like the "you're not allowed" or is it
419 Terry: It would be you can't
420 Leslie: You don't
421 Terry: Like you, it's impossible, like
422 Leslie: Yeah, it's impossible.
423 Terry: Well, it was because if you added it all up, the skunk
424 Dale: You'd only get, like, fifteen.

425 Terry: The skunk would have come.
426 Chris: Yeah, you'd only get fifteen so if the skunk is that...
430 Terry: Because the skunk was gone.
431 Interviewer: It would have been impossible.
432 Terry: Yeah, yeah
433 Interviewer: So if someone says *can't*, ... if I told you that you can't divide by zero in a lesson on dividing would you think that that means that you're not allowed to or that it is impossible to do?
434 Chris: That it is impossible.
435 Interviewer: Why would you think that?
436 Terry: Because you can't divide by zero.
437 Interviewer: Why can't you?
438 Terry: Because it is impossible.
439 Interviewer: How do you know?
440 Chris: Because you can't
441 Terry: Because you can't
442 Chris: If it is zero, you can't put it in any groups.

In this case, Terry introduced the adjective *impossible*, to clarify the meaning of *can't*. No one had used the word before this in the interview. As with "have to", the students distinguished among instances of *can* and *can't* based on context. During and after this interview, we wondered how students could make this distinction for instances in which they do not know a convincing logical argument for the assertion. With the example of division by zero, the students now knew that it is impossible, but how might they have thought about it the first time they heard their teacher say "you can't divide by zero"?

The students introduced three adverbs/adjectives that indicate degrees of probability into the interview. The word *probably* was first used by Leslie and not used again by others. When Leslie and Terry were considering whether or not to make the same choice about going home as the other group, Terry remarked, "One of [our groups] won't lose everything and the other would" (turn 204), and Leslie replied, "It is probably going to be us" (turn 205). The adverbs *absolutely* and *impossible* came up in the conversations about language choices when the students were trying to explain what the modal expressions meant, as noted above.

Other modal verbs used included *would*, which was first used (accidently) by the interviewer and used liberally later by the students, and *may* as in "you may be able to win" (Dale, turn 263). Another specialized linguistic form used by a student was the if-then statement, first used by Chris: "If it was two numbers then it would make a difference" (turn 39). This was in the discussion about the playing skunk with a die.

In addition to the relatively specialist terminology for modality (the modal verbs and adverbs), students expressed degrees of certainty in other ways. Terry introduced the expression "I think" in a conversation about playing skunk with the die. The researcher had asked if the number of berries they got would be different if the skunk came on a one instead of a six, to which Terry replied, "I think it would because we roll the one a lot" (turn 45). Terry introduced another expression to describe the differences between playing skunk with cards and with the die. In turn 236 Terry said, "You never know what is going to happen" (with the die). Terry also said "the odds are harder" (line 273) when the probability of success became lower. Dale was inventive too, and used the expression "I had a feeling" (turn 126) after "going home" to stay safe. This was in reply to the researcher asking, "Did you know that this was the skunk?"

Finally, the absence of any modal expressions is significant in the consideration of modality as well. The use of bald assertions can replace strong modal verbs or adverbs. Dale said, "the skunk is right there" (line 74) while pointing at the skunk card, as yet unrevealed but evidently the skunk by deduction. We might expect "the next one has to be the skunk" or "I am certain that the next one is the skunk" but the bald assertion serves the same function. Chris did the same on line 82 saying "it's there." In this interview (and others), there were many instances of this method for expressing certainty.

DISCUSSION

The four students in the interview described above demonstrated a wide repertoire of language for expressing degrees of certainty. Each of them used a range of expressions, and each of them introduced expressions that no one else had used before. Terry was the most talkative in the discussions about language meaning, but we caution that it would be unwarranted to make conclusions in comparison to the others on this basis. Many of the expressions introduced by the students came late in the interview, which tells us that if the interview had been shorter, we would not have known whether or not the students had these expressions in their repertoires. This serves as an exemplary caution against deficit-based assessments. Similarly, when one student said something, there was no need for the others to say it again or even speak about it unless they disagreed. Also, if students use an expression that has just been used by the teacher or tester, it may not be fully "acquired." We cannot assume someone does not possess certain language simply because they do not use it. However, we can claim that a student has an expression in their language repertoire if they introduce it. This is why we went to the lengths that we did for structuring our prompts carefully.

In addition to using (and introducing) specialist language, the students in the interview at times demonstrated ability to convey their meaning using very limited technical language. In particular, they could make their ideas clear when talking about the extremes of certainty – when events were impossible or certain. The more specialised language seemed to be relied upon either for describing events that were somewhere between impossible and certain, and for clarifying meaning on the extremes when pressed to do so. As noted above, Rowland (2000) introduced the idea of the zone of conjectural neutrality to describe language that specifies degrees of certainty, which is "in defiance of the cultural norm that the pupil is judged to be 'right' or 'wrong'" (p. 211). He claimed it to be helpful for a conjecturing atmosphere. We note that the same terminology is used to describe probability, and thus specialised modality language can defy situations in which predicted results may be between impossibility and certainty. We have only begun to consider the implications for pedagogy considering that the language is shared for both conjecture and probability spaces.

This brings us to discussion of the second research context, which was set up to be similar to but distinct from the game of skunk – a twist on the context. In both contexts, students were making predictions. What is the difference between a train and a pile of cards, both of which are sequences of physical objects? One difference is that the cards are shuffled and train cars are sequenced with some sort of intention. Nevertheless, our experience of real trains is that the sequence of cars seems to be quite random, or in groups (e.g., the boxcars first, followed by a bunch of tankers, followed by a few flatbeds, and finally the rest of the tankers). We have never seen trains with patterns similar to the ones introduced in our research – patterns like yellow boxcar, green tanker, blue flatbed, yellow boxcar, green tanker, blue flatbed, etc. A Grade 4 student in the second year of research involving the trains became increasingly frustrated with the rest of the class identifying what the 50th car would be. This student kept saying that it is impossible to know, while the class continued to ignore him. This student refused to make predictions.

This tension points to the presence of some sort of pedagogical contract in which students generally expect intention from their teachers. Even in the game of skunk, when the interviewers showed all the cards to the students and shuffled the cards directly in front of them, the students sometimes expected some kind of lesson – the appearance of a second skunk card, for instance. With the trains the phenomenon was more obvious; the students (with some exceptions, most notably the Grade 4 student noted above) assumed that the patterns would continue even though the researcher and teacher never said that these were patterns and the described context was one of a real-life train. The anger displayed by participants when they saw the fifth train (the random train) made clear to us the students' expectations for pattern. There is something about the transposition of a narrative into a mathematics classroom that changes it to a scenario in which everything should be predictable (and known by the teacher, or researcher).

In our research project, student predictions were based on both the probabilities inherent in the given scenarios and the students' second-guessing of teacher/research choices in constructing scenarios for pedagogic or other reasons. This raises questions about how students experience probability learning. Uncertainty in the mathematics classroom is experienced differently than outside the classroom. Furthermore we note that the language of conjecture shares language with probability, and so we wonder whether this ought to confound similarly our understanding of the way students experience proof and reasoning.

Finally, we turn our attention to implications beyond the classroom. Increasingly significant social phenomena, such as climate change, involve both calculations of risk, which are based on assumptions, and conjectures (hypotheses). The fact that risk calculation and conjecture share terminology may complicate communication about such social phenomena. Furthermore, both risk calculation and conjecture language about certainty is also used to express authority, as demonstrated in the above conversation about authority. When people in the public sphere who appear scientific make claims that sound authoritative, how are listeners to know whether these claims are warranted? It is incumbent upon mathematics teachers to be aware of these shades of meaning and the risk of ambiguity on such important social issues.

ACKNOWLEDGEMENT

This research was supported by the Social Sciences and Humanities Research Council of Canada, as part of a grant entitled "Students' language repertoires for investigating mathematics" (Principal Investigator: David Wagner).

A case study comparing the comments written by two students on their mathematics notebooks

Matías Arce, Laura Conejo and Tomás Ortega

University of Valladolid, Valladolid, Spain, arcesan@am.uva.es

The mathematics notebook of the student is a very usual tool in Spain, but, at secondary level, students are usually free to develop and use it as they want. Here, we put our attention on a particular aspect: the kinds of comments the students add in their notebooks when they are writing in them. As a first step, we have carried out a case study in which we compare the notebooks of two high school students with high grades. There are some similarities, like the large amount of comments, which link different concepts, but, also, important contrasts related to the role of the notebook.

Keywords: Notebooks, writing, comments, case study, high school.

RESEARCH QUESTIONS, FRAMEWORK AND METHOD

The mathematics notebook (MN), understood as the place in which students take their class notes, carry out and correct tasks and collect their mathematical work, is a very common tool in Spain. At secondary level, teachers usually do not indicate to their students how to develop it. We could see the MN as a tool with various use schemes among the students, but there is little research on this (e.g., Fried & Amit, 2003). In our research, we are looking for different profiles of elaboration and use of MN in students, in which writing plays an important role. Students usually transcribe in their MN the theoretical development of a topic (definitions, examples, theorems) and the solving of exercises. But students can add other written elements such as memories of previous concepts, clarifications or study aids. We call them *comments* and here we present an exploratory study focusing on them, with two research questions: What types of comments can we find in a student's MN? What are the relationships between them and how the students use their MN to study?

In the 80s and 90s a lot of studies about writing and its role in the learning of mathematics were developed. Some of them propose different classifications of students' writing in particular given tasks, according to the understanding and learning they reflect: in mathematics journals (Waywood, 1992) or in explanations of concepts (Shield & Galbraith, 1998). In our study, we do not have any particular task but we adopt these classifications as a basis to study what kinds of comments they add in their MN.

Four classes of high school students, chosen by availability, have participated in our research. The four have mathematics teachers with "traditional" methodology (theoretical exposition of contents, posing and solving of exercises). To start the study of the written comments, we have done a case study selecting two students of different classes with high grades in mathematics: a girl (S1) and a boy (S2). We have done photocopies of their MN to analyse the comments found in them (with the aid of the previous research) and an interview with each student about her/his use of the MN.

ANALYSIS AND FIRST RESULTS

In the poster we present and illustrate the similarities and differences between the kinds of comments we have found in the MN of these two students. Besides, we link them with the role of the MN and the way they use this tool to study mathematics, in order to extract the first results. Regarding the similarities, there are a high number of comments linking different concepts (or new concepts with prior knowledge) and justifications about the need to introduce some concepts or techniques or why they can apply a procedure. Comments of these types seem to be an indicator of good achievement in mathematics; they show that the students are beginning to understand the relational and logical nature of mathematics (Shield & Galbraith, 1998).

But there are key differences. The memories and clarifications about processes are more common in the MN of S1, and only in it can we find some recommendations about the resolution of exercises ("recipes" or good practices). We have found in S1's MN some signs (smiles or question marks) about her understanding (or not) of concepts and processes. In the interview, she says to base her study of the subject on the revision of theory and on the review and repetition of exercises made in her MN. These kinds of comments act as study aids for her, reinforcing an algorithmic aspect of mathematics (Shield & Galbraith, 1998) and a utilitarian stance towards knowledge (Waywood, 1992). In addition to these aids, she says she needs the visible correction of mistakes (using colours, marks or signs) and the order and cleanliness in her MN. It seems that S1 constructs her MN as a personal "textbook", emphasizing some clarifications and her difficulties to conduct her study throughout the reading of it.

There are almost no comments of those types in S2's MN, probably due to the different role of the MNs for him and his vision about mathematics. To prepare the test, instead of reviewing the exercises of his MN, S2 solves other exercises in which he has the solution to check. He seems to see mathematics as a constructive activity more than a gathering of contents submitted (Waywood, 1992). In the next steps, we have to extend the study to more students to learn more about the different types of comments and their functionality, in order to develop a classification of them.

Talk about patterns in the mathematics classroom

Filip Roubicek

Academy of Sciences, Institute of Mathematics, Prague, Czech Republic, Filip.Roubicek@seznam.cz

The poster deals with the talk in the mathematics classroom which is focused on looking for relationships in a pattern. The communication of students is observed in the environment of geometrical patterns in a triangle grid and their transformation into arithmetic patterns or algebraic functions. It shows how pupils/students reason about relationships in these patterns and among these patterns, how they describe and express their generalizations in words or symbols.

Keywords: Talk, discourse, mathematics classroom, patterns.

DISCOURSE ON MATHEMATICAL TOPICS

The mathematical discourse among students is an attribute of thought-provoking classroom. Discourses are defined as different types of communication (and thus commognition) that draw some individuals together while excluding some others (Sfard, 2008). The classroom based on discourse approach brings a lot of situations of communication among students and among them with their teacher. They describe procedures of calculation or construction, verifying, justifying, deducing, generalizing, etc. Their talk reflects their mathematical experience, knowledge and thoughts. Under this perspective, the analysis of the students' talk is expected to enable to diagnose part of their mathematical understanding.

PATTERNS IN MATHEMATICS

Patterns represent the type of interesting and challenging tasks for students and the suitable environment to develop their mathematical thinking. "Generally, if we see a pattern in mathematics, we look for the relationship which will describe the pattern. Patterns are found in all aspects of mathematics, arithmetic, algebra, statistics and games." (Littler & Benson, 2005, p. 203) In the described case the environment of geometrical patterns in a triangle grid is transformed into arithmetic patterns or algebraic functions.

Talk among students is observed on the basis of modelling of geometrical patterns which are assembled from toothpicks in a regular triangular grid (geometrical figures are made of identical equilateral triangles). Series of these figures (see Figure 1) can be constructed by lengthening (the figure type is preserved but its shape is not) or by enlarging (the shape of the figure is preserved – similar figures). Elongation is characterized by a different quantitative change than construction of a sequence of similar figures.

At first students construct figures made of identical equilateral three-toothpick triangles. Then they state how many toothpicks the figures are made of, describe the arithmetical regularity in the sequence of figures and express the number of toothpicks needed for figure of length n.

Teacher: How many toothpicks are these parallelograms made of?

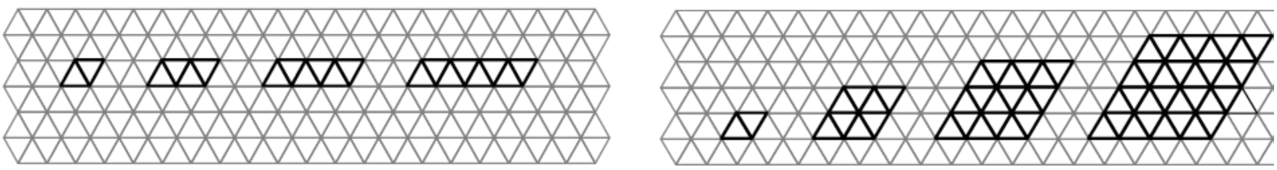

Figure 1: Two types of a geometrical pattern in the triangular grid

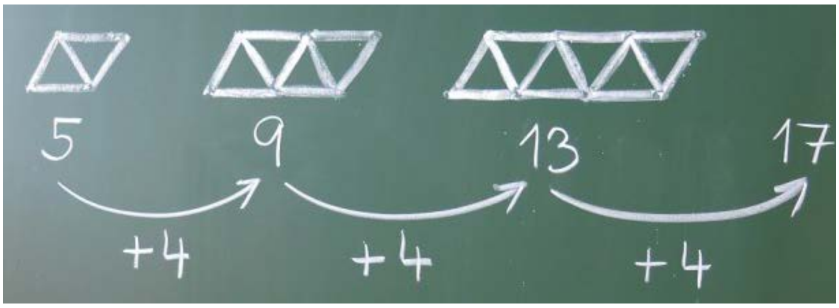

Figure 2: Transformation of a geometrical pattern into the arithmetic sequence

Student A: *She counts the number of toothpicks in the figure one by one.* The first one is made of five... the second out of nine...
Student B: ... and the third out of thirteen.
Teacher: How many toothpicks will you need to construct the next parallelogram?
Student A: I will add one, two, three, four... well, the next one will be made of seventeen.
Teacher: So, how will this go on?
Student B: Always plus 4... 21, 25, 29, 33...

The poster describes how students communicate their mathematical thoughts while looking for relationships in a pattern and express them through arithmetic rules or algebraic functions.

Testing and diagnostics of students' difficulties in CLIL teaching

Alena Šteflíčková

Charles University in Prague, Faculty of Education, Prague, Czech Republic, alena.steflickova@seznam.cz

The poster deals with CLIL and assessment and evaluation in CLIL. It summarises main positive and negative aspects of CLIL with regards to a Czech teacher and it concentrates on ways of diagnosing if a student has problems with language (English) or content subject (mathematics) while writing different types of tests. There are two main principles used – analyzing on the basis of the combining solutions in different tasks in set of tasks (alternative test) and analyzing of the procedure of a student. The poster introduces examples of several works of research and different alternative tests and it shows some possible ways how the test CLIL students. It also shows examples of diagnosing student's difficulties, mainly in language.

Keywords: CLIL, testing, assessment, alternative tests.

THEORETICAL FRAMEWORK

The current globalised world requires modern methods of teaching and learning. CLIL (Content and Language Integrated Learning) is one of these methods; it integrates learning of content subject and a language other than the language of instruction. Both of these subjects are taught at the same time and via each other. The method is in the spotlight of researchers and scholars who see it as one tool for better language education, also in mathematics education research.

CLIL has some positive aspects and also some problematic ones. One of these is assessment and evaluation. A key question is what should CLIL teachers assess and evaluate – content only (according to Hofmannová, Novotná, & Pípalová, 2004, this is the most common way in CLIL teaching), language only, both content and language separately or both content and language at the same time. Assessing and evaluating of both content and language at the same time can be difficult because sometimes it is not easy to distinguish if the difficulties of a student originated in language or content. Then there is one important question emerging: "How to integrate both parts?" (Novotná, 2011). A connected question is: If a student did not answer a question or answered the question incorrectly, what does it mean? Does it mean he/she did not understand the question or did not know the answer or was not able to produce it? A plain fact is that it is usually not possible to separate these items.

The poster aims at integrating math and English and the main objective of the poster is to introduce several types of alternative tests or tasks which were created and used in ongoing research regarding diagnosing where the difficulty of a student was.

METHODS

Assessment and evaluation is a part of CLIL which is not very often discussed. The ways of written assessment in CLIL are tests aimed at content or vocabulary, alternative tests, performance tests (students perform what they are asked for), portfolios and "can do" tables (there is a list of skills students should learn and the teacher ticks the ones the student has already learnt).

The examples of tests and tasks in my study are based on two basic principles. The first principle is inspired by Novotná (2011) who introduces an alternative test, which is a set of gradated tasks – some tasks are graduated in English and some are graduated in mathematics (gradated in difficulty). By comparing results in different tasks it is possible to make an educated guess where the student's difficulties are. The second principle is analyzing the procedure of a student's solution in order to understand his/her train of through.

CONCLUSION

Dealing with assessment and evaluation, if we choose to assess and evaluate content subject only, the tasks and tests would need to be in native language, because as my units of research showed the assignment in second or foreign language (L2) is one factor which influences the understanding. If we assess and evaluate in L2 then there is a question how to diagnose if the student's difficulty is in language or content subject. One possibility is to use an alternative test or to study the procedure of a student solution. To understand the procedure and train of through of a student is important for a teacher, so he/she is able to analyze knowledge of a student or a whole class and can use the information for other teaching. Further research could deal with other tests, comparing one test in different languages, as well as studying student's difficulties in oral testing or different school mathematical domains.

Adaptivity challenges for relational scaffolding

Larissa Zwetzschler

University Duisburg-Essen, Essen, Germany, Larissa.Zwetzschler@uni-due.de

Scaffolding is a mean to support students' ability of expressing ideas in written language and to foster conceptual understanding. It is well known that scaffolds in words and chunks must be topic specific and adaptive to the individuals' steps of proximal development, but not what that means in detail, for example for percentages. The case study reported in this poster investigates which topic specific scaffolds are needed and reconstructs students' challenges with topic specific scaffolding as well as effects on their conceptions.

Keywords: Language, scaffolding, writing, percentages, adaptivity challenges.

THEORETICAL BACKGROUND

Scaffolding consists of chunks or parts of sentences, which students can use for their written texts (Smit, van Eerde, & Bakker 2012). Thereby the ability to express something in written language shall be developed. But students write texts topic specific challenges in percentages must also kept in mind. Parker and Leinhard (1995) resume backgrounds why percentages are so hard to learn; one reason is that connections between different elements (like part and whole) are often invisible in the language. These connections are part of a *relational understanding* that Skemp (1976)

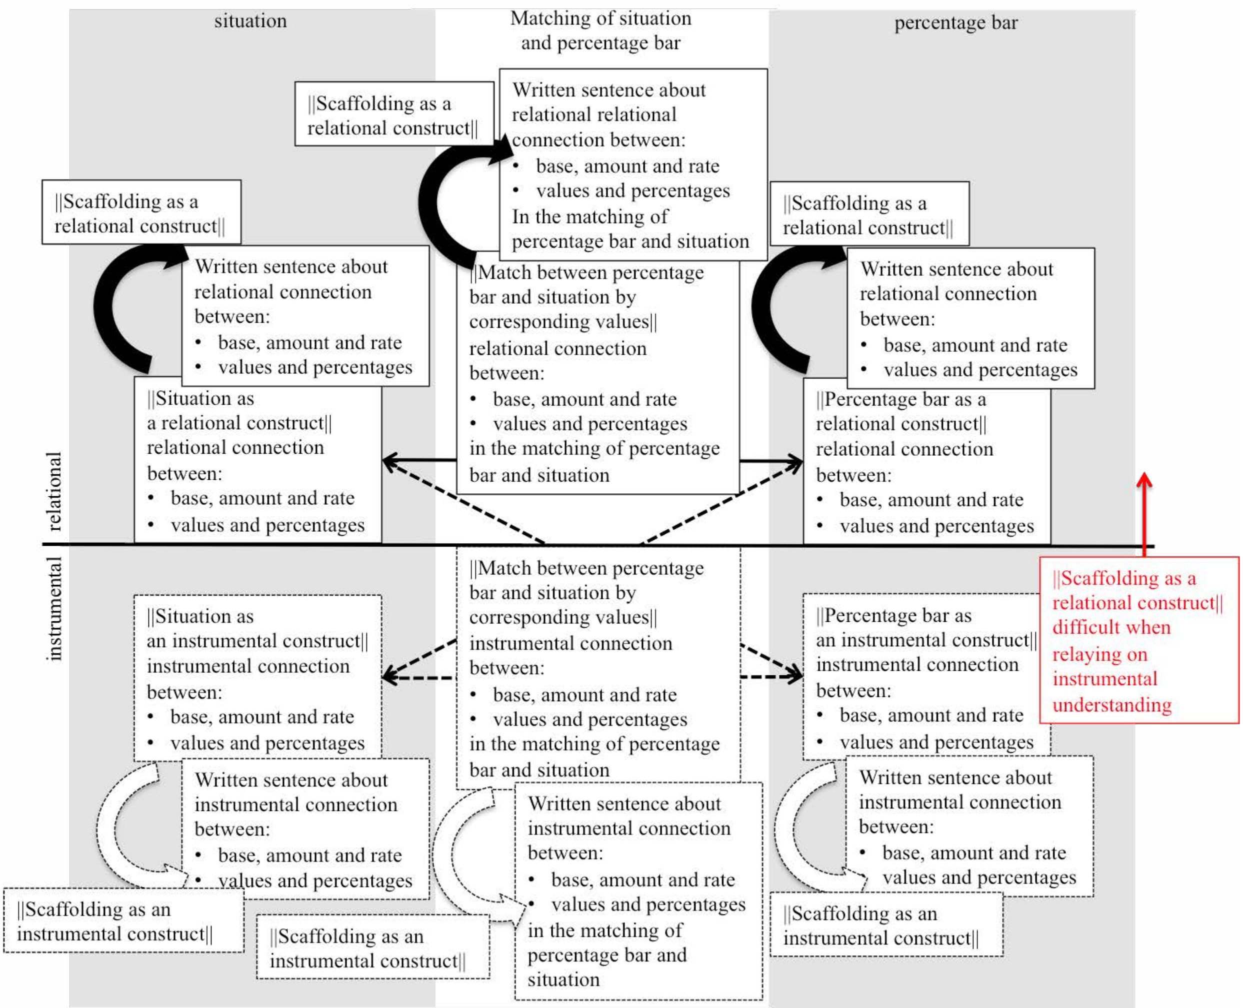

Figure 1: Adaptivity challenges for relational scaffolding

opposes to instrumental understanding. They are therefore chosen to be a core of a developed teaching learning arrangement in which students are asked to explain an error in a false advertisement (false rate). Their writing and understanding process is supported by scaffolding and percentage bars.

DATA GATHERING, ANALYSIS AND FIRST EMPIRICAL RESULTS

The learning arrangement was investigated by videotaped design experiments in laboratory settings (18 students of grades 7–8) and in 8 design experiments in classroom settings (with similar students), each lasting 35 to 50 minutes. Vergnaud's analytical model of concepts- and theorems-in-action is used for the data analysis, as "a fruitful and comprehensive framework for studying complex cognitive competences and activities and their development" (Vergnaud, 1996, p. 219).

The data analysis shows students difficulties to use relational scaffolds like 'because the base is... and of this the discount is reduced', if they had an instrumental understanding. A student says in those situations, that the scaffolding isn't helpful: "Because there, I – can't make the beginning of the sentences". Figure 1 shows the analysed interplay between an instrumental or relational understanding of the situation and the percentage bar, a matching of both and the consequences for instrumental or relational scaffolding. To sum up, relational scaffolding is needed to understand and express matching in percentages, but students can hardly make use of it when relying on an instrumental understanding.

TWG10

Diversity and mathematics education

Introduction to the papers of TWG10: Diversity and mathematics education – social, cultural and political challenges

Lisa Björklund Boistrup[1], Tamsin Meaney[2], Mônica Mesquita [3] and Hauke Straehler-Pohl[4]

1 Stockholm University, Stockholm, Sweden, lisa.bjorklund@mnd.su.se
2 Bergen University College, Bergen, Norway
3 Universidade de Lisboa, Lisboa, Portugal
4 Freie Universität, Berlin, Germany

SCOPE AND FOCUS

Thematic working group 10 is interested in discussing diversity and mathematics education within the realms of the societal, the cultural, and the political. The working group was established at CERME7 in Rzeszów, Poland, in 2011 (Valero, Crafter, Gellert, & Gorgorió, 2011; see also Pais, Crafter, Straehler-Pohl, & Mesquita, 2013), but was an extension of the language diversity group which had been part of CERME since the first conference.

In the work of the group, mathematics education is assumed to refer to more than the encounter between an individual and a mathematical object and to wider contexts than exclusively classroom settings.

The group is specifically interested in discussing research that addresses how diversity affects possibilities in mathematics education. Diversity might be expressed in terms of gender, ethnicity, language, socio-economic status, disability, qualification, life opportunities, aspirations and career possibilities, etc. Contexts are diverse in terms of the variety of sites where mathematics education takes place, and the differences in the organization and structure of practice in such contexts—schools, homes, workplaces, after-school organisations etc. Contexts also include the political structures where policies are formed that draw on, make use of, or ignore mathematics education research. Diversity also occurs in relationship to who is doing the research and who is being researched, posing methodological issues of an ethical nature. These multiple diversities intersect, and in so doing pose challenges to intended and actual learning and teaching practices in their multiple forms.

ORGANISATION OF TWG10'S WORK

In the seminars during CERME9, papers were presented in a similar way to what had occurred in CERME7 and CERME8 in that the authors did not present their own paper. Instead each paper was presented by another author giving a neutral description of the main ideas from the perspectives adopted in the paper. The author(s) then had a few minutes to add to or comment on the presentation, with the possibility of pointing out or emphasising important aspects. The presenter prepared one question/comment for the author, which was discussed in connection to the presentation. In the end of each session, there was time for discussing the presented papers. These discussions firstly occurred in pairs or small groups and then were shared in the whole group. This was done to facilitate the contributions from as many participants as possible to the work of TWG10.

Although the papers in each session were grouped to facilitate discussions about similarities and connections between papers as well as tensions and contradictions, each session was not labelled as such in advance. One consequence of this procedure was that the efforts to thematize the contents of the research presented became a joint process within the group.

A poster session with 6 posters was held in which all presentors had 2 minutes to describe the content of their poster. The poster authors then positioned themselves next to their respective posters to engage in discussions with group members.

THE PAPERS DISCUSSED

In this section, we briefly describe the papers from TWG10 following the schedule from CERME9. We address some (dis)connections between each paper and the subsequent paper as examples of the diversity of papers in the group.

In the paper by *Albanese*, ethnomathematical dimensions are adopted as tools for analysing observations of teachers participating in workshops aiming at influencing their conceptions about the nature of mathematics. *Parra-Sánchez* similarly has an interest in ethnomathematics, but not as a tool adopted in empirical research in school, but as a broad focus of the study itself through a literature review. Parra-Sánchez problematizes the relationship between researchers and researched communities in the ethnomathematical field and proposes a more symmetrical approach. While this paper has an interest in power relations between the researcher and the researched, the next paper by *Hauge and colleagues* applies an approach where the gap between the researched (master students) and researcher (Hauge as main author) is closer than in much empirical research in a study on how mathematics related classroom discussions may enhance critical citizenship (drawing on Skovsmose).

Similar to Hauge and colleagues, the paper by *Kitchen and colleagues* critically scrutinises quantifications taking place in society, but with another topic in focus. Kitchen and colleagues focus on how teachers' assessment practices were largely influenced by the pressures to prepare students for success on the US state's standardized test. *Bagger* similarly presents research where assessment in mathematics was critically investigated. While Kitchen and colleagues pay attention to how official assessments affected teachers' practices, Bagger's interest is in effects on students, in terms of student positions which were construed drawing on Foucault. *Turvill,* similarly to Bagger, has an interest in mathematics education in relation to young students but with a theoretical object of a study on inequalities. Turvill examines number sense from the perspectives of cognitive psychology, situated cognition and Bourdieusian social psychology. In the paper by *Lembrer*, the children referred to are younger than in the case of Turvill, while also drawing on sociology, in a study on the relationship between socialisation and mathematics education in Swedish preschools.

Montecino and Valero present a theoretical analysis on texts, as does Lembrer. While Lembrer analysed official documents, Montecino and Valero adopt Foucault and Deleuze to explore how discourses in research literature are operating as part of the fabrication of the mathematics teacher as a subject and in the production of truths about them. *Pansell and Björklund Boistrup* also have an interest in the mathematics teacher but with data from communications within a collaborative teacher meeting where one teacher's justification of her professional decision making as part of a socio-political context is analysed and discussed. The teacher's decision making concerned, for example, calculations and this was an interest in the theoretical paper by *Kollosche*. Here, the focus is on connections between calculation and bureaucracy. Adopting a methodology following Nietzsche and Foucault Kollosche points out implications for mathematics education. Similar to Kollosche, the paper by *Dahl* is theoretical, although Dahl takes on a more structural perspective when adopting concepts from Bernstein suggesting how problem solving can be viewed in three different ways: as an ideology, a competence and an activity.

Dahl presents a foundation for a methodology for investigations of problem solving in mathematics education. *Norén and colleagues* also pay attention to methodological matters when revisiting their own research with a focus on methodologies for performing research while paying attention to diversity and equity issues, in this case in relation to newly arrived students. In *Radovic and colleagues* as well as in *Norén and colleagues* there is an engagement in the perspective of the students. Radovic and colleagues report on the intersection between mathematics identity and the peer positioning of high attainment girls in a particular mathematics' classroom in Chile. Also *Marks* has an interest in students' perspectives and this paper examines questionnaire and interview data to identify pupils' prevailing mindsets in primary mathematics. The findings, where a fixed-trait belief is dominating, are discussed in relation to mathematics education policy and practice in England.

Although having an interest in mathematics education in school, the paper by *Andrade-Molina and*

Valero takes on a more historical perspective than Marks when adopting cultural historical strategies (Foucault) to research the functioning of the school geometry curriculum, arguing that school geometry fabricates the scientific minds of the future. Similar to Andrade-Molina and Valero, *Helenius and colleagues* present a theoretically driven analysis. Drawing on Bernstein's ideas about vertical and horizontal discourse their paper raises issues about how the connection to the everyday in problem solving could reduce children's opportunities to learn mathematics.

Similar to Helenius and colleagues, the paper by *Albersmann and Rolka* concerns problem solving. Albersmann and Rolka do not critically examine the everyday context, but use problems with every day contexts when investigating parent-child cooperation in the course of a workshop. A quite different scope has the paper by *Black and colleagues* where the data derive from a mathematician. In this paper, the role of 'others' is explored in one woman's mathematical identity with the role of 'caring' as a cultural resource to identify as a mathematician. While Black and colleagues examine data related to the discipline of mathematics, *Mukhopadhyay and Greer* argue for the necessity of maintaining diversity in all its human forms, including mathematics and mathematics education. Central to this position is respect of the conception of mathematics and mathematics education as human activities, inextricably embedded in forms of life.

AN ELABORATION AND PROBLEMATISATION OF INCLUSIVENESS AND QUALITY IN MATHEMATICS EDUCATION

In TWG10, we agreed that matters discussed within the group were essential, not only for this group but for research in mathematics education in general. In relation to an interest in inclusiveness and quality in mathematics education research, discussions in the papers from TWG10 would be productive for elaborating and problematizing the research of the field, for example, concerning the development of research ethics, or finding productive ways of addressing the situatedness of any research process in mathematics education.

For TWG10, this concerns respect for diversity in a variety of ways, which also is constantly changing. Different demands for ethical responsibility were discussed, for example, a virtue of respect for participants/collaborators in research, such as teachers and students, when performing research with an emphasis on recognizing knowledge where it is situated; or, going further, the establishment of deepened connections between the researcher and the researched through allowing the researched a true stake in the collaborative development of the research project, thus sounding out political common ground. While TWG10 obviates a fixation of general demands for ethical responsibility, it formulates reflexive controversy as a requirement for mathematics education research that seeks to locate itself within the realms of the societal, the cultural, and the political. A consequence from such a view is an awareness of how the actions by any researcher within the field of mathematics education have political consequences.

In the work of TWG10, labels were discussed as "needing" not to being taken for granted, such as challenging the meaning of "success in mathematics education" or how a student "in need" may be construed. In discussions as well as in papers, the importance of investigating what lies between and behind labels was addressed.

Another theme within TWG10 was an interest to problematize and challenge mathematics education research done with the aim of identifying the teaching and learning practices that "work best". In the discussions within TWG10, the focus shifted from "what works" towards the question of rather „how what works looks like – and for whom". Furthermore, research within TWG10 addressed how the enforcement of accountability measures within many societies of today is not likely to promote any "deep" mathematical competence.

One such aspect was a discussion in which many of the issues within mathematics education were taken as not only being problems of scenarios of learning mathematics, but issues within the broader political context that still concern mathematics education. Consequently, while some of the papers explicitly established the relation between the local context, for example, a classroom, and the broader political context, discussions steadily established such relations where it was not an explicit focus of the respective papers.

In TWG10, we also identified tensions where perspectives within the group were not coherent. One such tension was a research interest in the subject of mathematics where mathematics education could be viewed as a gatekeeper where social order should be maintained. In other works from the group, the emphasis in the research rather was on how to invite all students into the discipline of mathematics. This included a discussion about mathematics itself in terms of how useful it may be for the individual, but also for societies as a whole. Different kinds of usefulness, at times not compatible, were discussed, such as mathematics as a problem-solving tool in life, or as a selection device (for example, to higher education).

Closely connected to this tension was a discussion in the group about whether change at all was possible, and in that case how. In some discussions, (mathematics) education was emphasized as a facilitator for changing the world we live in, whereas other discussions had a stronger emphasis on (mathematics) education as being structured by the world, with limited power to be a departure for a change in society. The dynamics of the discussions suggest a reflexive approach towards the relation between mathematics education and the societal structures in which it is embedded.

Similar tensions were discussed at CERME8 (Pais et al., 2013) and during CERME9 more topics were included in the discussions. The diversity of TWG10 is also possible to experience through a sound installation made by the group, the "cacophony" on link: https://www.dropbox.com/s/id10kp598jkc872/TWG10%20cacophony.m4a?dl=0

Ethnomathemathical dimensions for analysing teachers' conceptions about mathematics

Veronica Albanese and Francisco Javier Perales

University of Granada, Faculty of Education, Granada, Spain, very_alba@hotmail.it, fperales@ugr.es

As Ethnomathematics involves deep epistemological implications about the nature of mathematics, we decided to hold a workshop for pre-service and in-service teachers, in order to influence their conceptions about the nature of mathematics. The aim of the research is to analyse the observations of these teachers related with the conceptions of the nature of mathematics after the proposed workshop. In this paper, we present different dimensions for analysing the teachers' conceptions about mathematics from the perspective of Ethnomathematics.

Keywords: Ethnomathematics, conceptions, teacher education, sociocultural perspective.

INTRODUCTION

Ethnomathematics is grounded in the anthropological studies on mathematics of indigenous peoples and aims to recognize and describe the ideas and practices of different cultural groups, indigenous communities as well as labour guilds (D'Ambrosio, 1985; Barton, 1996). Later, in the attempt to make sense of the confrontation of different perspectives of Ethnomathematics, its purpose was extended to address a broad view of mathematical knowledge in relation to its development in different cultures (D'Ambrosio, 2012). Ethnomathematics seeks to explain what and how different individuals show different interests, talents, skills and strategies to generate, organize, and share that knowledge. This sociocultural perspective is supported by the contributions of various disciplines which share a relativist position.

As the perspective of Ethnomathematics involves deep epistemological changes to move away from a positivist posture, many researchers propose seminars, courses and Ethnomathematics workshops for teacher education, with the common goal of raising awareness about the nature of mathematics as a social and cultural product and hence, directly or indirectly, influencing the participating teachers' epistemological conceptions.

In the United States of America, Presmeg (1998) organized courses where pre-service teachers became aware that mathematics is a cultural product, starting to affirm value and leverage in their future professional life concerning issues related to cultural diversity.

In Costa Rica, Gavarrete (2012) organized a course for training teachers who work in indigenous environments. She promoted relativistic conceptions of mathematics that integrated academic knowledge with traditional indigenous cultural knowledge and that was applied to various activities of the daily life of these communities.

Building on the work of Presmeg (1998) and Gavarrete (2012), we held a workshop for a group of pre-service and in-service teachers of the University of Buenos Aires. One of the workshop's objectives was to influence the teachers' conceptions about the nature of mathematics.

The aim of the present research is to illustrate the potential of different ethnomathematical dimensions for analysing the development of the participating teachers' conceptions concerning the nature of mathematics after the workshop. This allows us to point out the changes that the work-shop made. The dimensions themselves were defined from the point of view of the ethnomathematics program. We show how these dimensions were useful in order to systematize participants' conceptions.

We decided to work in Buenos Aires because the workshop was about the mathematics involved in an Argentinian craft and because the legislative documents of the educational reform of 2006 promote a model of teaching and learning where knowledge is conceived in relation to its development in cultures and its use in daily life (Albanese, Santillán, & Oliveras, 2014).

THEORETICAL BASES

The ethnomathematical dimensions

Based on a literature review, we propose three dimensions that we consider crucial for systematizing the perspective of Ethnomathematics.

The first dimension is the practical dimension: mathematics is *a tool that man develops to relate, understand, manage and eventually change his environment*. This dimension comes from the definition of D'Ambrosio (2008) of Ethnomathematics as a way (*tics*) of knowing (*mathema*) in the environment (*ethno*); in other words, mathematics is considered as a tool for the systematization and interpretation of reality such as identifying patterns that govern environmental elements and the relationship between them. Thus, mathematics is a way of knowing how to perform daily activities, acting in and controlling the surrounding context and eventually modifying it.

Secondly, we consider the social dimension: *mathematics is a consensual construction of a set of rules and norms within a group of people that decide to share it*. This dimension comes from Barton's (2008) proposal of interpreting mathematics as a system of meanings through which a group of people gives a sense of quantity, space and relationships (QRS-systems). These systems are built by communities that share the same vision of reality and agree on some common codes to communicate.

The third and last dimension is the cultural dimension: *different forms of mathematics exist in different cultures*. Ethnomathematics establishes a profound relationship between mathematics and culture. From a philosophical point of view, many of the researchers, like Barton (2012) and Knijnik (2012), insist on the importance of a relativistic perspective that allows the coexistence of different mathematics.

Teachers' conceptions

To delineate the notion of conception we consider the contributions of Ponte and Chapman (2006) and Pajares (1992). However, different to these authors, we decided not to distinguish between conception and belief, as we considered this distinction not clear enough, and as our interest was actually focussed on what the participants believe that mathematics is, i.e. their conceptions about mathematics. We understand conceptions as the underlying organizational structure, or conceptual substrate, of a knowledge; they are idiosyncratic, derived from experience or fantasy with a strong affective and evaluative component. They do not have an internal consistency, they are more inflexible and less dynamic than knowledge [1], they tend to be perpetuated despite contradictions; they are usually acquired through the process of cultural transmission.

METHODOLOGICAL ISSUES

The workshop

The workshop was about the mathematics and mathematical thinking involved in an Argentinian braid craft that we studied in some previous research (Albanese, Oliveras, & Perales, 2014; Albanese & Perales, 2014; Oliveras & Albanese, 2012). The aim of the workshop was to present mathematics from a different point of view and therefore to influence the participants' conceptions about mathematics.

The workshop was held by the main researcher as a part of a course of mathematical modelling of the degree of mathematics for secondary school teacher of the University of Buenos Aires. The participants in the workshop were twelve pre-service teachers, students of the course, and their two teachers.

The workshop employed a methodology based on direct experience where we showed and asked them to make braids, working in small groups as well as on the content that focused on a specific manual task.

The idea of the workshop was that the participants investigated, constructed and agreed on a creative representation of the making of a braid. Then the participants shared the different representations they made in small groups and we pointed out the difference and similarities between them and a craftsman's representation of the practice.

At the end of the workshop we invited the participants to answer five open questions about final observations on the work and its epistemological and educational implications. These questions are listed below.

1) What mathematical thought did you put into effect to make, represent and invent braids?

2) What implications about the nature of mathematics are involved in this activity?

3) Which aspects of Ethnomathematics have you experienced?

4) What aspects of the experience do you consider relevant in relation to the methodology of work?

5) What potential educational purposes can you see in this type of work?

The research
The research can be considered as an educational ethnography, that is, ethnography of small work groups or classes (Goetz & LeCompte, 1988). Ethnography was chosen for its affinity with the perspective of Ethnomathematics, as well as for the interest of the attitudes, opinions and beliefs of the people who we were researching.

We considered the oral and written observations of the participants as evidence of their conceptions about the nature of mathematics. We performed a qualitative analysis of the data based on content analysis with the help of the computer programme MAXQDA7 to systematize the information and to assign codes and categories.

The descriptive codes were obtained in a process combining both inductive and deductive procedures. The original idea for a drafted grid of categories came from a pre-analysis phase, in which we were first drafting and working with preliminary codes. Then we went back to the theory of Ethnomathematics and refined the original idea against the backdrop of to the theoretical bases described above. Thus, we finally obtained the three dimensions of Ethnomathematics in a deductive manner. These dimensions were then combined with the five items from the questions, that we posed to the participants. These questions were discussed according to their scientific relevance and validity for our research objectives by a group of expert ethnomathematics researchers. Fifteen potential categories resulted from the combination of the three dimensions and the five items. Finally, we inductively obtained the descriptive codes to fill these categories in confrontation with the empirical data. The development of the descriptive codes therefore follows an inductive-deductive cyclical process that produced eighteen descriptive codes, leaving one of the fifteen potential categories empty and allowing for a further differentiation of four of the categories within the practical dimension.

SOME RESULTS

Here we present the descriptive codes for the written observations, evidencing the empirical relation of teachers' conceptions about mathematics with the practical, social and cultural dimensions of Ethnomathematics. In Table 1 we summarize the descriptive codes obtained in the analysis, organized by item and category.

We will illustrate the descriptive power of the codes, by describing in detail the codes that came from the answers of the participants to the second item: *what implications about the nature of mathematics are involved in this activity?* These are summarized in the second column of the Table 1.

Items / Dimensions	1. Mathematics thinking	2. Nature of mathematics	3. Ethno-mathematics aspects	4. Methodology	5. Potentiality
Practical dimension	***→Model real situation***	***→Model of daily life*** ***→Patterns***	***→Experience, research*** ***→Mathematics of the practice***	***→Concrete experience*** ***→Motivator***	***→Daily life in school*** ***→Mathematics of reality***
Social dimension	***→Agreement***	***→Social construction***	***→Collective, consensus***	***→Group***	***→Social interactions***
Cultural dimension		***→Other mathematics***	***→Different mathematics***	***→Different point of view***	***→Thinking differently***

Table 1: Table of the codes distributed by item and by category

JO: This activity clearly shows the potential of mathematics as a modeler of daily events.

MAR: Mathematics arises as a need to systematize a concrete practice, while it allows people to imagine other possible braids.

These two participants underline the role of mathematics in creating models of daily life, these models give us the possibility to manage and control reality (like inventing new braids). We assigned them the code "model daily life" and we categorized them in the practical dimension.

VAN: Through this activity we could make a case analysis and generate patterns for modeling and generalization about braid weaves.

JE: Mathematics is (in part) to create representations of a part of reality and of its internal relations (or some of them), and from that model, to generate new knowledge on that portion of reality.

These two participants go a little further, they both recognize that mathematics is a tool to model reality but they also insist on identifying the internal relations and the patterns. So we coded these as "patterns" and again we considered these observations as referring to the practical dimension.

KA: Mathematics is a socially constructed science.

This participant makes explicit that mathematic is a social construction so this observation clearly belonged to the social dimension.

DI: Wondering: what is mathematics? Reflecting on transformations throughout history and open to new transformations.

This participant made evident his reflection about the nature of mathematics, and reflects in a historical way, seeing the transformation that mathematics has made over time. We associate this observation with the idea that, as mathematics is a historical product, it is a social product, so we considered it in the social dimension.

MAT: Mathematics is more than school mathematics or academic mathematics.

VE: The arbitrariness of the notations, the coexistence of some representations (over others) the relationship of that coexistence with the particular "reading" of each one using such representation.

These last two answers show respectively the existence of a different kind of mathematics with respect to the academic one, and the existence of different points of view of the same problem (with the consequent elaboration of different notation) and the different interpretation of the same representation depending on the viewer. Both these observations are related to the existence of different mathematics, that's why we categorize them in the cultural dimension.

The classification of conceptions according to the three dimensions allows us to summarize the results of the whole group of participants. Ten of the 13 participants who answered the question "*What implications about the nature of mathematics are involved in this activity?*" observed that the activity showed the importance of mathematics to *model everyday situations*, to represent reality and to recognize and control relationships and *patterns* to handle general cases (Practical category). Four participants manifested ideas related to the social category: mathematics is a *socially constructed* science, it is intrinsic to human activity, it is transformed throughout history and they recognized the role of institutions in indicating where there is mathematics. Finally, three referred to evidence of the cultural category: two of them suggested considering *something else* other than formal and classical mathematics and one insisted on the coexistence of different representations valuing the way of thinking of each one.

CONCLUSIONS

Our findings suggest that, in general, the codes of the social and cultural categories are much less present than the practical category, and we perceived that the social and cultural dimensions were always manifested in the participants' observations indirectly, the ideas were delineated but not fully developed while the ideas related to the practical dimension were richer and more developed in the teachers' conceptions about mathematics after the workshop.

The definition of three ethnomathematical dimensions, the practical, social and cultural dimensions was fundamental for carrying out the analysis. The definition of these dimensions provided the tools to interpret the teachers' observations. We think that the description of these dimensions is an important achievement of the work and its usefulness has been confirmed during the analysis of our data, as we could recognize almost all the participants' observations by assigning a category of conceptions.

The explanatory potential of similar operationalizations of dimensions of mathematics, could also be demonstrated by other studies, e.g. that of Albersmann (2015) about parents' utility-oriented beliefs about mathematics. Albersmann's study considers three dimensions that are related to the ones presented in this paper, which are conceptualized as 1) pragmatic relevance, 2) methodological relevance, and 3) cultural relevance.

In the studies of Presmeg (1998) and Gavarrete (2012), changes in teachers' conception have been recognized, but our work goes a little further because indicates the multiple directions of these changes.

Finally, this demonstrates how fruitful it was to link different philosophical contributions to Ethnomathematics by different authors, identifying and giving voice to their different positions. D'Ambrosio (1985, 2008) insists on the practical and moreover social dimensions, as he is a mathematical historian. Barton (1996, 2012) starts from the social dimension but he ends up focusing on the cultural dimension, because of its work with indigenous tribes. Our findings highlight the importance for ethnomathematical research to take into account both points of view.

Parent-child cooperation in mathematics learning: Insights into maths-experience days

Natascha Albersmann and Katrin Rolka

Ruhr University Bochum, Bochum, Germany, natascha.albersmann@rub.de

Considering the fact that the influence parents have on their children's mathematical development is unavoidable, it should be less the question whether parents should participate in their children's mathematical education, but more how their participation could be incorporated more consciously. This issue becomes even more crucial with regard to secondary school mathematics. In this paper, one approach is presented, namely a family math in which parents and their children get the opportunity to deal with mathematics in problem-based discovery learning environments together as a team. The focus of this paper lies in the investigation and characterisation of parent-child cooperation in the course of the first workshop of the project, as well as factors promoting such cooperation or hindering it.

Keywords: Parental involvement, secondary school, cooperation, problem-solving.

INTRODUCTION

The critical role that parents play in their children's educational development in general and specifically in mathematics is undeniable (Desforges & Abouchaar, 2003). Parental beliefs about mathematics, its teaching and learning, emotions regarding mathematics or parents' mathematical competencies, to name just a few factors, come together to diverse influences on their children's mathematical education. What is more, parental participation in mathematical learning activities seems to decrease with their children getting older. In this context, Eccles and Harold (1993) mention, among other reasons, a change in parents' views of their competences to help their children with schoolwork as they enter higher school grades. In particular, with the switch from primary into secondary school, in Germany at the beginning of the 5th grade, mathematical contents start to become more and more unfamiliar for parents. Whereas they could rely on being an omniscient answerer or the conveyer of knowledge in earlier school years, parents ultimately need to shift roles in order to further support their children regarding mathematics. Besides mathematical contents, parents may also feel that current methods of teaching mathematics may differ a lot from those they experienced in their school years (Eccles & Harold, 1993).

All in all, the conditions for parental support in their children's mathematical education change fundamentally in the course of secondary school years. Therewith, new challenges but at the same time new possibilities for parental involvement in their children´s mathematical learning emerge.

INVOLVING PARENTS IN MATHEMATICAL EDUCATION

Initiatives for parental integration in their children's mathematical education often consist of one-way transmissions of information and materials from schools or other educational institutions. However, drawing on the social constructivist view, learning is not a simple process of transferring information, but involves an active social interaction. The emphasis thereby lies on learning as an ongoing process in activity-based learning situations with meaningful purpose (Vygotsky, 1978). In this context, findings from a project called MAPPS (Math for Parent Partners) indicate that giving parents opportunities to actively construct their own understanding of mathematical concepts provides an indisputable foundation for their work with their children. Moreover, research results of this project imply that the nature of interactions that parents developed with their children might be even more relevant than their ability to help them with specific content (Civil, Guevara, & Allexsaht-Snider, 2002). These findings emphasise that it is not only necessary to introduce parents to current mathematical concepts in an active way, but also to foster parent-child interactions in mathematical contexts.

Since in secondary school mathematics parents' knowledge advantages decline, the foundation for parent-child interactions in context of mathematical problems change. Following the idea of a "community of learners", one goal is that parents and children work together with everyone serving as resources to the others, with varying roles according to their understanding of the problem at hand (Rogoff, Matusov, & White, 1996). This concept goes hand in hand with a cooperative learning approach that constitutes a foundation from which parent-child interactions can be fostered in the context of secondary school mathematics. In this sense, we understand parent-child cooperation as one main feature to describe the nature of parent-child interactions in mathematical learning situations.

Guided by the concept of dialogic learning, conversations in a cooperative learning approach should follow an egalitarian dialogue where different contributions are taken into consideration according to the validity of their reasoning instead of the position of power held by those who make the contributions (Flecha, 2000). Thus, in order to foster parent-child cooperation, it is essential to create a learning situation in which parents will not automatically act as the conveyer of knowledge, but rather become a learning partner for their children. This speaks for a concept with open-ended and problem-based discovery learning situations (Bruner, 1961) in which parents and their children get involved with a mathematical problem in a self-directed way (Hmelo-Silver, 2004).

Considering the demand to integrate parents more actively in their children's mathematical secondary school education, the questions arise: How does the cooperation of parents and their children in the context of a discovery learning situation work out? Which facets promote a parent-child-cooperation, which not?

METHODOLOGY

The project and its participants

One possibility to investigate forms and conditions of parent-child cooperation in an open-ended and problem based discovery learning situation is provided by a family math project, called maths-experience-days. This project started as a pilot project in the school year 2012/13 with parents and their children from a 5th grade (10–11 years old) of a German higher-level secondary school, a so-called gymnasium. The project workshops lasted three to four hours and took place in the school building on Saturdays, hence outside of schooldays. The participation was on a voluntary basis.

In the first workshop, which builds the basis of the results presented and discussed, twenty-two families participated with both parents appearing in five cases. Hence, a total number of twenty-seven parents attended the first workshop, among these seventeen mothers and ten fathers. The parents' ages varied between 36 to 52 years old. Due to incomplete data sources only the data of twenty-five could be taken into account in the research presented.

The families participating in the project live in rather high socio-economic conditions. With respect to parental educational backgrounds, it can be noted that every parent has a school leaving-qualification. All in all, seventeen parents achieved the general qualification for university entrance, of which fifteen of those parents obtain a university degree and two did an apprenticeship. Moreover, seven parents achieved a subject-related entrance qualification. Two of those parents finished a polytechnic degree and five an apprenticeship. Only one parent achieved an intermediate school-leaving certificate who did an apprenticeship as well. The occupational fields are diverse and range, for example, from business management, law to medicine, natural sciences or social professions. Each and every parent has a job at the time of the survey.

The first station of the discovery journey – content and structure

According to the above-mentioned general conditions for the learning environment, a didactical reduction of the mathematical content seems to be reasonable. This concerns the complexity of the problem presented to the parents and their children at the beginning of the workshop (see Figure 1).

„A friend of mine, let's call him Harry, used to be a paper boy when we were a bit younger. His job was to deliver a free regional newspaper once a week. He loved working in the fresh air and meeting all the people living in his delivery district. However, there

„A friend of mine, let's call him Harry, used to be a paper boy when we were a bit younger. His job was to deliver a free regional newspaper once a week. He loved working in the fresh air and meeting all the people living in his delivery district. However, there was one thing, he struggled with. His tour took far too much time.“

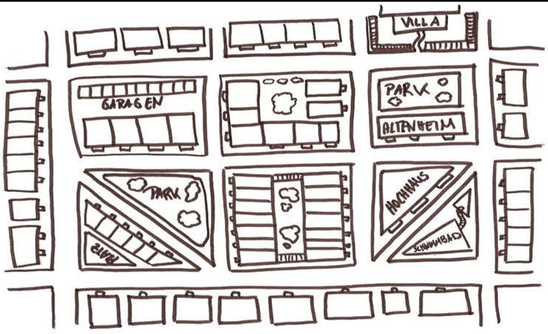

Figure 1: Problem and Harry's delivery district – working material

was one thing, he struggled with. His tour took far too much time.“

Due to the requirements for autonomous learning and performance of the parent-child teams, the role of the workshop coordinator rather consists in encouraging cooperation by scaffolding strategies like recruitment, direction maintenance and frustration control than providing scaffolding methods with stronger content-related guidance (Wood, Bruner, & Ross, 1976). In the need of content-wise support, parent-child teams can draw on different hint cards according to their progress in problem-solving. Those hint cards are constructed on the basis of scaffolding methods like reducing degrees of freedom by simplifying the task as well as accentuating critical and relevant features or, at last, demonstrate the solution itself.

The phase of the problem investigation is structured through the cooperative learning method "think-pair-share" (Sharan, 1994), which particularly shall subserve parent-child cooperation. First, parents and children think about possible approaches to solve the paperboy's problem for themselves and, then in pairs (parents and children) exchange their idea is, carrying them forward together. At last, the ideas are collected and discussed in the whole group.

Data sources

We have several data sources at our disposal that play a role for the analysis and hence the presentation of the results. While considering multiple data sources, we draw on an approach that is characterized by triangulation of data (Schoenfeld, 2008).

Before the first workshop, and again after the last workshop, parents are asked to answer a questionnaire containing both open and closed items. Besides personal information like age, gender, school education, vocational training, and occupation, the questionnaire consists of parental beliefs about mathematics considering both cognitive and affective aspects as well as their personal reasons for participation.

Likewise, data concerning the process of working on the problem in the course of each workshop is collected. Here, reflective journals are used which have become an accepted method for qualitative researchers to gain insights into their participants' thinking (Mewborn, 2013). On the one hand, parents and children document their mathematical considerations during the problem investigation. On the other hand, the reflective journals are used by parents and children at the end of each workshop. In order to encourage reflection, guiding questions are displayed which address their experiences, difficulties that occurred as well as strategies to overcome them and new insights that parents and children gained during the workshop.

Besides parents' and children's journal entries after the first workshop, the results presented in this paper are based on field notes taken during and immediately after the workshop by the coordinator.

Analysis

The experiences of parents and children during the first workshop indicate diverse aspects for an analysis, all of which cannot be taken into account. In this paper the focus lies on the analysis of data referring to parent-child cooperation during the problem-solving process.

On the one hand, parents explicitly referred to forms of parent-child interactions throughout the entire reflective journal from which the nature of their cooperation could directly be derived. On the other hand, some parents did not mention their children or the work with their children at all. Thus, cooperation patterns were implicit. In order to interpret those journal entries and moreover validate interpretations, they were matched with other data sources like the corresponding journal entries of their children and field notes taken by the coordinator of the workshop.

The analytical framework for the open data sources is informed by the principles of qualitative content analysis (Mayring, 2010). First, hints on parent-child cooperation were independently selected from the reflective journals by the authors and significant themes identified with the goal to induce a categorisation of parents' cooperative behavior. Second, interpretations were compared between the authors and discrepancies were discussed. A category formulation was determined and checked in a final sifting through reflective journals. Finally, in due consideration of all data sources, parents were assigned to one of the inductively developed categories.

RESULTS AND DISCUSSION

To understand the whole picture, some facts need to be pointed out before the discussion of results. First, the sample consists of parents with a high socio-economic status and therefor is of limited representativeness. Second, they participated in the family math project voluntarily. Consequently, the sample is selective by its nature. However, taking into account all of the conditions, the data still allows some interesting insights.

The findings show that parents can be assigned to one of two categories: *parents as learning partners* and *parents as learners*. The two notions of parental roles are similar to those used by (Civil, 2001), although the conditions of parental integration are different from the MAPPS project with regard to the direct involvement of children in our project. While the first category *parents as learning partners* could be observed for thirteen parents, six parents were assigned to the category *parents as learners*. Another six parents do not give any information about the parent-child cooperation and could not be coded.

In the following, we first briefly describe the meaning of the two categories and use excerpts from parents' and children's journals to exemplify our shared understanding of the categories. In the course of exemplifying the categorisation, some aspects with a positive effect on parent-child cooperation, but also some with a negative effect are pointed out. We indicate the authors of the answers by M for mother, F for father, and C for child, combined with a respective number.

Parents as learning partners

In the category – parents as learning partners, the parents are open to cooperation with their children and accept the children as "equal partners" (M20) in the discussion, like it is intended by the above-mentioned dialogic learning approach. Here, parents often emphasise the positive experience of this cooperation. In what follows, we give an example of a statement on the parent-child cooperation experienced as positive:

[The process of solving the problem was] constructive, through cooperation with my child. [...] and we perfectly complemented each other. [...] My child approached the problem with more enthusiasm and curiosity than me. That made me happy. (M8)

Additionally, field notes give a closer insight in the kind of cooperation between mother and child. During the problem-solving process the mother took a step back, gave her daughter room and let her explain her approaches and insights first. Here and there, the mother summarised partial results and asked some crucial questions. Thereby the mother-child team got further in their problem-solving process and at the end reached an overall solution. It moreover is interesting that the daughter shares this positive experience of working together with her mother, as she expresses:

> We solved it [the problem] in teamwork. That was cool. (C8)

In this context, one identifiable factor for the positive experiences regarding parent-child cooperation is that the mathematical problem is not only unknown for the children but the parents as well. Moreover, since the problem is open-ended, both, parents and their children could contribute to the problem solution in their own ways. They could even approach it on an equal footing. However that was not the case for every parent-child team. In a few cases the fact that the problem was an unknown riddle for both, parents and children, did not work in favor of parent-child cooperation, but against it. Those cases are discussed below in the part of *parents as learners*.

Other parents emphasise the good parent-child cooperation during the workshop while confirming the stressful relationship to mathematics learning situations in context of school mathematics at home, like for example:

[...]. I especially do find the cooperation between child and parents very refreshing. Away from the mathematics-homework-problems to a "voluntary" learning and approach to mathematics. [...] There was no "school pressure" as probably usual. It simply was fun and had a good result. (F11)

The child as well remarks the positive parent-child-cooperation but furthermore values the mathematical context away from numbers and calculations like it is excessively stressed in school.

I liked it because it was something new and in maths with Miss H we always do calculations. (C11)

Indeed, arithmetic commonly builds a focal point in school mathematics. With that, this comment points out that an open-ended and problem-based discovery learning environment is a fruitful opportunity to gain positive new experiences with and diverse insights into mathematics, which are often missed out in school contexts.

Other parental journal entries clearly show that a cooperation does work, when parents do not take over a dominating role, a role of being master of knowledge, but become a learning partner for their children, sometimes on an equal footing. This aspect is for example reflected by the following parental expression:

At times the cooperation was good, when we came closer to the solution and respected each other as equal "providers of ideas / partners". There also were moments when my child lost interest [...] when the solution of the problem at times receded into the distance. (M20)

One main problem becomes apparent with this quote. Sometimes children get set back by occurring difficulties in the mathematical problem-solving. In this case parents should support their children more actively in order to overcome the difficulties together and refocus. Such situations in the workshops constitute an opportunity to impart methods and techniques to parents for supporting their children in a critical mathematical learning situation.

Parents as learners

In the category – parents as learners, it becomes obvious that parents are keen to learn mathematics for themselves. They are fascinated by the mathematical problem at hand and take the opportunity of getting fully absorbed in the task. Being completely engaged in their own problem-solving process, they lose sight of their children and do not enter into cooperation with them.

One mother describes in detail her work on the mathematical problem, exclusively using the first person. For example, she comments on her thinking process, occurring difficulties while working on the problem, and finally concludes with the following statement:

> I would have liked to cooperate more closely with my daughter. (M7)

Not only the field notes point in a similar direction, but also the child comments on the workshop exclusively using the first person. This further strengthens the impression that no cooperation took place.

Other responses give a closer look into forms of cooperation between parents and children. One father points out, that he would have liked to accomplish the problem solution on his own and hence is not content with *his* work. He solely refers to his child in one line with the coordinator and the other participants when asking for exchange as he got stuck in his own problem-solving process:

> Thinking into an impasse, solved it via exchange (with child, coordinator other participants). (F22)

However, the field notes confirm the impression of the father deepened into his own problem-solving process and completely forgot his child over it. The child himself tried to get some glimpses at his father's problem-solving process, asking for insights, but was on his own for the rest of the problem-solving process. This impression is again strengthened by the child using only the first person in his journal entries, not referring to his father at all.

The following example, where the child together with father and mother took part in the workshop, is another illustration for the category of *parents as learners* where a competitive thought is decisive for a lack in parent-child cooperation. While the father describes his point of view in a concise way, the mother is more detailed and discusses her despair in the problem-solving process, but also her ambition to overcome her difficulties on her own. The problem-solving process of this family can be best described as competitive, which can be confirmed by the following mother' statement.

> What my husband is able to accomplish, I need to accomplish as well. (M24)

Nevertheless, she clearly expresses her wish for more cooperation in her further remarks.

> [I would have liked] that we cooperated more closely – instead of everyone for himself. (M24)

The child strengthens the impression of competition and the lack of cooperation by writing the following:

> Nasty that dad always was the first one to find out everything. (C24)

Taking the competitive nature of some parent-child teams into account a different approach is needed in order to strengthen parent-child cooperation. One promising approach could be to let parents and children work on a mathematical problem that directs them to work together as a team in order to compete against other parent-child teams. Such a context could fuel the competitive nature of some parents and children, but at the same time strengthen their team building.

CONCLUSION AND OUTLOOK

The discovery learning situation of the paperboy's problem, presented here, offers parents and their children a possibility to investigate a mathematical problem on an equal footing. They have the opportunity to experience mathematics in an open, assessment-free setting together as a team and therewith could gain positive feelings of social relatedness, as well as mathematical competence. Sometimes such experiences between parents and their children were more intense, sometimes less.

Searching for parental attributes that may be linked to the form of parents working with their children in context of the math-experience-days, namely *parents as learners* or *parents as learning partners,* no direct relation to parental gender, age, educational qualification or the occupational field could be found. That does not mean that there is not any connection to those attributes, but that they are not explicitly related to the parent-child-cooperation, rather multifaceted in its nature or interwoven with other factors. Those factors could for example be parents´ emotional dispositions towards mathematics or parental motivations to do mathematics. In some cases it already became obvious that parents´ desire to investigate a mathematical problem on their own, their ambition to solve the problem for themselves is so dominant that the risk exists that they forget to cooperate with their children. Such factors influencing parents' ways to work with their children need to be investigated further in future research on the family math project.

Furthermore, it would be interesting to investigate more closely the impact of such a family math project on mathematical learning situations at home. As it seems, general mathematical learning situations at home, mostly in context of homework, are often accompanied by tension and stress. Several parents mention this issue in their answers being completely aware of the project's special status. In this context, the here presented results first and foremost indicate that an open-ended, problem-based discovery learning situation represents a fruitful context for children working together with their parents on a mathematical problem. In any case, the risk that parents overtake the role of the conveyer of knowledge is minimised by the nature of the presented learning environment. When, moreover, the task for parent-child cooperation is explicitly defined by activities like investigating the problem, comparing approaches and therewith generating ideas or strategies without pointing to an existing solution, the pressure to find an overall solution could be reduced even more. Hence, one promising approach, in order to foster parental involvement in their children's mathematical learning, could be to integrate such open-ended, problem-based discovery learning situations as special parent-child homework.

However, the nature of parent-child cooperation in those problem-solving contexts needs to be investigated further. It is clearly not enough to examine only the course of one workshop, with one type of mathematical problem at hand, in order to get a holistic picture of parent-child cooperation and promoting or hindering factors. Consequently, it needs more and diverse family math workshops to investigate the conditions and dynamics of parent-child cooperation in open-ended, problem-based discovery learning environments. That will follow in the main survey.

The sightless eyes of reason: Scientific objectivism and school geometry

Melissa Andrade-Molina and Paola Valero

Aalborg University, Faculty of Engineering and Science, Aalborg, Denmark, melissa@learning.aau.dk, paola@learning.aau.dk

There is a gap between the aims of school geometry in terms of the teaching of spatial abilities to young children, and the dominance of a school geometry rooted in Euclid's axioms and abstractions. Such gap is not to be explained in terms of a "misimplementation" of the curricular intentions. Rather, the gap evidences elements of the power effects of school geometry on children's subjectivities. We problematize both the truths circulating in school geometry discourses and the effects on children's subjectivities, by adopting cultural historical strategies to research the functioning of school geometry curriculum. We argue that school geometry fabricates the scientific minds of the future by educating students to see not with the eyes of their bodies, but with the eyes of reason and logic.

Keywords: Objectivity, subjectivity, school geometry, power effects.

INTRODUCTION

Nowadays it is argued that spatial visualization ability plays a key role in shaping the successful scientific minds of the future, probably as important as verbal and mathematical thinking (Newcombe, 2010). This ability becomes critical when developing expertise in STEM domains (science, technology, engineering, and mathematics). It is believed that including spatial ability as a criterion for identifying talented youth would help recruiting many adolescents with potential for studying STEM fields, but who are currently being missed (Wai, Lubinski, & Benbow, 2009). There is a research trend claiming the importance of providing spatial education for young children because "increasing access to a preschool "spatial education" constitutes a safe bet for fuelling school readiness and igniting long-term performance gains in STEM-related fields" (Verdine, Golinkoff, Hirsh-Pasek, & Newcombe, 2014, p. 20).

But why has spatial visualization become so important? One possible reason is how research has found that visualization is central in the conceptualization processes of scientific discoveries. For example, the use of spatial reasoning is implicated in several physics discoveries such as Galileo's laws of motion, Faraday's electromagnetic field theory, and even Einstein's theory of relativity (Kozhevnikov, Motes, & Hegarty, 2007). Furthermore, the discovery of the structure of DNA was "centrally about fitting a three-dimensional spatial model to existing flat images of the molecule" (Newcombe, 2010, p. 29).

It is postulated that "spatial thinking can be taught; [... and that] it is possible with appropriately structured programs and curricula" (National Research Council [NRC], 2006, p. 109). Several studies on school geometry deal with the development of spatial abilities in students, from introducing diverse activities with building blocks to changing the entire school geometry curriculum. Despite the recognition that spatial ability is a key element to science and that it can be taught, it is also highlighted that the teaching of this ability is largely ignored in formal school settings (Clements & Sarama, 2011).

It is the contention of this paper that there is a gap between the aims of school geometry in terms of the teaching of spatial abilities to young children, and the dominance of a school geometry rooted in Euclid's axioms and abstractions, which prompts to a flat and abstract world. Our assumption is that such a gap is not to be explained in terms of a "misimplementation" of the curricular intentions. Rather, the gap evidences elements of the power effects of school geometry on children's subjectivities. Adopting cultural historical strategies to investigate this contention in the constitution of school geometry, the paper deploys an argument in three movements. Firstly, we examine how notions of space move between discussions of perception and formalization. The formalization of the language of Euclidean geometry, through scientific objectivism, provides ways of building a scientific self. Secondly, we explore how such objectivation entails the subjectivation that takes place through the discourses of school geometry. By examining the curricular materials of Chile, we exemplify the existing gap between such discourses and the expressions of the ideal student. Finally, we problematize both the truths, in terms of Foucault, circulating in school geometry discourse and the effects on children's subjectivities. We evidence how the school practice of knowing geometry has effects on how students understand and train themselves to see space.

ANALYTICAL STRATEGY

There are many truths that circulate in mathematics education research, and such truths constitute unproblematized understandings of the practices of mathematics education. The type of research deployed in this paper assumes that mathematics education practices are political because they govern subjectivities in both productive and constraining ways (Valero & García, 2014). Evidencing the subject effects of a series of practices and discourses, such as school geometry, is a contribution in understanding how the school mathematics curriculum fabricates the subjectivities of children through educational processes. This is important since mathematics education is not only a process of knowledge objectivation, but also a process of subjectivation or of becoming within culture.

More concretely, this approximation is inspired by the work of Michel Foucault. Our strategy is composed by some concept-tools we borrow from Michel Foucault (subjectivity, discourse, truths). We bring this concept-tools to help us reasoning about the problem of the apparent gap between the aims of school geometry in terms of the teaching of spatial abilities and the dominance of a school geometry rooted in Euclid's axioms and postulates. Our empirical materials consist of students' textbooks, curricular guidelines for teachers and geometry maps of learning progress, all of them produced by the Chilean Ministry of Education (MINEDUC).

Since discourses are produced by the interaction of different spheres of social life and are shaped by statements and their related truths (Foucault, 1972), to understand how school geometry is operating it is also necessary to study how geometrical knowledge has been shaped. Here we delineate elements of such study connecting geometry with cultural historical studies of science (e.g., Daston & Galison, 2007). The discussion of objectivation/subjectivation in science and geometry invites us to approach the school geometry curriculum as practices that govern subjectivities through the enunciation of the ideal student. Hence, problematizing the naturalised truths that circulate in school geometry discourse and the statements about the aims of school geometry will help us to elucidate the effects of geometrical knowledge objectification on the self.

THE OBJECTIVATION OF SPACE

Mathematics lives in a world of abstractions, axioms and formulas. There is a perfect and ideal world within mathematics, every calculation applied correctly should work impeccably, even if is not about a real object. For de Freitas (2013), mathematical objects are taken to be entirely free from spatio-temporal conditions. Hence, if mathematics is universal and has no context it is possible to understand it as a blind sight, without inference, interpretation or intelligence (Daston & Galison, 2007).

However, it is believed that mathematics can describe the world we live in. But if geometry can describe what we are able to see, our surroundings, why has it become a blind sight? According to Boi (2004), the anatomy of the eye entails light on a curved retina, therefore our visual system deploys a projective geometry rather than Euclidean metrics. An experiment conducted by Blumenfeld (Hardy, Rand, & Rittler, 1951) demonstrated that phenomenological visual judgments do not satisfy all Euclidean properties, he revealed that physical configurations do not coincide with Euclidean geometry (Suppes, 1977)[1]. Likewise, Burgin (1987) claims that the conception of Euclidean geometry's space was based on technique rather than on visual evidence. It was based on axiomatic, which deployed an idealized world of ideal shapes, such as triangles, squares, platonic solids and so on. It is an objective knowledge.

For Daston and Galison (2007)[2], objectivity in science was not a matter of viewing nature as it really was, but as it should be to be studied – nature as an ideal nature –. The result of objectivism was an annulation of the self by the self, it was "the suppression of individuality, including images of all kind, from sensations of red to geometrical intuitions" (Daston & Galison, 2007, p. 46). Images, within science, were 'left behind' because it was the only way to break the mental world of individual subjectivity.

If objectivity in science aspires to a knowledge that bears no trace of the knower, how is geometry supressing individuality? For Daston and Galison (2007), objectivity becomes an 'epistemic virtue' when abstractions are able to transform subjective representations into objective concepts. For example, Tazzioli (2003) shows that Mario Pieri, an Italian mathematician, introduced the axioms and methods of projective geometry without any reference to intuition (neither to monocular vision). He was close to cut the link between geometry and empiricism. Hilbert's work, inspired by Pieri, was the masterpiece that led to a geometry based on logic, axioms and theorems (*règles*), a form of geometry in which intuition and experience do not have a strong role. This led to a space that can only be reached by mathematics, very distant to the one we are able to see and interact with.

But space is a product of concrete practices and attempts to representing them; it is not abstract at all. However, when it comes to the knowledge that traditionally has dealt with space —geometry—, then it becomes the realm of abstraction. It becomes an objectified space. For instance, according to Lefebvre (1991) space can be understood in three forms: space as perceived, as conceived and as lived. The first form takes space as a physical form, as real space, a space that is generated and used. The second form, the space of knowledge (*savoir*) and logic, takes space as an instrumental space. Space becomes a mental construct, an imagined space. The third one, space of knowing (*connaissance*), sees space as produced and modified over time and through its use. It is a space that is real-and-also imaginary. Geometrical space is a space of *savoir,* within Lefebvre's forms; it is an idealized, imagined and constructed space.

In the same fashion, school geometry is leading us to see space as an instrumental space, a mathematical space of *savoir*. Space becomes Euclidean, Cartesian, and flat. It is very distant to the one we can perceive. Ray (1991) stresses that school mathematics has been based on the axioms of Euclidean geometry because they provide an internally consistent system, evident to the eye. But this objective geometrical space deployed by Euclidean geometry is limited, in terms of Lefebvre's forms of space.

BLINDING THE CHILD

In school, geometrical knowledge tends to be constructed outside the body. It is a fixed knowledge that has to be learnt by students. School geometry is based on abstractions, very distant from our perception of 'daily space', as if we had a body without the sense of sight. In other words, dealing effectively with school geometry tends to fabricate a sightless body. Then, learners are not really prompted to use their senses to learn or interact with geometrical knowledge.

For example, Chilean mathematics curricular guidelines claim that mathematics was developed to solve diverse challenges of mankind and of mathematics itself, within history and culture. Therefore, school mathematics must provide and facilitate the understanding of the real world we live in (Ministry of Education of Chile [MINEDUC], 2010). In this sense, school mathematics should supply students with tools to interact with the world they are able to see. An analysis of official documents of the Chilean Ministry of Education (MINEDUC) shows that its claims are built around certain statements, in a Foucaultian sense, that delineate the features of an ideal child, such as:

> School mathematics curriculum is aimed to provide students with the basic knowledge of the field of mathematic, and, at the same time, that students develop a logical thinking, deduction skills, accuracy, abilities to formulate and to solve problems and abilities of modelling situations (MINEDUC, 2010, p. 3, our translation).
>
> To learn mathematics enriches the understanding of the reality, facilitates the selection of strategies to solve problems and contributes to an autonomous and own thinking (MINEDUC, 2010, p. 3, our translation).

School geometry becomes a valued and useful knowledge, a set of tools that will help students to fulfil any situation of the real world. For Valero, García, Camelo, Mancera and Romero (2012), school mathematics "inserts subjects into the forms of thinking and acting needed for people to become the ideal cosmopolitan citizen" (p. 4). In this case, an ideal student should be

When students have achieve this level, they solve activities as the following:

- To calculate, by using geometrical and analytical methods, the area between four circumferences of radius a, which centers are the vertices of a square of length 2a.
- To determine the number of diagonals of an n-sided polygon, by using combinatorial techniques.
- To prove by contradiction, that a line is tangent to a circle when the radius drawn to the point of contact is perpendicular to the tangent at that point.
- To prove, by using congruence axioms, that the exterior angle of a triangle is grater that either of the remote interior angles.
- To construct a regular pentagon using a compass and straightedge or a software, and to justify the construction.
- To deduce the vector equation of a line from its Parametric and Cartesian form.
- To formulate and to verify which geometrical shapes satisfy that: the sum of the areas of the shapes built up on the sides of a right triangle is equal to the area of the shape built up on the hypotenuse.

Figure 1: Seventh level of the map of progress (MINEDUC, 2010, p. 18, our translation)

a logical thinker and a problem solver. The student should be capable of modelling real life situations by only using mathematical knowledge.

Furthermore, the Chilean Ministry of Education (MINEDUC) established a map of progress with seven levels that students have to achieve along school geometry in compulsory education. An ideal student should perform successfully in activities where he/she must be able to solve problems by only using geometrical axioms and theorems (see Figure 1), which leads to a notion of space in terms of the formal system of Euclidean geometry. What it takes to deal successfully with these tasks is far from spatial visualization. It seems that this ability is something that has to be developed by the student itself.

The mismatch between the expectations and the description of abilities could be related to the fact that Chilean school geometry is based on Euclidean, Cartesian and vectorial geometries, necessary to cope with other school subjects, such as physics.

> The world we live in is three-dimensional [...]. It is aimed that students are placed in a real three-dimensional context, providing new tools to make spatial and flat representations, such as the vector model. This model constitutes one of the basic foundations of physics and mathematics. (Ministry of Education of Chile [MINEDUC], 2004, p. 68, our translation).

According to this quote, it becomes important to link "reality" with school mathematics. By doing so, it is assumed that students will be able to use geometrical tools to solve everyday-life problems. The way to achieve this link is by introducing three-dimensionality to students. Within school, the "world we live in" becomes vectorial. Consequently, the expressed desire to link spatial thinking and the real world seems to blur, and the only important part left are the perennial mathematical abstractions. This generates a new type of space, the space of school, which has been 'chopped' and has been restricted.

As an example, the MINEDUC (2004) enhance certain types of activities where students "emphasize relations between Cartesian and vector equations within geometrical shapes" (MINEDUC, 2004, p. 68, our translation) than other type of activities where students could develope spatial skills. Space for school is in terms of XYZ, a space than can be modelled by school mathematics. Chilean school geometry is based on a flat geometry, mainly Euclidean. But in Euclidean geometry the studies are on objects situated in the void; objects that are not real (Kvasz, 1998). A possible question to pose is if Euclid of Alexandria was living in an abstract world? The easy answer is that of course not he was, and, moreover, he started his studies by analyzing his surroundings. He developed a theory known as Euclid's optics. Which is a theory of vision and of intuition (Suppes, 1977).

According to de Freitas (2013), logic and axiomatic relations in mathematics tend to erase the temporal and ontological. As a result, school mathematics is an untouchable knowledge that becomes universal, decontextualized and, therefore, without culture or the possibility to influence in it (Valero & García, 2014). It is an unalterable truth, installing mathematics as the science of pure logical structures and negating all connections between mathematics and the real world we live in (Kollosche, 2014).

> The concept of space to be reconstructed in the students' understanding is that of a rational, referential space with fixed points in two or three dimensions. It is assumed that the conceptual development of the child will lead to an internal and abstract representation which will contribute to making a decontextualized child, freed from the practical capacities of acting with objects in space, particularly of those spaces where everyday life occurs (Valero et al., 2012, p. 7).

However, school keeps making this link between what we are able to perceive and the abstract space of mathematics. We claim that there is a gap here to explore.

THE SIGHTLESS EYES OF REASON

We deployed a discourse analysis of official curricular materials of the Chilean Ministry of Education. This analysis, built from Foucault, has pointed to the existence of statements circulating about an ideal student. In this existing discourse, it is believed that by connecting school geometry and reality students will become problem solvers, logical thinkers, 'reality modellers' and so on. The existing discourse requires that students perceive themselves as agents who are able to change the world, but also as agents who are responsible for their own learning (Foucault, 2009). More precisely, school geometry deals with power-knowledge relations [3], by promoting the fabrication of a certain type of subject, a scientific trained child.

But, how is school geometry discourse operating on students? Here the discussion is not about the contents of school geometry itself rather it is on how school geometry is operating in the fabrication of children's subjectivity. In other words, it is on the power effects of school geometry in fabricating forms of being in the world. In this sense, human beings become subjects through the objectifying effects of scientific knowledge, a knowledge that is also objective (Foucault, 1982). And, at the same time, the practice of knowing generates effects in the form of knowing and in the subjects who know (Daston & Galison, 2007). Therefore, students must train themselves to become part of a practice. An example of this self-training is illustrated in the following activity proposed in the 6th level of the progress map of Chilean school geometry (MINEDUC, 2010, p. 17).

> A young girl is observing a pit formed by two concentric circumferences, 1 m. and 1.2 m. of radius respectively, and 3.5 m. of depth. Using this information, she is able to make a model by drawing a rectangle ABCD in a coordinate system XYZ. It is asked to the girl to determine the rectangle's vertices and to argue on which axis the rectangle must rotate to obtain a three-dimensional representation of the pit. Finally it is asked to the girl to calculate the pit capacity, in litters.

Clearly the ideal student must forget about his/her senses; must train him/herself to be able to model real life situations using geometrical deductions; must be able to think space in terms of XYZ. It is not necessary to use spatial visualization ability to solve this activity because is useless. Is it relevant to mention that the

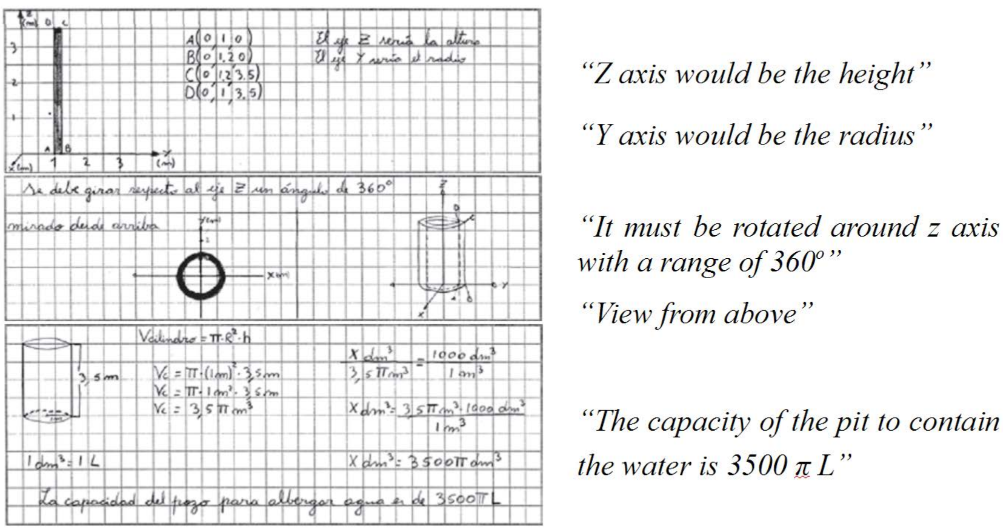

Figure 2: Example of a expected answer of a student

girl was observing the pit? Would it make any difference if the problem had not been contextualized to a real life situation? Why is it relevant to use a coordinate system to calculate the volume of the pit?

This evidences a gap between the aims of school geometry on curricular materials of Chile, in terms of the teaching of spatial abilities, and the notion of space that school geometry promotes, which is rooted in Euclid's axioms and abstractions. Reasoning with the objectification of space in geometry, to shape a scientific self implies to suppress the self, which means to cut all links between perception and geometrical formalizations. This suppression leads to perceive space and geometrical knowledge as decontextualized, and as universal and timeless.

Nonetheless, space outside the school is not universal neither timeless. What if this notion of space changes? Sanjorge (2003) argues that the space in which the subject is constructed has already changed; consequently the subject itself has been changed. There are virtual movements, where there is no orientation, not right or left, it is a post-Cartesian space, which is nonlinear. It is a "spherical space, where up and down are not positions in the world but situations of the viewer" (Sanjorge, 2003, p. 5, our translation). This is a notion of space unfolded by technology, a virtual world that is subjectifying children to perceive no orientation, where everything is reachable by a 'click'. It is a space opposed to Cartesian movements within 'school space' and the different spaces are not related at all.

At the end, the interplay between power and mathematics education is on how the school mathematics curriculum generates cultural and historical subjects (Valero & García, 2014). Then, school geometry becomes a technology of the self and the others, by regulating children's conduct, and by developing 'cultural thesis' (Popkewitz, 2008) about an ideal student who is able to see with sightless eyes. This generates systems of reason in which forms of life and subjectivity are made possible, organized and constrained. Therefore, school geometry has power effects on how students understand and train themselves to see space. Such subjectification pursues to fabricate the scientific minds of the future by educating students to see not with the eyes of their bodies, but with the eyes of reason and logic.

ENDNOTES

1. Blumenfeld performed a series of experiments with parallel and equidistant alleys. One of the tasks in the experiment was to arrange two rows of point sources of lights as straight and parallel to each other as possible. The lights were placed on either side of a plane. The results revealed that physical configurations do not coincide with Euclidean geometry. In Euclidean geometry, parallel lines are equidistant along any mutual perpendicular. However, in the experiment, the resulting lines diverged, they were not parallel at all. He concluded that Euclidean geometry does not apply to our visual space.

2. Daston and Galison (2007) analysed images on scientific atlases to study its history, emergence and development.

3. This power is not to be understood in terms of domination of the self; it is not an imposition to train students' sight. This power understands 'the other' as a person who acts on his/her own; depending on the freedom of the subject (Foucault, 1982). Likewise, school geometry discourses are not a form of impositions; they are produced because we reproduce them through language. They are an 'action upon action' (Foucault, 1982).

Pressures and positions of need during the Swedish third-grade National Test in Mathematics

Anette Bagger

Umeå University, Department of Science and Mathematics Education, Umeå, Sweden, anette.bagger@umu.se

This paper presents and discusses parts of a large-scale [1] ethnographical and longitudinal study that has followed the process of implementing the National Test in Mathematics for third graders (Ntm3) in Sweden during its first three years (2010, 2011, and 2012). Pupil talk from 2011 about pressure and what is at stake was used to construe three positions of need that might characterize pupils during the National Test in Mathematics in their third school year: the position of shame, the position of unfamiliarity, and the position of stress. How these might be handled in educational practices is discussed briefly.

Keywords: National test, pressure, mathematics, third grade, position of need.

INTRODUCTION

The National Test in Mathematics for third graders (hereafter called Ntm3) in Sweden was introduced in 2010 (Utbildningsdepartementet, 2012). Since this test in its current form is a new phenomenon, research is scarce. Levlin (2014) has investigated how reading and langugage skills in the second school year predict achievement on the National Test in Mathematics for third graders, test anxiety and its connection to acievement have also been examined (Nyroos, Bagger, Silfver, & Sjöberg, 2012), and the tests have been studied as a technology of disciplinary power (Foucault, 1980) exercised over children (Sjöberg, Silfver, & Bagger, 2015). Other research on tests for children of similar ages has shown that national tests can contribute to difficulties in mathematics (Sjöberg, 2006). There are ways of handling test anxiety, coping with stress, and learning test-taking skills (Sena, Lowe, & Lee, 2007), but these require identifying needs and pupils in need. The very concept of a pupil who needs support in mathematics is used and understood in a variety of ways in research, contributing to challenges in communicating and building knowledge about needs and support for these pupils (Bagger & Roos, 2014). The concept of *need* is in this paper understood as a position that a pupil might move in and out of, depending on the situation and the individual or the environmental prerequisites (Silfver, Sjöberg, & Bagger, 2013). This paper looks further into some of the discursive preresiquites for developing the position of 'being a pupil in need'. The approach is to investigate pupils' perspectives from an ethnographic point of view. Hereby I strive to adopt an insider's perspective in the research by revealing the participants' perceived experiences and, through this, building an emic narrative. The pupils are then the source for the emerging story about being a pupil in need. Three focus areas guide this investigation in exploring how pupils are positioned and position themselves in terms of possible needs: (1) pupils' talk about the experience of pressure, (2) whether and how stakes are expressed by the pupils describing negative pressure, and (3) pupils' talk about the position of being in need. This paper represents a pilot study that elaborates on the methodology before it is applied in a larger sample of pupils at the same three schools. Larger numbers will make it possible to discuss issues of diversity and equity and to take socioeconomic factors into account.

NATIONAL TESTS IN SWEDEN

Educational reforms in which assessment and comparison of pupils have played key roles have become more common internationally in the last decades (Clarke, Madaus, Horn, & Ramos, 2000). One purpose of the testing is to identify pupils at risk of not achieving the educational targets (Wyatt-Smith & Castleton, 2005). Media often publicize the results, reporting how well schools perform in relation to each other and whether more or fewer pupils have succeeded. Thus, the tests sort and categorize not only pupils but also schools. This can be understood as part of an international trend in neoliberal educational policy, whereby schools are governed and govern through the test (Hudson, 2011). Parents' choice of schools might then be described as a consumer's choice of education, where the child's knowledge is perceived as a product (Lange & Meaney, 2014). In this way, the discourse surrounding testing activates power relations between schools, teachers, and pupils.

Ntm3 has the purpose of both evaluating the pupil's level of knowledge and evaluating education at large. It also aims to support a just evaluation of pupils' knowledge by securing the equality in teachers' assessments (Björklund Boistrup, & Skytt, 2011). The third-grade National Test in Mathematics is taken by all pupils with few exceptions and requires approximately one month to administer. It consists of several subtests connected to different (but not all) parts of the curriculum. In addition, there initially is a self-evaluation section and a co-operation subtest. The test is administered and corrected by the classroom teacher. Afterwards, the schools' test results are saved in databases (SIRIS, Swedish Ministry of Education).

THE PUPIL IN NEED DURING TESTS

Pupils might experience standardized tests as a pressure on them, but whether the pressure is perceived as positive or negative varies. Negative pressure can increase failure rates and affect the learning progression because it threatens pupils' self-worth (Putwain, Connors, Woods, & Nicholson, 2012). Putwain and colleagues (2012) describe how stakes relate to negative pressure:

> Higher stakes tests increase the threats to self-worth, unfamiliarity increases the uncertainty of being able to demonstrate competence and low competence beliefs increase the likelihood of failure, all of which result in the appraisal of tests as threatening rather than challenging. (p. 300)

That is, if pressure is negative, the pupil might fear or imagine that something is at stake, and this could contribute to pupils "in general" being transformed into pupils in educational needs. A need is not only constituted of what the individual wishes and asks for but is also a matter of necessity and depends on the situation at hand (McLeod, 2011). The need for support during tests can be explained as an occurring agency need that for some individuals remains also on other occasions and at other times but may also be caused by a dispositional educational need. An occurring need may therefore be temporary or persistent and in some cases both. Teachers are good at detecting achievement but are less skilled at detecting what the pupil thinks about him- or herself (Urhahne, Chao, Florineth, Luttenberger, & Paechter, 2011); thus, it is crucial that research seek to clarify pupils' understandings of themselves. Research about how pupils position themselves in testing situations contributes to this end, since it may reveal some of the social dimensions of testing from the pupil's perspective and positions of need that are foreseen. Giving pupils support and equal chances of passing the test is especially urgent because reports indicate that the school system is segregating pupils, which might be seen in test scores and grades (see, e.g., Swedish Agency for Education, Swedish School Inspectorate, 2012). Drawing on Atweh, Graven, Secada, and Valero (2011), I understand the issue of providing high quality mathematics and equity as an ethical imperative that schools must address.

METHODOLOGY

Ethnographical data were produced before, during, and after the national test. Contextual facts were collected before the test regarding the municipalities, schools, and classes.

Data collection and selection

In order to access the pupils' firsthand experiences about the test, video-stimulated recall dialogues (VSRD) were conducted with pupils individually and video recorded (see Silfver, Sjöberg, & Bagger, 2013). The technique used in interviewing the children was inspired by Morgan (2007). Data from these interviews have been analysed, whilst other data from the project constitute a contextual background for understanding and interpreting the interviews. The pupils with the highest and the lowest test scores at three schools in one municipality (2011) were selected. Choosing these pupils presumably brought forward some of the critical issues regarding mathematics testing. The selection makes it is possible to investigate preresiquites for needs regardless of achievements, gender, background, or skills. The schools ranged in size from medium to large, and their locations varied from inner-city to suburban and from lower class, immigrant-majority to native Swedish-speaking, middle-class areas. The selection of schools allows for the discussion of social justice and diversity, in addition to discourses in the area of test taking in both policy and practice.

Year 2011	Outer-city school		Inner-city school		Non-city school	
Pupil	Sofie	Ali	Ellen	Emmanuel	Anna	Sara
Passed subtests	All	None	All	None	All	None
Score (max 101)	87	55	89	19	97	75

Table 1: Pupils with the highest and the lowest test scores from three classes (2011) in three schools, from various socioeconomic settings (the names are fictional)

Analytical process

Data were examined using Transana, a computer software for encoding and analysing video and audio recordings. Analysis was performed in three steps, according to guidelines from Heath, Hindmarsh, and Luff (2010) and is displayed in Table 2. Clips were organized, after repeated reviews, into collections with open codes. Patterns, such as similarities and contradictions, were searched for between collections. Positions of need were construed as categories to summarize the patterns found. This is presented in the results. Examples are given of what was said.

Negative pressure was identified in the talk when pupils implied that they had felt uncomfortable and experienced disturbing thoughts about the test, math, and themselves. *Positive pressure* was identified when the talk was influenced by positive feelings, expectations about the test, math, and themselves. Whilst searching for things at stake, I applied Putwain and colleagues (2012) definition of *stakes* as

> the real or imagined consequences of testing students' academic credentials (test scores or grades), educational access (for example to a particular school) and educational progression/ability setting, and also for teachers professional status (e.g. from school league tables). (p. 291)

Instead of *teachers' professional status*, I searched for *pupils' status*.

Positioning and discourse as analytical lenses

Drawing on Foucault, one can understand discourse as constructing and constructed by individuals and society through systems of representation. Through these systems, knowledge, truth, and power are produced (Hall, 2001). An individual's ability to speak is regulated by discourse in determining how, when, and from what position people may speak (Davies & Harré, 2001). These positions depend on the discursive context, the participants themselves, and the activity at hand (Lofors-Nyblom, 2009). This means that the discourses in the test situation will govern possible positions of need and the ways that the test can be talked about. An important theoretical distinction is that a position of need is not the same thing as one pupil's *being* in one fixed position of need. The concept is instead a construction of possible positions of need that a pupil may take on or be given in the test situation. One pupil's talk might in this way contribute to several positions of need, depending on the position from which that pupil is talking. It is not the subject (pupil) who talks but the discourse that talks through the subject (Foucault, 1983).

RESULTS

Positions of need construed from pupils' talk about pressure and stakes are presented in the following paragraphs. Positions of need were expressed only in regard to negative pressure. Positive pressure, along with what could be described as positions of 'the good test taker,' is also displayed. In pupil talk about positive pressure, no needs were apparent; neither was any talk about stakes.

Pressure as positive and the understanding of responsibility

Sofie and Ellen were both high achievers who talked about the test as interesting and the nervousness as stimulating. Ellen emphasized that loneliness and being on one's own contributed to the feeling of positive pressure. These two girls were emphatic about positive aspects of the test. Ellen said, 'The teachers want to see what we can do, so that we can achieve our goals.

Selection of pupils	Review 1	Review 2	Review 3: Analysis
Highest and lowest performing in class	Talk about pressure and test consequences	Talk about negative pressure and stakes involved	Positions of need during tests

Table 2: Process of analysis

I think it's really important—it's important to achieve goals in school, and you can do that if you take the test.' Ellen had great trust that the actual accomplishment of the test would help her reach her goals. And Sofie was very clear about where the responsibly for her development lay:

> Because this test is for—I think it's for you to see what you already know and what you need to practise. And what the teachers will ... if they need to give someone more instruction and if they should be clearer on something ... So it's really the teachers that get to know if they did well or not.

Despite this outlook and the fact that Sofie had the highest score in her group, she referred to skilled boys in order to position herself as talented:

> Yes, I think I had the fewest mistakes in the class, because there are two other boys that have other math books since they are so good ... [and] I had one mistake less than them.

Lack of curiosity regarding the test

Sara did not express pressure in either direction but thought that the math on the test was difficult. She implied that she might lose knowledge that is important to managing in life—for instance, 'if you have to go somewhere, or buy things in a store.' She also said that it could be fun to take the test because she was allowed to draw, something she liked to do. And it was fun to write the test because it was something unusual. Although she had the lowest scores, Sara passed all the tests. Her school's area was a white, middle-class neighborhood, and almost all its pupils spoke only Swedish.

Pressure as negative and what is at stake

In the talk about negative pressure, three different positions of need were construed: the position of stress, the position of shame, and the position of unfamiliarity. The talk also contains signs of things perceived as at stake. Of the six pupils, four talked about the test as pressuring them in negative ways and mentioned things being at stake.

The position of stress

Both high achievers (Anna) and low achievers (Emmanuel and Ali) reported having experienced anxiety and stress or disturbing thoughts in connection with the test. These emotions were felt in the body, whilst only the high achiever Anna described stressful thoughts. Emmanuel said, 'I was nervous; my hands shook. It felt like they would write the wrong answer.' Anna talked about the fear of not being able to retrieve her knowledge whilst working on the test. Even though she was sure that she was good at math because adults had told her so, she was insecure about whether her knowledge could really be trusted:

> But later on, I had a little panic ... so that I could barely ... I was still nervous, so I panicked because I was writing it. But exactly when you needed it [the knowledge] most and you needed ... to write the answer ... to remember the answer—then it flew out of your mind, and when you don't need it, it comes back. I got more than a little irritated.

Anna also vividly described how stressed she felt during the test and how she tried to handle these feelings. She was worried about not finishing in time and about making mistakes; several times she indicated that she was afraid of not being permitted to continue to the fourth grade. Her social belonging was at stake: 'If you didn't get the right answer, maybe then you would have to retake third grade. It felt like that.' At the same time, she understood that this was not the case: 'I know that it's not like that, but I just got that feeling, and it also felt like I would get a heart attack a little.' The feeling of potentially loosing her social context grew whilst Anna was waiting for the results: 'Waiting for the results felt like waiting to know whether I had to retake third grade or could move on to grade four.' The stress may also have involved knowing that the test would be difficult and that the situation would demand concentration and intense thinking. Ali commented on this: 'It's hard, and you have to think really, really hard, and that might be tough.' He also spoke of finishing as a relief from pressure: 'Finally, I'm done, and now I'm free.'

The position of disappointment

Ali implied that knowledge might be lost if a pupil did not pass the test: he assumed that taking the test *in itself* generated mathematics learning. Along with this lost knowledge, his dignity would be at stake if he did not learn more, along with a potentially loss of social status:

> I think you can embarrass yourself sometimes if you don't know it [math] ... also, if we answer questions ... and they say how much is one times

> one or ten times ten, and when you don't know, then you might embarrass yourself.

He also mentioned another possible outcome of not succeeding in the test—namely, feelings of sadness: 'If you don't pass, you'll be sad and feel sorry that it didn't go well.'

The position of unfamiliarity

The fear of not knowing mainly involved feelings about scores. Both Ali and Anna said, 'What if I make a mistake?' Anna also worried about being able to finish in time; that is, she did not know whether she had enough time. Emmanuel spoke of uncertainty about his skill and his possible results. 'Will I pass this? (Interpreted as: I'm afraid I won't.)' This fear may have arisen partly because the test took place in an unknown situation. Anna said, 'Beforehand, I didn't know what to expect, what the test would look like, and I wasn't prepared.' This concern could be connected to Anna's fear of being unable to retrieve knowledge and putting her educational progress at stake.

DISCUSSION

The analysis of how pupils talked about pressure in order to study discursive preresiquites for positions of need in the test situation seems to have yielded rewarding results, since the pupils talk about pressure and stakes seem to give valuable information to possible educational needs in the test situation. To perform the same analysis in a larger sample of pupils might reveal still other positions of need, beyond the ones discussed here. Clearly, issues of power and governance were involved in the practice of test taking for the pupils in this article. They talked about the risk of losing social belonging, pride, and knowledge. Some critical gendered issues, as well as matters of diversity and social justice, are revealed, and it will be interesting to examine these further in a larger study. One conclusion from this limited sample, is that the test leads to a comparison and sorting of pupils. Pupils start to relate their achievements to those of others in order to understand their placement within the competitive discourse, which is more apparent in the multilingual schools. Comparisons were highlighted more often by the pupils in the multilingual schools, regardless of which kind of pressure they expressed. This implies that pupils on these schools are participating in a competitive discourse regarding scores which position them as having the potential of 'not winning' or 'loosing'. In the suburban school in a middle-class and mainly Swedish-speaking area, neither of the pupils compared themselves with others. Instead, they talked about their knowledge as the focal point in the testing situation. Those pupils are in this way participants in a testing and learning discourse where their knowledge is at stake. Anna is a key informant since she had much to say about her experiences. It is an important methodological reflection that the boys who reported negative pressure and stakes did not manage the Swedish language very well, going to the multilingual schools. It could be that their test performance was hindered because of this problem, which might cause negative pressure. It might also be that if they had been interviewed by someone who could speak their language, they could have provided much more information.

The results suggest that the position of unfamiliarity could both lead to uncertainty about one's ability and derive from uncertainty about one's ability. One educational need here is to cultivate knowledge about skills and the test, before the test. Knowledge about skills could decrease the risk of test anxiety (Ahmed, Minnaert, Kuyper, & Van der Weerf, 2012), but that would require that the teacher learn whether pupils lack these insights and have these feelings. The test situation enhances the focus on scores, which might lead to a heightened risk that teachers will not notice how pupils think or feel about this issue (see Urhahne et al., 2011). This also applies to the position of shame. Talking about these feelings would most probably positively affect both the achievement in the testing situation and the overall learning situation. Tests can actually create good opportunities to talk about feelings of putting things at stake, not remembering, not knowing, and embarrassment. This might lead to a balancing of the test situation so that pupils' needs come to the fore—not only the needs of the test. Clarifying the purpose of the test, how it will be used, and how it is understood by the teacher could perhaps lead to a leveling of inequalities for the pupils.

Mathematics as caring: The role of 'others' in a mathematical identity

Laura Black[1], Yvette Solomon[2] and Darinka Radovic[1]

1 University of Manchester, Manchester, UK, laura.black@manchester.ac.uk

2 Manchester Metropolitan University, Manchester, UK

In this paper, we explore the role of 'others' in one woman's mathematical identity. We draw on sociocultural theory to analyse identity in terms of the relationship between self and others: that is, as mutually shaped in interaction with others through the enactment of an 'identity in practice'. Our analysis focuses on the role of 'caring' as a particular form of this relationship, suggesting that our respondent uses this as a cultural resource to identify as a mathematician. We argue that caring supports her access to central mathematical spaces and, consequently, her potential to change the nature of mathematics itself.

Keywords: Gender, caring, identity, others.

BACKGROUND

Mathematics is perceived by many people as abstract, masculine, irrelevant, boring, uncreative and difficult (Mendick, 2006; Schoenfeld, 1992). Such negative views of mathematics appear to be particularly common amongst certain social groups – e.g. girls, low achievers, low SES (Forgasz & Rivera, 2012). Girls, for example, criticize school mathematics as repetitive and rote, and show a "quest for understanding" (Boaler, 2002) which places both the relevance and use of mathematics as central. A considerable body of research has suggested that such negative attitudes are symptomatic of a wider process through which girls are excluded from high status mathematics as a white, male, privileged social practice. Walkerdine's (1989) now classic study highlighted how from a very young age girls enter into mathematics though enacting domestic/caring roles in play with their mothers. But once at school, this "domestic mathematics" was discounted and de-valued against "formal-school mathematics" which subsequently positioned girls as merely hard working in contrast to boys' perceived natural and effortless ability. In school, the girls in Walkerdine's study continued to find social status within the classroom through exercising domestic/caring roles (such as being the class helper), but were positioned as lacking in school mathematics, foretelling restricted access and participation in mathematics later in life. Walkerdine thus highlighted how the domestic/caring roles that girls are socialised into ultimately served to exclude them from higher status forms of mathematics valued by school.

In this paper, we explore this account of 'caring' and its connection to girls' access to mathematics further. Whilst we recognise that many students' experiences of mathematics are shaped by its position as a gatekeeper to powerful and privileged domains, we argue that the processes by which individuals are included/excluded from mathematics are complex and that in certain circumstances, individuals may 'succeed against the odds'. Thus much of our previous work has provided examples of successful women (from non-privileged backgrounds) who have persisted with mathematics, examining the complex and contradictory structural conditions which have afforded their success (Solomon, 2012; Black, 2013, 2010; Solomon, Radovic, & Black, submitted). With this in mind, we hypothesise that 'caring' (both for others and by others) whilst still a result of marginalisation more generally, can potentially act as a cultural resource for individuals and, in the right circumstances, sustain a positive mathematical identity. We explore this hypothesis here by drawing on one of our previous examples – Roz – a professional 'academic' mathematician who one of us (Yvette) interviewed on a number of occasions over a period of 5 years. This period included an interview with Roz as a PhD student (Solomon, 2012) and as a post-doctoral researcher (Solomon, Radovic, & Black, submitted). We draw primarily on Holland, Lachicotte, Skinner and Cain's (1998) theory of figured worlds, and the ways in which individuals draw on cultural resources and models in 'identity in practice', using this as a lens for understanding the role of caring and its relevance in Roz's history of engagement with mathematics.

Theorising identity and 'caring for/by others'

Holland and colleagues (1998) argue that identities (rather than identity) are relatively durable entities which are drawn on and constructed in the stories we tell ourselves about who we are. Thus, they are multiple in nature and connected to the various practices we engage with. This is elaborated by Holland and Lachicotte (2007) who suggest that our perception of our own self is rooted in how we are perceived by others as we engage in practice:

> We actively internalize a sense of our own behavior as compared to the behavior of others acting in related roles and positions. We develop an inner sense of the collective regard that society is likely to have for our performances. Then, we craft our own way of being in roles and positions in relationship to this "generalized other," the collective sense that we gradually develop from those who evaluate us (Holland & Lachicotte, 2007, p. 107).

Elsewhere we have argued (Black et al., 2010; Black & Williams, 2013; Solomon, Radovic, & Black, submitted) that 'the internalisation of our own behaviour' which Holland and Lachicotte outline here takes place through reflection – in reflection we construct a story about who we are and thus our subjectivity (our own behaviour in practice) becomes crystallised as an identity (I am a certain kind of person). Crucially then, the stories we construct are mediated and shaped by our subjectivities 'in practice' to the extent that we cannot simply decide to adopt a particular identity on a discursive whim.

We find the idea of cultural models useful in this respect since they lie on the boundaries between 'practice' and the narrated self (Gee, 2010; Holland et al., 1998). Holland and Skinner (1987) describe cultural models as shared implicit knowledge about types and ways of talking about them, which become crystallised so that the knowledge/story/assumptions that they embody remains implicit. Gee (2010) provides an example in questioning 'Is the Pope a bachelor?' – which illustrates that although the Pope might be included in the formal definition of the term bachelor (a male who is unmarried), he does not typically fit with the implicit story or assumptions which have become crystallised through our use of this term. Therefore, we can argue that cultural models are culturally and socially shared and, to a large degree, shape what is possible and what is not. In Holland and colleagues' (1998) account of the US college dating scene, we see cultural models relating to various figures (jocks, nerds and so on), and these determine a story about who can date which kind of girl. Applying this to our concern with girls and women in mathematics raises the issue of what cultural models and figures intersect with self-positioning in mathematics, and the related issue of what kind of engagement with mathematics these models support. Furthermore, given Walkerdine's (1989) conclusions regarding the role of caring for others (in domestic roles) in excluding girls from mathematics, we are interested in how this particular cultural model might be used by someone who is female and yet apparently successful in mathematics. In this paper, therefore, we address the following questions: What is the role of 'caring for/by others' in a developing mathematics identity? How does the individual draw on a 'caring self-other relationship' in their self-authoring as a mathematician? How does 'caring for/by others' relate to the construction of mathematics itself?

METHODOLOGY

Roz began her university career at the age of 44, taking undergraduate, masters and PhD degrees in mathematics. At 52, she is now engaged in post-doctoral study at the same highly prestigious university where she undertook her PhD. The interview, which was fully transcribed, took place in a university cafe, and was loosely focused on her ongoing mathematics career, and her account of the past, present and future, including the impact of being a mother on her career. We see the interview as a place which encourages reflection and, therefore, supports identity formation of the kind we have described above. It provides the space for Roz to reflect and thereby, co-construct with the interviewer a story about who she is and what identities she positions herself towards. In our analysis, we focus on the role of caring and others in her account of herself as a mathematician, and in particular the part they play in her vision of the mathematical world and her place in it.

ANALYSIS

The role of caring for/by others in a developing mathematical identity

Roz's talk is populated by references to the role of caring for/by others in her decision to become a mathematician, and her on-going identification of what kind of mathematician she is. She especially identifies her relationships with her mother and father as crucial. Specifically, Roz locates the origins of her desire to become a mathematician in terms of a 'genetic' alignment with her father:

> ... when we were tiny he would bring home the scrap paper with all the technical drawings on for us to use the other side of – it was a purple one. (?) I was just fascinated with the drawings themselves, and the precision with which they designed even the (inaudible) in the lid, and how things worked – I just loved it. And I was just gazing at these and how things worked and whatever ... so it was always in there I think. ... I mean part of it's intrinsic isn't it, genetic – I'm much more like my father than my mother. So the things that he liked – I like. I don't feel let down by him in the way I feel let down by my mother. So there's all those things going on, but there's also sort of the natural being drawn to those pictures rather than turning it over and scribbling on the other side ... so that was already intrinsic. So I think it was already in there to a large degree.

Here we suggest that Roz is re-constructing a particular type of relationship with her father based around shared interests and enjoyment which, she believes, has resourced her mathematical identity. This relationship is presented in direct opposition to that with her mother with whom she feels 'let down by'. Elsewhere in the interview, she explains this more negative relationship in further detail:

> She was a social worker, so she was working shifts in a home for children who'd been taken away from their parents. [..] So there was no regular routine at home. I was the eldest so I was expected to look after my sisters. [..] And I think ... it might be the particulars of her job, but she never had time for us. She did loads of stuff for us – washing, ironing, cooking and everything ... but never anything with us. [..] So I think it really was important to me to stay home with my boys. Because she was always saying 'Not now Roz, not now Roz' but there was never a time when it was okay to talk to her. And if you can't share the trivial things, you can't share the important things – cos you don't establish a relationships. So ... yeah. So that's why I say that.

Whilst she recognises that in some ways she was cared for by her mother in that 'she did loads of stuff for us', the contrast she constructs between this and the 'with us' type of relationship she had with her father is notable. Roz clearly dis-aligns herself from this more distant relationship with her mother – for her, it was 'regrettable' that her mother worked when her children were young, and she emphasises her own choice to be a 'stay at home' mother, placing value on 'being there for them':

> I was 20 years full time at home with my boys, I was. [...] but at the same time I could be there for them, and they weren't left to squabble it out, fight it out between themselves in the school holidays like we had to.

We suggest that Roz's account of how she became interested in mathematics and how she came to identify with it is shaped by her re-telling of these significant relationships with caring others. In this re-telling she invokes a type of being cared for which involves spending time together and sharing interests. This is manifest in the relationship she had with her father whom she identifies as a critical 'other' in explaining the origins of her love of mathematics. But this is also not a simple causal relationship of positive parental influence = positive mathematical identity since Roz also frames her father's influence in terms of what it is not i.e. the negative, more distant relationship with her mother who she was 'let down by'. We suggest that these two ways of 'being cared for' ('spending time with' versus 'doing stuff for') have shaped her trajectory in becoming a female mathematics academic at different moments of her life. First, by resourcing her original interest in mathematics through shared interests with her father, and then, by motivating her late entry to academia as a mature student which emerged from her decision be a 'stay at home' mother.

The role of a 'caring self-other relationship' in being a mathematician

In a previous paper (Solomon, Radovic, & Black, submitted), we noted how Roz constructed a narrative of her present and future self as a mathematician which entailed negotiating the contradiction of being feminine but doing 'male' mathematics. We suggested that this contradiction led her to enact her mathematics activity in a particular way, hybridising femininity (through dress, investing in relationships with other staff members and organising social activities) with her interest in the 'theoretical stuff' which she sees as belonging to the 'masculine', systematising domain. These findings relate to the focus of this paper, since the 'caring-other' relationships we have discussed appear to be crucial in enabling Roz to negotiate this contradiction. For instance, in the following extract, Roz discusses how her previous experience as a stay at home mother (caring for others) has affected her current role as a mathematician:

I	Being a mother and being a mathematician, do they ... sort of go together?
R	I think it's added to me as a person. ... [..] And I think that part of coming to maths as a mature student has given me things to hook it onto. [...] And I can understand it more quickly because I can relate it to things I already know. And I think that being a mother has helped me to be the kind of person who will help the other students and who they can relate to and that kind of thing, and that persists. .... and I think that being a mum has helped me with that.

Here, we can see that being able to 'relate to others' is not only valued by Roz but also that she sees it as helping her to perform her role as an academic, connecting to her earlier emphasis on the form of 'caring for others' as sharing interests. The fact that she connects this to 'being a mum' re-iterates the particular kind of parental, caring relationship she values – one which now enables her to act in a certain way as an academic mathematician:

> But when I'm here [in her department] I'm... you know okay I can be very firm ... you know if need [to talk to] people with ice behind my eyes I can do that and get them to do what I need ... but I can also be thoughtful ... and people say 'Oh I didn't think of that' – and it's the most obvious thing, like you know just being extra careful to talk to the new person, or you know every day 'How are you getting on?' – this kind of thing.

The role of 'caring for/by others' in the construction of mathematics itself

The particular form of 'caring for/by others' that Roz values not only appears to resource her identity as an academic mathematician in the context of her university department, but is also evident in her construction of what mathematics itself is. Roz's research expertise lies in the area of complexity theory and statistical modelling to address real world problems such as finding the most effective treatment in healthcare and structuring networks for food security decision support. A persistent theme in her story is an emphasis on mathematics as a means to 'describe the world' and make it a better place (see Solomon, 2012; Solomon, Radovic, & Black, submitted), and in describing this mathematical activity she sees herself as 'helping people' – she uses the term 'the people element' frequently. This suggests that the 'caring-other' relationship which Roz invokes in describing both her historic love of mathematics and her current identity as an academic mathematician is also part of her construction of her mathematical activity itself.

But crucially, Roz is at pains to point out that she is not succumbing to a dominant (gendered) discourse about mathematics which creates a division between those who do applied, 'people friendly' mathematics/statistics and those who do 'real' theoretical mathematics (see Mendick, Moreau, & Hollingworth, 2008). This is apparent when she discusses the kind of work she does in her current role:

> ... the thing is it's such an outward facing role – the ability to engage with people is you know the thing that's really really important. [..] I started picking through some papers to get ready for the interview [for her current role], I was kind of like ambivalent about the job. And then I saw this 'algebraic statistics' and there was ... it was talking about ideals and this kind of stuff, and I was thinking 'It's real maths, I don't feel like I've done that for ages, oh I really want this job now.' And just suddenly I thought ... Yeah real maths! Oh ... it's a dichotomy isn't it, because this is the really pure stuff, that really is not meant to ... I mean the model was [for helping] people, but this is the really pure stuff, and it's just kind of playing with toys, and I think 'Ooh ...' [..] But also we needed to prove some stuff so ... with its coherence... And I need to get into Bayesian statistics which I've not done before, and I need to go into

> ... yeah apparently you can represent a Bayesian network as a set of polynomials, in which case the algebraic geometry comes in and you can prove stuff about it.

Here we suggest that whilst Roz recognises that a dichotomy between applied and pure mathematics exists in people's perceptions of mathematics, her insistence that she can do both in one role indicates that she feels they are not mutually exclusive – i.e. her current 'identity in practice' involves doing mathematics which is both 'outward facing' and 'the really pure stuff'. In this way, Roz does not merely engage with mathematics to enact a feminine 'caring for others' role but, rather, envisages herself as changing the context of mathematics itself so that the traditional gendered and excluding binary (male – pure mathematics vs female – applied mathematics) no longer exists. The following extract highlights the energy and motive that is provided by this perception that she is changing mathematics:

> I sat through a series of lectures that my now boss gave,... and the lecture that I absolutely adored had a proof with three lemmas in it you know and .... 'I really am a mathematician – I just love this stuff' – my heart was racing, I just enjoyed it that much, you know. [...] And um ... when I was at [her undergraduate university] ... it was actually to do with coding and cryptography. But then you were calculating in rings and we were doing some stuff like that, and we just did a little bit of algebra ... and even then I was kind of like 'Oh I wish I could do more of this, I wish I could do more of this' you know. So ... and this is the precisely the sort of thing I'm going into now.

DISCUSSION

In this paper, we have highlighted how a particular form of the self-other relationship – 'caring for/by others' – can be used as a cultural resource in narrating a positive mathematical identity. Our analysis of Roz's story has shown how she uses this cultural model to account for the kind of person she has become and to self-author as a particular kind of academic mathematician. We have also argued that her use of this cultural model has mediated a particular view of what mathematics is and what mathematics communities should be like. So, rather than subscribing to a gendered binary division of mathematics (female-applied vs male-pure) such as that reported by Mendick, Moreau and Hollingworth (2008) in their study of undergraduate students' perceptions, Roz sees herself as enacting both 'people friendly' and 'real maths' in her one role and, thus changing the world of mathematics itself.

The role of the 'caring for/by others' relationship in this process is worth commenting on. We recognise that 'caring' as a construct is heavily loaded with connotations that relate to unequal gendered divisions of labour in society which for many women are a source of marginalisation. As Walkerdine (1989) has suggested, 'caring' plays a particular role in marginalising girls away from school mathematics at a young age. Here, we suggest that given the right circumstances, caring for others AND being cared for by others can be used to good end. Rather than being a source of dominance/manipulation of women which reinforces their marginalisation, caring can be used to develop a positive mathematical identity and potentially a tool for change. However, our reference to the 'right circumstances' here is pivotal – Roz's story must be seen in context as one of 'success against the odds'. In taking up her role as a mathematician in a prestigious university, she has to some extent already overcome the powerful structural conditions which make becoming a mathematician particularly difficult for women like her. Now, Roz's ability to use 'caring for/by others' as a cultural resource and thereby construct a way of doing mathematics that combines 'helping others' with 'real maths' is a result of her new found location in a profession where relating to others now holds value and where this form of capital is not perceived as readily available to many of her male colleagues.

The implications of this argument are significant. Archer, DeWitt, Osborne, Dillon, Willis and Wong (2013) have recently suggested that in order to raise girls' aspirations in relation to STEM subjects (including mathematics), interventions are needed which make a future in STEM more acceptable to girls. They note that many (predominantly working class) girls focus on practical subjects and do not see science in this light. Their findings denote particular forms of capital which include caring and domestic competences which are not seen as part of science:

> The data from the girls without science aspirations reinforce the importance of capital in that their stated aspirations are clearly rooted within particular forms of social and cultural capital

> (family contacts, everyday experiences of e.g. babysitting/childcare, fashion and sport). The absence of science capital within their daily lives renders science aspirations less conceivable (and achievable), not only reducing their opportunities for developing a practical 'feel' for science but also of being able to see science as a 'thinkable' performance of femininity (p. 186)

Thus Archer, de Witt and Willis (2014) suggest, among other measures, that

> In practice, our study indicates that "one size fits all" approaches to increasing science participation (whether generally or for "girls" or "boys") are unlikely to have much effect on improving post-16 participation. Approaches that are sensitive to young people's gendered and classed identities would seem more appropriate for delivering STEM enrichment and/or interventions aimed at increasing participation. (2014, p. 24)

While this appears to be a reasonable suggestion, it is less than clear what exactly this would entail, and an emphasis on 'broader forms of engagement', while laudable, might not address the binaries which Archer and colleagues (2013) themselves have noted, and which may simply position girls and women in particular (lower status) areas of STEM. Archer et al add that there is also a need to change cultures:

> there is also a need to ensure that the cultures operating within post-16 science (in colleges, universities and workplaces) are indeed equitable and do not alienate or disadvantaged 'non-traditional' participants. (2013, p. 189)

Again, however, it is less than clear how this might be brought about or what it in fact entails. True equity means enabling access to powerful knowledge and deepening engagement rather than simply widening participation; our findings suggest that this requires a fundamental change in the high status contexts of STEM to create new practices which critically engage with and ultimately transcend the binaries we have outlined. We argue that Roz's approach to mathematics can ultimately challenge the structures which define its status as a powerful gatekeeper in maintaining wider social divisions of class and gender.

The three faces of problem solving

Jonas Dahl

Malmö University, Malmö, Sweden, jonas.dahl@malmo.se

The point of departure in this paper is my previous research in which I analysed how the idea of problem solving is recontextualised into the mathematics curriculum for upper secondary school in Sweden and how this increases the risk for excluding lower SES students from future power. I discuss how this research could be followed up through a suggestion of how problem solving could be viewed in three different ways: as an ideology, a competence and an activity. Bernstein's pedagogic device and dichotomy of vertical and horizontal discourses are crucial in this suggestion. By seeing problem solving as an activity, and connect this to what Bernstein labels the evaluative field, I thereby tie the whole pedagogic device together by taking an overall view of problem solving as global policy-speak.

Keywords: Pedagogic device, evaluative field, vertical and horizontal discourse, social equity, problem solving.

INTRODUCTION

> Certain aspects of our way of life, certain kinds of knowledge, certain attitudes and values are regarded as so important that their transmission to the next generation is not left to chance in our society but is entrusted to specially-trained professionals (teachers) in elaborate and expensive institutions (schools) [...] Different schools may make different priorities, but all teachers and all schools make selections of some kind from the culture (Lawton, 2011, pp. 6–7).

This selection is not only about what kinds of knowledge, attitudes, and values that should be transmitted, but also to whom. Since this selection is often made on socio-economical grounds, school reproduces social inequity (Bernstein, 2000). Instead of 'school being for all' (see, e.g., Skolverket, 2012b) there is instead a risk of 'school being for some' (Dahl, 2014).

Furthermore, education should not only be the transmission of tools to interpret the world, but also the means to change the world (Atweh & Brady, 2009). Bernstein (2000) suggests that what schools should provide students with for them to become citizens with a stake in society is a sense of, what he calls enhancement, inclusion and participation. According to Wheelahan (2007) this has to do with the form of knowledge that students are given access to:

> Unless students have access to the generative principles of disciplinary knowledge, they are not able to transcend the particular context. Students need to know how these complex bodies of knowledge fit together if they are to decide *what* knowledge is relevant for what *particular* purpose, and if they are to have the capacity to transcend the present to imagine the future. (p. 10, italics in original)

In the mathematics curriculum for upper secondary school in Sweden (year 10–12) problem solving is emphasised as a main competence that students should develop (Skolverket, 2012a). This emphasis, both on competences and problem solving, is common to other curricula and frameworks, for instance *Curriculum and Evaluation Standards for school mathematics* (NCTM, 1989), *Principles and Standards for School Mathematics* (NCTM, 2000) and *Adding It Up* (Kilpatrick, Swafford, & Findell, 2001) in the USA, the KOM-project in Denmark (Niss, 2007) and PISA (Programme for International Student Assessment) (OECD, 2012). Sweden, in following this international trend without questioning the roles of competences and problem solving can be seen as adapting to, what Ball (2013) calls the global policy-speak (Dahl, 2014). Global policy-speak "produces, or is the effect of, a cutting-off of research in mathematics education from its political responsibility and consequences and from its philosophical and political roots" (Gellert, Barbé, & Espinoza, 2013, p. 303).

I have in previous research (Dahl, 2014) investigated how the need for problem solvers is expressed in the Swedish mathematics curriculum, where Sweden is seen as an exemplar of a wider trend in mathematics education. I have also suggested that, with the new curriculum in Sweden, launched in 2011, there is a greater risk of reproducing inequity through school compared to the older curriculum; mainly due to the greater division between vocational education and academic preparatory education that is more solidly build in to the system with the curriculum (Dahl, 2014). These different types of programmes attract students with different social background with vocational education attracting to a greater extent from lower SES groups (Broady & Börjesson, 2005).

The curriculum is here defined as the official documents that address teachers and in Sweden these are the same for all upper secondary schools and includes the national tests since one purpose with these tests is to concretise the curriculum (Skolverket, 2012b). Together, these documents inform teachers and students of what should be taught/learned, in some sense how it should be taught, but also what should be assessed and how. Questions that arise from this are about what really happens in schools and in the classrooms in regard to competences, and especially problem solving competence. Is there a difference, as the curriculum suggests that there should be, between different educational tracks? If so, how does this intended difference affect students' foregrounds?

Before moving in to the theoretical background and framework, I need to describe what I mean with *the problem-solving citizen*, a term I introduced in my previous research. The problem-solving citizen is a citizen who is flexible, employable and one who gives his/her "best in responsible freedom" (Skolverket, 2012b, p. 4). Drawing on OECD in defining the problem-solving citizen, I add that he/she also has to be(come) an "intelligent consumer" (OECD, 2006, p. 72). With this view on the citizen, which is the dominant view in the curriculum, the citizen is one with duties to the country rather than rights (Dahl, 2014). As a contrast, with Bernstein's view on the citizen, the rights of a citizen are emphasised.

THEORETICAL BACKGROUND AND FRAMEWORK

Bernstein (2000) described the pedagogic device as illustrating how education acted as a filter for ensuring that class distinctions were reproduced. The pedagogic device consists of three sets of interdependent rules: *the distributive rules* regulate the power relationship by distributing different forms of knowledge to social groups; *the recontextualising rules* regulate the formation of pedagogic discourse; *the evaluative rules* constitute pedagogic practices that are realised in instructional and regulative texts (Bernstein, 2000). In relation to the problem-solving citizen, the distributive rules can be considered as controlling how the discussions of politicians, education bureaucrats and educational researchers are relayed to those formulating the curriculum. The recontextualising rules control how the distributed knowledge about problem solving is incorporated into the curriculum and national tests which in turn control the ways that educators in schools and the wider education sector come to discuss problem solving. The evaluative rules control how teachers teach problem solving in classrooms. Within this field, the regulative discourse is dominant over the instructional discourse (Bernstein, 2000). The regulative discourse "refer[s] to the forms that hierarchical relations take in the pedagogic relation and to expectations about conduct, character and manner" (p. 13). The instructional discourse "refer[s] to selection, sequence, pacing and criteria of knowledge" (p. 13).
