From a Bernsteinian perspective, the "generative principles of disciplinary knowledge" mentioned above in the quote from Wheelahan, could be equated with knowledge forms in a *vertical discourse*, which is context-free or generalisable, in this case, from the world of mathematics. The opposite is forms of knowledge in a *horizontal discourse* which includes mundane or common sense knowledge. According to Bernstein (2000), this latter form of knowledge is context-dependent and not easily used outside the given context, thus not generalisable. The difference between knowledge from the horizontal and vertical discourse is not a matter of abstract or concrete; rather, it is a matter of reference to a specific material base, that is, to a context outside mathematics (Bernstein, 2000). For instance, in school mathematics, a task or problem that is situated in a context outside mathematics can be regarded as within a horizontal discourse. These contexts could be domestic areas, such as best-buy strategies, or vocational settings, but also other school subjects, such as economics or chemistry. Knowledge from the vertical discourse is context-free and can be realised in mathematics tasks that make no reference to the outside world, such as find the greatest area of a triangle with a given perimeter. Due to their context-independency, tasks such as this are generalisable to different contexts or can give access and insights to the esoteric world of mathematics. From the point of view of social equality, access to the vertical discourse is crucial.

In her small study, Lubienski (2000) raises questions about NCTM's (1989) suggestion that problem solving should be a means for developing other mathematical skills or competences. Drawing on Bernstein, Lubienski (2000) states that "contextualised mathematics problems seem to align nicely with lower-class students' preferred ways of thinking" (p. 457) and "[o]ne might expect that if lower SES students tend to have a contextualised orientation to ideas, they would benefit from contextualized problems" (p. 467). However, she concludes that this is not the case. Lubienski draws the conclusion that the lower SES students in her study were not able to transcend the context of the problems and had greater difficulties learning from solving contextualised tasks than their higher SES peers. Her conclusion was that by putting mathematical problem-solving tasks in a context, some students, particularly students from a lower socio-economical background, are hindered in their mathematics learning.

Similarly, when it comes to assessing through problem solving tasks, Cooper and Dunne (1998) found that sometimes students, in solving contextualised tasks draw too much on the real world and, at other times, too little. They further suggest that there is a relationship to students' socio-economic background wherein students from lower socio-economic backgrounds struggle more often to bring in the appropriate knowledge form.

Bernstein (2000) states, "to make specialised knowledge more accessible to the young, segments of *horizontal discourse* are recontextualised and inserted in the contents of school subjects" (p. 169). Following Lubienski (2000) this is problematic when it comes to teaching or learning through problem solving. Following Cooper and Dunne (1998) it is also problematic when it comes to assessing problem-solving competence. This means that problem solving is problematic both when it is seen as a means for developing other mathematical competences and as an end in itself, both views highlighted in the mathematics curriculum in Sweden (Skolverket, 2012a). As Bernstein suggests, segments of the horizontal discourse can be brought into school mathematics as hooks, but "using horizontal discourses other than as a 'hook' to entice pupils into vertical discourses is to destroy what is distinctive about pedagogic communication" (Whitty, Rowe, & Aggleton, 1994). From a categorisation of school mathematics tasks in a textbook series with tracks for different ability levels, Dowling (2005) concluded that students who are labelled low-ability, mainly from working class are denied access to, what Dowling calls the esoteric domain. This is another way of saying that the students are denied "access to the generative principles of disciplinary knowledge" (Wheelahan, 2007, p. 10).

Thus, although the purpose of using contextualised problems is to develop mathematical awareness and competences, it may have the opposite affect, especially if students from low socio-economic backgrounds are the students given these tasks more often, as suggested by for instance Dowling (2005), Lubienski (2000) and in my analysis of the mathematics curriculum in Sweden (Dahl, 2014). Contextualised problems, including those based on the students' own experiences, can be used to hook students and promote mathematics, but can be problematic if, in solving them, students never leave the horizontal discourse and enter the vertical discourse.

FitzSimons (2008) suggests "these complementary discourses, vertical and horizontal, need to converge in formal education settings in order to enable richer forms of knowledge construction by learners" (p. 3). In order to see and understand the boundaries that exist between them, students need access to both discourses. Access to the vertical discourse may be denied to certain groups of students. In particular, low achievers from low socio-economical areas (Dowling, 2005; Lubienski, 2000; Wheelahan, 2007) may be restricted access into the vertical discourse. In order to gain equal outcomes and ensure that social differences are not reproduced, *all* groups of students need access to the vertical discourse in order to "transcend the present to imagine the future" (Wheelahan, 2007, p. 10). Therefore, a way of ensuring equality becomes

<table>

</table>

Table 1

a question of ensuring equal access to the vertical discourse. My analysis of the mathematics curriculum in Sweden (Dahl, 2014) suggests that there is a risk this is not the case. Instead there is a risk that lower SES students are hindered from access to the vertical discourse.

Sjöstedt (2013) draws the same conclusion, but adds Bernstein's ideas about visible pedagogy (Bernstein, 2003). In viewing pedagogic practice as a cultural relay, Bernstein (2003) discusses some criterial rules about "criteria which the acquirer is expected to take over and to apply to his/her own practices" (Bernstein, 2003, p. 64). Visible pedagogy has to do with whether or not these rules are explicit in the pedagogic practice. If the criterial rules are visible, students see the connection between pedagogy and evaluation; that is, they know what is expected of them. The syllabus in Sweden is divided into core content (what should be dealt with in the classroom) and competences (what should be assessed and graded). If there is a difference in what happens in the classroom and what is assessed, then there is a risk that the pedagogy becomes invisible, meaning that the students will not know what is expected of them. According to Bernstein (2003), this is problematic for lower SES students. For a more equitable outcome, there is, besides being given all access to the vertical discourse, also a need for the pedagogy to be visible.

THE CONNECTION BETWEEN THEORY AND METHOD

The term problem solving is ambiguous and my suggestion is that problem solving can be seen to have three different faces: 1. Problem solving as an activity, that is, when someone, for instance a student, solves a problem. 2. Problem solving as a competence, that is, an interpretation and a description of problem solving in, for instance the curriculum, and 3. Problem solving as an ideology, that is, how problem solving is a part of the global policy-speak. I further suggest that these three faces can be connected to the evaluative field (EF), the recontextualising field (RF) and the distributive field (DF) respectively.

Bernstein (2000) distinguishes "between an *official recontextualising field* (ORF) created and dominated by the state and its selected agents and ministries, and a *pedagogic recontextualising field* (PRF). The latter consists of pedagogues in schools and colleges, and departments of education, specialised journals, private research foundations" (p. 33, italics in original). In Table 1, I add this division of the recontextualising field but also suggest that the ORF is the bridge from the DF to the RF and the PRF is the bridge from the RF to the EF.

Furthermore, within the recontextualising field, Bernstein (2000) distinguishes between two different discourses: the instructional discourse (ID) and the regulative discourse (RD). RD is dominant over ID and "refer[s] to the forms that hierarchical relations take in the pedagogic relation and to expectations about conduct, character and manner" (p. 13). Those students become and act as genuine problem solvers is seen as the main goal of mathematics education, the end in itself.

To summarize and put things in different words: Problem solving as an ideology is when politics, following a global policy-speak, talks about and uncritically assume that problem solvers is something all need to become. Within the RF this is transformed into competences and goals of the school. In the classroom (the EF) problem is an activity, used both to develop other mathematical competences but also for assessment, that is, to assess if the students "have the competence", if they have become problem-solving citizens. That the RD is dominant over the ID means that the actual goal of problem solving as an activity in the classroom is to make the students behave as problem solvers (problem solving as a competence) because it is assumed what the country needs (problem solving as an ideology).

In my previous research, it is the operation of the distributive and recontextualising rules that are in focus around the construction of the problem-solving citizen and this project was an analysis of the curriculum, including the national tests. In order to see the whole picture, an investigation of what happens in schools and in the classroom needs to be added. By moving the analysis into the classroom would mean an investigation situated within the evaluative field which would cover the whole pedagogic device because "[t]his is what the device is about. Evaluation condenses the meaning of the whole device" (Bernstein, 2000, p. 36). The issue on the level of evaluative rules (the classroom) could be transformed to be an issue about how the instructional discourse (about problem solving) supports or hinders access to the regulative discourse (the problem-solving citizen). My suggestion is that this is an investigation of problem solving seen as an activity but also that it connects back to the other views on problem solving.

INITIAL THOUGHTS FOR A METHOD

To investigate the evaluative field there is not only a need to investigate *how* problem solving is reused as an activity. There is also a need to investigate *why* from the teachers' points of views. And also what the effects could be from the students' points of views. This would give indications of the influence that the global policy-speak (problem solving as an ideology) and the curriculum (problem solving as a competence) have on teachers and students and will hence tie the whole pedagogic device together.

The investigation should have as it aims to find differences and similarities between vocational programmes and academic preparatory programmes. Further, it should be based on access to the vertical and horizontal discourses. That is, how do teachers within the different types of programmes interpret problem solving as an activity?

It is also important to address another dichotomy that I used in the analysis of the curriculum (Dahl, 2014): if problem solving is seen as a means for other competences or areas or if it is seen as an end in itself. This categorisation is important because of the issues that arise when problem solving is seen as a means for learning mathematics highlighted by, for instance, Lubienski (2000) and Dowling (2005). Together with the why question, this dichotomy is also important in order to investigate how the instructional discourse supports or hinders access to the regulative discourse.

Finally, the visibility of the pedagogy is important to take into consideration. With an assumed risk of more recontextualisation for the lower SES students there is also a greater risk of the pedagogy being invisible. The risk of the lower SES students "looses" is then doubled.

Critical reflections on temperature change

Kjellrun Hiis Hauge, Maria Astad Sørngård, Tor Inge Vethe, Terje André Bringeland, Andreas Austlid Hagen and Marius Sætren Sumstad

Bergen University College, Faculty of Education, Bergen, Norway, khh@hib.no

Advanced mathematics often plays an important role in risk evaluation, for example in relation to climate change. How can mathematics related classroom discussions enhance critical citizenship when societal issues are accompanied by advanced mathematics? In a master course in mathematics didactics, a figure from IPCC was discussed. The figure shows developments of the average global temperature changes. In this paper, we analyse the classroom discussion in accordance with Skovsmose's six reflection steps, with focus on societal aspects. The students reflect critically on the data used to support the figure, on characteristics of the models, on the models' significance in society and on their own participation in the classroom discussion. We discuss the results in a broader educational and societal context.

Keywords: Critical mathematics education, climate change, reflective knowing.

INTRODUCTION

Mathematics often plays an important role in risk evaluation as support for policy making, for example in relation to climate change. However, risk issues are often associated with complexity, uncertainty and conflicting stakes, which implies that mathematics supporting political decisions is advanced, but also associated with uncertainty (Funtowicz & Ravetz, 1993). A consequence of this uncertainty is that mathematics based arguments can support opposite political stances.

This is in line with Skovsmose's claim that mathematics has a formatting power in society in that it influences how reality is perceived (Skovsmose, 1992). He further argues that the ability to recognize this formatting power, and reflect on it, is an essential democratic competence in order to balance the experts' influence on politics and society. He refers to this ability as reflective knowing. The role of offering critique to experts and politicians on societal issues can be denoted as critical citizenship (Jablonka, 2003). Mathematics and science educators offer perspectives on what critique may signify in relation to the issue of climate change in education. Barwell and Suurtamm (2010) argue that the mathematising of climate change makes human activity invisible and call for more visibility in the modelling process, for example through information on model assumptions to help evaluating whether the model fulfils its purpose. They suggest that mathematics education has a responsibility in facilitating reflective knowing on the role of mathematising climate change and call for research within the area. Barwell (2013) further supports these arguments by showing how a particular philosophy of science matches ideas from critical mathematics education, as for example the formatting power of mathematics, reflective knowing and critical citizenship. Hansen (2010) discusses what critical democratic competence might be in relation to predicted sea levels as an effect of global warming. As Barwell and Suurtam, she links this to the modelling process and underlying assumptions, and her emphasis is on mathematical modelling as a classroom activity to prepare students for future critical engagement in such issues.

All these three papers are theoretical papers and include the idea of mathematics education as a preparation for critical citizenship. Although they suggest various student activities for enhancing reflective knowing, they do not suggest how this reflective knowing may be expressed when facing claims developed through advanced mathematics of climate science. Looking to science education, Erstad and Klevenberg (2011) describe a classroom study where the student task was to explore topics in "An inconvenient truth" with Al Gore. The aim of the task was to learn about aspects on science in society. From searching the internet, the students discovered that certain controversies on climate change were linked to disagreements between scientists. The paper thus addresses complexity in climate change through expert disagreements.

The issue of climate change may be too complex for students to develop alternative mathematical approaches that can pinpoint socio-political consequences of mathematized information. A crucial area of research would therefore be on what kind of critical reflection non-experts can provide on advanced mathematized information that is useful for critical citizenship.

In our study, students of a master course on mathematics education discuss a figure (Figure 1) taken from a report by the Intergovernmental Panel on Climate Change (IPCC, 2013) as an introduction to critical mathematics education. The authors of this paper are five of the master students and the lecturer. The IPCC graph presents different modelled courses of average global temperature changes. The mathematics supporting the graph is far too advanced for the students and the lecturer to grasp. Still, can reflecting on the graph enhance mathematical understanding that is useful for critical citizenship?

The research question of our study is: 1) What kinds of reflection related to critical citizenship are expressed during the classroom discussion on the IPCC graph? In the following, we describe the data and present Skovsmose's (1992) six reflection steps, which we apply to our data analysis. In the analysis part, we follow the course of the classroom discussion and offer examples of expressed reflections. Finally, we discuss the significance of our findings to critical citizenship.

DATA AND METHOD

As an introduction to critical mathematics education in a master course, the nine students and the lecturer (Kjellrun) discussed a graph produced by IPCC on predicted temperature changes (see Figure 1). The discussion was followed by a lecture on selected literature from critical mathematics education, where links between the initial discussion and the literature were collectively drawn. The lecturer chose this figure because of its potential for generating reflections about mathematics and its use: (1) its political relevance and dispute, (2) it expresses uncertainty through statistical spread, different pathways of future emissions and implicitly through dissenting model results, (3) the social construct of "global average surface temperature" and (4) the problem of measuring temperature in space and time. Her intended role was to keep the discussion as student driven as possible, but at the same time ensuring that student reflections took place. Before the discussion, the lecturer invited the students to write an academic paper on an analysis of their discussion together with her. The analytical tool to be applied was part of the curriculum. Five of the students accepted the offer and are co-authors of this paper.

The classroom discussion is analysed by using Skovsmose's (1992) six reflection steps, of which five are later picked up by Gellert, Jablonka and Keitel (2001) and referred to as five reflection levels. The steps can be summarised as reflections related to the following questions: (i) Are the calculations right? (ii) Was the right algorithm used? (iii) Is the mathematical approach reliable? (iv) Could the problem be solved without formal mathematics? (v) How does the mathematical approach affect the specific context of the problem? (vi) Could we have reflected on this in another way? The six reflection steps refer to what Skovsmose calls steps towards reflective knowing and which is essential for critical citizenship. They represent steps of students' reflections while engaged in problem solving.

The first pair of steps refers to reflective thinking within pure mathematics, the next within applied mathematics and the latter within a broader, societal, understanding of mathematics (Skovsmose, 1992). As these reflection steps are developed for situations where students reflect on their own problem solving, in contrast to our case, we have adjusted the reflection steps for our purpose. We have chosen (i) and (ii) to include our reflections on the mathematics expressed in the graph, which are developed by others. Since the underlying mathematics is hidden for us, we have concentrated on our understanding of the graph contents, for example: Have we understood the graph correctly? Have we understood underlying algorithms? We consider such reflections as a required basis for reflective knowing and critical citizenship and are therefore relevant to include in our analysis.

The two classroom discussions on the graph and on applying the reflection steps on the graph are audiotaped. Additional data include notes and the lecturer's PowerPoint presentation. We have applied the

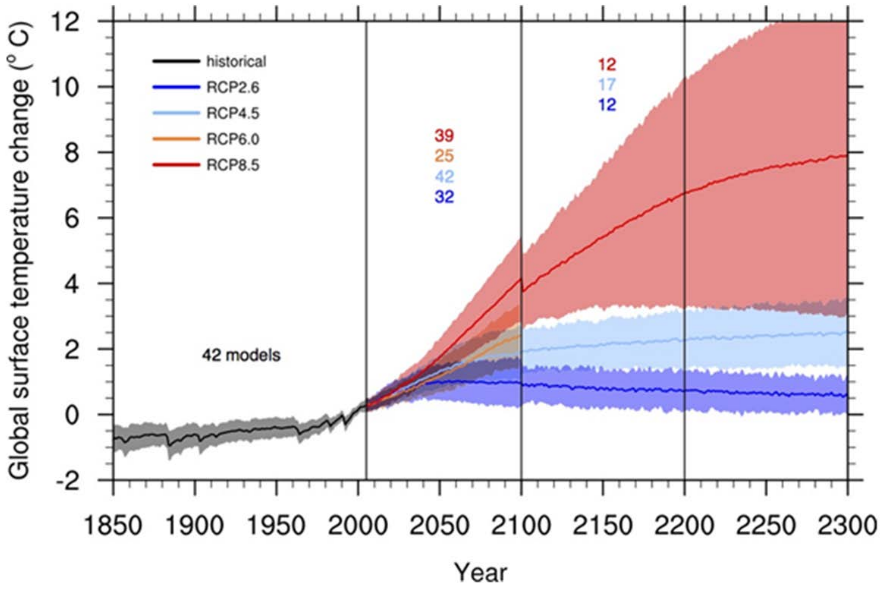

Figure 1: Temperature change. The graph shows modelled developments of the global annual mean temperature change (IPCC, 2013, p. 89). The change is calculated relative to the period 1986–2005. Four future scenarios are presented with mean (the coloured trajectories) and 90% confidence interval (the coloured shadings). The colours represent different possible emission levels of greenhouse gases (RCP – representative concentration pathways), which will depend on today's and future global climate politics.

authors' names in the excerpts. The other names are anonymised. The audiotaped discussions were transcribed and coded by the students in accordance with the six reflection steps. The coding turned out to be challenging as the steps were not straight forward to apply. This was discussed during meetings.

ANALYSIS

In the following, we present some excerpts from the classroom discussion, which we analyse in accordance with Skovsmose's six reflection steps. The beginning of the discussion was dominated by the students making sense of the figure (Figure 1): the general features, the significance of the colours, the lines etc. Repeated words are deleted in the excerpts. The first excerpt takes place early in the discussion.

Tor Inge: Where does the limit go for where the measurements fall within?

Maria: It depends on which scenario is taken into account. If they have calculated with an RCP value of 8.5, and that resulted in. Those who achieved the lowest values at the lowest one, right? And then they calculated with the same model with a value of 2.6. And that could have resulted in one of the lowest values there. While some with a high value could have ended down there. What you can see here is that there's a lot of variation here. That here it seems that they disagree much more.

Tor Inge: More uncertain?

Maria: Yes, while at the blue, they quite agree all the way, in a way. They are more certain.

Tor Inge seems to misunderstand what the colours represent, as "limit" may refer to dividing mathematical model *output* into colour categories. Maria responds by explaining that the colouring depends on the *input* of the model, "which scenario is taken into account", determined by specific RCP values (see Figure 1 for an explanation). Further on, she offers a reason on why the shaded areas vary in magnitude: "they disagree much more." When Tor Inge asks "More uncertain?", he is probably asking whether Maria refers to the spread in the graph, or uncertainty.

When Tor Inge asks his first question, he is probably seeking to understand the graph, which can be categorized as Skovsmose's reflection step (i). Indirectly, Maria expresses that the figure is based on several models that do not produce the same results. The students do not discuss further what this disagreement implies, for example how and why the models are different, the reliability of the various models or whether such disagreements can explain why there are climate change deniers. This means that the excerpt has onsets to Skovsmose's reflection step on reliability (step iii) and on implications for society (step v).

The next excerpt is taken from a part where the students discuss natural temperature fluctuations, exemplified by ice ages. Tor Inge has expressed that he would have liked to know more about the temperature back in time.

> Tor Inge: Yeah, I would have gone further back in time, and seen. We talk about they only are natural fluctuations, which also have taken place before, right? And how high were the peak temperatures longer ago, before the measurements?

It is likely that Tor Inge imagines that knowing "the peak temperatures longer ago" would have strengthened his confidence in that the temperature development after year 2000 is extraordinary. Since Tor Inge is addressing the reliability of a conclusion drawn from the graph, we categorize his utterance to be a critical reflection in line with Skovsmose's step (iii). However, the reflection can also be denoted as step (v), since the utterance may suggest that a different mathematical approach could have affected his perception of climate change.

In the following, Kjellrun draws the students' attention to a specific feature in the graph.

> Kjellrun: [...] But if we look at year 2100, what is happening there? [pause 16 sec.]
> Anne: [inaudible] is a shift?
> Kjellrun: Yes, why is that?
> Anne: At least the red one.
> Kjellrun: Yes, at least the red one, that's very distinct.
> Anne: There are fewer models, you know.
> [...]
> Tor Inge: I'm thinking that the most critical until 2010 do not continue further in the models, [Kjellrun: Yeah, well that's true.], so that the curve isn't as steep when it continues.

The combination of Anne pointing to that "There are fewer models" and Tor Inge stating that "the most critical" models "do not continue" after the drop, suggests that Tor Inge reflects on how the prediction results depend on which models are used. We assume that Tor Inge means 2100 and not 2010, and we interpret "critical" models in this case to be the models predicting greater and more dramatic temperature changes. Anne's statement that "There are fewer models" can be denoted as reflection step (i), as she seems to be in the process of making sense of the shifts in the graph. Tor Inge's remarks can be categorised as questioning whether the right algorithm was used in selecting models (step ii), whether the approach is reliable (step iii) and whether the selection of models affects the perception of the severity of the problem (step v).

Later, Kjellrun asks about the relevance of graphs like the one we had discussed:

> Kjellrun: Has it had an impact? Have the climate panels' - I guess we can call it warnings?
> Terje: Maybe routines and control measures have become stricter?
> Anne: I'm thinking about the discussion he had with Vesterålen and Lofoten. The loss of oil. This model may influence whether in fact there will be oil production there, because you can see what oil production causes.

Terje and Anne (and other students) suggest various impacts of the graph, or maybe IPCC graphs in general, and thereby argue that such graphs do have an impact on society and has certain potentials. Anne is probably referring to the Minister at the time ("he") of the Ministry of Petroleum and Energy in Norway, who was in favour of oil exploration in the Vesterålen and Lofoten area. In the continuation of this excerpt, the students also reflect on how IPCC has had limited influence, for example in regard to the Kyoto Protocol. Since these reflections link the graph to societal aspects we characterise them as Skovsmose's reflection step (v), although the students declare that mathematics makes a difference rather than discuss how the mathematics influence ways of understanding.

Towards the end a student started reflecting on the discussion:

> Andreas: Well, I thought that we were trying to find shortcomings or flaws in all statements, on the graphs you have shown

us. That we have been very, well, very. Don't know if we've been negative, or ...

Theodor: Are receptive to flaws in the models. [Andreas: Yeah. Yeah.]

Tor Inge: We had that starting point all the time. I'm thinking about that the headline for the lecture is "in a critical". [Andreas: Yeah.] I imagine this [Theodor: Yeah.] goes into that direction.

Andreas: There have been few positive arguments for the things that have, the statements, on the graph. There have been few arguments on that they are right or that it is correct, and, on, of the researchers, of the. Yeah. ...

Kjellrun: So, we have, in a way, been looking for shortcomings or flaws? Or how it was expressed? But *are* there shortcomings about what the climate panel does? So, is our critique completely unreasonable?

Anne: No, but you know, it's. When saying that there's a 95% probability, for example. That there's a great divergence here. That maybe that's why you become so critical?

Marius: The critique has shed light. That, the critique, by closer inspection, then this critique will strengthen, you know, the findings, or what I should call it. Not the findings, the prognoses. That if we investigate further, we'll read more what was done. Then we maybe: how often do they measure the temperature, right? You know, we find: "Yeah! They do the measurements quite often, which means that they have quite accurate prognoses". Then this would strengthen this graph. That, when we take a critical stance, it can also strengthen our impression. It's hard to explain. That they, what we read here is. We believe it, maybe, [Kjellrun: Uhum.] that when being critical, you can. Difficult to explain.

Several of the students express unease about having been critical during the discussion. For example, Andreas says "we tried to find shortcomings or flaws" and expresses a concern for having "been negative". When Tor Inge suggests that the topic of the lecture may have influenced the critical stance, he too indicates that they might have been too critical. When Anne points to the "great divergence" she may be suggesting that the lack of certainty to be an explanatory factor, although her reference to "95%" is unclear. She is probably referring to the 90% confidence intervals in the figure, or she might be referring to an IPCC statement that was presented early in the discussion about human influence causing global warming. While Andreas, Theodor, Tor Inge and Anne seem to associate "critical" with negative criticism, Marius suggests that "critique will strengthen [...] the prognoses". He indicates that critique can also increase confidence in a graph. Since the students are suggesting that they could have reflected in different ways, the whole excerpt can be categorised as Skovsmose's reflection step (vi).

DISCUSSION

The analysis shows that the students reflect in accordance with most of Skovsmose's six reflection steps, taking our modifications of the steps into account. The students help each other interpret the graph, they question whether the graph supports IPCC's claim on the present situation being extraordinary and they respond to the information about the graph being constructed by a number of models and which produce diverging results. They thereby reflect on the relevance and sufficiency of the mathematical approach, and they further reflect on how the approach affects perceptions of climate change. Some students show resistance to their own critical reflections, expressing them to be negative, while one of the students defends them as *critique* of the graph rather than *criticism*. The analysis suggests that reflecting together on the graph, helping students to understand its mathematical contents, was vital for the later reflections linked to the reliability and the implications of the graph. This supports Skovsmose's (1992) reasoning that reflective thinking about the mathematics itself and its application is necessary for reflective knowing.

Skovsmose (1992) further promotes reflective knowing as essential for critical citizenship. Although the students demonstrate reflective knowing, key questions remain. Do our findings show that these reflections are significant for critical citizenship? We argue that in several ways they do. We experienced that the graph was challenging to interpret, requiring insights in statistical concepts and mathematical modelling. Yet, the discussion demonstrates that although we did not have the expertise to understand the mathematics behind the graph, the students are capable of reflecting on how the mathematics relate to its context. A key capability for critical citizenship is being able to question whether certain data are included, model assumptions and whether certain perspectives are taken into account (Barwell, 2013; Barwell & Suurtamm, 2010; Hansen, 2010; Funtowicz & Ravetz, 1993), of which all were demonstrated in the discussion. On the other hand, the students had only onsets to expressing a connection between uncertainty aspects and the role of this uncertainty in society and policy making. The students connect uncertainty in the temperature time series to society's perception of climate change, but they do not explicitly reflect on the significance of the discrepancies between models.

This brings us to another question: What is the role of the lecturer/teacher in promoting reflective knowing? Should the lecturer have been more active in making links between the mathematics and society? She did bring the students' attention to some of the features of the graph, as for example the shift. She also asked about societal impacts of the graph. Still, she could have taken a step further and invited the students to specifically reflect on the formatting power of mathematics, as for example the significance of the shift for how climate change is perceived, how society can cope with the uncertainty they had addressed and the difference between critique and criticism in this context. This might have led to other crucial aspects of critical citizenship, as for example uncertainty in science and why there are disagreements about "facts" and how we should cope with this uncertainty (Funtowicz & Ravetz, 1993). We thus conclude that Barwell's (2013) call for addressing the formatting power of mathematics in climate change was partly achieved in the classroom discussion, but that it still had a potential that was not fulfilled.

With some amendments, Skovsmose's reflection steps showed to be useful as an analytical tool for our study. Still, they are quite broad and do not guide a lecturer or a researcher on what specific attributes of the involved mathematics that can be connected with societal aspects and how. In our case, the time series, the predictions, the spread, the number of models and the drop were significant mathematical features for the discussion. We therefore recommend the development of a framework that captures attributes of various mathematical models in society, of which students/citizens would benefit from gaining insights in. Jablonka's (2003) paper on mathematical literacy shows a potential for such a framework as she characterises a handful of mathematical model categories accompanied with their limitations.

Taken together, the classroom discussion demonstrates that students are capable of reflecting on mathematical information although the underlying mathematics is too advanced to grasp. There are various attributes to the involved mathematics which non-experts, like us, could critically reflect on. We find such reflections useful for critical citizenship because it shows that non-experts can contribute by posing crucial questions about mathematics in a given context. As a final remark, we would like to add that discussions on IPCC graphs can also facilitate learning about climate change and that there are several other ways to discuss climate change in classrooms which complement our approach. We welcome research on related issues in classrooms, spanning both primary and secondary school levels.

ACKNOWLEDGEMENT

We would like to thank our fellow students for letting us site them. We are also grateful to IPCC for granting a permission to reprint the figure.

Problem solving can involve using mathematics to solve everyday problems. In this study, we examine an interaction between a teacher and a class of six-year olds in Sweden around an open-ended problem, from an everyday context. Using Bernstein's ideas about vertical and horizontal discourse, a mixture of everyday and mathematics understandings is identified in the interaction. This mixture seems to result in confusion for both the teacher and the children over what should be the focus. This paper raises issues about how the connection to the everyday in problem solving could reduce children's opportunities to learn mathematics.

Keywords: Real-life problems, Bernstein, vertical discourse, horizontal discourse, young children.

INTRODUCTION

Problem solving is often considered to provide a purpose for students to learn mathematics (Dahl, 2014). For example, van Oers (2001) discussed how Freudenthal (1973) promoted the use of real-life contexts in his realistic mathematics education – "the realism of mathematics then is seen in the applicability of self-invented mathematics in a meaningful problem, and for many people this seems to mean a real-life problem" (p. 64). Nevertheless, van Oers (2001) queried whether it was possible for higher levels of mathematics to arise from real-life problems:

> Despite the enormous innovation this view could produce in the content and activities of the mathematics classrooms, it entails a serious danger by focusing too exclusively on the real life quality of the contexts from which the mathematical thinking originates. (p. 64)

In high school classrooms, research has shown that the use of contexts can result in some students being excluded from mathematical learning opportunities (Meaney & Lange, 2013). This could be because they have difficulties recognising the mathematics in a problem solving task when it is posed in an everyday setting (Zevenbergen & Lerman, 2001). Students also can be uncertain about whether they are expected to ignore their everyday experiences (Gellert & Jablonka, 2009). Similarly, Boaler (1994) raised two related issues. The first is that students do not know how much or how little of the everyday they should use. The second is that students may not realise that the rules of the mathematics classroom require them to suspend their knowledge of reality to make sense of the mathematics classroom reality. Her research found that girls gained poorer marks on problems of which they had had real world experiences.

Although it has been suggested that using contexts could support working class students' learning of mathematics (Lubienski, 2000), previous research has shown that these groups of students are more likely to draw on their everyday experiences than those with middle class backgrounds (Cooper & Dunne, 1998; Gellert & Straehler-Pohl, 2011). For example, Cooper and Dunne (1998) found that "working class children are almost twice as likely as service class children to refer only to their everyday knowledge in answering our enquiry" (p. 128).

As is the case with the research already described, most research on the confusion caused from drawing on everyday knowledge to solve mathematics problems has been done with high school students. Little research has investigated how young children make sense of mathematical problems set in everyday contexts. Therefore, our research question is: how do young children solve mathematical problems situated in their everyday knowledge?

The research is situated in a Swedish preschool class with mostly six-year-olds. This class is considered a bridge between preschool and school and as such is the first place children have contact with formal, school knowledge and ways of working.

THEORETICAL FRAMEWORK

In order to respond to the research question, we follow Gellert and Straehler-Pohl's (2011) and Dahl's (2014) lead in using the concepts of vertical and horizontal discourse developed by Basil Bernstein. Over several decades, Bernstein developed a systematic sociology of education which included the development of many different ideas. One of these was the distinction between what he labelled the horizontal and vertical discourses:

> A vertical discourse takes the form of a coherent, explicit, and systematically principled structure ...
>
> A horizontal discourse entails a set of strategies which are local, segmentally organised, context specific and dependent, for maximising encounters with persons and habitats. (Bernstein, 1999, p. 159)

Horizontal discourse is vital for solving specific issues relevant to the solver. Consequently, it is often related to everyday understanding, gained through practical experiences. However, the knowledge gained through the horizontal discourse is not easily transferable to other situations because of how it is organised and its strong connection to a specific context (Bennett & Maton, 2010). Vertical discourse is considered generalisable to a range of situations. In reviewing research on these concepts, Knipping, Straehler-Pohl and Reid (2012) suggested that vertical discourse is often equated with the knowledge learnt in schools.

Bernstein (1996) stated "to make specialised knowledge more accessible to the young, segments of the *horizontal discourse* are recontextualised and inserted in the contents of school subjects" (p. 169). Therefore, the distinction between vertical and horizontal discourse seems useful because although school mathematics problems are often situated within everyday contexts, they require generalisable knowledge to be solved. In order to make use of these concepts, they need to be operationalised. Before describing the operationalisation, we provide background to the collected data.

DATA COLLECTION AND ANALYSIS

In the first half of 2013, video recordings were made in one preschool class on four different occasions. Our wider research aim is to investigate what mathematics is or could be in preschools and our video recordings in this preschool class were to be compared with the preschool data. In order to get comparable material, we specifically asked to video problem solving sessions. In the problem solving situations, the children worked in pairs, groups or by themselves, with a sharing session at the end. We had permission from parents for 12 children to be filmed and the films to shared, but not all children were present at each session. The class had 2 teachers who shared being filmed and working with the children whose parents did not give permission for them to be filmed.

The lesson examined in this paper was typical in the format of all lessons, by beginning with a warm up activity, in this case around pairs of numbers that added to ten. Then a problem was posed to the children, who were given time to solve it, this time, individually. The problem in this lesson was about ten children in a small preschool class who needed to be distributed to three different activities, woodwork, baking and painting. The teacher stated that there are no wrong or right answers and that it might be possible to distribute them evenly or it could be that one group had more children or another group had no children at all. The children were given paper on which to record their groups but were told that they could record them in any way that they liked. While the children worked, the teacher moved around the class, talking with each child. At the end of the session, the teacher had the children fold their papers and sit down in a horseshoe. She told the children that they must explain why they have distributed the class in the way that they did. With more or less help from the teacher, each child constructed a story about their distributions.

We discuss three children's interactions with the problem, using photos and transcript extracts. In order to identify whether the teacher and/or the children

Discourse	Characteristics	Examples
Horizontal	Context specific	Filippa's reason for only splitting the ten children into two groups was that only two teachers would be needed. In her class there were two teachers, suggesting she drew on her own experiences.
	Segmentally organised knowledge	In the presentation session, the teacher queried the children about their distributions. The children did not know that they needed to have a story for their distributions until they did their presentations. The solving of the problem and the telling of their stories were separated both in time and in space and so can be considered as taking place in different sites and thus were segmentally organised.
	Maximising encounters between persons and habitats	When Nicolas presented a paper, on which there was written, 5, 5, 5, the teacher worked hard with the other children to provide a story that allowed for this, so Nicolas could be considered successful. The emotional demands of not having a child fail became the issue to be resolved.
Vertical	Coherent, explicit and systematically principled structure	Lova uses a series of different strategies (using her fingers, making marks on the paper) to determine different combinations of 3 numbers which added up to 10. Although she does not systematically list all of the possible answers, her actions suggest that she is aware of the underlying principles which allows her to determine appropriate solutions.

Table 1: Characteristics of vertical and horizontal discourses

used vertical or horizontal discourses, we looked for particular characteristics as identified in Table 1.

THREE CHILDREN'S PROBLEM SOLVING

We have chosen to discuss the problem solving of Nicolas, Lova and Filippa as they illustrate a range of responses as well as showing different problem solving methods.

Nicolas

In the warm-up activity about ten-friends, Nicolas was

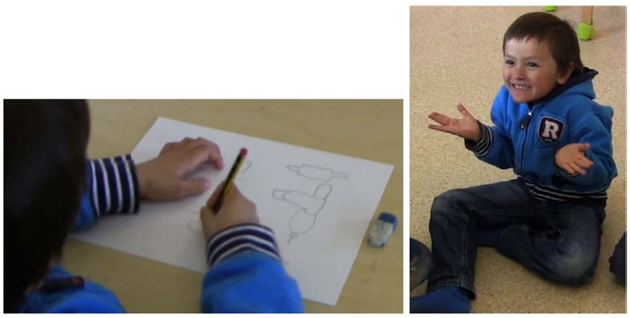

Figure 1: Drawing distribution and showing uncertainty in the presentation

given a card with 9 on it. Teo had 1 and soon located Nicolas. Teo ensured that they are acknowledged by the teacher as having the correct answer. During the individual work, Nicolas sat next to Teo and followed him in spending time copying the symbols (rolling pin, hammer, paint brush) for the three groups. He then wrote 5, backwards, against each of the symbols (see Figure 1). When the teacher called the children together, Nicolas was the fourth child to show his solution. The following exchange accompanied, Nicolas turning over his paper. When the teacher asked in the first turn, how many he had he shrugged his shoulders (see Figure 1) to indicate that he was uncertain.

Teacher: Nicolas, can you show? You've got five, is it fives? Five and five and five in each group. How many children is that? I see five here and five and five. How many children is that? (Nicolas kan du visa? Du har gjort fem, är det femmor? Fem och fem och fem i varje grupp. Hur många barn blir det? Jag får se här fem och fem och fem. Hur många barn blir det?)

A child: Twenty? (Tjugo?)

Children: Fifteen. (Femton.)

Teacher: Fifteen children, how many children were there? (Femton barn, hur många barn var det?)

Nicolas: Ten. (Tio.)

Teacher: Ten, how many children too much? Did you mix in a few more children from another preschool class? You thought fifteen children were better so you could share or? (Tio, hur många barn för mycket? Blandade du in lite barn från en annan förskoleklass? Du tyckte femton barn var bättre så man kunde dela eller?)

One child: It may be that five new children have started in that preschool class. (Det kan ju va så att fem nya barn har börjat på den förskoleklassen.)

Teacher: That I did not know of. So it became five in each group. I'll take it. Thank you very much. (Som jag inte visste om. Så blev det fem i var grupp. Jag tar den. Tack så mycket.)

The discussion initially focused on the numbers, both on how many Nicolas used and how many more this was than in the task. At this point, the conversation seemed to be within the vertical discourse, as the teacher is sequencing the knowledge in a cohesive, structured manner. However, Nicolas' body language (see Figure 1) indicated that he had become aware that his response was incorrect, perhaps because the teacher asked him number questions that she had not asked earlier presenters. The teacher then shifted direction and provided a possible story so that Nicolas' numbers could be considered appropriate, perhaps because she had earlier indicated that there were no right or wrong answers. By producing a story about Nicolas' numbers, the teacher moved back to the context-specific-ness of the horizontal discourse and restored the personal relationships. The difference between 10 and 15 disappeared from the focus and was replaced by a discussion about how 15 was a better number to share and how this number of children could come about. Nicolas made only one contribution to the discussion. It is therefore unclear whether he had understood either the vertical discourse about the difference between 10 and 15 or the horizontal discourse about the ease of splitting the class into 3 groups. The teacher's shifting between the two discourses seems to provide him with no opportunities to develop his problem solving skills either in a context-specific or more generalised format.

Filippa

In the introductory warm-up activity, Filippa had a card with 5 on it. It was not until all the other pairs were formed that Filippa realised that Hugo did not have a partner and therefore their numbers (5 and 5) must equal 10.

In giving the instructions about working individually, the teacher specifically mentioned Filippa. Filippa seemed to have taken the request to heart in that she covered her work with her arms so that Lova could not

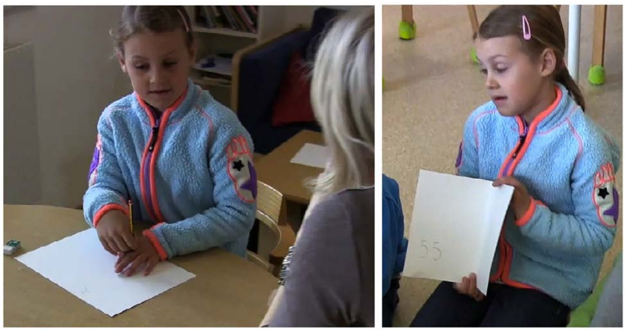

Figure 2: Filippa's problem solving

see what she did. After Lova was moved by the teacher, Filippa looked at Teo using his fingers to work out a solution. It was not possible to hear, the teacher's comments to Filippa as she moved around the room but the consequence of it was that Filippa erased the beginning of a symbol for the first group on her paper. Filippa's presentation was the third presentation. Her paper showed two 5s.

Teacher: Filippa, can you show what you have done? Okay, you've written five and five. Five in two groups, it is. Which group was it that there was no one in? Baking, woodwork or painting? (Filippa, kan du visa vad du har gjort? Okej du har skrivit fem och fem. Fem i två grupper blev det. Vilken grupp var det som det inte blev någon i. Baka, snickra eller måla?)

Filippa: Woodwork. (Snickra.)

Teacher: Woodwork there was no group of, no children at all, but why not? Do you remember, how you thought? (Snickra blev det ingen grupp i, inga barn alls i, men varför inte det? Kommer du på det, hur du tänkte?)

Filippa: Because they will do it another time. (För dom skulle göra det en annan gång.)

Teacher: They would do woodwork another time instead so then it became an equal number of children in each group. (De skulle snickra en annan gång istället så då blev det lika många barn i varje grupp.)

Filippa: Otherwise they thought that it became a little too bustling with everything. (Annars tycke de att det blev lite för stimmigt med allting.)

Teacher: Yes it could be, they would have had to be many teachers. Thank you so much. (Ja det kan ju bli. De hade ju fått va många fröknar. Tack så mycket.)

Filippa: Although they had only two teachers. (Fast de hade bara två fröknar.)
Teacher: Two teachers and then there was one teacher in each group. Brilliantly solved. (Två fröknar och då blev det en fröken i var grupp. Strålande löst.)

As with Nicolas, the teacher presented the drawing and immediately asked which group did not have any children in it. From this question, both the teacher and Filippa built up the story about why there were only two groups. Filippa was complemented by the teacher as having a brilliant solution. In developing the story, it seemed that Filippa drew on her own experiences of only having two teachers in the class and finding moving between too many activities busy and noisy. At no time, did the teacher bring up mathematical understandings. Whereas Nicolas' unexpected answer resulted in the teacher moving into the vertical discourse, the interaction with Filippa remained firmly situated in the horizontal discourse. Unlike the girls in Boaler's (1994) study, Filippa did not seem confused by the familiarity of the context, rather the teacher emphasised that she wanted the context-specific information.

Lova

In the warm-up activity, Lova was the first to stand up and try to find the pair number for her 2. However, it was her partner, Svante, who told the teacher about their pair. As the teacher described the problem of sharing ten children in the three groups, Lova could be seen using her fingers to work out possible solutions (see Figure 3). Before she collected her paper, she shared her solution with Svante who also used his fingers to find a solution.

In working on the problem, Lova moved from using her fingers to putting tally marks next to the symbols for each of the groups (see Figure 3). She seemed to recognise that there was more than one solution. After she has added one round of tally marks, she counted them before adding the next round. Lova's actions suggested that her interest was in the vertical discourse surrounding the principles connected to adding three numbers together to make 10. When sitting in the horseshoe, Lova was one of the few children who the teacher asked to present her response (see Figure 3), although in this case, the teacher indicated that Lova had a proposal, not a solution.

Teacher: Lova, what proposal do you have? Oh, okay what is there? Can you tell me? (Lova vad har du för förslag. Oj okej vad står där? Kan du berätta för mig?)
Lova: Three, five and one. Three, five and two. (Tre, fem och ett. Tre fem och två.)
Teacher: Let me see, three five and two, okay. It is, let's see here. (Jag får se, tre fem och två okej. Det är, ska vi se här.)
Lova: Three in one group, five in another. (Tre i en grupp fem i en.)
Teacher: But where are the three, is it in the baking group? (Men var är de tre, är det i bak gruppen.)
Lova: Yes. (Ja.)
Teacher: And then it's five in the woodworking group and two in the painting group. (Och så är det fem i snickargruppen och två i målargruppen.)
Lova: Because the woodworking group, it's many more who like to do woodwork, less who like to paint and in between who like baking. (För att snickargruppen, det är mycket mer som tycker om att snickra, mindre som tycker om att måla och mittemellan som tycker om att baka.)

Figure 3: Lova's problem solving

Teacher: So they could choose for themselves in that class, okay. (Så dom fick välja själva i den klassen, okej.)

In presenting her solution, Lova seemed to focus on the numbers, suggesting that she wanted to stay within the vertical discourse. However, the teacher shifted her to the horizontal discourse by asking about which group had three children in it. Lova happily participated by providing details about why she had split the ten children.

DISCUSSION AND CONCLUSION

Previously, van Oers (2001) highlighted how too much attention on children's everyday experiences could be detrimental to their learning formal mathematics knowledge. In this study, we have examined examples from one lesson in a Swedish preschool class which suggests that the issue is more complex.

To acknowledge the preschool class as a bridge between the informal learning in preschools and the formal learning in schools, teaching activities could invite children to participate in both vertical and horizontal discourses. Certainly, the problem solving in this lesson provided a context with plenty of opportunities to work within both the horizontal and vertical discourses. However, the interactions within the three cases suggest that the two discourses, metaphorically speaking, are conflated.

In the case of Nicolas, the teacher made an initial attempt to work in the vertical discourse by discussing the relationship between 5, 10 and 15. In a few, very complex and fast moves a horizontal discourse was created in which the question "what numbers are good for creating three groups" became legitimate. Like the initial vertical discourse discussion, the new horizontal discourse "story" from Nicolas' perspective seemed to make little sense. In this exchange, Nicolas' opportunities to extend his understanding of either the horizontal or the vertical discourse seemed to disappear.

Filippa herself made use of the horizontal discourse to make a connection between the story and the mathematical context. The teacher had opportunities to introduce potential mathematical obstacles to Filippa's story by suggesting that there could be as many teachers as groups. This would have indicated that in mathematics, it is possible to make such assumptions. However, the discussion stopped and was kept within the horizontal component where Filippa seemed most comfortable. Possibilities for learning about the vertical discourse of formal mathematics never eventuated.

Finally, Lova presented her answer in such a way that it invited a discussion about numbers within the vertical discourse. The teacher subtly hinted at this by remarking that 2, 5 and 3 "is okay", but then shifted the discussion to the horizontal discourse. Thereby Lova, who of the three children, showed the most interest in the principles behind the different combinations of numbers that added to ten, lost an opportunity to extend her understanding.

The three cases reveal a group of children, which although not homogeneous, had in common the experience of not being provided with possibilities to connect their experiences to formal mathematics knowledge. The children were not confused over the knowledge needed to solve the problem. They all understood that numbers were expected. Instead confusion may have occurred when the teacher brought the solutions into the horizontal discourse of everyday knowledge, but without extending the children's social concerns, such as having sufficient teachers. If similar lessons continue to highlight the everyday knowledge, even when children such as Lova show interest in the mathematics, then there is a risk of mathematical exclusion.

Student assessment in an era of accountability

Richard Kitchen, Sarah Ridder and Joe Bolz

University of Denver, Morgridge College of Education, Denver, USA, richard.kitchen@du.edu

In this research paper, the assessment practices of mathematics teachers at an urban high school in the USA who primarily taught racial and ethnic minority students and low-income students are described. We found that the teachers' assessment practices were largely influenced by the pressures to prepare students for success on the state's standardized test. For instance, teachers regularly used the language found on "the test" to classify students by their performance (i.e., Unsatisfactory), was regularly used by the teachers to label students, and was used in both assessment design and assigning student grades. Moreover, student performance on the test influenced how teachers viewed students, and consequently, how they viewed them in the assessment process. This is problematic given the long history in the USA of low-income, diverse students being denied access to challenging mathematics instruction.

Keywords: Assessment, diversity, urban education.

INTRODUCTION

The purpose of this research study is to examine how the assessment practices of mathematics teachers at a highly diverse urban high school in the United States of America (USA) were influenced by their students' performances on the state test ("the test"). At a time when large-scale assessments such as No Child Left Behind mandated tests (NCLB, 2001) [1] have been dominant in the USA, more research is needed to understand the impact of these tests on teachers' practices. It is important to understand how the test influences teachers' assessment practices because assessment is at the heart of what Ball and Forzani (2007) refer to as the "instructional dynamic."

The five teachers who participated in this study taught at Chavez High School [2] during the 2013–14 school year, a school situated in an urban school district in the state of Colorado. Chavez High served slightly more than 2,000 students in grades 9–12 and had a highly diverse [3] student population. In 2013–14, the Free Reduced Lunch rate at the school was 75%; 64% of the Chavez High student body was Hispanic, 15% was African American, 13% was White, 4% was Asian American, and 1% was Native American or Native Hawaiian [4]. At the time this study was conducted, the standards-based Transitional Colorado Assessment Program (TCAP) assessment in mathematics was being administered to all grade 3–10 students in the state in the spring. The research question that we address in this paper is: How did the Colorado state mandated test in mathematics influence the assessment practices of mathematics teachers at Chavez High? Before we offer our research findings and address our research question, we provide reviews of the relevant research literature in classroom assessment and research pertaining to the mathematics education of low-income and diverse students. The research methodology used in this study is also described and we conclude with a brief discussion related to our research findings.

CLASSROOM ASSESSMENT

Classroom assessments are used to inform teachers, students and parents about student knowledge and understanding of mathematical concepts, processes and skills (Wiggins, 1993). Two ways of viewing assessment are assessment as an evaluative process focused on "an accounting of what is" (Webb, 1992, p. 663) and grade assignment (Kulm, 2013), and assessment as "the process of gathering evidence about a student's knowledge of, ability to use, and disposition toward mathematics…" (National Council of Teachers of Mathematics, 1989, p. 3). The former, summative assessment focuses on what students know at a given time (Guskey & Bailey, 2001). The latter, formative assessment, differs from summative assessment in that the focus is not just on summarizing students' learning, but on using information derived from assessments to inform instruction (Black & Wiliam, 2009). After more than a decade in which large-scale summative assessments such as No Child Left Behind mandated tests (NCLB, 2001) have dominated the educational landscape in the U.S., we agree with Kulm (2013) that it is time to "reclaim the true meaning and purpose of enlightened mathematics assessment" (p. 4). Such assessment places a premium on using assessment to support teachers and the development of their instruction for the betterment of their students. For instance, Shepard (2000) called for assessments in which students actively make meaning of mathematical concepts by building on their previous knowledge and experiences and making connections to previous knowledge and new understandings.

With the introduction of the No Child Left Behind (NCLB) legislation and the testing that accompanies it (NCLB, 2001), educators and researchers have expressed a number of concerns about the impact that the introduction of high stakes, large-scale testing in the United States have had on teaching and learning (Nichols, Glass, & Berliner, 2006). For instance, students are reduced to test performers and "teachers find themselves using students to protect or help themselves… The marketplace mentality expands its reach" (Gergen & Dixon-Román, 2014, p. 8). "Teaching to the test" not only limits the content that is taught to what is tested, but also promotes superficial student learning that tends to be more skill focused and furthers student alienation toward school and learning (Nichols, Glass, & Berliner, 2006). Furthermore, instruction may be more targeted to those students who are close to meeting proficiency on the test and less instructional attention is paid to those who are far above or below meeting proficiency (Harlen, 2007). In a nutshell, high-stakes tests have had many negative consequences such as categorizing students as numbers to be compared to their peers, while limiting instruction to the detriment of students and their educational opportunities (Linn, 2000; Messick, 1995a; 1995b). Rather than holding schools and teachers accountable simply for student achievement on high-stakes tests, a range of student assessment information should be collected that will also inform teachers about how to improve their instruction (Harlen, 2007).

MATHEMATICS FOR LOW-INCOME AND DIVERSE STUDENTS

Globally, mathematics has served the historic role of sorting and stratifying students by race, ethnicity, and gender (Gerdes, 1988; Jurdak, 2014). In the U.S., white and Asian middle class and upper-middle class students have been privileged to have greater access to challenging mathematics curriculum and instruction (DiME, 2007; Tate, 1995). Educational opportunities and access to such opportunities are influenced by where one lives, what Tate (2008) refers to as the "geography of opportunity" (p. 397). Massey (2009) contended that advantages and disadvantages procured from an individual's socioeconomic status (SES) are both reinforced and compounded by geographic concentration. For instance, students from low-income communities attend schools in which pupil expenditures compare unfavorably to pupil expenditures in schools located in wealthy communities and achieve at lower levels than their wealthy counterparts (Payne & Biddle, 1999). Hogrebe and Tate (2012) found that algebra performance is also influenced by where students live; the SES of local communities is significantly related to students' performance in algebra. Brynes and Miller (2007) found that SES has direct effects on mathematics achievement and indirect effects on both the opportunities students have to enroll in advanced mathematics classes in high school and on their propensity to take advantage of learning opportunities in mathematics.

In addition to poverty and SES, student access to a challenging standards-based mathematics education is influenced by race, ethnicity, and English language proficiency (DiME, 2007; Gutiérrez, 2008; Martin, 2013). A role that mathematics has played historically is to sort and stratify students by race, ethnicity, and gender (DiME, 2007; Gerdes, 1988). Specifically, white and Asian middle class and upper-middle class students have been privileged to have greater access to challenging mathematics curriculum and instruction (DiME, 2007; Tate, 1995). Schools that enroll large numbers of African American students often have disproportionally high numbers of remedial classes in mathematics in which instruction is focused on rote-learning and strategies that are intended to help students be successful on standardized tests (Davis & Martin, 2008; Lattimore, 2005). In response to NCLB (2001) and the demands to increase test scores, Davis and Martin (2008) argue that the preponderance of skills based instruction "[negatively] shape the lives of poor African American students in more significant ways than middle-class or affluent students" (p. 18). An extensive research base demonstrates that low academic expectations and lower pupil expenditures have historically been the norm for schools that serve students from low-income communities and racial and ethnic minority students (Ferguson, 1998; Knapp

& Woolverton, 1995). Given this research, it is not difficult to surmise that millions of low-income students of color are being denied access to instruction in which students regularly engage in mathematical reasoning and discourse to solve complex tasks (Davis & Martin, 2008; Kitchen, Burr, & Castellón, 2010; Téllez, Moschkovich, & Civil, 2011; Valero & Meaney, 2014).

RESEARCH METHODOLOGY

Beginning in the fall semester of 2013, we visited Chavez High 2–4 times a month for the duration of the 2013–14 school year. A school visit included two classroom observations of one of the five participating mathematics teachers on consecutive days in fall 2013 and again in spring 2014. A classroom observation consisted of videotaping the participating teacher teach a mathematics lesson as well as videotaping a group or groups of students who had provided consent to participate in the study. Every attempt was made to videotape in a manner that minimized interference in the mathematics lesson (e.g., the video camera was placed in a location in the classroom such as the back of the room so as not to block students' view of their teacher, the whiteboard, and any other instructional resources used by the teacher). An interview was conducted with each participating teacher immediately following the first or second observation. Interviews with individual teachers were 30–45 minutes in length. Two focus group interviews were also conducted in spring 2014. Four of the five participating teachers participated in the initial focus group interview and all five of the participating teachers attended the second focus group interview. An interview was conducted with the Chavez High principal in the spring of 2014 as well.

For the purposes of this study, the data analysed were all the interviews conducted that included the individual interviews conducted with participating teachers, the two focus group interviews and the interview with the Chavez High principal. The interview transcripts were analysed using interpretive methods (Erickson, 1986; Maxwell, 2005). Each interview was read as a whole, followed by a period of open coding to allow for the emergence of themes, and themes were then compared across interviews conducted. After a set of themes were obtained from the dataset, we searched for commonalities and differences across interviews conducted (Miles, Huberman, & Saldaña, 2013). We also sought both confirming and disconfirming evidence by searching for supportive and non-supportive evidence (Erickson, 1986; Miles, Huberman, & Saldaña, 2013).

The five mathematics teachers at Chavez High who participated in this study were Ms. H, Ms. K, Ms. S, Mr. T, and Ms. V. All five teachers were chosen by the school's administration as among the best mathematics teachers at the school and were recommended for inclusion in this study. Ms. S is Hispanic and was the only teacher of color in the group of participating teachers.

HOW "THE TEST" INFLUENCED ASSESSMENT PRACTICES

In this study, we investigated how the Colorado state mandated test in mathematics influenced the assessment practices of the mathematics teachers at Chavez High. It became clear from the outset of this study that the teachers' assessment practices we report here were largely the result of administrative mandates to improve student achievement at the school. For example, teachers were frustrated that students were often allowed to retake assessments on which they had not performed well. Ms. H discussed a concern shared by her colleagues about how some students approached assessments; "I'm sick and tired of hearing that before I hand out the test, 'there is a re-test, right?'" (Ms. H, Faculty Focus Group Interview, May 19th, 2014). Teachers explained that they were under pressure from the school's administration to do everything they could to avoid failing students in their classes. Teachers knew that if 20% or more of their students failed a class, they would be called in for a meeting with a Chavez administrator (Faculty Focus Group Interview, May 19th, 2014). Thus, students were often allowed to take an assessment more than once to improve their grade. Many of the assessment practices that the teachers pursued, and discussed below such as "deployment" and Exit Tickets had been mandated by the Chavez administration.

Our first finding was that because of the intense focus at Chavez High on students' performance on the TCAP ("the test"), it was common for teachers and administrators to refer to students as Advanced Proficient or just Advanced, Proficient, Partially Proficient ("Bubble Students") or as Unsatisfactory (or just as "Unsats"). This language reflected not only how students had performed on the test, but had also become language that teachers had adopted to design assessments and even assign students grades. The "Bubble Students" and "Unsats" were specifically earmarked for additional mathematics instruction as a means to change their status to "Proficient students." We also found the "Bubble Student" or "Unsat" label persisted; it was well documented who these students were and teachers were well aware of who was a Bubble Student and who was an Unsat student. "Bubble students" were specifically targeted for supplemental instruction since these students were within reach of achieving Proficient status on the test.

Though students were classified as a "Bubble Student" or as an "Unsat" based on performance on the previous year's test, teachers also used these categories to label student performance on summative and formative assessments that they used in their classrooms. For instance, mathematics teachers at Chavez High School engaged in what was referred to as "deployment." Students who were evaluated as Partially Proficient or Unsatisfactory on a unit test were "deployed" to receive supplementary instruction on the mathematics unit just completed. After the 1–2 day deployment, students were administered a post-test. When discussing the impact of one such deployment, Ms. K reported that "77% of the Unsats moved up to Partially Proficient" (Ms. K, April 17, 2014) on one of the re-tests administered.

Teachers also discussed aspects of classroom assessments they designed using the language from the test. For instance, parts of unit tests used during deployments included "Unsat" items, or questions that generally required less of students (e.g., recall of mathematical vocabulary). The "Unsat" portion of an assessment was meant to provide "access points" for students (Ms. S, Focus Group Interview, April 17, 2014). By this, Ms. S meant that the content of the "Unsat" portion should be more elementary, focusing for example, on vocabulary items in geometry. Teachers explained that the majority of the test items on summative assessments and even formative assessments such as Exit Tickets were "Unsat" items (e.g., 70–80% of the items), while the remainder of the items on the assessment were more advanced. Mr. T explained that he generally included only "the naked" or skills based tasks on his Exit Tickets (Mr. T interview, 2-20-14). The content of mathematics assessments was clearly influenced by the content teachers perceived would be included on the test. Ms. S, for instance, discussed modifying the curriculum she used because, in her opinion, it did not align well with the TCAP.

Finally, mathematics teachers at Chavez High used the test language categories to assign grades to their students. For instance, Ms. S used the classification language used on the test as part of her grading system, she did not assign grades based upon percentages: "I don't have any numbers in my grade book. It's a Partial, Unsat, or Advanced" (Ms. S interview, 10-24-13). For Ms. S, grades were assigned based upon how each student was performing, in a holistic manner, relative to language aligned with the test: "Unsat is they have some knowledge of some of the math that we did, so that's about a D. Partial Proficient is C-ish. And Proficient is about a B because you're doing what the standards are asking you to do. For students to earn an A, they have to take the math they've been doing and apply it to new problems that hasn't been taught to them." (Ms. S interview, 10-24-13).

In summary, we learned that the TCAP, Colorado's standards-based test profoundly impacted teachers' assessment practices, including their grading practices. Because of the strong focus by the Chavez High administration on student achievement on the test, and their goal of increasing student test scores, much of how teachers classified students and designed instruction was driven by the need to improve student achievement. Perhaps more importantly, student performance on the test greatly influenced how teachers viewed students, and consequently, how they viewed them in the assessment process. The language that was used on the test to classify students by their performance on it (i.e., Advanced Proficient or Unsatisfactory) was used as a means to label students and had become the taken-for-granted language teachers had adopted in many of their daily practices.

DISCUSSION

Few studies exist in the U.S. that examine how a state's large-scale test impacts high school mathematics teachers' assessment practices, specifically at a secondary school that serves primarily low-income and diverse students. An important contribution to the research literature is our finding that the test influenced the mathematics teachers at Chavez High to frequently use assessments in a summative manner and that they used their assessment results to categorize students vis-à-vis student performance categories used on the TCAP. Moreover, the mathematics teachers were largely concerned with their students, mostly low-income, students of color, deriving correct answers to skills based assessment tasks, rather than engaging them in solving rich mathematical tasks. This is problematic given the long history in the U.S. of low-income, diverse students being denied access to challenging mathematics instruction (Davis & Martin, 2008; Kitchen, DePree, Celedón-Pattichis, & Brinkerhoff, 2007). The intense focus on preparing students for the test, specifically students who have historically been denied access to a strong mathematics education program in the U.S., is continuing the destructive legacy of prioritizing low-level mathematics instruction for students from marginalized and oppressed communities (Davis & Martin, 2008; Lattimore, 2005). Finally, attaching a label such as "Unsat" to any student is unjust, particularly so when we consider that most Chavez High students were from historically marginalized and oppressed communities.

ENDNOTES

1. The No Child Left Behind Act of 2001 was passed by the U.S. Congress and requires states to develop assessments to be administered at the state-level. To receive federal funding, states must give these assessments to all students at select grade levels <http://en.wikipedia.org/wiki/No_Child_Left_Behind_Act>.

2. "Chavez High" is a pseudonym.

3. "Diverse students" refers to students who are members of a racial or ethnic minority group and is synonymous with "students of color," a phrase commonly used in the U.S.

4. The ethnic/racial categories reported here are the categories used by the school district in which Chavez is located.

School mathematics and bureaucracy

David Kollosche

Universität Potsdam, Potsdam, Germany, david.kollosche@uni-potsdam.de

This essay focuses on the connections between calculation and bureaucracy and points out implications for mathematics education. A genealogic analysis which methodologically follows Nietzsche and Foucault is used to show these connections firstly on a historical and secondly on the level of styles of thought. In the process, Weber's theory of bureaucratic administration, Sybille Krämer's history of formalisation and Foucault's analysis of the modern episteme will be considered. This study shows that mathematics – even in its unapplied and theoretical form – and bureaucracy share a common style of thought. Consequently, school mathematics can be understood as an institution which trains and examines a bureaucratic style of thought – an understanding supported by Paul Dowling's sociology of mathematics education.

Keywords: Calculation, formalisation, bureaucracy, Foucault, genealogy.

FROM SKOVSMOSE'S QUESTION TO THE METHOD OF GENEALOGY

In mathematics education research, calculation tasks, i.e. tasks which can be solved following prescribed rules for the manipulation of terms of numbers and variables, are often considered to be too 'bureaucratic' and to be over-represented in the mathematics classrooms. Usually, this claim serves to promote innovative approaches in mathematics education, but within this study it has not been possible to find research with such an object of an academic study itself. Ole Skovsmose (2005) also refers to the dominance of calculation tasks to distinguish his *Critical Mathematics Education.* He tries to explain the social function of the vast amount of calculation tasks each student has to solve during his school career. He refuses some common explanations and eventually asks:

> Could it be that 'normal' students in fact learn 'something', although not strictly speaking mathematics, and that this 'something' serves an important social function? If we look back again at the 10,000 commandments [which students have to solve during their school careers], what do they look like? Certainly, not like any of those tasks with which applied mathematics occupies itself, tasks in which creativity is needed to construct a model of a selected piece of reality. Nor do they look like anything a working mathematician is doing. However, they might have some similarities with those routine tasks, which are found everywhere in production and administration. An accountant has to do sums day after day. A laboratory assistant has to do a series of routine tasks in a careful way. [...] All such jobs do not invite creative ways of using numbers and figures. Instead things have to be handled carefully and correctly in a pre-described way. Could it be that the school mathematics tradition is a well functioning preparation for a majority of students who come to serve in such job-functions? (Skovsmose, 2005, pp. 11–12)

At a first glance, it seems surprising that Skovsmose does not provide any answers to his questions although he might be considered one of the founders of socially concerned research in mathematics education. But a closer look shows that he does not consider mathematics itself but only its application and teaching as socially critical. For Skovsmose, mathematics education is "undetermined", "without essence"; it can "serve a grand variety of social, political, and economic functions and interests" (Skovsmose, 2011, p. 2). Indeed, only under this assumption can he reasonably promote his emancipatory pedagogy. Then again, this very assumption hinders him from socially analysing non-applied calculation. So what if this assumption is misleading, if it is hindering us from discussing the social functions of what might belong to the essence of mathematics education: pure but nevertheless socially relevant mathematics, e.g. calculation? The question would then not only be how calculation *is* *applied*, but how it *can be applied*, which perspectives it allows and which ones it denies.

As calculation is no matter of applications and teaching alone, but one of mathematics itself, the usual methods of Critical Mathematics Education are not promising for a comparison of calculation and bureaucracy. Instead, this study uses the method of *genealogy* as introduced by Friedrich Nietzsche and continued by Michel Foucault. Genealogy is a method for "examining the historical origins of present day philosophical concepts, ideas and discourses along with the institutions that sprang from them" (Lightbody, 2010, p. 1). Unlike other historical approaches, it questions the ethical, metaphysical and epistemological values which implicitly underlie our knowledge and practices. It assumes that our ideas and practices are not born perfect, but have evolved in a struggle against other ideas and practices. Therefore, genealogy "is not the erecting of foundations: on the contrary, it disturbs what was previously considered immobile; it fragments what was thought unified" (Foucault, 1971/1984, § 3). By confronting the taken-for-granted with its fragile genesis, one gains the possibility of looking at it from an outsider's perspective and recognising the ideas it was directed against, the interests it served or the complicity into which it seduced us (Saar, 2007, p. 15). As every genealogy involves the danger of shaking our own convictions, it cannot be performed in any 'objective' way. Consequently, the purpose of genealogy is not to constitute any kind of 'true' history (although it might contribute to such an endeavour), but to help us understand our contemporary ideas and practices. Especially, it allows us to gain a critical distance from the values operating in mathematics education and to analyse calculation inside and outside school as a morally ambiguous socio-cultural phenomenon. Martin Saar states:

> Genealogy is more qualified than any other form of critique to grasp phenomena such as imperfect liberty, complicity with authority and subtle heteronomy, for it illuminates the conditions of the possibility of life forms in which heteronomy stabilises and power effects mentalities. (Saar, 2007, pp. 15–16; my translation)

The following analysis will first consider the genesis of calculation and bureaucracy in order to trace similarities in development. It will then match the styles of thought represented by calculation and bureaucracy in order to substantiate the claim that both share a common style of thought. The genealogic questions to ask are: *At what times, under which circumstances, to satisfy which needs and to serve whose interest did calculation and bureaucracy develop? What are the values underlying calculation and bureaucracy? What can the history of both tell us about commonalities between them?*

TOWARDS A GENEALOGY OF CALCULATION AND BUREAUCRACY

Unfortunately, neither a genealogy of calculation nor one of bureaucracy exists. Therefore, this study will try to sketch a genealogic approach from the theory that exists on the history and theory of calculation and bureaucracy. Contemporary theories of bureaucracy are still based on the sociology of Max Weber (Anter et al., 2010). Apart from that, his approach towards bureaucracy is particularly valuable for this study as it has genealogic features (Saar, 2007, p. 296). Weber describes an 'ideal type' of bureaucracy which is well summarised by Robert K. Merton:

> A formal, rationally organized social structure involves clearly defined patterns of activity in which, ideally, every series of actions is functionally related to the purposes of the organization. In such an organization there is integrated a series of offices, of hierarchized statuses, in which inhere a number of obligations and privileges closely defined by limited and specific rules. Each of these offices contains an area of imputed competence and responsibility. Authority, the power of control which derives from an acknowledged status, inheres in the office and not in the particular person who performs the official role. Official action ordinarily occurs within the framework of pre existing rules of the organization. The system of prescribed relations between the various offices involves a considerable degree of formality and clearly defined social distance between the occupants of these positions. (Merton, 1949, p. 151)

Although Weber considers the rise of bureaucracy a modern phenomenon and contrasts it with patrimonial forms of administration, which were typical for pre-modern monarchies, he acknowledges that some of its social and economic preconditions (such as the economic need for an effective, professional and centralised administration or the development of monetary economy) existed before, leading to historical forms of administrations with bureaucratic traits. He explicitly mentions the New Kingdom of Egypt, the late Roman Principate and the absolute monarchies of early modern Europe (Weber, 1922/1972, pp. 556, 560).

It is striking that our records of the development of calculation date back to the very same places and eras. In Sybille Krämer's unique history of formalisation (1988), which builds on the work of Jacob Klein (1936/1992), the outstanding contributors to that development of calculation from purely arithmetic to algebraic forms are the Egyptians at the beginning of the New Empire in the 16th cent. BC, Diophantus at the time of the late Roman Principate and Vieta when monarchy began its change towards absolutism. In spite of their enormous contributions to philosophy, the (decentrally administered) ancient Greeks considered calculation unworthy of a scientific discussion. It took only 200 years and the uprising of strict philosophical logic to have many contributions of the Pythagoreans, mathematicians said to be influenced by the Orient, excluded from the corpus of mathematics, most notably from Euclid's *Elements* (Krämer, 1988).

In a collection of application tasks and solutions, the Egyptians documented their mathematical techniques which include fractions, written methods for multiplication and division, applications of the Pythagorean theorem, solving quadratic equations and calculating areas and volumes. The Egyptian 'aha-calculus' is the earliest record of the use of variables; it documents the transfer of algorithms from numbers to signs. Different from our use today, the Egyptian variable could only stand for a specific, yet unknown number. It could be used in expressions such as $4 + h = 15$, but not in expressions which describe relations of values such as $y = 4x - 1$ or $a + b = b + a$ (although we have to keep in mind that these expressions could only be recorded verbally as our formalistic writing of mathematics developed only during the last few centuries). The variable was always connected to a certain number, it was its placeholder; and initially this was the only reason to treat it as a number (Krämer, 1988). Greek algebra separated values from their contexts of application and linked them to geometry. While expressions such as $a + b = b + a$ could now be interpreted as an apposition of line segments, the use of algebra and variables was constrained by the necessity of its geometrical interpretation. Five centuries after Euclid, Diophantus emerged as the *enfant terrible* of classical mathematics: he added lengths and areas, thought of triangles as triples of numbers, introduced symbols for operations and facilitated a formal notation for terms and equations. Nevertheless, he still considered variables the mere placeholder of a fixed number. Thus, he was unable to present universal algorithms and had to document his techniques in examples of tasks and solutions (Krämer, 1988; Klein, 1936/1992). This did not change until Vieta developed his algebra. Vieta was the first to consider variable as autonomous entities, independent from any number(s) it might represent and defined only by its rules of calculation:

> Algebra is no longer calculation with unknown numbers. Instead, it can be conceived as a calculation with characters, i.e. with 'undetermined' symbols which can represent all possible numbers that – substituted into a given equation – form a right expression [...] This is how the mathematical formula came into the world. (Krämer, 1988, p. 61; my translation)

A COMMON STYLE OF THOUGHT

The joint development of calculation and bureaucracy merely indicates a connection between both. The further analysis will show that calculation and bureaucracy do not only share a common style of 'bureaucratic thought', but that this style of thought is exemplary and prototypical for the modern thought since the 17th century. To this end, considerations about the characteristics of symbols in modern thought will lay the basis for analysing the role of bureaucratic thought in contemporary society.

Again, the genealogic analysis lays its focus on historical events of change and conflict. In this case, the biggest changes can be spotted around 1600, when Vieta's algebra became influential and the rise of bureaucracy allowed absolutism to develop. In his *Order of Things* (1966/1970), Michel Foucault identified a strong change in the episteme, i.e. the way people perceive and make sense of the world, in the years around 1600. Until the end of the Renaissance, thought was dominated by the principle of resemblance – a relationship considered to be unbreakable. Signs were "thought to have been placed upon things so that men might be able to uncover their secrets, their nature or their virtues" (p. 59). Signs resembled the represented, literature resembled truth, variables resembled numbers and money was made of valuable materials. In contrast to that, signs gain their independence in the 17th century. Suddenly, they are considered arbitrary constructs and require legitimisation. Consequently, science begins to discuss the criteria for the significance of symbols, leading to the appreciation of calculation and the evolution of formal logic. From then on, symbols are interrelated by their order (*taxonomy*, connected to logic) and by their measure (*mathesis*, connected to calculation) (pp. 71–76).

In his history of Algebra, Klein argues that while "in Greek science, concepts are formed in continual dependence on 'natural,' prescientific experience, from which the scientific concept is 'abstracted'", in modern science "nothing but the internal connection of all the concepts, their mutual relatedness, their subordination to the total edifice of science, determines for each of them a *univocal* sense". Klein recognised that "the nature of the modification which the mathematical science of the sixteenth and seventeenth century brings about [...] is *exemplary* for the total design of human knowledge in later times" (Klein, 1936/1992, pp. 120–121). From that perspective, modern calculation is not only an example of the new episteme, since it uses autonomous symbols; it is also a condition of the possibility of the modern episteme, for it constitutes a method to interrelate autonomous symbols. Accordingly, Klein points out that the new form of calculation is not a mere "device" of science but predefines the forms, e.g. the possibilities and restrictions, of scientific understanding (pp. 3–4).

The modern episteme is a prerequisite of bureaucracy, too, for it builds on the dissolution of the resemblance and the installation of symbolic practices. Bureaucracy has the purpose to provide predictable and equitable, i.e. non-arbitrary, forms of administration. For that reason, administrative acts are bound by "a consistent system of abstract rules which have normally been intentionally established" (Weber, 1921/1947, p. 330) instead of resembling any natural, traditional or divine law. Within this system of rules, officials act in a "spirit of formalistic impersonality", "without hatred or passion", "without affection or enthusiasm"; "everyone in the same empirical situation" has to be treated equally and the official is not allowed any "personal considerations" (p. 340). According to this, obligations, administrative means and authority are linked to positions, which are abstract symbols within the system of rules and do not resemble any natural person; positions are only 'held' by persons (p. 330). Bureaucracy follows the principle of impersonality by separating the official and the client from the human, by ignoring their individuality: their hope, fear, anger, gratitude, concern and doubt.

Calculation embodies a similar style of thought. Firstly, calculation is used for non-arbitrary, i.e. 'objective' predictions. The German *berechenbar* means 'calculable' as well as 'predictable'. Secondly, calculation works along a system of abstract rules that are culturally established and that the individual has to conform to. Thirdly, this system of rules demands 'formalistic impersonality' as calculation operates by its rules alone. This formalism disregards any 'personal considerations' of the calculating individual just as it disregards those of the official. But on top of this, the variables of each calculation also have to be manipulated 'impersonally', i.e. without any regard for what they might stand for. Every situation is only perceived in the boundaries of the pre-defined cases, i.e. cases that rules (for calculation or administration) exist for. It is this separation of sign and represented, of case and individual, of variable and number in the modern episteme that allows both bureaucracy and calculation as known today. Calculation is not a mere tool of bureaucratic administration, but it is in itself a technique for the "de-humanised" (Weber, 1922/1972, p. 563) processing of situations. Therefore, calculation is not an "undetermined" technique that can "serve a grand variety of social, political, and economic functions and interests" (Skovsmose, 2011, p. 2); it is a technique which resembles a style of thought that is: bureaucratic.

CALCULATION AND BUREAUCRACY IN THE CLASSROOM

Merton acknowledges that bureaucracy has to exert "a constant pressure upon the official to be methodical, prudent disciplined"; it must attain "an unusual degree of conformity with prescribed patterns of action" in order to fulfil its purpose (Merton, 1949, p. 154). Accordingly, Weber states that the bureaucratic style of thought requires "specialised training" (Weber, 1922/1972, p. 552). He explains the uprising of general education in modern times with the need for preparatory training and selection. Mathematics education in particular has historically developed alongside the cultivation of bureaucracy, incorporating calculation which has been shown to share a common style of thought. As Skovsmose points out, students have to solve a large amount of calculation tasks during their school career (Skovsmose, 2005). Solving these tasks is a prescribed activity with abstract symbols, following prescribed rules. Compared to other tasks used in school, calculation tasks specifically cannot be solved *without* a bureaucratic style of thought: There is usually no other valued solution to a calculation task than the development or application of a rule-bound and impersonal algorithm. The experience of these ever-repeating challenges causes the student to adapt. On the one hand, she may be able and willing to cultivate a bureaucratic style of thought. This would allow her to perform well (at least as long as mathematics education incorporates calculation to a large extent) and experience herself as a successful learner. On the other hand, she may be either unable or unwilling to cultivate a bureaucratic style of thought. This would leave her to ever-repeating failure in calculation tasks. In the case of such a trauma, the only adaptation securing the student's dignity is to escape from the humiliating situations. As a physical escape is not tolerated, it has to be performed mentally: those students 'learn' that mathematics is 'nothing for them'. Ideal-typically, this organisation of the mathematics classroom results in the production of either accomplices or avoiders of mathematics, ensuring that mathematical rule goes unquestioned and thereby contributing to the domination of humans by mathematics which Roland Fischer (1984) has warned against.

In his *Sociology of Mathematics Education* (1998), Paul Dowling describes "myths" about mathematics which are spread in the mathematics classroom. He is especially interested in so called 'real world problems' in which problems formulated in situations of the real world are interpreted and solved by calculation. While no specific applications of calculation will be discussed here, Dowling's analysis helps to understand who calculation is *per se* positioned in the mathematics classroom. The *myth of reference* is a mechanism which makes students think that calculation is a universal tool capable of solving any real world problem. Dowling states and exemplifies that many 'real world problems' build on situations which would not be solved mathematically in everyday life (Dowling, 1998, pp. 4–7). In addition to that, the mathematics classroom does not usually present any 'real world problems' that cannot be solved mathematically. Therefore, school mathematics provides experiences which foster the belief that mathematics can be reasonably applied to solve *any* problem of the real world. To the extent to which these 'real world problems' are based on or result in calculation, 'real world problems' function as a mechanism to install calculation as an omnipotent means of perceiving and handling our world.

Dowling's *myth of participation* refers to a mechanism which fosters the belief that students will need mathematics to succeed in their everyday life outside school (Dowling, 1998, pp. 7–11). 'Real world problems' are often student-oriented, i.e. they build on situations that are close to the experiences of students, although the mathematics involved would usually not be used to solve such problems in the real world. Their latent message is: *Look at these examples from your everyday life and see how calculation is needed to manage them!* That is how school mathematics provides experiences which foster the belief that the students need mathematics and especially calculation to cope with their everyday life outside school.

Both mechanisms bear the possibility of intensifying the experiences students have with calculation tasks. On the one hand, those succeeding in calculation may be happy to master the seemingly omnipotent and even privately relevant, de-humanised, rule-bound approach towards our world. On the other hand, those failing in calculation may explain their failure with their own incompetence rather than with insufficiencies of the calculation method as the latter is believed to be omnipotent. Nevertheless, they may believe that calculation is important for their life outside school. In the end, they might come to think that they lack the ability to handle the mathematics necessary for a fulfilled life and feel compelled to lay their trust in mathematical experts. Thus, a function (although not an intended goal) of school mathematics would be not only to separate the capable and willing from the unable and unwilling, but also to make the latter appreciate their subordination.

As bureaucracy and calculation share a common style of thought, performance in calculation indicates whether or not students are suited for administrative positions: whether or not they can reduce situations to cases and calculations, and whether or not they can handle these cases calculations according to imposed rules disregarding their personal thoughts and feelings; whether or not they can separate from themselves an administrative or calculative processor of rules. But school mathematics also educates in the sense that it produces situations in which students cultivate their relationships towards calculation. Whether or not, or rather: how far this experience affects the student's relationship towards bureaucracy, is hard to tell. It seems at least natural that the estrangement from calculation to some extent coheres with an estrangement from any practices sharing a similar style of thought, especially from bureaucratic ones. Therefore, school mathematics can be considered an institution which (alongside other functions) identifies and trains a calculatory-bureaucratic elite and teaches the rest to subordinate to the calculatory-bureaucratic administration of our society. And although this explanation deserves further theoretical and empirical elaboration, it can already serve as a first answer to Skovsmose's questions, contribute to the socio-philosophical discussion about the essence of mathematics, question the educational objectives which mathematics educators assign to school mathematics, explain why mathematics is such a polarising subject and shed light on anxiety and joy, motivation and estrangement in mathematics classrooms. Within the research community especially, it would also add a new dimension to socially concerned research in mathematics education and call for ways to deal with this social function of school mathematics.

Socialisation and mathematics education in Swedish preschools

Dorota Lembrér

Malmö University, Faculty of Education and Society, Malmö, Sweden, dorota.lembrer@mah.se

This theoretical paper investigates the relationship between socialisation and mathematics education in Swedish preschools. Socialisation is considered to be the process by which children construct their own childhoods and experiences as a preparation for adulthood. Mathematics education as defined by the curriculum outlines what learning possibilities preschools and the adults working in them should provide to children. The production and reproduction of cultural knowledge as components of socialisation are connected to the global issue of early year's education and schoolification. I suggest that it is important to discuss how learning of content and subjectivities is a key feature in an investigation of the relationship between socialisations and mathematics education in the Swedish preschool curriculum.

Keywords: Learning, mathematics education, preschool, socialisation.

INTRODUCTION

In the research on mathematics education, there is a perception that young children need to have strong mathematical understandings when they begin school (Duncan et al., 2007). However, the implementation of programmes to provide this has led to concerns about the schoolification of preschool. Schoolification is described as:

> an emphasis on the acquisition of specific pre-academic skills and knowledge transfer by the adult rather than a focus on broad developmental goals such as socio-emotional well-being and the gaining of understanding and knowledge by the child through direct experience and experimentation. The push-down of grade one materials, specific learning standards and the traditional primary school model of didactic instruction to pre-kindergarten and kindergarten in some US states has heightened concern about the possible schoolification of ECEC [early childhood education and care]. (Doherty, 2007, pp. 7–8).

Increased references to mathematics in the revised Swedish preschool curriculum (Skolverket, 2011) suggest that perceptions of its value as being beneficial to society have increased. In this paper, I contribute to a discussion of the role of mathematics education in early childhood studies by reflecting on its relationship to learning and socialisation. I link socialisation processes and mathematics education with two components: the reproduction of culture from one generation to another; and the recognition of young children in preschool as knowledgeable and active participants in today's society. Learning is a vital component of this investigation because it highlights the connection between content and subjectivities. Therefore, my aim is to offer a theoretical contribution regarding the understanding of socialisation processes and what learning possibilities preschools should provide.

By placing a particular emphasis on preschool as the site of socialisation processes, I argue that there is a need for a discussion on what grounds and in what ways are children modified by the institution of preschool (Kampmann, 2004). Preschool as an institution is a place where children's social context and experiences are formed (Ebrahim, 2011), but with a specific focus on learning and development. Consequently it can be said that society considers preschools to be the necessary institutions for strengthening children's social competence and general ability to develop their childhood so that they can live in a modern world both independently and as part of a democratic society. However this raises the question, how does increasing the importance of mathematics education affect children's socialisation and learning?

SOCIALISATION

Socialisation occurs from living within a society and taking part in activities with others (Thorne, 1987). Given that in 2013, 77 per cent of children aged between one and three years and 94 percent of children aged between four to five years attended Swedish preschools[1], it can be stated that children are socialised within the institution of preschool as this is where they participate in society:

> By interacting with playmates in organized play groups and nursery schools, children produce the first in a series of peer cultures in which childhood knowledge and practices gradually are transformed into the knowledge and skills necessary to participate in the adult world. (Corsaro, 1992, p. 162)

Walzer and Miller (2007) stressed that within culturally diverse societies, educational opportunities provide an understanding of some of the meanings to be found in that society. Socialisation provides an educational structure which children learn to recognize and interpret (Trondman, 2013).

Socialisation as replication

Socialisation for young children, including that which occurs in preschools, has been equated with a process or a journey towards adultness. This journey contributes to children's gaining of knowledge of their own and others' roles in society, in order to reproduce society's key institutions (Lee, 2001). James, Jenks and Proud (1998) stressed that socialisation includes a transmission of culture from one generation to another, in order to ensure that societies sustain themselves over time. As a consequence of the process of change and alteration, the child is seen as developing socially, so that they become the adults that society needs.

Curriculum as a body of knowledge is an example of institutionalisation of the norms and values seen as important by a society, but also as an example of adults determining what skills, norms and values children need to become acceptable adults. The mathematical goals in Swedish preschool curriculum represent some of these institutionalised norms and values. The goals related to mathematics require preschools to provide opportunities for children to:

> develop their understanding of space, shapes, location and direction, and the basic properties of sets, quantity, order and number concepts, also for measurement, time and change,
>
> develop their ability to use mathematics to investigate, reflect over and test different solutions to problems raised by themselves and others,
>
> develop their ability to distinguish, express, examine and use mathematical concepts and their interrelationships,
>
> develop their mathematical skill in putting forward and following reasoning (Skolverket, 2011, p. 10)

In these goals, what mathematics is has been already determined. Inclusion in the curriculum means that they take on the aura of being the valuable cultural knowledge which should be transmitted to children so that society can be sustained over time. However, if the process of socialisation is for children to gain valued knowledge about the subject, as part of the reproduction of society's key institutions (Lee, 2001), then children may need to recognise the activity as mathematics.

Yet, a focus on the future may lead to unwelcome consequences. Sarama and Clements (2004) argued that such a focus can limit a child's own hunger for knowledge and their willingness to engage in mathematical activities. As well, it may be that the inclusion of more mathematical goals in the revised Swedish preschool curriculum (Skolverket, 2011) could restrict teachers' possibilities in planning activities which value what children already know and can do. Concerns have been raised that the focus on mathematical knowledge needed for school learning is a form of schoolification regarding the effect on the kind of socialisation that preschool children receive (Alcock & Haggerty, 2013; Gunnarsdottir, 2014; Sofou & Tsafos, 2010).

Socialisation as creation

An alternative view of socialisation is that it can be considered as a process in which children co-create new cultural norms and values together with others (Thorne, 1987). For Ebrahim (2011), socialisation is the process by which people, who inhabit a society, create it. From this perspective, children need to be considered as knowledgeable, active participants in

1 For more information see http://www.scb.se/en_/

the construction of their childhood and experiences (James et al., 1998). This would include producing norms and values connected to the societies of their childhoods.

In the Swedish preschool curriculum (Skolverket, 2011), the preschool is expected to provide opportunities for children to engage with more general goals. Although many general goals also suggest that adults determine the necessary knowledge and skills for young children to know, some position children as having possibilities to create rather than just replicate cultural norms and values. These include:

> Each child should have the opportunity of forming their own opinion and making choices in the light of their personal circumstances (p. 4)
>
> Children should also have the opportunity to explore on their own issues in greater depth and to search for their own answers and solutions (p. 5)

In these goals, children are situated as persons with their own rights, interests and experiences who can influence the acquisition of the necessary skills to perform as functioning members of their society.

Having different emphases in the goals (creating versus recreating societal values and norms) could restrict teachers' possibilities in planning activities (Lembrér & Meaney, 2014). The focus of the goals for mathematics education on replicating cultural knowledge, including valuing certain aspects of mathematical knowledge, may mean that teachers do not consider children as needing opportunities, for example, to form their own opinions and make choices about mathematics. This could be an example of schoolification where the kind of socialisation that preschool children receive is restricted to ensuring that they become the kind of mathematicians needed for school learning.

Replicating and creating through socialisation

Socialisation as a process of creating/recreating society and the transmission of culture is connected to perceptions of what young children are capable of doing. For example, Lee (2001) highlighted how a young child's age affected adults' perceptions of them having rights to have opinions and desires, as often children are considered too young to be worth listening to. Discussions such as these make it difficult to recognise children as fully human or people in their own rights (James & Prout, 1997). Consequently, researchers have discussed the necessity of making such a distinction. For example, Thorne (1987) discussed the adult/child dualism as being socially constructed and therefore possible to change.

Rather than seeing creating and replicating cultural norms and values as being in opposition, it has been argued that children's own knowledge can be a starting point for initiating social interaction in play and promoting construction of subject knowledge (Edo, Planas, & Badillo, 2009). However, this requires a delicate balance between production and reproduction of societal norms and values, a sense of responsibility for the future of the society while at the same time allowing them to create own values, knowledge and even cultural understanding.

LEARNING

Although curriculum goals frame the operationalisation of mathematics education in preschools, they alone do not determine the socialisation that children gain from participating in activities. Instead, learning, not as a cognitive activity done by individuals, but as that done within societies and in particular in societal institutions such as preschools, needs to be considered in relationship to socialisation. Radford (2008) stated, "learning does not consist in constructing or reconstructing a piece of knowledge. It is a matter of actively and imaginatively endowing the conceptual objects that the student finds in his/her culture with meaning" (p. 223).

Often preschool children's early learning is described as essential for further learning processes. Children acquire the understanding, skills and awareness of different mathematical concepts, developed in the course of their own experiences (for example, Brenner, 1998), through the process of learning and the reproduction of norms and values (Lee, 2001). Studies of how children learn mathematics together with their peers, family, environment and in culture, indicate that interactions around mathematical activities are of importance (for example Carruthers, 2006).

However, within discussions of socialisation, learning is conceived as being about learning knowledge or skills, either already found within a society as valued norms and values or newly created within the process of learning. Such discussions fail to recognise that learning cultural norms and values results in children (and adults) learning to become someone, in other words – learning subjectivities. Such a view of learning positions children as human and contribute to an understanding that mathematics learning is socially constructed, not merely reproduced, so that children can explore and thus produce new forms.

Osberg and Biesta (2008) describe learning as something that can occur anywhere at any time but that education was about learning about taking on a particular subjectivity such as being a responsible member of society. Radford (2008) also saw learning as being more than simply learning about ideas. He stated that learning is "not just about knowing something but also about becoming someone" (p. 215). The role of the curriculum in shaping the kind of person that evolves from participating in activities in preschool.

> This 'shaping of subjectivity' is generally understood to be achieved through the curriculum (and the pedagogy 'supporting' the curriculum). With the concept of 'education' the notion of curriculum therefore acquires a very specific meaning. It becomes a course by means of which the subjectivity of those being educated is directed in some way. (Osberg & Biesta, 2008, p. 314)

From this perspective, Biesta (2007) considered much of what occurs in institutional settings, such as preschools, to be socialisation, as for him socialisation is the "insertion of 'newcomers' into existing cultural and socio-political settings" (p. 26). On the other hand, education as defined by Kant is the self-education needed to achieve rational autonomy in order to become fully human. Biesta (2007) argued that this view of education was also a form of socialisation because it set up what the end product of self-education had to be, that of rational autonomy. Education of this kind results in individuals taking on the attributes of existing members of a society but without a recognition of the role of the community in this process (Radford, 2008). Socialisation, then, must be considered as a not just learning cultural norms and values but living those norms and values, as with becoming a rational human being.

However, this suggests that those who did not have or did not gain the appropriate attributes could not be considered human (Biesta, 2007). Thus, young children can be categorised as being non-human as they do not have the necessary desired rationality. As research has come to highlight the importance of mathematics in early years (Ginsburg & Amit, 2008; Sarama & Clements, 2009), this category of being non-human could be extended from not being rational to not being mathematical sufficient or "at-risk" from beginning school without the mathematical knowledge deemed necessary by adults (Meaney, 2014).

In contrast, Biesta (2007) postulated that education should be deemed as preparation for an uncertain future, where freedom "needs to be realised again and again" (Biesta, 2007, p. 32).

In a report for the Swedish National Agency of Education (Skolverket), Johansson (2011) stressed that the Swedish preschool curriculum clearly states that children's own experiences should be actively drawn upon in preschool contexts because it is a source for knowledge and learning. Activities are to be based on a creative form of play, with opportunities for other kinds of expressions. This can be seen in the following example of goals from the curriculum (Skolverket, 2011):

> Learning should be based, not only on the interaction between adults and children, but also on what children learn from each other (p. 6)
>
> The preschool should promote play, creativity and enjoyment of learning, as well as focus on and strengthen the child's interest in learning and capturing new experiences, knowledge and skills (p. 9)
>
> Take account of children's eagerness, desire and enjoyment to learn, as well as strengthen confidence in their own ability (p. 11)

In these goals, although children are positioned as having a major role in their own learning, their developing subjectivities are only apparent in regard to the kind of learner they should be encouraged to be. Similar points can be made about a lack of awareness of the subjectivities that preschool children learn while engaged in mathematical activities.

As noted earlier when children's socialisation is discussed in terms of learning mathematics, knowledge and skills are considered crucial. However, what young children are capable of doing mathematically is determined by the opportunities provided for them to engage in activities. When preschool children are often actively engaged in mathematical activities (see, for example, study by Lange, Meaney, Riesbeck, & Wernberg, 2012), they can construct new knowledge as well as making sense of existing knowledge in a process of cultural reproduction. Becoming aware of the knowledge they are learning can be seen as an active process of meaning making based on understanding and interpretation. In an earlier study on measurement (see Lembrér, 2013), a group of preschool children drew a map. As they became aware of the importance of different measurement attributes like the length of the boat and the height of the train, they utilised the knowledge that they already had to gain culturally valued knowledge that extended their measurement understanding. Consequently, learning is a process in which socialisation is bound together through mathematical activities. The subjectivities that the curriculum suggests should be available to children through participating in mathematics activities are not explicit. Still the goals in the curriculum indicate that preschool children's possibilities for learning certain subjectivities is to be reproducers of existing norms and values.

SCHOOLIFICATION AND SOCIALISATION

While engaged in activities based on the Swedish preschool curriculum (Skolverket, 2011), such as those involving mathematics, children learn to reproduce societal norms and values so as to become the adults society expects as a result of socialisation. This is likely to occur even when children are recognised in the curriculum as active participants, rather than passive learners. Thus, learning is associated with socialisation.

Societal views and perceptions of children and childhood influence what is stated in the curriculum. For example, research, such as that reviewed in Clements and Sarama's (2007), indicates that the development of young children's mathematical ideas and skills has come to be regarded as one of the core purposes of preschools in some countries. What is included in the curriculum in turn influences how activities are implemented and children then are socialised. In regard to the revised preschool curriculum (Skolverket, 2011), Lembrér and Meaney (2014) indicate that schoolification through the increased emphasis on mathematical goals is likely to be affecting preschool education in Sweden and this may have an impact on the subjectivities available to children. The results of their study suggest that there are societal expectations about children's need to acquire the skills to perform as members of their society. This contributes to a tension between schoolification, where expectations about what children can learn shifts from school to preschool, and traditional foundations of preschools as institutional practice in Sweden, which has focused on children learning through play.

However, not only the curriculum determines the available possibilities for children concerning subjectivities. These possibilities are further determined by an interplay, including how the curriculum is interpreted and implemented by teachers, but also how children respond to the activities developed from it. Furthermore, dialogues with peers and adults can contribute to children gaining awareness of their own ability regarding mathematical knowledge, by inventing new meanings for improving their mathematical knowledge and for widening their awareness of possible subjectivities that are available (Lembrér & Meaney, submitted). Thus, when engaged in open-ended activities, children can encounter mathematical concepts/knowledge which can contribute to them asking for new knowledge, interests and ideas. This realisation of freedom can lead to children being better prepared to face the uncertain future that present-day adults are unable to predict (Biesta, 2007). This implies children developing the ability to be an agent for their peers, teachers and/or other adults in preschools. However, a tightening of what is acceptable as mathematical knowledge and skills and a restriction of the way that young children interact with it as a result of schoolification may lead to children being exposed to a narrowed range of potential subjectivities. Rather than being prepared for an uncertain future, children learn how to become the adults of today. Society would waste the potentials of imagining a tomorrow that could be different than today.

CONCLUSION

In this paper, I examine the connection between socialisation and mathematics education in Swedish preschools. Based on the curriculum, adults in preschools mediate children's learning by creating mathematical activities or environments with an expectation that valued norms and values are passed on to the children. However, the curriculum does not situate this delivery of cultural norms and values as a passive process for children. Rather children are proposed to be seen as active participants. However, learning cannot be considered to be a mere passing of norms and values, whether or not this is done as an active or as a passive activity. This is because learning something also results in learning how to become someone. It is therefore possible to conclude that an individual is socialised when she or he has learnt to think and feel according to society's expectations.

Socialisation processes may vary depending on the institutional setting and educational discourses. As almost all Swedish children attending preschool, this institution plays an important role in children's lives. Children become organised by institutions' norms and values which have profound effects on the socialisation process.

The impact of mathematics education as stated in the preschool curriculum is dependent on the interpretation of the goals and guidelines of the curriculum and hence on how children are seen by teachers and working teams in preschools. In this endeavour, it is relevant to consider the tension between schoolification and traditional foundations of preschools as institutional practice in Sweden which saw children as having a wider set of possibilities of subjectivities open to them. When the possibilities for the norms and values transmitted through mathematics narrows the types of activities that adults in preschools feel able to offer children, then there will also be a limiting of the type of subjectivities made available to children to adopt. Therefore, mathematics education has a major impact on early childhood education in Sweden. When schoolification affects how preschool teachers implement mathematical learning situations, children's possible subjectivities are narrowed by moving from broad developmental goals to learning mathematics.

Primary pupils' perceptions of mathematical ability

Rachel Marks

University of Brighton, School of Education, Brighton, UK, r.g.marks@brighton.ac.uk

There is increasing evidence that holding a growth-mindset in mathematics, and hence a belief in the capacity for change, pays dividends in terms of mathematical engagement and attainment. However, much mathematics education policy and practice in England is embedded in fixed-trait theories; a belief that some people can do mathematics and some people cannot. Drawing on a wider mixed-methods study involving 284 pupils and 13 teachers in two primary schools, this research used attitudinal questionnaire and interview data to identify pupils' prevailing mindsets in primary mathematics. Pupils were found to hold predominantly fixed-trait theories strongly grounded in a biological discourse. The potential implications of these perceptions are examined.

Keywords: Primary mathematics, ability, growth-mindset, fixed-mindset.

INTRODUCTION AND CONTEXT

Ability-grouping has long been proposed as one answer to concerns over standards in school mathematics. With a controversial history and concerns over equality and diversity, ability-grouping is often central to educational debates. As I write this, England is witnessing ferocious political and media discussion as to whether setting – between-class ability grouping for individual subjects – should be made compulsory in secondary education with its use mandated through the inspection system. Whilst the literature on ability-grouping in secondary mathematics is quite extensive, the literature for primary mathematics is more limited. However, the wider study this report draws on suggests that primary ability-grouping practices and their impacts essentially mirror the literature in secondary mathematics [1], and there is evidence that the use of ability-grouping is currently increasing in primary schools (Hallam & Parsons, 2013).

Underlying ability-grouping practices must be some notion(s) of "ability", yet defining this concept is far from straightforward. Mathematical ability is a pervasive discourse within the English education system. Selection practices, such as ability-grouping, are commonplace, being grounded in 'common sense' fixed-ability thinking where individual potential is thought to be immutable and easily determined (Marks, 2013). The concept of individual boundaries, neatly described as ability, is entrenched in social attitude. A belief in the 'correctness' of this underlies many educational debates. This was vividly illustrated during a television debate on secondary school selection:

> It seems to me that 1000 kids in a comprehensive, sooner or later, the ones who are good at maths will have to be told "you are good at maths" and the ones who aren't, will have to be told "you are not good at maths" and you should be doing your darnedest to break the barriers but you should be learning as a young person that there are limits to what you can do. (Richard D. North, The Big Questions, BBC1, 26.07.2009)

This paper examines how pupils' come to understand themselves and others within this discourse and practices. The paper asks: How do pupils construct themselves as mathematicians within the prevailing discourse of ability in primary mathematics? Understanding this is fundamental in that beliefs about the capacity for change are known to impact on mathematical engagement and attainment (Dweck, 2000). This paper extends previous work, being grounded in primary mathematics, and hence allowing us to examine belief development within the earliest stages of schooling.

THEORY: THE CONCEPT OF ABILITY IN PRIMARY MATHEMATICS

Adopting a socio-cultural approach, learning is taken as a process of participation and enculturation (Kirshner, 2002). In developing an understanding of how pupils construct themselves as mathematicians within the prevailing discourse of ability, mathematics education is taken to extend beyond the classroom, incorporating the wider cultural contexts in which pupils participate. Learning is seen as identity development in which pupils negotiate between themselves and the social context in which "a culturally and personally located social schema" may be "transacted, redefined ... resisted and, like discourse, called upon when the moment is opportune" (Carr, 2001, p. 527). In doing school mathematics, pupils can adopt and adapt available learner and/or mathematical identities and thus become enculturated to the mathematical world. However, this identity 'choice' is both constrained and constraining, with some identities excluding learners from mathematics. It should also be highlighted that, whilst research on affective issues generates considerable interest, exploring pupils' beliefs is complex (Hannula, 2011).

Ability is a difficult concept that lacks solid definition and is conceptually challenging (Howe, 1997), with these complexities debated in earlier CERME papers (e.g., Brandl, 2011). Despite this complexity, the term ability is in widespread use in education, usually going unquestioned. The dominant view of ability in schools – and perhaps particularly in mathematics – is as a fixed determinant of pupils' future attainment, relatively impervious to change. Through a long history, such beliefs have become elevated to the status of truths through the simple stories they tell and the appeal to a "basic human need to stratify society" (Kulik & Kulik, 1982, p. 619). Within this research, ability is conceived of as an aspect of identity rather than an individual attribute. Ability is co-constructed through discourse within social practices and pupils construct their ability identity in relation to those around them.

METHODS

This research formed part of a wider study into ability in primary mathematics. The aspects of the study presented here sought to ascertain primary pupils' perceptions of their mathematical ability and elicit their views as to what mathematical ability is and the stability of their constructs. The wider study was a longitudinal mixed-methods study conducted over one academic year in two primary schools – Avenue Primary and Parkview Primary – in Greater London. [2] Both schools had similar Contextual Value Added scores (used to measure academic improvement) but employed different degrees of ability-grouping, allowing for a range of experiences. All pupils in Year 4 (ages 8–9) and Year 6 (ages 10–11, the final year of primary schooling in England) were included in the sample for the quantitative aspects of the study, totalling 284 pupils. From this sample, a sub-sample of 24 focal-pupils representing a range of attainment was selected for the in-depth qualitative aspects.

Data collection

Attitudinal questionnaires were conducted with all pupils (n=284) as pre- and post-tests (testing construct stability) in October 2007 and July 2008. This instrument consisted of four sub-scales: motivational orientation, beliefs about the causes of success, perceived ability and enjoyment of mathematics. Reportage is limited to perceived ability. Given widely acknowledged difficulties in measuring affective characteristics, with no 'best test' (Kline, 1990), the instrument used was developed, with permission, from earlier work by goal-theory researchers (Nicholls et al., 1990). This instrument has been widely used, particularly in mathematics education, and favourably acknowledged in reviews. Perceived ability was presented as a one-item scale asking pupils to indicate their perceived standing in mathematics related to their peers. The original instrument had high test-retest reliability (0.83). Pupils were presented with a horizontal line labelled from 'best in maths' to 'worst in maths'. Pupils marked the line to indicate how good they were at mathematics, with piloting interviews suggested that this was easy for the pupils to understand. Questionnaires were administered, following training, by class teachers in lesson time with administration observed in two classes. Data were collated for analysis in SPSS.

Individual and group interviews with the sub-sample of 24 focal pupils were used to "examine individuals' thoughts, feelings, and experiences, which are not easily observed" (Moore, Lapan, & Quartaroli, 2012, p. 251). Individual pupil interviews were semi-structured using tasks adapted from Personal Construct Interviewing techniques. Focal-group interviews were semi-structured with a schedule and tasks – including a discussion of mathematical work – developed from earlier work by the researcher. Follow-up group interviews were used as a form of participant validation developing conversation around themes emerging from early analysis. All pupil interviews were conducted away from the classroom and developed as conversations with themes explored as brought up by the pupils. All interviews were audio-recorded, transcribed and filed with task outcomes.

Data analysis

Following the first administration of the perceived ability scale, the distribution of the data was graphed, then descriptive statistics, Kolmogorov-Smirnov tests of normality, and z-scores for skewness and kurtosis calculated to establish the characteristics of the data and appropriate statistical analysis tests. The first administration produced a distribution that did not differ significantly from a normal distribution, D(219)=0.06, $p=0.08$, allowing the use of parametric tests. The data for the post-test did differ significantly from a normal distribution but it was considered that the overall distribution was near normal and that the parametric tests were robust enough for them to be used on the untransformed data.

Transcripts from interviews were imported into a single NVivo project allowing for consistent coding and analysis. Interview analysis was conducted using constructivist grounded theory, the more theory-driven approach developed by Charmaz (2000) in response to criticisms of grounded theory as narrowly empiricist and atheoretical. In this approach, analytical categories (codes) were derived from reading the data alongside existing theoretical analyses. Codes were structured into trees prior to axial-coding. Mirroring Hamilton's (2002) secondary-school work on ability constructions, analysis was split into internal beliefs and external references. From the corpus of data appended to each theme, extracts, often critical incidences, were selected which best illustrated the area under discussion.

Reliability and validity were key considerations throughout the data collection, analysis and presentation processes. Where possible, established instruments with known reliability and validity were used; in all cases instruments were extensively piloted. Across the analysis, quantitative and qualitative data were linked using methodological triangulation (Denzin, 1997) where data types were compared to determine if there was convergence, difference, or some combination. Participant validation and inter-researcher scrutiny of coding use and application provided a proxy for the validity of the themes drawn from the data (Kurasaki, 2000).

RESULTS: PUPILS' PERCEPTIONS OF MATHEMATICAL ABILITY

The data suggest pupils tend to perceive ability as an internal construct, determined biologically and relatively impervious to change. Self-perceptions of ability appear to remain fairly stable. There is a tendency towards positive self-perceptions but this is accompanied by a long tail of pupils holding weak self-perceptions.

Primary pupils' perceptions of ability: Questionnaire analysis

The self-perception of ability scores for the post-test covered the range of available scores from 0–100 with a median of 68.5. These are illustrated in the boxplot in Figure 1. These data are significantly non-normal, D(239)=0.09, $p<0.0001$, being negatively skewed ($Z_{skewness}$=–4.73). A median of 68.5 suggests a tendency towards more positive self-perceptions. However, there is a long tail of weak self-perceptions with outliers representing pupils holding very low perceptions. Change in ability-perception scores were calculated (post- minus pre-test scores) (M=3.2, SE=1.4, sd=20.3) with scores ranging from -44.0 to +96.0. On average, there was a small increase in self-perceptions between the pre- (M=61.4, SE=1.6, sd=23.0) and the post-test (M=64.6, SE=1.5, sd=20.9). This difference was not significant $t(396)=-1.46$, $p=0.15$. Overall, pupils' perceptions remained fairly stable over the year.

Primary pupils' perceptions of ability: Interview analysis

Of note, when conducting the interviews – both individual and group – no pupil struggled to place themselves or peers on the perceived ability line. As Howe (1997, p. 2) suggests is the case with the wider population where "people today have so little hesitation about ranking individuals as being more or less intelligent", many pupils appeared enthusiastic in positioning their peers. Pupils regularly talked about ranking and had no difficulty in labelling how 'good' or 'bad' they were or of categorising other pupils into a dichotomy of the 'top' and the 'others'. Whilst all avail-

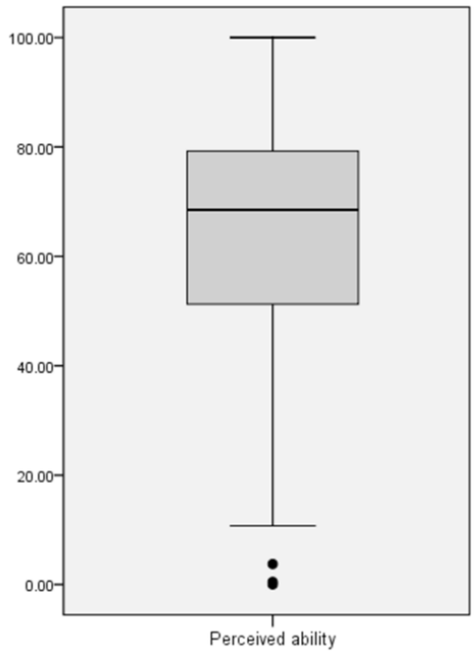

Figure 1: Pupils' perceived ability – full dataset

able evidence points towards a continuum of attainment (i.e., there are no distinct high or low attaining groups) and shows that learning trajectories are not fixed (Brown et al., 2008), the mathematical identities dominating pupils' talk seemed to be predicated on a notion that some are, and some are not, mathematical.

Using Hamilton's (2002) internal beliefs and external references dichotomy for coding, there was a discernible bias in where pupils perceived mathematical ability to be located. Across the data set, pupils made 121 references to ability being an internal construct (biologically determined) and 52 references to mathematical ability being driven by external factors (such as age and experience). 81% of pupils' references at Avenue Primary, which employed strong ability-grouping, located mathematical ability internally, compared with 54% of the total references made by pupils at Parkview Primary which employed weak ability-grouping structures.

Many pupils constructed mathematical ability, mirroring societal conceptions, as something real and located within the individual rather than being an aspect of a person's developing and changeable identity. When asked what caused high or low mathematical ability pupils tended to recourse to natural variation and neurological and genetic differences. Of all pupils experiencing setting for mathematics, pupils in top sets made 80% of these links suggesting they held a stronger belief than pupils in lower groups in a biological explanation for individual differences in mathematical ability. Pupils expressed a belief that differences in mathematical ability were apparent from birth "because you are born with an ability" (Victoria, Avenue Primary, Year 4, Top Set). When asked, individually, what made someone good, or otherwise, at mathematics, pupils repeatedly talked about those who were good at mathematics as being born to be good at mathematics and vice versa:

Wynne: Their brain's bigger. And they're cleverer and better [...] I don't know, it just happens. They were born like that. They were born clever.
Zackary: Some people are just not born clever.
Yolanda: Some people are really good at maths and some people aren't that good at maths. Probably it sometimes runs in the family.
(Avenue Primary pupils, Year 4, Bottom Set)

Talking about ability differences was a natural discourse to the pupils and strong links emerged between this and the ability-grouping practices they experienced:

Uma: Cause it's like the erm, ability of what you can do, so there's like a high, there's like a top maths group, then a middle maths group then a bottom maths group
Victoria: And then you know which one is which
Uma: Because if you are like in one big maths group and you're all different abilities then there might be something too hard for like the people that need to do easy questions, and the people that need to do it hard, it would be too easy for those people
(Avenue Primary, Year 4, Top Set)

In interview, the pupils introduced the language of ability themselves; in the extract above the pupils brought the terminology in at the beginning of the interview in response to being asked to describe what happens in their mathematics lessons. For these pupils, ability, and the practices of ability, are important constituents of what mathematics is. The extract, in common with many pupil interviews, carries an unquestioned assumption that there are different types of people in terms of ability levels and these can be clearly demarcated into groups. Based on this belief in clear groups, pupils voiced an acceptance that "some people are more clever than other people" (Catherine, Parkview Primary, Year 6, Top Set). People are seen as different, with, as in society more generally, ability providing a simple explanation for individual success and failure. Pupils accepted that this was right without question. These beliefs may be influenced by ability practices:

> Natalie: Well some people are just, you know, cleverer than other children, that's what decided our groups in year 3 and it hasn't changed.
> (Avenue Primary, Year 6, Top Set)

Pupils construct an explanation that fits what they see. They hold the belief that individual differences lead directly to group placement and that group placement has not changed as differences are innate and unchangeable. Holding a fixed-ability belief appears to be self-perpetuating with pupils viewing mathematical ability as an internal force that drives, and limits, what they can do. External factors are seen as relatively inconsequential to outcomes with a belief that individuals can only take their attainment to a maximum level determined by internal limits.

Given that limits to attainment appeared to feature strongly in pupils' constructs, I asked pupils if they felt they could improve upon their current position. The responses across schools, ability-groups and year-groups were consistent and stark:

> Zackary: I think I would not move. I think I would normally stay in the same place. I don't think there's anything I could do to make myself better.
> (Avenue Primary, Year 4, Bottom Set)
> Megan: I think I could move a few centimetres further up the line, not far.
> (Avenue Primary, Year 6, Top Set)
> Peter: Just about here, not a huge way, well because you can only do so much can't you, it's quite hard.
> (Avenue Primary, Year 6, Bottom Set)

Most pupils suggested limited room for improvement. They positioned themselves within a hierarchy seen as normal and accepted the place they, their teachers and others gave them, believing they simply did not 'have' something that others did which might have allowed them to achieve more highly in mathematics. Peter's statement was not made as a question, but as an acceptance coupled with an assumed shared understanding with myself as the interviewer. Other pupils made similar comments. Whilst there were some positive statements from pupils who felt that some improvement could be made through teaching and learning in mathematics, this was tempered by the consistent underpinning theme of immutable limits:

> Researcher: Could anything help you to improve?
> Uma: Yes, if we had something like, Mr Iverson, if he explained it out a couple of times and actually came up to me in the lesson and talked it through then I would understand it a bit better.
> Researcher: Could that make you move up higher?
> Uma: No, because I have some trouble on a lot of sums with carrying over. I'm way past there in history though, but not in maths, there's this bit [≈ the top 20% of the perceived ability line] I can't get.
> (Avenue Primary, Year 4, Top Set)

Although Uma suggests that intervention from her teacher could lead to improvement, she does not see this as having an impact on her ability, which she constructs as fixed and internal. She talked about a part she would never be able to attain, even with teaching, suggesting a belief in upper boundaries. Extending this, pupils suggested that effort cannot overcome predestined limits:

> Natalie: I don't think all children can do really well in maths though
> Megan: Even if they tried really hard, even if they tried really hard
> Natalie: If they tried really hard their best might not be a 5A, but if you have lots of ability and you tried your best then you would do very well in maths. So not all children can do well. [...] If you're determined you might be better but I don't think all children, I don't think, all children can't be, well they could be okay at maths but not really brilliant, because...
> Megan: Well you could have people who had lots of ability but they just weren't trying hard enough so they were considered to be not as good but then when they try

> hard they are really good, but they have to have lots of ability.
> (Avenue Primary, Year 6, Top Set)

Natalie and Megan suggest that you can have ability and not use it but that you cannot move beyond innate ability limits; effort alone is not enough to achieve success. Such persistent fixed-ability beliefs hold implications for mathematics education.

IMPLICATIONS FOR MATHEMATICS EDUCATION

This paper is significant for those working in mathematics education, illustrating how the pupils were, as Boaler (2000) suggests, not only learning mathematics, but also learning to be a mathematician. Understanding these pupils' constructs has important implications for future research, as these foundations cannot be ignored when looking at any intervention aimed at increasing engagement or attainment.

From early on in their mathematics careers, pupils are engaged in producing understandings of mathematical-ability that are likely to be carried forward into and beyond secondary mathematics. These productions are strong in Year 4 and particularly salient in Year 6, mirroring the "evolving sense of ability identity" found in Hamilton's (2002, p. 601) secondary school study. Pupils' models of ability portray a stable concept with little plasticity. These models can be complex, drawing on multiple ways of thinking including internal and external references. However, the overriding view of mathematical-ability is as an innate, biologically determined quantity, residing within individuals in specific quantities, with limited possibility for change. Few pupils suggested they could move in terms of their mathematical attainment and those that believed they could move placed boundaries on this.

It is perhaps not surprising that pupils are holding entity-theories of mathematical ability given the clear and consistent messages to this effect they receive from teachers, parents, and the media. Previous writing has suggested that primary teachers are engaged in reproducing their own relationships with mathematics in their language and practices (Hodgen & Marks, 2009). As such it is imperative that spaces and opportunities are provided for primary teachers to engage with their perceptions of mathematical ability and disrupt 'common-sense' practices which may set-up, or perpetuate, the limits pupils impose through their constructions.

Statements and discourses about the mathematics teacher. The research subjectivation

Alex Montecino and Paola Valero

Aalborg University, Faculty of Engineering and Science, Aalborg, Denmark, montecino@learning.aau.dk

The research fabricates an image of mathematics teachers, which shape our knowledge and truths about teachers. This image sustains the development of different discursive formations. The image's configuration is entangled with spatio-temporal conditions, which are shaped by diverse social, cultural and political contexts. In this work, we are studying discourses —about the mathematics teacher that are circulating in the research— from some theoretical toolbox of Foucault (1980) and Deleuze (1994) and from the methodological toolbox of Pais and Valero (2012). We are seeking to explore how discourses are operating in the fabrication of the mathematics teacher as a subject and in the production of truths about them.

Keywords: Statement, discourses, subjectivity, dispositive, mathematics teacher.

INTRODUCTION

The research on mathematics education, focused on the mathematics teacher, has been a growing subfield of research since the 1990s. The research has shaped the constitution of diverse discursive formations around teachers. Also, from the research, certain images, truths and corresponding systems of reasoning have emerged to encourage us to think about the mathematics teacher from pedagogical topics that mainly emphasize teachers' knowledge (of mathematics, of mathematics for teaching, of pedagogy, etc.), competencies and skills. A cognitive perspective has dominated most research. The impact of socio-cultural theories in the understanding of teachers has added different views, such as identity formation and communities of practice.

The diverse studies about the mathematics teacher have attempted to set an understanding, a problematizing and a reasoning about the mathematics teacher. These studies have established ways of thinking and ways of understanding the mathematics teacher, which are configured from the confluence and the convergence of ideas, notions, interests and reasoning. Since, the discourses circulating within mathematics teacher research are shaping what is accepted or rejected and what is considered true or false about mathematics teachers.

This paper opens up a discussion that will help us to understand the configuration of different discourses that circulate about mathematics teachers and how these discourses operate the construction of knowledge, of truths about teachers. We are seeking to show how discourses are operating in the fabrication of the mathematics teacher as a subject and how is configured an ideal image of them, which produce truths, knowledge and an ideal to follow or to aspire. Hence, in this paper we develop a discursive analysis focused to understand how the research is shaping an ideal image of subject, the mathematics teacher.

To construe the mathematics teacher from the ideal image displayed in the literature will help us to position the teacher as an historical and political product, which is produced through games of power. In other words, this will help to conceive the teacher as a person subjected to diverse technologies (Foucault, 1980, 1997) and dispositive of control (Foucault, 1980), where thinking about the mathematics teacher is a dynamic idea, a theoretical construct established from diverse practices. This study is built upon three premises: (a) intentions, needs, and desires configure the conditions to set mechanisms of power, truths and discourses; (b) power produces knowledge, that is, the power is both the object and instrument of knowledge,

> "What makes power hold good, what makes it accepted is simply the fact that it doesn't only weigh on us as a force that says no, but that it traverses and produces things, it induces pleasure, forms knowledge, produces discourse' (Foucault, 1980, p. 119);

(c) the mathematics teacher is an historical and political product. The idea of the mathematics teacher — as construct — is in constant development, and this development depends on spatio-temporal conditions.

STUDYING THE RESEARCH DISCOURSES ON THE MATHEMATICS TEACHER

We consider the discourses as a group of statements with regularities in its use and enunciation (Foucault, 1980). Therefore, the discourses are not understood in terms of "a particular instance of language use —a piece of text, an utterance or linguistic performance— but describing rules, divisions and systems of a particular body of knowledge" (Arribas-Ayllon & Walkerdine, 2008, p. 99). The discourses are generated in spatio-temporal conditions. Moreover, the production of discourse is controlled, is selected and is redistributed by a number of procedures (Foucault, 1971). In every society the

> "production of discourse is [...] controlled, selected, organized and redistributed according to a certain number of procedures, whose role is to avert its power and its dangers, to cope with chance events" (Foucault, 1972, p. 216).

The discourses are established as truth through diverse dispositive of control, where regularity in the use of certain statements leads to the configuration of certain discourses, which are accepted as true and naturalised. Therefore, these discourses are not questioned and are accepted. For this work, we keep in mind that the discourses are composed of statements.

> "We shall call discourse a group of statements in so far as they belong to the same discursive formation [...discourse] is made up of a limited number of statements for which a group of conditions of existence can be defined. Discourse in this sense is not an ideal, timeless form [...] it is, from beginning to end, historical – a fragment of history [...] posing its own limits, its divisions, its transformations, the specific modes of its temporality" (Foucault, 1972, p. 117)

And, the prohibitions that are surrounding the discourse reveal its link with the desired and with power (Foucault, 1971).

Thus, we consider the discourses that are configured around mathematics teachers as a technological power, which "determine[s] the conduct of individuals and submit them to certain ends or domination" (Foucault, 1997, p. 18). Mathematics teachers are subjected to discursive formations, since, the discourses that circulate are shaping the 'must be' of teachers. This 'must be' is leading to ideas and images, which generates ways of subjectivity. Within the discourses that circulate in the research about the mathematics teacher, it is possible to see resonances and recurrences in the statements that constitute these discourses. These resonances emerge from predominant rationalities, through the entanglement between the desired and ideas and ways of thinking. The predominant rationalities lead to some statements becoming the discourses that are repeated again and again. And these discourses are shaping ways of being for teachers from what is desired by society.

All research is developed given certain intention, assumptions, ideals, and rules or notions, which are part of games of power that are configured within a social, political, and ideological contexts. The research shapes practices and knowledge through discursive formations that are set in the diversity of studies. Moreover, the research establishes networks, where it is valid or possible to enunciate determinate things about the mathematics teacher. These enunciations are the product of predominant rationalities, which lead to ways of understanding and thinking about the teacher. The subject is fabricated and configured within these networks; thus, the mathematics teacher as a subject and as an ideal image will be the result of discursive formations produced by the research.

This study is focused on the discourses that circulate about the mathematics teacher within the mathematics education research. We seek to understand two questions: (a) how discourses are configured? In other words: What were the necessary conditions to establish these discourses and their prevalence through time? And why has a particular discourse been established (predominate discourse) about the mathematics teacher and not others? (b) What are the implications of those discourses. In other words: How are discourses operating in the fabrication of the mathematics teacher and how is an ideal image of them configured, which produce truths, knowledge and rationalities, to produce an understanding about them.

ANALYTICAL STRATEGY

In our strategy we deploy concepts from the theoretical toolbox of Foucault (1971, 1972, 1980, 1997) and Deleuze (1994); our focus is mainly on discursive formations and its resonances. Hence, we will deploy a discourse analysis, which will allow us to detangle the statements, revealing the possible conditions of power effects by studying the discourses that circulate in the research. Valero (2014) argues that the mathematics education research creates language for naming study objects and ways of thinking about these objects. This language is composed of discourses, which are configuring new discursive formations and/or strengthening the diverse discursive formations that are circulating.

Therefore, in this study, we perform a Foucault-inspired discourse analysis, which seeks to ascertain the regularities and systematicities that lead to discursive formations, where the diverse statements form a rhizomatic field affecting the desired subjects within mathematics. The role of the analysis is to reveal the convergence of a complex network of discursive practices and to allow us to study the constitution and configuration of ideas or notions within diverse games of power.

With this discourse analysis enables us to view the mathematics teacher as a discursive formation, namely, as a subject immersed in discursive practices and configured from such practices. Within discourses, the images of the mathematics teacher are configured, establishing ways and networks to think about teachers, to formulate ideas about them and to validate statements.

To perform our discourse analysis, we consider —as empirical material— the 17th volume of the Journal of Mathematics Teacher Education (Journal of Mathematics Teacher Education [JMTE], 2014), composed of 6 issues; each issue has 3 or 4 papers with an introduction written by the editor. This journal was selected because it is one of the most important sources of mathematics teacher research. Moreover, the journal publishes research about mathematics teachers from diverse topics and theoretical frameworks. This analysis of recent documents is a part of historicizing of the mathematics teacher configuration. With this analysis, we are seeking to establish the shaping of the current image of the mathematics teacher from our historicity.

The focus is on statements that circulate in research and its resonances. These resonances lead to discourse formations about the mathematics teacher. When analysing the research, we took only the enunciations; we did not evaluate the researcher of the study. In our analysis as the focus is on the regularities or resonances of statements and not the people that formulated it, which led us to lose the notion of author. Rather we have quoted the journal pages because the journal provides us with the empirical material that evidences how the mathematics teacher is thought of.

We propose, in a Foucaultian sense, that discourses are generated by a spatio-temporal rationality and not by some particular people. Authors reveal the convergence of a complex network of discursive practices; hence, the discourses are not established because a person formulated them, rather because we reproduce them through discourse, "the function of an author is to characterize the existence, circulation, and operation of certain discourses within a society" (Foucault, 1977, p. 124).

Studying the diverse statements formulated in the research, it is possible to see regularities or resonances in the different arguments deployed or in the antecedents or in the conclusions of the studies. This study has allowed us build a rhizomatic web of statements that circulate, leading us to formulate categories of statements that emerge from ways of thinking and reasoning about mathematics teachers. The resonances are shaping to desired images of the mathematics teacher and lead to conditions that configure the teacher as a subject. From the diverse resonances that emerge in the research it is possible to establish two categories, these categories are clustering the discourses that emerge and circulate in research. In both categories, the mathematics teacher is configured as a discursive formation, synthesizing in him or her that which is desired and feared. The categories present the "must be" of the mathematics teacher and shapes truths about an ideal subject.

In short, these two categories emerged from: first, we selected our samples of text, the investigations reported in 17th volume of the JMTE. Subsequently, we have identified, how in our empirical material is shaping conditions of possibility, which are configuring enunciates about the mathematics teacher. But, we focused on enunciates that had resonances and recurrences. On the one hand, these resonances and recurrences have systematicity in its use and configuration; on the other hand, these resonances and recurrences show continuities and discontinuities in statements and its ideas, notions, intentions, social interest, among others. Finally, we have clustered the diverse enunciates in two categories —through an interpretative work.

TRUTHS AND KNOWLEDGE ABOUT THE MATHEMATICS TEACHER

"Truth is a discursive construction and different regimes of knowledge determine what is true and false" (Jørgensen & Phillips, 2002, p. 13). Truth is founded on systems of reason that characterize community and society; this system of reason sustains the production of knowledge and lead to the fabrication of a particular teacher subjected within a system of beliefs and ways of thinking. For example, currently it is possible to see a predominate reasoning, which prioritizes the calculation and standardization of everything (e.g., JMTE, 2014, pp. 5–36, 429–461), where the concept of the mathematics teacher forms part of this reasoning and in turn contributes to its construction. This reasoning is based in the objectivity of knowledge that has developed around mathematics teachers. More precisely, "objectivity and subjectivity are expressions of a particular historical predicament, not merely a rephrasing of some eternal complementarity between a mind and the world." (Daston & Galison, 2007, p. 379)

Moreover, from a Foucaultian approach, knowledge is conceived as a set of assumptions; these are based on the theoretical and personal experiences that emerge within a network and engage in interplay of different practices. Hence, knowledge is understood as an event, not as a universal structure, unique, absolute, or unbiased. The "knowledge is always a certain strategic relation in which man is placed. This strategic relation is what will define the effect of knowledge" (Foucault, 1970, p. 14). Knowledge is produced within different discursive practices; it cannot be conceived without a particular discursive practice and a discursive practice is defined by the knowledge itself (Foucault, 1972). In short, knowledge is composed of a series of continuities, events and discursive formations established by diverse configurations of power. Knowledge is partial and fickle in relation to its historical-political context. Therefore, far from preventing knowledge, power produces it (Foucault, 1980).

Truth and knowledge that emerge from the discourses that circulate in the research shape ideal images of mathematics teachers and configuring a subject. This ideal image is used as a framework to think about the teacher, to speak about him or her, to recognize the teacher socially, and to understand his or her practices, training, and work. Moreover, this ideal image is a product of the detangling of diverse games of power, dispositive regimes of knowledge, discursive formations, and rationality. Through this detangling, we can formulate the two statements category, where it is possible to see statements, such as:

> Many PPTs [prospective primary teachers] wanted to continue taking another mathematics course because they wanted to improve their mathematics knowledge and skills not only for themselves but also for the sake of their future students (JMTE, 2014, p. 356)

The statements that circulate about the mathematics teacher are composed of enunciations that evidence "well-intentioned" principles about the mathematics teacher. For example, it is possible to find enunciations, such as, "[the teacher should] provide students opportunity to clarify and communicate their thinking" (JMTE, 2014, p. 483). Showing the desired and feared ideas about mathematics teachers; therefore, these principles help to configure an ideal image, knowledge, practices and discourses, and moreover, help to configure the subjectivity of the mathematics teacher.

TEACHERS' KNOWLEDGE AND THEIR PASTORAL CALL

The job of the elementary school mathematics teacher (i.e., teaching), is generally regarded as a complex and demanding practice that requires a mixture of both theoretical and practical knowledge, rehearsed skills and deep understanding of children (White, Jaworski, Agudelo-Valderrama, & Gooya, 2013). In addition, the practices of mathematics teachers are configured within a network of practices and discourses, which fabricate the rational, objective, and universal subject to become the modern cosmopolitan citizen (Valero & García, 2014). Therefore, the mathematics teacher becomes an important agent for governing others, since, currently, governance is required to shape particular types of subjects. In other words, the mathematics teacher has an important role in developing and fabrication of the modern subject. In the 19th century, the narrative connected progress to economic superiority, and citizens began to develop an intelligible mathematical competence; by the end of the 20th century emerged the connection between people's mathematical qualifications and social progress (Valero, 2013); Changes in demands for skills have profound implications for the competencies which teachers need to acquire to effectively teach 21st century skills to their students.

Through an analysis of empirical research materials on the mathematics teacher, it is possible to observe how the regularities in the statements that circulate in the research are shaping ideal images of mathematics teachers. Moreover, these ideal images are setting the "must be" of the mathematics teacher; hence, these ideal images regulate the understanding of "a good teacher," and also define the knowledge, skills and qualities that the teacher should have to reflect that ideal. The regularities observed are clustered into two categories: The first category considers statements where the mathematics teacher is reduced to the knowledge and the skills that he or she has, for example, mathematical knowledge and pedagogical knowledge, among others. The second category considers statements where the mathematics teacher is thought of as a useful tool for the governance of others, to conduct others, and to conduct oneself, for example, the teacher is responsible for the fabrication of a particular subject, a rational and logical student.

Examples of these two categories of statements that emerged in the discourses of the research on the mathematics teacher are revealed below:

The first category: The mathematics teacher is reduced to his or her knowledge and skills

> They found that teachers' lack of content knowledge interfered with their judgements and that there was a mismatch between their perceptions of students' difficulties and the actual difficulties demonstrated by their students. (JMTE, 2014, p. 405)

> [Teachers need to] develop professional knowledge in support of their practice. (JMTE, 2014, p. 455)

> There is a strong correlation between the teacher's knowledge of mathematics and successful classroom practice. (JMTE, 2014, p. 373)

The second category: The mathematics teacher as agent for governing.

> Mathematics teachers play a unique role as experts who provide opportunities for students to engage in the practices of the mathematics community. (JMTE, 2014, p. 105)

> ... promoting reform, considered by many to be a major responsibility of prospective teacher preparation (JMTE, 2014, p. 295)

It is possible to enunciate that both categories emerged from the statements that circulate in studies, which are based on an ideal of perfection (ideal teacher, ideal situations, ideal practices, among others) and on the mathematics teachers' "must be" configured from an ideal image. This image is shaping from diverse forces that are part of the society and at the same time this image promote what the society desired with the mathematics teacher.

More specifically, the first category responds to objective knowledge and the importance that was given to mathematical knowledge in modern society. Mathematical knowledge is privileged knowledge and is related to progress and the societal development. The second category argues that discursive formations are favouring the fabrication and conduction of the subject toward an ideal, located in an epistemology of that which is desired, therefore, the mathematics teacher is thought of as a dispositive. Hence, mathematics teaching is thought of as a profession that has a pastoral call. For example, the mathematics teacher is believed responsible to promulgate the ideas and the ideals that mold the desired citizen by impelling to his/her students toward what is desired, aspired for, and accepted within society.

In some statements it is possible to see both categories imbricated, as for example:

> Teachers rely on established beliefs to choose pedagogical content and curriculum guidelines [...]; and teachers reflect their beliefs in their teaching, thus shaping their students' beliefs [...]. (JMTE, 2014, p. 305)

> They [effective teachers] ensure that the lesson content has a strong mathematical focus and contains opportunities for students to think, reason, communicate, reflect upon and critique mathematics. (JMTE, 2014, p. 299)

These two examples show that mathematical knowledge is not questioned; the knowledge is considered an important and sacred truth. This stance toward knowledge influences how students understand the world, which favours a type of rationality and subject.

CONCLUSIONS

The discourses reveal our historic, ideological and political framework. Because the statements express desired ideas about the subjects involved in education and the role of school mathematics to imagine a better world, they also express some truths circulating in diverse teaching practices of school mathematics and its learning (Valero & García, 2014). Moreover, we can understand the discourses as forces acting on the subject, since these discourses are promoting practices, rationalities, thoughts, assumptions and knowledge, among others, from a spatio-temporal context, all which favour the fabrication of a particular subject. Therefore, we can understand discourses about the mathematics teacher as a dispositive power.

From the review of the pedagogical research on mathematics teachers, it is possible to see that it seeks to homogenize mathematics teachers in a context where differences and particularity are predominant. Moreover, diverse research promotes a denaturing and an abstraction of mathematics teachers, ignoring aspects of the complexity of teaching, for example, about the particulars of teaching as work, the internal dynamics of the work place, etc. The denaturation and objectivity in the research promotes a rationality, which favours the thought of the mathematics teacher as a neutral and perfect subject, an established ideal image. A large number of researchers have sought to compare the mathematics teacher (subject) with this ideal image, favouring the establishment of an epistemology of the deficit knowledge. Consequently, many researchers have focused on exploring the skills and knowledge of mathematics teachers, emphasizing their deficiencies and their negatives aspects. For example:

> ...the teachers' knowledge of functional thinking was below the level expected for teaching middle-school algebra. This provides further evidence of teachers' inadequate understanding of mathematics for teaching (JMTE, 2014, p. 418)

This can generate a paradox because the ideal is defining the mathematics teacher from an unattainable idea, but when the teacher approximates this ideal, the ideal is redefined and increases the distance between the ideal and the subject (the mathematics teacher). In addition, this ideal is constantly reformulated, according to the research and the new demands of the society.

Hence, the diverse affirmations that were found in researched enunciations can establish a framework and a network for imagining the subject of the mathematics teacher, establishing statements about good practices, appropriation and management of specific knowledge, and its importance for society. For example, it is arguable that "mathematical knowledge for teaching stresses the importance of using mathematical knowledge to bring about pedagogically useful mathematical understanding" (JMTE, 2014, p. 229). Consequently, the intention of the mathematics education research is not only to show, question or analyse what mathematics teachers doing. Mathematics education research configures a disposition that shapes the subjectivity of the mathematics teacher, where the knowledge has great value and the mathematics teacher is thought of as an agent for governing others.

We can see that the statements established have been strongly influenced by objective ideas, the favouring of certain practices, and discursive formations seeking abstraction and generalization. Moreover, thinking of the mathematics teacher from a social perspective, we can see diverse discourses that establish knowledge of a useful subject that seeks to form part of the desired truth and conduct other toward the desired truth. The discourses and knowledge established from the research are subjected to the study of the mathematics teacher under a particular logic that defines the real; this logic is developing from an epistemology of ideas both desired and feared. In addition, the discourses determine what is true or false about mathematics teachers, which helps establish a particular ideal image of the teacher and a particular subject. In the words of Deleuze (1994), the subject does not pre-exist, the subject isn't reproducing the repeats that are part of the world. But rather the subject is produced by the multiples games of the real and these games are validating practices and knowledge.

ACKNOWLEDGEMENT

We would like to thank the members of the Science and Mathematics Education Research Group at Aalborg University for their comments to previous drafts of this paper. This research also makes part of the NordForsk Center of Excellence "JustEd".

Cultural responsiveness and its role in humanizing mathematics education

Swapna Mukhopadhyay and Brian Greer

Portland State University, Graduate School of Education, Portland, USA, swapna@pdx.edu

In opposition to neoliberal forces that are furthering homogenization of mathematics education worldwide as part of globalization, we argue for the necessity of maintaining diversity in all its human forms, including in mathematics and mathematics education. Central to this position is respect is the conception of mathematics and mathematics education as human activities, inextricably embedded in forms of life.

Keywords: Diversity, cultural responsiveness, ethnomathematics.

INTRODUCTION: GEOPOLITICAL BACKGROUND

Among the most salient aspects of education in the United States and many other parts of the world are: privatization and corporatization of public education, with associated profiteering by IT and publishing corporations; homogenization that ignores all forms of diversity; as well as excessive and irrational use of high-stakes standardized tests (Apple, 2000; Picciano & Spring, 2013; Spring, 2008).

Aspects that bear particularly on mathematics education include:

— homogenization of the mathematics curriculum, reinforced by international testing

— pervasive rhetoric about the necessity of high levels of formal mathematics education, typically phrased as essential for economic competitiveness in the global marketplace

— unwarranted weight afforded to performance on tests of mathematics as a gatekeeper to educational and economic opportunities

— continuing perception of mathematics as acultural, and academic mathematics as a purely European achievement

In this paper, we present a counterposition.

MATHEMATICS AND MATHEMATICS EDUCATION AS HUMAN ACTIVITIES

We take it as axiomatic that mathematics itself, and mathematics education, are human activities, embedded in historical, cultural, social, and political contexts. Accordingly, we argue for mathematics education that valorizes diversity in all its forms, stemming from diversity in forms of life, that we term "culturally responsive mathematics education" (CRME). In opposition to the corporate goal of (mathematics) education as a means to increase human capital, we would redirect it towards increasing human capability, which Sen (1997, p. 35) defined as "the ability of human beings to lead lives they have reason to value and to enhance the substantive choices they have". In short, we argue for humanization of mathematics education.

Mathematics as cultural construction

> [...] mathematics must be understood as a human activity, a social phenomenon, part of human culture, historically evolved, and intelligible only in a social context (Hersh, 1997, p. xi).

Particularly since the 1980s, the position expressed by Hersh has been articulated among teachers, scholars, and researchers who critique the sociopolitical systems of mathematics education. Central to the concerns we raise in this paper is the Ethnomathematics movement, essentially launched when Ubiratan D'Ambrosio gave a plenary talk at the International Congress on Mathematical Education in Adelaide in 1984 on "Socio-Cultural Bases for Mathematical Education", and the conference included an extra day on the theme "Mathematics Education and Society". Shortly afterwards, in another key work, Bishop (1988) framed mathematics education as enculturation and identified counting, measuring, locating, playing, designing, and explaining as mathematical activities found in essentially all cultures.

One definition is that:

> Ethnomathematics is the mathematics practiced by cultural groups, such as urban and rural communities, groups of workers, professional classes, children in a given age group, indigenous societies and so many other groups that are identified by the objectives and traditions common to these groups (D'Ambrosio, 2006, p. 1).

Thus, although much of the work in Ethnomathematics analyses mathematical aspects of practices in non-industrial societies, it also applies to cultural groups in the industrialized world. For example, carpenters in many cultures operate very efficiently, when measuring or designing, with decimal fractions or binary fractions such as $\frac{3}{4}$ and $^5/_{16}$ – they never need to calculate something like $^3/_7 + ^4/_{11}$. From this perspective, it must be considered a major weakness in mathematics education as typically practiced in many parts of the world that there is a lack of connection between what happens in schools and the lived cultural and sociopolitical experience of students, their families, and their communities, and, for most people, their future lives.

Emphatically, the statement just made in no way negates society's need for a cadre of people with mathematical expertise to provide the benefits that come from technological advances (and indeed to advance mathematics as a discipline that continues to evolve (Hersh, 2006)). What seems absurd to us is pervasive rhetoric (in which many in our own field join) about the need for *all* students to learn substantial amounts of technical mathematics, ignoring the most obvious fact about any society, namely that it relies on people filling a diversity of roles. Thus, instead of a soundbite such as "algebra for all", we would suggest a less catchy, but more real, slogan like "a great deal of algebra for a few, a lot of algebra for a larger number, and the opportunity to learn useful algebra for everyone" together with the understanding that lack of performance in formal algebra should not be a barrier to lives and careers for which it is not necessary. We also suggest that the opportunities for Internet-based learning, including courses delivered by top mathematicians, are ideally suited for the nurturing of the next generation of mathematically gifted students, who are typically self-motivated.

While the study of mathematical practices among cultural groups may be defined as the essence of Ethnomathematics, from its inception another focus has been the construction of a counter-narrative to the Eurocentric – indeed, arguably, racist (Raju, 2007) – account of the history of the development of academic mathematics, as addressed in the collection of key papers edited by Powell and Frankenstein (1997). Historians have documented the contributions of many cultures, including Indian, Chinese, and Arab, to the development of academic mathematics in Europe (Joseph, 1992; Raju, 2007). In other parts of the world, very sophisticated and elaborate systems of mathematics, astronomy, navigation, engineering, and science, were developed across millennia. D'Ambrosio (1985) pointed out that colonialism grew in a symbiotic relationship with modern science, in particular mathematics and technology, and Bishop (1990) characterized mathematics as a tool of imperialism. Mathematics was, and remains, a powerful way to convey the supposed intellectual superiority of Europeans and cultural groups deriving from them. Accordingly, the rewriting of history of mathematics is essential, not just as a matter of truth and justice, but also because the continuing belief in the intellectual inferiority of non-White people as doers of mathematics, deeply and unconsciously rooted among the colonizers and internalized by the colonized, is an obstacle to the construction of the identity of a non-White person as a doer of mathematics, for example an African or Asian immigrant in a European school.

Humanizing mathematics education

Mathematics education, like mathematics, is a human activity – indeed, even more so, given the centrality of interpersonal relationships in learning/teaching. An adequate analysis of the relationship between mathematics-as-discipline and mathematics-as-school-subject is beyond the scope of this paper; we simply state our convictions that mathematics education is not reducible to the immaculate transmission of a structured body of knowledge from experts to learners, and that mathematicians may be necessary, but are certainly not sufficient, when it comes to framing mathematics education.

Paulo Freire's observation that "education is politics" (Freire & Macedo, 1987, p. 47) applies specifically to mathematics education in many ways, with far-reaching consequences. A very important case is the extent to which so many aspects of modern life are governed by mathematical models that are often invisible to, and almost always beyond the control of, most people – what Skovsmose (2005, p. 86) termed "mathematics in action". We have argued elsewhere (Greer & Mukhopadhyay, 2012) that mathematics education predominantly fails to prepare students to become citizens with a critical disposition to understand, and agency to disrupt, misapplied mathematical models, for example in relation to economics. We would argue that this failure in mathematics education serves to protect political systems from critique. By contrast, Gutstein (2012), operating in the spirit of Freire, has shown how mathematics can become a weapon in the struggle for social justice by teaching students how it can be a tool for analyzing and then acting upon, issues of importance in their sociopolitical reality (reading and writing the world, in Freirean terms).

To raise another political theme in relation to mathematics education, there is pervasive rhetoric across the world to the effect that advanced levels of mathematics (and science) education are essential for all students for a given country's economic survival in a globally competitive world. Indeed, within the United States of America, this rhetoric is increasingly couched in terms of threats to national security. Contrast this nationalistic stance with D'Ambrosio's (2010) passionate plea that mathematicians and mathematics educators should collectively be seeking solutions to the crises facing humanity.

CULTURALLY RESPONSIVE MATHEMATICS EDUCATION

In the previous section, we argued for a conceptualization of mathematics as culturally constructed and for humanizing mathematics education, including recognition of its political roles. In this section, we consider, as an important aspect of humanization, making mathematics education culturally responsive. This theme plays out, with variations, all over the world, of which we mention just a few.

As movements of populations increase, for many reasons, children find themselves in complex intercultural life situations. By way of example, Ali (2012) presents a detailed account of a young Pakistani immigrant in Barcelona constructing her mathematical identity and planning her career in a multicultural city, in the context of several languages (Punjabi, Urdu, Catalan, Spanish, English) and having experienced greatly contrasting styles of mathematical instruction in Pakistan and Saudi Arabia before coming to a school in Barcelona in Grade 10.

As a more general example, with the ending of colonialism in its original form in many countries, liberated peoples face the issue of reconciling their cultural identity with the need to be economically competitive. Arguably the clearest example is South Africa (Graven, 2014; Vithal, Adler, & Keitel, 2005). In many other parts of the world, such as South America, Australia, and New Zealand, campaigns for the rights of Indigenous peoples include work on both mathematics education and on Ethnomathematics (Ferreira, 2015), not without many conflicts and dilemmas (Greer, 2013). A very striking manifestation of tension was manifest in a report (Atweh & Clarkson, 2001, pp. 86–87) of interchanges at a conference at which Clements (1995, p. 3) stated that "Over the past 20 years I have often had cause to reflect that it is Western educators who were responsible not only for getting their own mathematics teacher education equation wrong, but also for passing on their errors to education systems around the world". Yet, at the same conference, the president of the African Mathematical Union (Kuku, 1995, p. 407) "warned against the overemphasis on culturally oriented curriculum for developing countries that act against their ability to progress and compete in an increasingly globalized world" (Atweh & Clarkson, 2001, p. 87).

In India, activist academics have been striving to create curriculum and textbooks for elementary mathematics that "address diverse children's knowledge through a (re)humanizing pedagogy of empathy, despite the constraints of a large bureaucratic and increasingly neo-liberal state system" (Rampal, 2015). In the same context, Subramanian raises ethical issues involved in designing and developing a uniform curriculum for an educational system of such a size and with such diversity of languages and cultures.

In the United States of America, since the passing of the legislation "No Child Left Behind" in 2001, intensive use of standardized tests, combined with disaggregation of test scores by ethnicity, has led to considerable attention being focused on attempts to reduce the differences in test scores among ethnic groups, in particular to raise the test scores of Black, Latino/a, and Native American students. (The usual terminology for such efforts is "closing the achievement gaps" which is problematic for a number of reasons, including connotations of deficit models, the positioning of white students' achievements as the norm, and concerns about the nature of the tests that yield the scores.)

Attention to these aspects has been concentrated by rapid demographic changes – at the time of writing, the US Department of Educational Statistics has just projected that in the coming school year, the proportion of school students that are White (by the classification structure used) will be less than 50%. The teaching population, on the other hand, remains predominantly White, being 83% in 2007.

Against this background, the concept of culturally responsive teaching has made considerable progress within the United States in the last twenty years (Gay, 2010; Ladson-Billings, 1995; Villegas & Lucas, 2002). Contributing to its emergence, movements within critical education that have been foundational include Multicultural Education and Critical Race Theory. The term "Culturally Responsive Mathematics Education" (CRME) originated in a 2004 conference in Washington which we helped to organize, leading eventually to an edited volume (Greer, Mukhopadhyay, Powell, & Nelson-Barber, 2009).

Given that central to all education is the relationship between the student and the teacher, then the cultural and mathematical identities of both students and teachers are of paramount importance, as is the degree to which they do or do not align, particularly in terms of culture, ethnicity, and class. In the context of the United States of America, Gay (2009, p. 189) posed many key questions: "How can middle-class monolingual European-American math[ematics] teachers work better with students who are predominantly of color, attend schools in poor urban communities, and are often multilingual?". Similar questions apply in all educational settings in which there are class, ethnic, and cultural differences between students and their teachers. Gay (2009, p. 194) also stressed that teachers-in-training should examine questions such as "What is it about the way math has been socially constructed that is exclusive, rather than inclusive to culturally, racially, ethnically, and socially diverse students?". She also pointed to the fact that:

> [many students] find it difficult to see the relevance of many math concepts, principles, and operations to real life, when they are perpetually presented as decontextualized formulas and abstractions. Teachers need to be taught how to humanize mathematics, and to place these reconstructions into the lived realities of different racial, cultural, social, and ethnic groups. (p. 195, emphasis added)

There is a conception that an educational system full of human beings, with all the complexity that implies, can be treated as a black-box model controlled by crude external levers of standardized testing designed to expose schools to market forces that will automatically improve education. This conception has its epicentre in the United States of America, but the seismic effects are widespread. Quite apart from the absurdity of such a position, and the lack of any evidence that it is viable, in the context of the current paper, we point out that standardized, mass-administered tests by their nature cannot take account of the diversity of students' lives (Miller-Jones & Greer, 2009).

CONCLUDING THOUGHTS: HONORING DIVERSITY IN MATHEMATICS EDUCATION

We argue for mutual respect for the Other, through:

> [...] celebration of diversity in all its human forms, specifically in relation to mathematics and mathematics education: culture, ethnicity, gender, forms of life, worldviews, cognition, language, value systems, perceptions of what mathematics education is for (Greer, Mukhopadhyay, & Roth, 2012, p. 1).

One way to frame the argument that we are seeking to advance in this paper is to consider interactions between three families of mathematical activities, namely mathematics-as-discipline (MD), mathematics-as-school-subject (MS), and mathematics-within-culture (MC). The simplistic notion held by some mathematicians that the role of MS is simply to pass on the rudimentary contents of MD to another generation, primarily as groundwork for the reproduction of their own species, needs to be confronted because it exerts unwarranted influence on mathematics education, in our view. Rather, we believe that MC should play a central role in constructing mathematical schooling, a position aligned with the concept of "funds of knowledge" that is based on a simple premise, that "people are competent, they have knowledge, and their life experiences have given them this knowledge" (Gonzalez, Moll, & Amanti, 2005, pp. ix-x).

As argued in this paper, a clear implication of this viewpoint is that diversity in all its forms, of which diversity of forms of life may be considered the bedrock, must be fundamental to mathematical schooling. Skovsmose (2012) draws attention to the variety of sites for learning mathematics, the variety of forms of mathematics in action, and the variety of educational possibilities. With reference to the first, he points out how research discourse in our field is dominated by an unexamined stereotype of "the prototype mathematics classroom" that ignores the reality of many classrooms around the world. The second type of variety that he mentions is an effective response to the question "But isn't mathematics the same everywhere?" which is not tenable if the boundary of mathematics is drawn to include its applications (and, as Raju (2007) has pointed out is negated by the predominant reliance of Western mathematics on two-valued logic, a cultural choice). And the third is central to the argument in this paper.

While we have not enough space within this paper to address linguistic diversity, it is of the greatest importance, not simply in its own right in a world increasingly under the sway of English, but also in relation to issues in multilingual classrooms and the importance of language in framing and communicating thinking, including in mathematics.

Epistemological pluralism is another central issue, even from the perspective of mathematics-as-discipline. Pinxten, van Dooren, and Harvey (1997, pp. 174–5), citing the fundamental different epistemology of the Navajo, in particular in relation to space, point out that diversity is essential in order for evolutionary selective processes to operate in the further development of MD. They comment that "Through a systematic superimposition of the world view and thought system of the West on traditional non-Western systems of thought and action all over the world, a tremendous uniformization is taking hold... The risks we take on a worldwide scale, and the impoverishment we witness is – evolutionarily speaking – quite frightening" (p. 174).

Newly arrived students in mathematics classrooms in Sweden

Eva Norén, Jöran Petersson, Cecilia Sträng and Petra Svensson

Stockholm University, Stockholm, Sweden, eva.noren@mnd.su.se

In this paper, we discuss how newly arrived students experience, and perform in, school mathematics. There is little research on immigrant students' initial time in Swedish school, and it is methodologically underdeveloped. Our own research will be revisited, and we give an account of the methodologies we have developed. We look for analytical tools using both qualitatively as well as quantitatively, to interpret classroom interaction, social practises, individual performance and achievement. Our attention to diversity and equity issues includes avoiding deficit discourses explaining both success and failure in school mathematics, in relation to backgrounds, language and culture.

Keywords: Newly arrived, mathematics education, methodology, foreground.

INTRODUCTION

Sweden today is a multilingual and multicultural society. Some suburban schools in the largest cities, Stockholm, Gothenburg and Malmoe have schools with up to 98 % of students speaking first languages other than Swedish. 44 % of the total amounts of immigrated students, 7–19 years of age (Statistics Sweden, 2014), are from outside Europe. Several of these countries suffer from political instability and some of them are developing countries. Newly arrived student numbers increase as the worlds' hot spots spread. The term *newly arrived students* is used in Swedish education policy and academic discourse. It defines students arriving from abroad during the time of primary or secondary school as newly arrived (Utbildningsdepartementet, 2013). In Sweden, students can be regarded as newly arrived up to four years from arrival. Resources are tied to that time span within the educational system, and offers optional teaching in both mother tongue and Swedish as a second language (Utbildningsdepartementet, 2013). The students cannot yet speak Swedish, and are entitled to a special introduction to school. The present years Arabic is the most common mother tongue spoken after Swedish (Skolverket, 2013/14).

There is little research on immigrant students' initial time in a Swedish school, and there are no studies comparing Sweden with other countries. Bunar (2010) mapped and reported research on newly arrived students in Sweden. He found the Swedish research is "scarce and theoretically and methodologically underdeveloped" (p. 6). It is impossible to draw certain conclusions and the Swedish research does not support understanding of learning conditions for newly arrived students. Bunar also states there are, to a high degree, local variations and a lack of a common educational policy, that might lead to arbitrariness and uneven quality in education. This paper is a response to Bunar's call for more research on newly arrived students in Sweden and the purpose is to discuss the question:

How do newly arrived students experience, and perform in, school mathematics in Sweden? To do this we look at data from our own research retrospectively. An underlying aim is to pay attention to diversity and equity issues in mathematics education, and to develop theoretical and methodological tools for research on newly arrived students in Swedish mathematics classrooms.

In the following section, a brief review of research on newly arrived students in Sweden is given, and thereafter our own earlier research will be summarised. The methodologies of our presented work will be indicated and then some final remarks for future research will be made.

BACKGROUND

Studies on newly arrived students that have been undertaken in Sweden are divided into mainly three areas: 1) A social and individual perspective that include mostly identity formations among adolescents, the power relations in the society, and how students integration are affected by these factors. 2) An institutional perspective that focus on transitions and on measurements of the importance of migration age for students' achievement. 3) A pedagogical perspective that focus on second language development and learning in a second language (Bunar, 2010). The studies come from a variety of academic disciplines.

Newly arrived students contribute to characterize the Swedish school with an increased diversity of languages, ethnicities, cultures, religions and nationalities. Their introductory time in school is crucial to their continued performance in the Swedish school. Introductory teaching differs greatly between different schools and we know very little about what works (OECD, 2006; Nilsson & Axelsson, 2013). Education for newly arrived students is commonly arranged in introductory classes, providing a basis in the Swedish language for later transition to mainstream classes. In order to deal with language requirements of academic school work in the language of instruction (Swedish) it is necessary to develop what Cummins (2008) refers to as Cognitive Academic Language Proficiency - CALP. That means to be able to use language in context-reduced situations such as advanced school mathematics. In a second language environment it may take about seven years to fully develop CALP skills, in the second language. Hakuta (1986) suggests that CALP skills are transferable across different languages.

Criticism from both researchers and authorities inform us that students are retained in introductory classes for too long. In fact, it is the individual student's progress that determines when s/he will be integrated into a mainstream "regular" class. The rules on how the assessment of this progress is done and by whom is unclear. And as researchers have pointed out this assessment could be disastrous for the newly arrived students' motivation to study if there are delays in their transition to mainstream classes (OECD, 2006). In their recent study, Nilsson and Axelsson (2013) analysed the social and pedagogical resources in the contexts of introductory classes and how newly arrived students experienced the time in and transition between introductory and mainstream classes. The students had arrived during the last years of lower secondary school. The result points to a tendency of allocating responsibility for newly arrived students' education solely to the introductory classes or the individual student. Nilsson and Axelsson (2013) argue that this is an insufficient praxis, and that pedagogical and social provisions also have to be made in the mainstream system in order to fulfil inclusive and educational aims.

In an introductory class where students have different backgrounds, different educational background and knowledge of the Swedish language, there are often also various forms of trauma in the picture. One important factor for integration in school is that teachers take into account the interactions and, above all, to create a supportive network around the individual student (Rodell-Olgac, 1999).

EARLIER AND ONGOING STUDIES IN SWEDISH MATHEMATICS EDUCATIONAL CONTEXTS: DRAWING FROM OUR OWN RESEARCH

Norén (2007, 2010) investigated bilingually instructed mathematics classrooms where teachers and students used Arabic and Swedish. Some of the students in her study were newly arrived and attended introductory classes except for mathematics and physical education classes. According to Norén the newly arrived students, benefited largely from the bilingual education. Knowing and using several languages opened up an opportunity for mathematics development. The bilingual teaching of mathematics favoured learning the Swedish language as Swedish mathematics text books was used and Swedish was focused for mathematical concepts.

An example from the study (Norén, 2007) was centered on Nada, a 15 year-old girl originally from Iraq, Arabic as mother tongue. According to Nada, from interviews and participating observations, when she as a newcomer arrived into Swedish school, she was immediately placed in an introductory class where the focus was on learning the Swedish language at the expense of continued learning in mathematics. Nada was self-conscious about priorities in the introductory class, saying:

> Then we worked almost nothing with math. It was just numbers (arithmetic) and plus and minus.

> No texts. We invested in Swedish. Nothing in the maths. I have never got a passed grade in mathematics, I didn't know any maths. (Nada, from interview in eighth grade)

Her account is a reflection of a strong influential discourse "Swedish only", to learn Swedish first and fast. It is an everyday opinion that it would enable her to quickly start studying mathematics in her second language Swedish (Sjögren, 1996; Runfors, 1993). When Nada started eighth grade, she was offered, and said yes to participate in the bilingual mathematics education program. In a later interview Nada said:

> I have learned more (mathematics and Swedish) /…/ Arabic makes it easier and possible to learn more /…/ Language is an important issue. /…/ When I started the bilingual program with other Arabic speaking students, when they got grades like pass and higher, I thought I could get grades as well. (Nada, from interview in ninth grade)

Heading towards the end of ninth grade Nada started to identify herself as an engaged student working hard to pass the examinations in mathematics. That was also the expectations from her mathematics teacher. In the end of the ninth school year Nada got grades in mathematics good enough to get into the upper secondary school program she wanted.

In another example Norén (2010) informs us of a group of three newly arrived students from Iraq, 15, 15 and 16 years old. When working with text problems in mathematics, they had access to dictionaries. The context in the text problems was arranged around a fishing trip. Although students with help of the dictionaries, and a voluminous workload, managed to translate the information word for word the context was shrouded in mystery. With the help of the bilingual mathematics teacher who clarified the cultural contexts, the students solved the tasks. It is not common with fishing trips in Iraq, the teacher explained, and it is not that the translations of words and sentences from Swedish into Arabic help students solve text data in mathematics. By working with text data, students in addition to working with mathematics also learn some Swedish, and they learn something about the Swedish culture.

In an ongoing study Petersson (2012, 2013) investigated newly arrived immigrant students' achievement on various mathematical tasks on a test in mathematics. The tasks are formulated as to not cause language obstacles for second language learners, and to involve algebra, statistics, proportional reasoning and negative numbers. The performances of the newly arrived students, defined as those who immigrated during school years 8–9 are compared with students who immigrated during school year 1–7, and Swedish native students. One important result is how the achievement for the different student categories was distributed over different topics in mathematics. On most tasks newly arrived and early arrived immigrant students achieved similarly and on a level of about two thirds of the level of the native students. For tasks on advanced school mathematics, such as algebra and negative numbers, the newly immigrated students performed as native students or better while the earlier immigrants performed significantly lower than both native and newly immigrated students. Petersson concludes that there is a need for research on how different student categories perform in specific topics in mathematics. That is, how achievements and various solution strategies are distributed among newly and early arrived students. It is not sufficient to draw conclusions that immigrant students in general perform lower than native students or that immigrant students perform lower in mathematics the later they immigrated, like, for example, Böhlmark (2008) does. An assumption, by Petersson, is that early arrived students have had most of their mathematics instruction in their second language Swedish, while newly arrived immigrant students have had instruction and textbooks mainly in their first language. That newly arrived students in average perform better on some tasks and native Swedish students perform better on other tasks may have to do with the fact that teaching of mathematics in countries over the world put emphasis on different mathematical topics.

Svensson (2014) examined how immigrant students experienced their possibilities to learn mathematics. This was done to broaden and critique common explanations given concerning immigrant students' unsuccessfulness with mathematics. In their narratives in which, the fifteen years old students positioned themselves in discourses that contributed to poorer performance in school mathematics than Swedish native students. The students were often confronted with not belonging to the normal i.e. Swedish students and describing their experiences of alienation and a sense of injustice. The students seemed to create themselves as individuals with limited room for manoeuver in the present and in the future as they identified themselves as belonging to a problematic group of students. One of the students in the study, Khaled from Afghanistan, had been going to a introductory class for as long as three years, only the last year of compulsory school (ninth grade) was in a regular mainstream class. He expressed the need of knowing Swedish to be able to manage mathematics instruction and the text books in Swedish, when he was talking to his fellow students in a focus group interview:

> Yes, but like this, I cannot so good language, I do not understand certain questions in math when they say it, I read it several times but I do not get it anyway, because I can not handle it. You have lived long time here, and know good Swedish so you can do it better than me. (Jo, men en del typ jag kan inte så bra språket, jag fattar inte vissa frågor på matematik när de säger det, jag läser det flera gånger men jag fattar det ändå inte för jag inte klarar det. Ni har bott länge här, och kan bra svenska så ni klarar det bättre än mig.)

Further on he says:

> It is not so easy to learn so quickly the Swedish and then change it to a maths language, to then I do not understand so much at math, some questions you do not understand so well / ... / like full sentences / ... / when I read it gets, it becomes quite strange to me so I do not understand so I skip it. (Det är inte så lätt att lära sig så snabbt svenskan och sen ändra det till mattespråket, till sen man fattar inte så mycket på matte, vissa frågor förstår man inte så bra /.../ typ hela meningar /.../ när jag läser det blir det, det blir helt konstigt för mig så förstår jag inte så hoppar över.)

Khaled tells about his experiences of being taught mathematics in Afghanistan. He does not believe that mathematics in Swedish schools is the same as in Afghanistan. He managed mathematics quite well there but not in Sweden. He says it may be because of language issues, and "I am mostly used to that, the Afghan maths one can say, what I did there". He also states that his father cannot help him with his mathematics homework because the father knows Afghan mathematics, not Swedish mathematics.

In a recently started study Norén and Sträng (in preparation) investigate how newly arrived immigrant students get access to mathematics teaching when starting school in Sweden. They will also investigate how the newcomers experience their education in Swedish mathematics classrooms. Sträng does participant observations during mathematics lessons in introductory classes. Norén interviews students, who just have been transferred to mainstream classes. Also their parents are interviewed as well as their teachers. The study is part of mapping mathematics education for newly arrived students in a Stockholm suburban municipality. There are yet no results reported from this study.

METHODOLOGICAL ISSUES

As this paper is a response to Bunar's (2010) call for more research on newly arrived students, and to develop theoretical and methodological tools, we give account of the methodologies we have developed in our research respectively. As we have concerns for equity in mathematics education we have to problematize how our research is carried out, in terms of "normality", Swedishness, and newly arrived students who not speak yet Swedish. It is about power relations as well as communication difficulties. To do so we use discourse theory in line with Foucault (2008). In classroom research, students' experience, performance and achievement analysis require a variation of research methods. So far we have used both qualitative and quantitative methods. Both may use document analysis and interviews while they typically differ in the use of classroom observations and statistical analysis of the outcome. So what are the methodological concerns when the focus is on how newly arrived immigrant students' experience, and perform in, school mathematics in Sweden?

NEWLY ARRIVED IMMIGRANT STUDENTS' EXPERIENCES OF MATHEMATICS CLASSROOMS

Part of our research is mainly qualitative, using participant observations (Hammersley & Atkinson, 2007), individual interviews, and focus group interviews (Kvale, 1997). The research is inspired by critical mathematics education research. Skovsmose (1994, 2005) has had a major impact as we are using his theoretical construct *foreground* (Norén, 2010; Svensson, 2012, 2014). According to Skovsmose (2005), a foreground represents a student' interpretation of his/her learning opportunities and life choices in relation to what the student finds acceptable in the current socio-political context, but also what a student in question perceives as available for him/her. Skovsmose (2005) writes:

> Intentions do not spring to life from nothing. They are grounded in a landscape of pre-intentions or dispositions, and I divide these into "background" and "foreground". The background of a person can be interpreted as the socially constructed network of relationships belonging to the history of the social group to which the person belongs. When one tries to understand an individual's intentions, one often refers to his or her background. But equally important is the persons' foreground. By this, I refer to those opportunities that the social situation makes to the social group to which the person belongs. Opportunities are not to be understood as sociological facts but as collectively or individually interpreted opportunities (p. 89).

Using *foreground* as an analytical tool, we have noted that students' success in school mathematics associates with the opportunities they have to positions formed in classroom practices. These practices are affected by public discourses on immigrant students and mathematics that occur on a societal level. Our focus is on the opportunities made available for the students to get involved in school mathematics, and in the long run, the hopes for the future that they will persieve through mathematics classroom practices. In line with Rodell-Olgac (1999) we argue for schools and teachers to take into account the social interactions in classrooms, and to create a supportive network around the individual newly arrived student. The contrast is what has been shown in earlier research: A focus on solely language aspects might position newly arrived students as "problems", and the answer to that will be the remedy "Swedishness" with a quest to homogenize (Sjögren, 1997; Runfors, 2003; Norén, 2010; Svensson, 2014). Students will be viewed and treated at the basis of what they lack, and what knowledge they don't have, in relation to how Swedish students the same ages are viewed and treated. The Swedish students will be the role model of what is "normal" while students whose mother tongue is not Swedish will be regarded as deviant with "weak language skills" (in Swedish). We name these aspects deficit discourses. In our research we look for other types of discourses.

Another part of our research is to compare how newly and earlier arrived students perform in different topics in mathematics. Seen as a sample for educational statistics purpose, immigrants are in many aspects a heterogeneous group. As discussed earlier they are a diverse group with respect to how recent they immigrated, their socio-economic situation, and their earlier experiences of schooling.

NEWLY ARRIVED IMMIGRANT STUDENTS' PERFORMANCE IN SCHOOL MATHEMATICS

Newly arrived students are rare. About 9 % of the students are born abroad; about 4 % are newly arrived the first school year and about 1.6 % of the 16-year-old students. The difference in percentage is mainly due to the longer stay of the older students and not due to age of immigration. This is a challenge when studying achievement data of newly arrived immigrants, since the sample must be large enough for conducting quantitative research. One example is Heesch (2000) who re-used TIMSS 1997 data for a study on Norwegian immigrants. In their study, there were few immigrants and the authors often failed to reach statistically significant results despite sometimes large differences in achievement. Secondary data may also have other limitations. For example test questions may be under secrecy and the sample may not be purposeful for the research question.

Another factor to consider is the socio-economic situation of newly arrived students. Some of them come as refugees, some with less schooling than others. For this reason there is residential area segregation due to economic resources of individual families. In larger cities with many schools, this causes school segregation since most students are enrolled in a nearby school. This indirectly has consequences for students' achievements. Schools with a high proportion of first and second-generation immigrants, also have a slightly lower ratio of qualified teachers and slightly higher ratio of turnover of employed teachers (Skolverket, 2004, p. 57). Hansson (2012) found a positive correlation between student achievement and whole class instruction in mathematics. She also found a correlation between high proportions of students' individual work and students with immigrant background or low socioeconomic status. This means that the students, who can be seen as in more need of teacher support, get less teacher support. Hansson interpreted this fact as existence of segregation in Swedish mathematics classrooms.

A challenge for quantitative studies is that random samples of entire classes needed for collecting a large enough sample of, say, newly arrived immigrants, and would be unmanageably large. An alternative to random samples is purposive sampling when designing a student sample (Cohen & Manion, 1994). Petersson (2012, 2013) used a purposive sample with the aim of decreasing the sample size needed as he selected schools with an over average proportion of first generation immigrants. There are challenges also with purposive sampling since the samples can be biased. There is a risk of comparing students from a similar background instead of comparing students that represents a national random sample.

Petersson (2012, 2013) handled the possible bias by comparing the achievements on the compulsory national test of the purposive sample with a national random sample. The latter sample was the same as was used for the evaluation of the national test.

FINAL REMARKS

This paper is a response to Bunar's (2010) call for more research on newly arrived students. Our focus on a particular school subject is important, as mathematics education has limited space in earlier research on newly arrived students. Newly arrived students must learn the new language while also having to acquire knowledge in other school subjects. For this to be possible, second language instruction has to be related to teaching in the school's all subjects. The effects of the positive impact mother tongue has for newly arrived students must not to be forgotten.

Our aim in this paper was to pay attention to diversity and equity issues in mathematics education includes avoiding deficit discourses explaining both success and failure in school mathematics, in relation to backgrounds, language and cultural issues. As shown in this paper, we look for analytical tools, qualitatively as well as quantitatively, to interpret classroom interaction, social practises, individual performance and achievement. Multiculturalism and multilingualism do not have to be constructed as obstacles to learning mathematics.

Justifications for mathematics teaching: A case study of a mathematics teacher in collegial collaboration

Anna Pansell and Lisa Björklund Boistrup

Stockholm University, Department of Mathematics and Science Education, Stockholm, Sweden, anna.pansell@mnd.su.se

The broad interest of this paper lies in how a mathematics teacher, Mary, justifies her professional decision making. The reported study draws on aspects of a PhD project and analyses Mary's communications within a collaborative teacher meeting focused on the teaching of mathematics to grade five students. The analysis, drawing on social semiotics, highlighted the significance of artefacts, such as multiplication tests, in Mary's articulated decision making. We also give account for what is addressed in a teacher's justifications and how the teacher relates to her students in the justifications. Finally, we discuss the wider social and political context in which the teacher is working.

Keywords: Mathematics teacher, mathematics teaching, teacher collaboration, case study, social semiotics.

INTRODUCTION

This paper is about a primary school teacher specialised in mathematics and science, Mary (pseudonym). She has about fifteen years of teaching experience. Together with Mary there are three teachers teaching about 100 fifth graders and they meet alternate weeks to discuss the mathematics they will be teaching. This study focuses on one of these meetings when the group discussed the assessment of multiplication tables and the use of textbooks to differentiate teaching. We followed Marys' communication through the meeting with an interest in how she justifies her professional decision making.

It is a challenge to discuss and understand why a mathematics teacher teaches the way she does. An easy response could be that the curriculum says so; another answer might be that the text book says so. From our perspective it is, in such a discussion, essential to understand that teachers' actions are undertaken within a particular social and political context. One example of this is how for the last twenty years, Sweden has had a decentralised curriculum that has forced autonomy on teachers. This forced autonomy, which has moved teachers to the centre stage of curriculum enactment (Skott, 2004), raises the demands on mathematics teachers to make informed decisions in the very complex set of actions that constitutes mathematics teaching. As a basis for teacher decisions there are different aspects of justifications possible to construe. The aim in this paper is, from a perspective close to a teacher's, to investigate her justifications when she discusses mathematics teaching with her colleagues. We also discuss the wider social and political context in which the teacher works, while focusing on artefacts as a part of the school system. We pose the following research questions:

1) What role do artefacts play in Mary's justifications in the teacher meeting?

2) What circumstances, contents and ideas are addressed in Marys' justifications?

3) What relational aspects concerning herself as a teacher and her students are a part of Mary's justifications?

LITERATURE REVIEW

When studying teachers in their social settings, one possibility is to examine how they collaborate with colleagues. Even though teachers are autonomous they need to work in close relationship with colleagues, parents and students (Hargreaves, 1994). Findings from research about teacher collaboration indicate that collaboration within a culture where teachers engage in mathematics teaching together, have a positive impact on both teaching practices and student achievements (e.g., Honingh & Hooge, 2014). Research situated in teacher collaboration is often used to study teacher development programs, e.g. professional learning communities (Riveros, 2012), communities of inquiry (Goodchild, 2014) or learning studies, which are common in Sweden today (e.g., Kullberg, Runesson, & Mårtensson, 2014).

Teacher collaboration research is rarely situated in a naturalistic setting, with a collaboration that would have taken place whether the researcher was there or not. A review of CERME proceedings 6, 7 and 8 reveal only a few papers on teacher collaboration (e.g., Spencer & Edwards, 2011) and none situated in an everyday situation. If research is situated in a development program it could be difficult to distinguish if the positive effects come from the collaboration or if it is from being in a development program. Here we can see a need for more studies on teacher's everyday life, also teacher collaboration.

Studies concerning mathematics teachers and their practices are diverse. In literature relevant for this study we can see that different countries have different school-cultures. Cross-nationally, students receive different numbers of mathematics lessons of different length, but within countries there is considerable consistency in how mathematics teaching is executed (Andrews & Sayers, 2005). This influence of tradition and school culture on mathematics teaching is, for example, described in the way teachers engage with and use curriculum materials (e.g., Remillard, 2005). As a part of a school tradition, mathematics curricular materials such as the mathematics text-book are said to have a prominent role and bear traditional forms of discourse (e.g., Johansson, 2006; Herbel-Eisenmann, 2007). Teachers deal with a complexity including the impact of culture, tradition, curricular materials and the competing objects and motives created by teachers and students (e.g., Skott, 2001).

METHODOLOGY 1: ANALYTICAL PROCESS

We have divided the methodology into two parts. Here we describe the interplay between preliminary data analysis and theoretical considerations which led to the analytical framework that we finally exploited. In another part, below, we describe more about the research design and data collections.

In order to acquaint ourselves with the data (transcripts from teacher meetings), we undertook several constant comparison readings, inspired by Glaser & Strauss (1967), with the purpose of identifying recurrent themes focused on a teacher's professional justifications. Our interest was directed only towards those justifications that were possible to observe in Marys' utterances and not those that Mary may have kept to herself. In the initial readings three major themes emerged. One related to artefacts as part of the school system, for example multiplication tables and the role they played in the teachers' discussion. Another was "what" Mary focused on in her justifications and a third concerned interpersonal aspects such as how Mary related to her students in her justifications.

In other words, during our initial analyses we identified themes with a conceptual similarity to those of social semiotics (Halliday, 2004; Van Leeuwen, 2005, Morgan, 2006). Consequently, refocusing our analyses around functions from this theory, provided a basis for new rounds of more focused readings.

ANALYTICAL CONCEPTS – SOCIAL SEMIOTICS

There are three social semiotic meta-functions that suited our preliminary analysis: textual, ideational and interpersonal. In this paper we adopt the meta-functions mainly according to a multimodal approach (Van Leeuwen, 2005; see also Björklund Boistrup & Selander, 2009). The meta-functions are not independent, they constitute each other.

The *textual* meta-function is, in this paper, understood according to the roles different communicative resources (such as artefacts, speech, voice, gestures and the like) play in communication, (Van Leeuwen, 2005). Communicative resources then constitute texts in a broader sense than only taking language into account. In this paper our interest is focused on what roles artefacts, for example textbooks, play in Mary's communication.

The *ideational* meta-function is used to reflect the explicit content of the communication under scrutiny (Herbel-Eisenmann & Otten, 2011). In this paper the ideational meta-function is used to discern what Mary focuses on and addresses in her observable justifications.

The *interpersonal* meta-function can be used to describe interactions, roles and relations between people "who are the participants in the interaction /.../ what relationships do they have to each other and to subject matter" (Morgan, 2006, p. 229). In this paper this meta-function is mainly adopted to construe how Mary relates to the students in her justifications.

METHODOLOGY 2: RESEARCH DESIGN AND DATA COLLECTION

Trying to understand a case, in this case when one teacher is studied, within the social setting and investigate it with depth is how case studies are used (Hammersley & Gomm, 2009). Consequently, we do not seek to offer material for generalisation but to provide a description of a part of one teacher's reality, and the result will widen our experience of mathematics teachers and these kinds of situations which could be seen as an alternative to generalisability in case study research (Donmoyer, 2009).

In this paper the collaboration between Mary and her colleagues served as the social setting where communications on mathematics teaching could be observed. We followed teacher meetings when Mary and her colleagues discussed different problems and possibilities concerning their mathematics teaching. Here we concentrate on one of the teacher meetings, although data on eight other meetings served as a background, and helped our understanding of this particular meeting. In order to capture mathematics teachers' collaborative discussions, audio recordings were made and transcribed directly in the software Videograph [1]. The same software was used to assign codes in terms of the research interest.

ANALYSIS AND FINDINGS

We present two excerpts, followed by our summary analysis, from the teacher meeting between Mary and her colleagues: Tomas, educated in advanced mathematics, but not in education; Peter, an experienced primary school mathematics teacher like Mary; and Sara, a primary school mathematics teacher a little bit less experienced than Mary and a new teacher at the school. The described excerpts serve as to illustrate the various features identified from the teacher meeting. The analysis draws on the three meta-functions which also are reflected in the research questions.

Episode 1: Discussion of a multiplication test

In the beginning of the teacher meeting a new teacher, Sara, was invited to describe what she had done during the previous week. Tomas, the official leader of the group, stated that one of Sara's teaching actions has been "really good" and referred the group to a times tables test comprising items such as 6 x 7, (the "really good" refers to the teacher having the test and not to the result of the test). In the following we present an episode from the meeting. To make the analysis as transparent as possible, some comments have been added to the excerpt.

1	Sara:	Yes, and then I did the multiplication test in the afternoon
/.../		[The teacher group talk about the result of the test which was not satisfactory]
2	Peter:	How many did you do? Five?
3	Sara:	Five minutes
4	Peter:	Hundred exercises?
5	Tomas:	How many exercises?
6	Sara:	Hundred and twenty exercises
/.../		[They talk about the test and other topics for about ten minutes]
7	Tomas:	Er, but then we have one or two in one class that thinks maths is like the plague and really hard, and that always feels like, and that has its grounds in this multiplication and then it was the worst anxiety attack and tears fell and it, it is really tough.
8	Mary:	Arr! [Said with a voice construed as compassionate]
/.../		[About five minutes of discussion on other topics]
9	Mary:	I am sitting here thinking about your test, 120 exercises in 5 minute. Is that reasonable is it a lot or little or is it...
10	Sofia:	That is reasonable! I had students that did it in three minutes
11	Mary:	Ah, well then
12	Sofia:	Two and a half minutes, if you know them it is there...
13	Mary:	Then it is...
14	Peter:	Yes
15	Sofia:	When you see the problem you know that it is, you don't have to.
16	Mary:	You don't have to figure something out no that is good...

17 Tomas: I can agree, if it was a long ago since last time, you could get seven, eight minutes the first time.
18 Mary: Yes
19 Tomas: But the thing you test is if they have automated it if they know...
20 Peter: Hmm
21 Tomas: Not that they will sit there and think five times five let's see that is five that is ten that is fifteen that is twenty, twenty five...
22 Mary: No, that's not, you don't have time for that...
23 Tomas: They should know that five times five is twenty five.
24 Mary: Hmm

Analysis of Episode 1

We view the test as an artefact and thus part of the multimodal "text" (Van Leeuwen, 2005). In this *textual* analysis we adopted social semiotics as "the way people use semiotic 'resources' both to produce communicative artefacts and events and to interpret them [...] in the context of specific social situations and practices" (ibid, p. xi). Our analysis revealed that, for Mary, the test played the role of reflecting the students' knowledge of automated multiplication skills. As the teachers discussed the test they talked about how the test was organised (line 2–6 and 9–14), and what the students need to know (line 12, 15–16, 19–24). We can also see the test having the role of a tradition keeper. Peter, who asked the question about how Sara did the test (line 2), almost said the answer together with Sara. This idea of having about 100 exercises in five minutes' was only questioned by Mary, for example, in line 9. No one offered an alternative or questioned the organisation of it. This way of doing this test seemed to be taken for granted. Drawing on Björklund Boistrup (2015), we argue that artefacts like this test, and how it is executed, are part of the assessment tradition within Swedish mathematics education. Looking at old Swedish text books, similar tests are found in teacher guides, so it can be inferred that this is part of a long term Swedish mathematics teaching tradition. When Mary tried to challenge the role of this test, she had not only her colleagues to argue against, she had a whole testing tradition to speak against.

We adopted the *ideational* meta-function (Herbel-Eisenmann & Otten, 2011) to analyse "what is being talked about or the specific content of the interaction". In this case, the content matter of Mary's justifications was knowledge concerning the automated recall of the multiplication tables. We construed this from the episode when Mary (line 16) said that it was good when the students do not have to calculate to know how much a simple multiplication is. In line 22 she agreed with Tomas that the test situation did not give time for calculation, and this was interpreted as Mary viewing it to be important when testing automated knowledge. Mary also agreed with Tomas in line 24 that the students should know five times five. Our analysis identified that Mary justified the test with the argument that the automated knowledge of the times tables is important mathematical knowledge. This was also present when the teachers talked, in another episode not discussed here, where Tomas said "they understand how you should calculate the more difficult exercises but since they don't know the times table it turns out wrong any way". On this occasion, Mary agreed with an "mm". This notion of 'important knowledge' was one of justification for Mary's support of the test.

We also identified an *ideational* aspect from Mary's justifications in an episode before this one, where Mary displayed resistance to the test. She then justified her questions and proposals drawing on the matter of how to organise classroom work in mathematics teaching. She stated that testing multiplication tables could take too much time from her lessons, saying "I do that in third and fourth grade but after that I don't want to use time from my lessons on this". Here we construed a hesitation in Mary's communication about the importance of doing the test.

Looking at *interpersonal* aspects in Mary's justifications, we were inspired by Morgan's (2006) description of the interpersonal meta-function as bringing forth relational aspects as well as "meanings, including the possibilities for emotional experiences" (p. 224). We then focused on how Mary's justifications in this episode concerned her relations with and emotions towards her students. Beginning at line 9, we identified a conclusion in Mary's question; that this test might not be for all students. A care for students is construed in Mary's justifications for resisting the test. Throughout the meeting Mary expressed a care for "low performing" students in relation to the test, for example her response to Tomas statement in line 7. Our understanding from this analysis is that the justification for Mary's resistance to the test came from this care for the students.

Episode 2: Discussion of mathematics textbooks

The next episode is when the teachers discuss text books. In this case the discussion concerns what text books to have available for the students.

1	Mary:	Yes, I will probably have Tom, he is on chapter four now, he will finish it soon...
2	Tomas:	Yes, then we have the book for grade six
3	Mary:	But then we have it so I don't have to order...
/.../		[A few minutes discussion on what books to order and not]
4	Tomas:	/.../ Peter and I agreed on, what we see as a wise thing. Those who work with more advanced mathematics so to say than grade five, they need two books. One for grade five and one for grade six /.../ they will do a test on this section to show, I can do this. If you showed that you can you can work in the grade six book but if you can't, then you need the teaching for grade five /.../ if it is too easy, you can show me that you can
5	Mary:	That's right
6	Tomas:	/.../ if they show us what they can do we should not hold them back.
7	Mary:	No

Analysis of episode 2

In our analysis we construed the role of the text book as a differentiating artefact. Mary agreed with Thomas, when he argued that if the students have a text book relevant for the "own level" they will have mathematics teaching suitable for their knowledge (line 1–2 and 4–7). This idea of using the text book as the solution for differentiated teaching says something about the position the text book holds.

Again we adopted the ideational meta-function to help us identify the idea that "high achieving" children need differentiated mathematics teaching. We construed that the teachers wanted to achieve a teaching suitable for these students through offering them more advanced text books. The teachers all agreed on the textbook as differentiator, as we can see when Tomas and Mary discussed this in lines 1–7. Tomas and Peter also had a special solution in line 4, concerning how to organise who get access to the more advanced text book and who does not. Mary justified her support for the idea when she expressed the need for one of these text books in her own classroom (line 1–3) and when she agreed with Tomas' idea in line 5. This is also construed from line 7 when Mary agreed that the students should not be "held back".

Looking at the interpersonal aspects of Mary's justifications, we can see how Mary agreed with Tomas in line 5, when he stated that the students could be trusted to take the responsibility to show what they can do before they got a text book different from the rest of the class. Here we construed that Mary related to her students with trust.

Another interpersonal aspect is construed when Mary, in line 1, made sure that there was a book for one of her students who would need it very soon. Here we identified that Mary related to her student with care, but, when compared to the case of multiplication tests, this time the care was for the high achieving students and the purpose was to challenge, not to be careful with.

CONCLUSIONS

In these two episodes, two artefacts were identified as indicators of Mary's professional justifications: the multiplication test and the text book. In the analysis, we construed the multiplication test as playing two roles, a reflector of students' skills as well as a tradition keeper, while the text book played the role of a differentiator.

Ideational aspects were identified in Mary's justifications. When she argued for and against the multiplication test, we identified in our analysis how she argued that automated recall skills of the multiplication table is important mathematical knowledge. We also identified how she wanted to allocate time for mathematics teaching in the sense of a communicative practice and that this test was taking too much of teaching time. Discussing the mathematics text book Mary justified the need for different books with the experience that her students would need a certain book and with the idea that "high achieving" children need a differentiated mathematics teaching.

We also read in our analysis how Mary related to her students in her arguments. In both these discussions Mary related to different students with care when she expressed how the students were in some kind of need. In the first episode she addressed "low achieving" students and the fear she had that they would suffer from failing at the test. In the second episode she addressed the "high achieving" students, whom she wanted to provide with the "right" kind of teaching. Mary also related to her students with trust when she agreed that they could be trusted to show that they could do the exercises in the ordinary text book before leaving it for a more advanced one.

To sum up, we have seen a variety of roles, ideas, experiences and relations in Mary's justifications. The result from this small study makes it clear to us that a mathematics teacher has a very complex broader context to take into account. The roles of the artefacts, such as tradition keepers and time savers, say something of the strong position they have. Discussing them, Mary also dealt with content-related issues and her students, in terms both of what teaching they needed and what they needed emotionally. All this was visible when Mary justified her views on mathematics teaching, negotiating with her colleagues.

DISCUSSION

The three meta-functions that underpinned the analytical process facilitated a diverse description and understanding of the data. They provided ideas to view the collaborative communication in different ways with and different aspects emerged.

In the case of the multiplication test as artefact, we described Mary's support of the test mainly in relation to an ideational aspect, the important knowledge, while her resistance appeared mainly in a relational aspect, the care for "low performing" students. This contradiction came close to what Skott (2001) describes as competing objects and motives. Something interesting here is that the importance of this knowledge wins over the care for the students, since Mary both questioned the test and seemed convinced that since they were testing automated recall it was okay. In the case of the text book as a differentiator there was support both from ideational and relational aspects which made the teacher group unanimous.

Looking at both the text book and the multiplication test with an interest in the socio-political context in which a mathematics classroom is immersed, we can see tradition (Remillard, 2005; Björklund Boistrup, 2015; Herbel-Eisenmann, 2007) shine through. The test has a role as a tradition keeper since it is a part of the school tradition. The discussion of the text book also offers an interesting perspective, being focused on differentiated teaching. It still shows the strong position the text book holds when the teacher group unanimous justifies this idea. There is no doubt that the relation between Mary and curricular materials (text books) is very complex, and it would be interesting to see deeper analysis of the role of curricular materials in relation to tradition connected to teachers' justifications.

Dialogues in ethnomathematics

Aldo Ivan Parra-Sánchez

Aalborg University, Denmark, Aalborg, aldo@learning.aau.dk

The relationship between researchers and researched communities in the ethnomathematical field has been conceived and developed broadly and deserves a problematization. A revision of previous ethnomathematical research is presented, finding how theoretical and methodological assumptions are related with leading notions of ethnomathematics, as dialogue, communication, respect and otherness.

Keywords: Ethnomathematics, ethnography, symmetry.

INTRO

Ethnomathematics emerged in the 80's within Mathematics Education, as a program of research in the History and Philosophy of Mathematics that seeks to understand mathematical knowing and doing throughout the history of humanity. It does so by studying "mathematics practiced by groups, such as urban and rural communities, groups of workers, professional classes, children in a given age group, indigenous societies, and so many other groups identified by objectives and common traditions" (D'Ambrosio, 2006, p. 1). Nowadays, ethnomathematics is a well-established field of research with a worldwide community of practitioners, most of them exploring implications in Education, using anthropological perspectives.

The field was based since their origins on a critical attitude that promotes the emancipation and equality of discriminated groups (Powell & Frankenstein, 1997). As two of the main leaders of the field assert:

> Ethnomathematics fits into reflection about de-colonization and the search for real possibilities of access for the subordinated, the marginalized, and the outcast, or excluded. The most promising strategy for education in societies that are in transition from subordination to autonomy is to restore dignity to their individuals, recognizing and respecting their roots (D'Ambrosio, 2006, p. 30).
>
> In other words, ethnomathematical studies may broaden the (intercultural) understanding of what are mathematics, of what are mathematical ideas and activities. There cannot be a sole, unified view of mathematics. For a monolithic and dominant view there is no basis. At the same time, for the other extreme, a cultural relativism concerning mathematics, there is also no ground: intercultural intelligibility seems possible (Gerdes, 2001).

As ethnomathematical research pursues the aim of valorising new understandings and recognitions, there is a strong need for the development of ways to relate and interact with communities. Therefore communication arises as an important issue. Some researchers consider it explicitly, with notions such as dialogue (Vergani, 2007), respect (Powell & Frankenstein, 2006) or mutuality (Adam, Alangui, & Barton, 2010) while others deal with it in a tacit way. Indeed, all of them make methodological decisions about the participation of the community and how that participation will be considered and registered in an academic diffusion of the research.

In an early attempt, S. Ferreira (1994) proposed ethnography as the proper and natural methodology for the growing discipline. To subscribe to that proposition has implications on how to conduct the relationship between research, researched and researcher. However, with the development of the field, several other methodological approaches have been attempted, including culturally responsive action and participatory action research (Mukhopadhyay & Roth, 2012). In addition, several ethnographical approaches were developed in the field of ethnomathematics.

This paper focuses on ethnomathematical research developed in, or with, living communities. The main goal is to problematize how that type of research has been devising the roles of communities and researchers, and contrast those enacted roles with well-known aims of ethnomathematics. To do so, a theoretical positioning is presented, introducing the concept of symmetry; then, an analytical strategy is proposed for a review of previous ethnomathematical studies, looking for some regularity within theoretical or methodological decisions. Some theoretical remarks are presented at the end.

THEORETICAL FRAMEWORK

As many practitioners adhere, ethnomathematics involves a program of research in the history and epistemology of mathematics (D'Ambrosio, 2006). For this analysis, epistemology of mathematics is not considered as a regular thing that exists in a void, but as a system of practices working in concrete places, where actual subjects make assertions. In that sense, for this approach, ethnomathematics has to cover not only an examination of the knowledge and practices that count as mathematics, but also encompass the procedures and instances of enunciation that allow to typify knowledge as mathematical.

This approach intends to give new insights to the recurrent discussion about the "ethnomathematical paradox" pointed by Millroy (1992). In that dilemma, it is considered problematic to use the "lenses of a mathematical observer" to analyse practices that are not originally based on Western mathematics. Important critiques and counter-critiques to ethnomathematics have debated that issue (Knijnik, 1996, pp. 84, 75; Pais, 2013) expressing concerns about the constraints and contingencies of the academic observation. Nonetheless, the debate could be reduced to a claim for reflexivity: "check your lenses", "research your own research" or "be aware that your standpoint" that does not alter the relation between observer and observed. However, building a broader vision of mathematics requires going beyond reflexivity, especially when living communities are researched. Such move towards a broader series of concerns is what I would call the problem of *symmetry*.

The problematic issue with ethnomathematics might not only be the use of mathematical lenses by the outsider researcher, but also to assume that insiders do not have their own ways to observe and analyse practices. Or even more, to assume that it is not possible to establish interchanges or interactions between those approaches. It becomes central to problematize how the involved subjects in the ethnomathematical field (both scholars and practitioners) position themselves with respect to each other trough the practices of research, recognizing or neglecting degrees of legitimacy that, therefore, allow or constrain the presence of multiple voices in the research. I am arguing that, instead of limiting the problem to reflexivity, ethnomathematics research can be problematized around the issue of *symmetry*. Symmetry as a problem of research in ethnomathematics is the study of how the participation of both researchers and practitioners have been conceived and expressed in research. In simple words, the problem of symmetry is the recognition that "the other has his own lenses" and that "researched people can research too".

Anthropology and sociology have explored several alternatives in the fieldwork to face similar problems, with approaches like collaborative ethnography, participatory action research, autoethnography, public ethnography and others (Denzin & Lincoln, 2011). All of them respond in different ways to the challenge that Woolgar identifies in the work of James Clifford, about a "dispersal of ethnographic authority in the sense that both researchers and natives be recognized as active creators (authors) of cultural representations" (Woolgar, 1988, p. 25).

A classic assumption of ethnographic fieldwork is encapsulated in the phrase "being there, writing here", demarcating a clear division between places, subjects and roles. In this paper I endorse a non-colonial posture about power and knowledge that questions such assumption, acknowledging the rights and the capacities to theorize that communities and subjects have. Elsewhere I have pointed:

> [Individuals and people] do not only have various types of knowledge, but also have the capability to disseminate them, broaden them and contrast them with the knowledge of others. Indeed, people and individuals have the power to define how, when and where their knowledge can circulate. (Parra, 2011)

Symmetry is related with the notion of infra-reflexivity that Bruno Latour proposed for studies in Sociology of Scientific Knowledge, trying to achieve "equal status for those who explain and those who are explained"

(Latour, 1988, p. 175) through an engaged interaction in each stage of the research process. I am aware that the word symmetry can raise many doubts because it can be easily associated with a supposedly friendly ideal horizontality that is often not the case. If we consider the complex power relationships involved in the very act of research, "equal status" has to be understood as a way to go, instead of a place to arrive. Notwithstanding that, I propose the notion of symmetry to stress the presence of practitioners as actors with voice and agency. Additionally, symmetry can subsume notions like dialogue, respect and mutuality, which are used by ethnomathematicians with very diverse meanings, when they explore possibilities of partnership, collaboration and reciprocity between scholars and practitioners in the ethnomathematical observations and representations.

In this paper, I assume that a singular piece of research does not express only the personal intentions of its direct developers [1], but also a shared set of truths and beliefs, that includes rules to follow, practices to perform, words to say and ideas to organize and explain within the research field. That set comprises what can be accepted in a specific space-time setting as a research experience.

Consequently, to scrutinize the understandings about symmetry within a particular ethnomathematical research project, it is necessary to observe this project as a whole, This includes an analysis of how symmetry is addressed in the methodology, in the theoretical approaches invoked, and also in the process of drawing conclusions. Moreover, whenever possible, subsequent activities of researchers and communities after the publication of the experience also should be observed because they allow to study the positioning of each agent about symmetry. Procedures are described in the next section.

ANALYTICAL STRATEGY

The empirical material for this paper will be a selection of ethnomathematical research projects that were reported in PhD theses or peer-review journal papers. The selected reports vary broadly in the date, language and place in which they were developed and in the places that their results were published in order to reinforce the fact that the main focus is to study assumptions that circulate within the field and not on particular researchers or research centers.

The goal is to trace some features, present or not, that allow to establish at what extent the interplay with the researched communities has been developed. For that reason it is important to elucidate the comprehensions that previous ethnomathematical research developed about symmetry, when they faced the problem. For analytical purposes, clusters of questions have been defined following a simple division in: inputs, actions and outputs. Research stages are distributed in the three clusters.

Inputs: this cluster covers justifications, antecedents, goals and theoretical positioning. It is important to observe the motivation to undertake the research; whether the community demanded the research beforehand, as part of their own interests and concerns, or whether the motives follow mainly the researchers' interest and how they found an agreement, if any. How the researchers have met the community or group, as well as if the goals and the objectives for the research explicitly mention some benefits to the studied community, even if it is in a long-term, is illustrative of the motives. It is further intended to trace symmetry into the theoretical framework exposed by the researchers, searching if they have used explicitly a definition of dialogue, mutuality, reciprocity or respect, or in some way made theoretical considerations about their interaction with the people being researched.

Actions: concerns about methodological and analytical strategies are treated in this cluster; In order to asses in which conditions the interaction was conducted, it is relevant to analyze the applied procedures to collect data, for example, if there was an immersion or a sequence of visits or for how long interaction was undertaken. In which roles were the members of the community and practitioners involved? In what stages of the research process did they contribute? These questions attempt to grasp the type of communication that researchers establish with the researched people. The attention provided to collaboration, reciprocity and partnership, even through any kind of feedback or reverting action, will be examined also in the ways that the selected projects analyzed and discussed their data.

Outputs: this cluster comprehends the research outcomes, including not only the conclusions and recommendations that the researchers can draw in a published text. Issues of intellectual property, applicability and uses of the research within the group can be considered. Long-term or short-term experiences can develop different kinds of partnership and dialogue in the aftermath of a published research.

PRELIMINARY FINDINGS

For the scope of this conference paper, I will only present the first results of literature review, covering mainly the first two clusters of questions, leaving for further study considerations about the continuity of the relationship between researchers and groups after a publication of the research.

For the first cluster, motivations for an ethnomathematical research can be inquired, suggesting that collaboration and partnership are strongly connected to the preexistence of a sociopolitical project providing a frame to the research, as we can see in experiences like (Knijnik, 1996, 2007), invited to participate in the Educational Literacy Project of the Landless movement in Brazil, or (Gerdes, 2007, pp. 227–256) commissioned by the government of Mozambique to educate mathematics teachers. Also the work of Meaney, Trinick, and Fairhall (2012) is embedded in the educational process of the Maorian people in New Zealand. In those three cases, researchers had in common the necessity to articulate their theoretical interests within a non-academic process that surrounds the research and demands some sort of result from the researchers. This does not imply that researchers were employees or militants of those processes but that they have to interact with them, and that a part of the projects' theoretical concerns were related with those non-academic processes.

Cases like those contrast with other experiences conducted for the pure sake of a theoretical interest, like the PhD project "Interpretacion matematica situada de una práctica artesanal" carried out by Albertí Palmer (2007), who worked in Indonesia, seeking to develop a method to identify mathematics in a practice, founding on the identification of mathematics in the Torajan architectural ornamentation, or a project carried out by Rohrer (2010), who interviewed sculptors in Mozambique, trying to solve questions like "Which mathematical means and tools do Makonde artists use and which mathematical knowledge can be revealed in their practice?"(Rohrer, 2010, p. 15) "Is it possible to find golden sections within their final sculptures, even though there might be no prior knowledge of this term as such?" (Rohrer, 2010, p. 149). Those questions where part of her doctoral thesis, which attempts to give resources for a theorization of ethnomathematics as an interdisciplinary theory.

Motivations in the projects of Albertí Palmer and Rohrer appear to act completely outside of the interests of the researched groups because they are devoted to register some specific practice or notion present within the community that can be identified by the researcher as mathematical, aiming to expand the idea of mathematics, from a culturally-free practice formalized by western rationality, to a human and contextualized one. However, such expansions happen inside a western academic context in the spirit of "Nothing better to show a new view of this Science [Mathematics] than observe how other societies are building it" (S. Ferreira, 1994, p. 94, my translation).

Moving to the theoretical positioning, S. Ferreira commented first about the relationship between researchers and researched groups, when he contributed to theorize ethnomathematics using modelling: "I can not dismiss ethnography, ethnology, validation and, mainly, *the action of return the model´s outcomes*" (S. Ferreira, 1991, italics added). Some years after he proposed a cycle based on those ideas, conceiving ethnomathematics as a pedagogical model, where the fieldwork involves an action over the community.

> In my view, *every ethnographic research has to have, by necessity, a return of their results* to the communities who are being researched. This proposal of a return is one of the *indispensable* actions in the process. It is up to the community to decide whether accept it or not. (S. Ferreira, 2004, italics added, my translation)

By addressing educational possibilities of ethnomathematics, authors like Lübeck and Rodrigues (2013), Vergani (2007) and Oliveira (2013) use explicitly the term "dialogue", invoking Paulo Freire`s ideas to guide the encounter between different people in a respectful way. Mutuality becomes central to ethnomathematical research with Alangui's (Adam et al., 2010) work:

> Mutual interrogation is the process of setting up two systems of knowledge in parallel to each other in order to illuminate their similarities and differences, and to explore the potential of enhancing and transforming each other. In the

> context of ethnomathematical research, mutual interrogation is a process facilitated by the ethnomathematician – the researcher (p. 11).

Mutual interrogation locates ethnomathematician as an intercultural speaker that gathers different worldviews, transmitting questions and answers among practitioners of different traditions of knowledge. This approach goes beyond classic ethnography, because the parties involved become researchers as well, blurring the borders among "there" and "here".

In the second cluster of questions, the amount of time invested in the fieldwork with the communities is considered a key issue to unfold questions around symmetry. Usually, when a research for a PhD thesis adopts ethnography as a methodology, the common option is to give a short full immersion of a couple of months to collect data, like the studies by Rohrer (2010, as discussed above) or Millroy (1992). In those cases the researcher did not know the members of the community before she entered the field and she had to elucidate which member could provide the best information. Then she tried to establish as soon as possible a communication with those special members. Inferences are built using only one data collection, and other resources come from previous academic literature.

It is less common in a Ph.D. thesis to make a sequence of visits along an extended period, like (Knijnik, 1996) or (Silva, 2013), who worked regularly with their studied groups before they accomplished their doctoral studies. This allowed them to interact with communities in other ways, to participate in community's special events, and to know a wider range of members of the community, obtaining contradictory and complementary data in each visit. These two experiences have transcended the scope of a PhD study and developed further books and papers

Far from classic ethnographical approaches, continuous long-lasting experiences made possible a deeper interaction between communities and researcher; projects like Urban Boundaries in Portugal (Mesquita, 2010), MACIMISER in Micronesia (Dawson, 2013), or the already mentioned works of Paulus Gerdes in Mozambique, as well Tony Trinick and colleagues in New Zealand. Those cases permanently collect data, create small projects framed within a bigger research process, release multiple publications and occasionally create re-elaborations of previous findings as a result of the continuity in the communication between researchers and researched. In these projects, community members can hardly be considered "informants" in a simplistic sense. They become another researcher in special stages of the experience, discussing and assessing questions, procedures or methodologies with the academic researchers. However, there is only one reported case (Caicedo et al., 2009) in which a group participated in the design and implementation of all stages of the research, even in the search for funding. This preliminary result does not deny the existence of some kind of reciprocity or collaboration in brief ethnographic experiences, but certainly confirms a basic idea: dialogue requires time, persistence and patience to be developed.

The third cluster of questions demands to seek for tensions outside texts, like the research impact. As announced before, few considerations resulting from the literature review are presented here. Even though it is a very uncertain question to identify what kind of outcomes can be considered as a contribution from the perspective of the researched group, collaboration can be traced in the multiplicity of products resulting in a research that can be used by community members: textbooks, booklets, portfolios, videos, and other resources.

Research in doctoral theses is often driven by its intention to answer a theoretical question. Very seldom does it create the opportunity to report implications of the research with the community, or at least to discuss the published thesis. The educational models produced in doctoral theses leave the possibility to be implemented to the community and remain on a level of proposals. This is consistent with the approach of Sebastiani quoted above.

Long-term research has to deal with several challenges, like the teamwork continuity, the funds for the research and the perception of the community about the presence of the researcher. Interactions and dialogues are developed between people defending their interests and immersed in power relationships. Questions about the social relevance of the research can appear after some years of continuous work: members of the community ask for the benefits that they can or cannot receive for their participation. Additionally, researchers in long lasting experiences become engaged with the community not only for the matter of research, but also with their social struggles. The relationship transcends the academic instances, gaining a personal dimension. Summarizing, these experiences involve ethical and political dimensions, not only theoretical or mathematical ones.

OUTRO

This literature review has suggested the classification of ethnomathematical research in two groups, concerning virtues like dialogue, collaboration and associate concepts. This distinction is related with, but not determined by, time. It is obvious that a clear cut about what is a "short" amount of time in research cannot be provided. Such classification does not intend to formulate any criteria to predict, to control or to evaluate ethnomathematical research. The intention is to pay attention to the existence of one dimension usually overlooked in the field, that I have referred to as symmetry. This dimension expresses concerns about the consistence and effectiveness of our own actions towards a wider conceptualization of mathematics.

Ethnomathematicians who work with communities, should be aware of the risk to betray their own goals, turning a thing that supposed to be a dialogue into a communication in only one way. To elude colonialism is not an easy task, because it is still present in our conceptualizations and beliefs about what can count as research. Classic ethnography exemplifies those beliefs, determining and distributing roles in the research process; as Woolgar states, ethnographers who stand for a division between image and reality try to maintain the exoticism of the reality observed and the epistemological superiority of the observer:

> Not only is the tribesman different, the implication is that this difference entails the subject's inferior access to reliable procedures for observation and report. In an almost paradoxical way, the more exotic the native, the more we can depend on the accuracy of the ethnographer`s report (Woolgar, 1988).

Of course, researcher's intentions cannot be simplified as "bad" or "negative". Most of the times, ethnomathematicians express their sincere respect of community heritage and act consistently with that. However, the less time invested in the fieldwork research, the more the researchers are tempted to do classic ethnography; despite researchers claiming their good intentions, not seldom the idea of dialogue in ethnography is in fact a dialogue between ideas interplaying inside the researcher´s mind. It is important to realize that institutional frameworks prompt research by imposing measurements of time to assess the quality and the impact of an investigation, and accordingly to that, to provide financial support. This economical rationality of completion rates promotes certain specific styles of research.

To conclude, it is not easy to imagine how a dialogue around mathematics could be established with a group. However, there is some research that can give indications. For instance, ethnomathematicians could include practitioner´s way of thinking, and give them more control in the research process, as a way to lose pre-eminence in the report, accepting other voices and other interests.

ACKNOWLEDGEMENT

This research is funded by Departamento Administrativo de Ciencias, Tecnología e Innovación (COLCIENCIAS) and Aalborg University in Denmark. This research also makes part of the NordForsk Center of Excellence "JustEd".

ENDNOTE

1. Of course the individuals are not helpless operators in that set, they can strength it with their actions, change some components, or eventually they can deflate its importance as paradigm, accordingly to the awareness and consciousness that each individual has about the ways that set operates. Studies like the intended here, try to provide such awareness.

The intersection of girls' mathematics and peer group positionings in a mathematics' classroom

Darinka Radovic[1], Laura Black[1], Christian Salas[2] and Julian Williams[1]

1 University of Manchester, Manchester, UK, darinka.radovic@postgrad.manchester.ac.uk

2 Bangor University, Bangor, UK

This research paper reports the intersection between mathematics identity and the peer positioning of high attainment girls in a particular mathematics' classroom in Chile. Following an ethnographic approach, we explore how this intersection mediates girls' perceptions of what mathematics is and how it is supposed to be done/practised. The main finding is that different female 'peer' group processes and identities appeared to mediate different mathematical positional identities. The discourse models of maturity/immaturity, compliance/resistance and effort/effortlessness appear to be crucial in mediating peer processes – these are used to define membership and identity of the peer group (including relations with boys) and also mediate girls' positioning in mathematics.

Keywords: Mathematics identities, peer relations, gender and 'maturity'.

BACKGROUND

The study of gender equity in mathematics education has been an important focus of research for 40 years. Several studies have tried to understand how girls have been persistently "counted out of maths" (Walkerdine, 1998), by lower mathematics grades (e.g., Hyde, Fennema, & Lamon, 1990) and lower representation in post compulsory mathematics courses and careers (e.g., Mendick, 2005) compared to their male counterparts. Recent studies have shown that these differences are not homogeneous across countries (Guiso, Monte, Sapienza, & Zingales, 2008), and national heterogeneity suggests cultural constructions of these differences. One concept that has been increasingly used in exploring this cultural diversity is that of identity (e.g., Solomon, 2008). For example, the concept of mathematical identity has helped explain how women in some countries (e.g. the UK) come to see themselves as not belonging in mathematical (or STEM) contexts, despite their high performance in the subject (Solomon, 2012).

Alongside concerns regarding girls conflicted relationship with mathematics, there has also been a significant amount of research trying to explain girls' high achievement in most subjects (including mathematics) when compared to that of boys. This research has focused on masculine subjectivities in schooling, suggesting the existence of a "laddish" culture of (particularly working class) boys rebelling against the school in contrast to a feminized culture of compliance, and effort more apparent amongst girls (Jackson, 2003). However, simple dichotomies (e.g. rebellious boys/compliant girls) have been recently challenged by evidence showing that girls often aspire to effortless achievement (Jackson, 2006)I found this book a fascinating and engaging read...It provides a useful analysis and exploration of the classed and gendered 'anti-school' ethic in place presently within many schools, and it will provide a meaningful analysis for academics, policymakers and practitioners and anyone with an interest in gender, education and young people.\" Fin Cullen, Goldsmiths College, Review in Gender and Education \"I would [therefore] urge everyone concerned with what is happening in schools to read this book, with its fascinating data and nuanced arguments.\" Heather Mendick, London Metropolitan University – Review in British Journal of Educational Studies This innovative book looks at how and why girls and boys adopt 'laddish' behaviours in schools. It examines the ways in which students negotiate pressures to be popular and 'cool' in school alongside pressures to perform academically. It also deals with the fears of academic and social failure that influence pupils' school lives and experiences. Drawing extensively on the voices of students in secondary schools, it explores key questions about laddish behaviours, such as: Are girls becoming more laddish and if so, which girls? Do boys and girls have distinctive versions of laddishness? What motivates laddish behaviours? What are the consequences of laddish behaviours for pupils? What are the implications for teachers and schools? The author weaves together key contemporary theories and research on masculinities and femininities with social psychological theories and research on academic motives and goals, in order to understand the complexities of girls' and boys' behaviours. This topical book is key reading for students, academics and researchers in education, sociology and psychology, as well as school teachers and education policy makers." (Jackson & Jackson, 2006, and furthermore, that the apparent girls' compliant behavior may also be a way of resisting conformity by becoming invisible rather than disruptive (Fisher, 2014).

With these arguments in mind, this paper aims to explore further notions of diversity in the construction of girls' mathematical identities in classroom cultures. Particularly, we are interested in understanding how high attainment girls' positionings in the peer group and in the mathematical practices intersect, and how this intersection mediates their mathematical identities in the classroom.

THEORETICAL BACKGROUND

In order to account for the relation between learning and identity, this study takes a sociocultural perspective on identity. This perspective considers that both learning and identity develop in moment-by-moment engagement with others in, and through, sociocultural practices (Holland, Lachicotte, Skinner, & Cain, 1998). In these practices, individuals are positioned, and position themselves in relation to others, thus, constituting *positional identities* (Holland et al., 1998). As people move between practices, these identifications are multiple and therefore a single identity is never crystalized. A consequence of such processes is that identifying with contradictory practices can prove challenging and sometimes even generate contradictions in or crises of identity (Black & Williams, 2013).

The prime cultural practice that needs to be considered when researching mathematical positional identities is the *mathematical* practice itself, and how notions of competence or 'smartness' are culturally constructed therein (Gresalfi, Martin, Hand, & Greeno, 2008). These notions constitute social norms and hence obligations against which students will be positioned by others, and will position themselves, for example, by resisting or complying with these obligations (Cobb, Gresalfi, & Hodge, 2009).

A second practice that has received attention by researchers is that of students' positioning in their peer group culture. Studies that have explored how the school culture relates with the peer culture, have found that bringing these two (sometimes opposite) cultures together in a developing sense of self, can be challenging for individuals. For example, in a recent study, Francis and colleagues (2010) found that for high achieving students, notions of high achievement were in conflict with social popularity with peers, requiring a particular kind of "identity work". This identity work was extremely challenging for girls, who had to negotiate demands for being both attractive/desirable (feminine) and clever/smart (masculine) (Skelton, Francis, & Read, 2010). This is particularly important in mathematics, as this subject is often seen as geeky/non-popular and male (e.g., Mendick, 2005b), so being mathematically able can act as a double marked category for girls (Damarind, 2000).

Considering the existing evidence, it appears necessary to explore further the complexity of cultures in the classroom and avoid essentialising specific cultural forms as male or female, both in the mathematics and in the peer cultures. Hence, this study explores how girls' peer group relationships and values relate to their mathematical identity in the classroom.

METHODOLOGY

Context of the classroom study

This study was purposefully situated in a school with average attainment, medium socioeconomic status (SES) and in a traditional working class area in Santiago, Chile. It was a private subsidized school that received government funding and charged parents a tuition fee. As some studies have found (Mizala & Torche, 2012), these characteristics generate a highly homegeneic population in terms of SES. In addition, it was considered a demanding school where students were asked to reach a 70% mark for a passing grade. Students that did not reach this score were held back a year.

The study focused on one case study in a year 7 mathematics classroom of 39 students. Not unusually for Chilean classrooms (see Ramirez, 2007), the students' scores varied between failing and excellent. In addition, because of the hold-back policy, the classroom was also diverse in terms of students' age, with a range between 13 and 16 years. These characteristics made this classroom a very typical one in this country for this type of population.

The mathematics' teacher [who we will call Ms. Paula] had 2 and half years of experience in teaching mathematics. She came from a general teacher-training course (non-mathematics specific) in a non-traditional University, with relatively limited experience and specific preparation in mathematics. However, the Head of Department and her students characterized Ms. Paula as a "very good teacher".

Similarly to many Chilean classrooms (e.g., Martinic & Vergara, 2007), Ms Paula's lessons followed a very consistent routine with three main parts: (1) whole class introduction of the day's topics; (2) students' working on exercises; and (3) a closure. In this particular classroom, during the closure part "reward points" were distributed among students according to whether they completed the activities. As also described in previous Chilean studies (e.g., Radovic & Preiss, 2010), most of the talking was done by the teacher in the whole-class parts, with students' role mainly focusing on answering the teacher's questions. Students had relatively more space for independent work and peer talk during exercises, where they could choose to work collaboratively.

Data collection and data analysis

This study used an ethnographic approach to access the classroom culture and individual student's and group's mathematics identities. Following Cobb and colleagues framework (2001), instruments were designed to capture both a social perspective (shared meanings in the classroom's culture) and a psychological perspective (individual student positionings in this culture), the latter particularly focused on girls. One of the authors [DR] visited the school regularly during the second semester of the school year, collecting data from individual and group interviews with students, conversations with the teacher and observations. Different interview techniques and schedules were used to allow students to talk about their classroom, lessons, teacher and peers.

A *Mathematical Groups* interview was concerned with the students' perceptions of the different mathematical groups in the classroom and their own place in these groups (self and other's positioning). It was used to explore what constructs of competence were working in the classroom and which students were consistently positioned as 'competent' or 'non-competent'. Sixteen students (7 boys and 9 girls) were sampled to represent different levels of attainment, and interviewed individually for about 5 to 10 minutes. They were asked to group their classmates by answering the following question: *are there groups of students that show a similar relationship with mathematics? Build as many groups as you want considering that students in a group should be similar within and different from other groups.* After grouping, students were asked to talk about what criteria they used to group their classmates.

A *Natural Peer Group* interview followed Cairns, Xie and Leung's approach (1998), approach that allows mapping the classroom's peer group structure in terms of 'naturally occurring' (i.e. informal, out-of-school, or non-academically shaped) social clusters. Students were purposely sampled to represent different peer groups that were observed or mentioned in previous interviews until reaching saturation (i.e. no new groups appearing). In total, 12 students were interviewed (5 boys and 7 girls). They were asked to group their classmates by answering the following question: *are there people in this classroom who hang around together a lot?* In a follow-up interview, meanings associated with each group were explored. Interviews again lasted between 5 to 10 minutes.

This paper's analysis is focused on 5 high attainment girls (between A- and A+) that were recognized as belonging to two big social peer groups, each of which included boys from the classroom, but in significantly different ways. These girls were also interviewed more in depth about their relationship with mathematics. In a semi-structured narrative interview that lasted about half an hour, they were asked to talk about their mathematics story and to describe how they felt, how they behaved, and how others saw them when doing mathematics. For the preliminary analysis that follows, the five girls participation in the classroom as observed during observations and their interviews were explored looking for communalities within the peer group and differences between the groups.

RESULTS: INTERSECTIONS OF GIRLS' MATHEMATICAL AND PEER GROUP IDENTITIES

When the students were asked to group their classmates in *terms of their relationships with mathematics*, they tended to consider oppositions in *achievement* (high v/s low achievers) and *effort* (high effort v/s effortless) as significant categories for distinction. Thus, three main groups were mentioned in this regard: Effortless High Achievers [two boys and three girls], Effortless ('*lazy*') Low Achievers [four boys, of whom 3 were held back], and High Effort students with various levels of attainment.

In terms of naturally occurring peer clusters, the analysis that follows is centered on the girls that belonged to two of the six peer groups named by students '*Adolescent*' and '*Normal*'. While the '*Adolescent girls*' were said to behave as if they were older teenagers (e.g. who 'wear make up and go out partying with boys'), the '*Normal girls*' were described as either immature or more appropriate to their age, and so positioned in contrast to the '*Adolescent*'.

Adolescent/Effortless girls

The intersection between the mathematical and the natural peer group revealed that the conformation of the '*Adolescent group*' mixed students from two contrasting mathematics groups: three effortless high achieving girls and four effortless low-achieving boys. Their classmates described them as the group that acted as if they were older, thought they were the 'coolest', showed off about what they owned (clothes/technology, i.e. making the link with higher economical capital), and appeared less concerned about school. Some classmates mentioned that the girls in this group were too worried about their appearance, wearing too short skirts, make up, and always hugging and kissing each other. Some of them, they said, even had boyfriends.

When talking about themselves, students from the '*Adolescent group*' said they were the most mature group in the class. They said other groups of students (especially the '*Normal group*', see below) played like children, ran about during breaktimes and were loud and euphoric. In contrast, the girls in the adolescent group said they hung out with boys and talked about their different interests: for example, Justin Bieber. They also claimed to balance their school life with other social obligations, like going out and partying. According to one of these girls, this was an important aspect of growing up.

> New things will come in life, people can't be all the time worrying about school. It's not that school goes to second priority, but that new things come to life (...) like more friends, new things, I'm starting to go out (partying) and those things are taking more of my time, and that's it... less time...

This notion of maturity was further supported by these girls' alignment with the 'effortless low achievers' boys' in the group who had been held back a year and who, in consequence, were one year older than the rest of the class.

During mathematics' lessons, these girls were on task but somehow also seemed disengaged from the classroom activities. During whole class teaching it was common to hear them making jokes (e.g., giving related funny examples from the telly) and commenting between themselves (in group) on what the teacher was saying, but without sharing this commentary with the whole class. They were never seen offering an answer to the teacher's question, or asking or commenting spontaneously to the whole class. Thus, they gave an appearance of not engaging but did so without being openly disruptive as such. During independent work, in contrast to other students, they remained sitting at their own desks, working with their partners. These girls were fast in their work, finishing ahead of time and, therefore, having the opportunity to chat about other things with their friends. Also, in contrast to other girls in the class (e.g. the girls from the '*normal group*' see below), they rarely engaged with the teacher while working; instead, they sat back and waited until someone came and checked their work.

During individual interviews, these girls reported that mathematics for them was an active, collaborative, and fast activity, where they were able to use their skills ("I'm good with numbers", "I'm good with finding the solution"). Their perceived competence allowed them to enjoy and value Ms. P's pedagogic approach as it allowed them to be mathematically active while remaining independent:

> I like maths more than other subjects because it is not always the same. Exercises change; there are always new things to do and new ways to do them. It is not like other subjects that are always write,

> read, write (...) Ms. P gives some time for doing the sheet and this time is like a little free time because you can.... I mean, not a free time in a bad sense, but you can work with your desk partner, or talk about the exercises with your group.

What they seem to accomplish in the classroom was the tenacity to maintain their academic performance as high achievers, but, at the same time, also preserve their status in the peer group.

> I try to do the exercises fast, so I can think in maths for a moment and then I can return to the "normal life" (...) that's what I like to do... to do my work and then relax...

These data suggests a relationship between peer group membership and mathematical positioning, where each one appeared to be resourcing the other. Their effortless identity as a high achiever in mathematics meant they could complete the work quickly – this then allowed them to accomplish their social 'obligations', which were vital to maintain peer group membership and cohesion (e.g., chat between them and with the boys during the mathematics lessons). At the same time, performing their social identity as 'mature girls' involved achieving a good balance between social peer-group maintenance work and academic work (i.e., not working too much, and not being seen to engage with the classroom process, with the teacher, or with their immature inferiors) which at the same time resourced their 'effortless' mathematical identities. This relationship allowed these successful girls to construct a positive relationship with the subject and with their teacher's pedagogic practice, while affording social independence and maturity as it aligned with the held back boys of their group.

The Normal/Non Effortless girls

The Normal Group presented a rather different intersection between mathematical and peer group identities. This group was comprised of six girls and three boys. Other students in the class described the girls in this group as 'the quiet ones'; the group that never got told off by teachers. Girls from the adolescent group also commented that these girls were childish, contrasting them with their own social identity as 'mature'.

Two of the girls within this group named themselves as the '*Normal Group*' (hence the adopted name) and, in opposing themselves to the '*Adolescent Group*', they said that they enjoyed childhood as appropriate to their age, not wanting to grow up too fast: as one of them said, "we live what we are supposed to live".

During observations, the high achievers girls of this group appeared as described by their peers and in contrast to the adolescents: always on task and actively participating in classroom activities. During whole class teaching, these girls consistently offered answers to the teacher's questions. As with the adolescent girls, the normal girls finished their work fast. However, instead of waiting for the rest of their classmates to finish, they would seek help from the teacher in order to check their answers. Furthermore, the relative compliance of these girls with the teacher provided a degree of freedom in their behaviour: during independent work, they were frequently standing and walking around the room. Although this was supposed to be against the rules and proscribed as disruptive, they were never reprimanded.

The Normal girls portrayed different ideas of what learning mathematics was when compared with the views of the Adolescent girls. Although they mentioned being relatively good at mathematics, they did not claim to value the independence of working alone to solve problems and felt that sometimes doing mathematics became too repetitive. For them, learning mathematics involved applying a method taught by the teacher and then waiting for the teacher to offer a new method if the first one was inadequate or too challenging.

> I would like the teacher to teach us techniques that weren't difficult so we could understand them in the moment and then we could move quickly, like the magic formula, easy procedures to understand (...) But in mathematics the teacher is like too serious and she explains everything as it is very complicated...

This version of what mathematics was (or was supposed to be) appears to relate to how they saw their peer group role in the classroom. The Normal girls talked about maturity in order to differentiate themselves from their peers (particularly the boys in their group), but for them this term appeared to hold a different meaning. For them, maturity involves being responsible in doing their work and helping their (immature) male classmates:

> Yes, because when we start working on exercises, I look around and all the boys are just playing... some of them have it done but most of them just play (...) I think it is just that women are more professional, more mature, they keep focus on things (...)
>
> I think we are 4 girls and we will have to be with the boys and we will have to help the boys to focus, we will have to be responsible, because I want to get a good grade...

These extracts again show how these girls' peer and mathematical identities are related. Being 'normal', acting according to their age, feeds into their version of how mathematics should be: a set of methods that the teacher has to transmit to them. How are their peer group social relations then related to their mathematical positioning/identity? One can hypothesise that this peer group is constituted as being 'child like' in their peer activities, but also in its compliant/dependent relation to adults – in this case the teacher – in contrast to the adolescent girls whose 'maturity' demands a degree of independence. Mathematically, this is associated with following rules and techniques, which should be simple and straightforward. Even the social relation to their male peers is not yet adolescent, and positions these males as in need of their (parent-like) surveillance/monitoring, reflecting their own compliance with the authority of their teacher.

CONCLUSIONS AND DISCUSSION

This study offers further evidence for the idea that mathematical identities are intertwined with the students' peer culture (Gholson & Martin, 2014). More specifically, this study contributes to the literature by describing a dialectical relationship where peer group membership and identities inter-relate with their engagement in classroom activity and mediate how girls come to see what mathematics is, and how it is suppose to be done. In turn, emerging mathematical identities in the classroom may play some role in maintaining peer group membership.

These preliminary results suggest that two cultural models can arise in this dialectical relationship: (i) effort/compliance with authority, and (ii) maturity. In the mathematics education literature, the notion of effort has been identified as crucial in defining mathematics as a male domain where essential ability involves effortless high achievement (Walkerdine, 1998). Evidence from this study challenges such an argument by suggesting that girls can also position themselves as effortless high achievers as was noticed by Jackson (2006). However, it is important to point out that these girls are not particularly high achievers when compared with performance of students in the private school system in Chile and did not mention intentions of continuing studying mathematics after compulsory schooling: it seams that this effortless identity is still counting them out of mathematics, or it will in the future.

This study also suggests that girls' relationships with mathematics is also influenced by the meanings they attach to the process of growing up, particularly to their notions of maturity, which is a central theme in peer group membership (including relations with boys). On the one hand, the adolescent girls use maturity as a way of addressing their need to position themselves outside the school academic culture, a process which is further aided by their alignment with the oldest boys: Despite the boys' being lower achievers – they gave status to the girls who wished to use maturity to differentiate themselves and their group from the rest of the class. On the other hand, the normal girls associated maturity with compliance with school culture – not just being compliant but even taking responsibility for the poorly behaved boys as another means of performing their (apparent) compliance. These different notions of maturity not only signify peer group membership but also how to approach mathematics, since for these girls their maturity was representative of the school culture (i.e. doing maths quickly, easily to allow for other activities v/s following rules/methods and verifying such procedures to perform well).

Number sense as a sorting mechanism in primary mathematics education

Rebecca Turvill

Brunel University, London, UK, rebecca.turvill@brunel.ac.uk

This paper aims to explore the way mathematics education systematically disadvantages particular groups of children, beginning in their early education. I focus on the concept of number sense to illustrate how it acts as a gatekeeper to wider mathematical learning and subsequently life opportunities. By examining number sense from the perspectives of cognitive psychology, situated cognition and Bourdieusian social psychology, I demonstrate inequalities in how young children develop number sense in primary school. I suggest that it is important to consider these different perspectives to reveal the dominance of cognitive theories on practice in primary schools. I propose that a Bourdieusian analysis of number sense reveals how number sense works to sort children and ultimately reproduce social divisions.

Keywords: Number sense, social justice, habitus, Bourdieu.

INTRODUCTION

Mathematics education systematically disadvantages some people (Zevenbergen, 2001). Crawford & Cribb (2013) report that high attainment in mathematics leads to higher earnings potential for individuals; with mathematics attainment at age ten being linked to individual earnings at age thirty. Similarly low numeracy along with low literacy is found to be a genuine barrier to employment (Wolf, 1999). We need to view such evidence alongside the knowledge that children from lower socio-economic backgrounds generally achieve lower outcomes in mathematics than their more advantaged peers (e.g., Nunes, Bryant, Sylva, & Barros, 2009). Thus there is a cycle of disadvantage, where children who are born into homes of low socio-economic status are likely to be failed by mathematics education and have limited opportunity to improve their life chances. In this paper I argue that an individual's 'habitus' (Bourdieu, 1989) causes misrecognition of number sense skills as mathematical ability. Such attribution of success to individual both ignores the systematic advantages and disadvantages for particular groups of children as they navigate the education system and actively creates further advantages and disadvantages for those groups.

Situated cognition has sought to challenge such outcomes through offering an alternative approach to teaching mathematics (e.g., Boaler, 2001). This is based on wider literature which suggests that mathematics in 'real-life' is not well supported by the mathematics taught in school (Carraher, Carraher, & Schliemann, 1985; Lave, 1998). However, I argue that situated cognition does not go far enough to explore the systematic failures children experience in schools. By placing a particular emphasis on primary schooling as the site of rapid development of number sense, I argue we need to broaden our view of number sense and that a Bourdieusian framework is useful in this context. Such a perspective allows us to explore how children are being sorted by their 'ability' in number sense in this very early stage of education, which becomes a self-fulfilling prophecy of how well children will achieve in mathematics throughout their education.

The purpose of this paper is therefore to offer a theoretical contribution regarding the examination of this development of number sense. Before outlining the contribution of the different theoretical perspectives, I begin with a short discussion of the construct of number sense.

NUMBER SENSE

Number sense is a term widely used in educational literature, curriculum documents and other academic fields such as cognitive psychology. In terms of education, as Greeno (1991) comments, although the concept is not defined well, we recognise it when we see it. Largely, the child's "fluidity and flexibility with numbers" (Gersten & Chard, 1999) is useful as an educational definition of number sense in primary education, although this is a much boarder definition than that usually employed in cognitive psychology. As I work through the theoretical positions of cognitive psychology, situated cognition and Bourdieusian social theory I demonstrate the aspects of number sense each focusses upon. I use this to illustrate the utility of a Bourdieusian analysis to highlight the structural inequalities that the concept of number sense reproduces through the education system.

COGNITIVE INFLUENCES ON NUMBER SENSE

Cognitive psychology offers a conception of number sense based solely on enumeration of numerosity. Within this definition mechanisms underlying numerosity discrimination continue to be explored. In general two systems for processing numerosity are proposed: subitising and approximate number recognition. The assumption I read from this literature is that these systems are taken to be innate, building on specific neural pathways. Xu & Spelke (2000) suggest that number sense develops spontaneously and have demonstrated how children as young as six months can discriminate between sets of two and three. Halberda & Feigenson (2008) demonstrate that this numerical discrimination improves rapidly throughout infancy and then continues to develop until approximately the age of thirty, suggesting the presence of a developmental mechanism. Finally, Feigenson, Libertus, & Halberda (2013) demonstrated a correlation between the accuracy of enumeration and individual mathematical ability as recorded in school attainment data, which was found to be reliable even when applied retrospectively across school records. Together, such data suggests an innate developmental mechanism which allows improvement in number discrimination and that this skill may be linked to formal achievement in mathematics. Such a perspective is influential on the development of primary school mathematics curricular (e.g., DfE, 2013) which replicate these proposed hierarchical mechanisms; early counting practices in particular are heavily influenced by work on the way children 'develop' counting skills (Wynn, 1990). There is suggestion however, that a curriculum based on developmental stages is outdated (Goswami, 1991), yet the pervasiveness of such a model remains within the education system.

I argue that a view where an innate capacity underpins mathematical learning can lead to a view that individuals have a particular 'mathematical ability'. It can also lead to a view that certain people will be able to learn mathematics better or worse than others. This is to some extent a mis-use of the cognitive literature, and indeed educational neuroscience is working to address such a misconception through work such as that by Howard-Jones (2007) which looks to examine how neurological evidence can be used to enhance the learning experience, rather than restrict it. What is important when reflecting on the dominance of such cognitive theories on the learning of number sense, is not simply how well the definition describes the concept, but to interrogate the effect of the concept on practice (Henriques, 1984). Thus, despite greater understanding of flexibility of neural pathways in learning, a fixed ability mechanism is common in mathematics learning (e.g., Marks, 2014). We attribute individual differences in mathematical attainment to differences in individual abilities and this becomes a self-fulfilling prophecy.

It is simple to see how such a situation operates in practice. For example, although there is no definitive list of skills, number sense is recognised when it is demonstrated (Greeno, 1991) – or perhaps when a 'lack' of it is shown. When children appear not to have mastered a particular aspect of this body of knowledge, say number bonds, this is identified as a 'gap' in their knowledge. Such children are given further time and additional practise to acquire this skill, contrary to the evidence that such an approach may not in fact allow them to develop the skill being targeted (Denvir & Brown, 1986). Thus children without the necessary number sense experience a curriculum of practice and repetition (e.g., Gersten & Chard, 1999). In contrast to this, children who experience success are given more advanced work, further extending their attainment. The achievement gap in mathematics is known to widen through primary schooling and such a model for teaching and learning begins to demonstrate a possible mechanism for this.

A further difficulty with operating in this paradigm to try and 'fix' number sense is that children are likely to be labelled. Those who need further practise of the basic number sense skill are then considered to be 'low-ability'; they do not have the required skill. Those who do have it are considered better. Not only then do the 'low-ability children get a narrowed curriculum, there is a high risk that they view themselves as unable to learn mathematics and have the associated difficulties of such a label, for example low self-esteem and low motivation. This aspect of identity will be referred to through the work of situated cognition.

Whilst cognitive psychology continues to provide us with increasingly sophisticated techniques to investigate and understand the neural basis of learning, over-emphasis on this paradigm may lead to a narrowed curriculum, particularly for those children who experience mathematical difficulties.

SITUATED COGNITION

Situated cognition offers an interesting lens through which to view number sense due to the discrepancies observed in formal and informal arithmetic. For example, Lave (1988) demonstrates how adults were able to use mathematical information in informal settings such as the supermarket to make 'best-buy' calculations and purchases. However, when the same scenario was presented as a 'pencil-and-paper' calculation, much like a school setting, the individuals often failed. As Greeno (1991) proposes, part of the concept of number sense is the ability to make connections and draw across different number concepts. In Lave's (1988) study this was largely attributed to the formal setting causing the individual to turn to the use of an algorithm which was then not successfully remembered or executed. I offer this as an interesting perspective on number sense as the presentation of a calculation seems able to affect the way an individual engages with it.

Situated cognition addresses this by proposing that mathematics as it is 'traditionally' taught in schools does not represent the mathematics used in real-life. McIntosh, Reys, & Reys (1992) state how as students increase their technical procedures in mathematics, they may in fact narrow their range of available strategies. If informal strategies are more generally called upon in 'real-life' mathematics then it is easy to see how procedural teaching limits the way mathematics is of use to people beyond school. The work of Boaler (2001) has shown improved attainment through working on 'real-life' problems in context. Not only did the children report that such problems made the mathematics they learned more relevant to their wider lives, the young people achieved more highly in formal testing than other students with higher prior attainment. Another important outcome was a reduction in the way girls were 'excluded' from mathematics.

The focus of Boaler's (2001) work is on the high school context. Whilst this work is important in understanding older pupils' engagement with mathematics, the concepts it addresses are ones I argue build on number sense. Children often report much greater dissatisfaction with mathematics at secondary school where they fail to see the relevance of the topics to their lives. This is not usually the case with primary school mathematics as the concepts involved are in fact largely 'number sense' and such learning is generally regarded as important by young people (e.g., National Audit Office, 2008). To solve more challenging problems requires prior learning; aspects of number sense need to be automatic to allow mental effort to be focussed on the more complex aspects of problem solving. If some calculations are not automatic, or at least fluent, then focussing on specific calculations becomes time consuming and distract from the wider task in hand. Situated cognition identifies this dilemma, where people cannot connect calculations presented in a particular format to one in which they are able to solve such a calculation, they cannot demonstrate the "flexibility" expected of number sense (Gersten & Chard, 1999). This again returns us to a cognitive paradigm of rehearsal and repetition of skills before moving onto more complex problem solving; it is just such a requirement to have fluency with basic calculation that leads to a narrowing of the mathematics curriculum for children struggling to demonstrate these skills.

Askew (2008) argues that it is not simply learning which is situated in mathematics, but that social identities in classrooms are also situated and that normalised routines of the classroom lead to maintenance of inequalities. Including social identity as an element of the situated nature of mathematics learning does broaden the context and it is important to examine the way children develop such identities in relation to mathematics learning. Number sense is well placed to allow such an analysis. Number sense as a cognitive domain where we make sense of situations and different contexts (Greeno, 1991) is likely to be influenced by how we feel in the situation, previous experiences and the response of others both to us and to our ideas – in short our mathematical identity.

Why, then, do children experience the same mathematical environment in such different ways? Situated cognition poses this as a challenging question. In order to begin to address this, I propose that a Bourdieusian perspective allows us to examine wider societal factors influencing the learning of mathematics, the cultural influences of the school environment and the school within its broader environment. We can appreciate that some children have already been excluded from learning mathematics by assessment of their number sense early in their schooling. I now turn to Bourdieu to develop this broader perspective in the role of number sense development.

BOURDIEUSIAN PERSPECTIVE

Viewing number sense with a Bourdieusian lens allows us to see this number sense not only as a body of facts, but as a way in which we interact with mathematical information. Bourdieu's method offers a set of conceptual tools through which to examine practice, namely field, habitus and capital. These concepts can be used to examine the way number sense is constructed demonstrating how it excludes particular groups of children.

Field

A field is defined by Bourdieu as "a universe in which the producers' characteristics are defined by their positions in relations of production" (Bourdieu, 1993, p. 51) and is considered a site of competing interests (Green, 2013); and as such 'primary mathematics education' is conceptualised as a field in this sense. Mathematics education is often used as a field in such analyses as it has a particular language, specific expectations and outcomes (Jorgensen, Gates, & Roper, 2013). Proposing primary mathematics education as a field allows the range of external and internal influences to be analysed. The nature of the British education system which separates largely primary and secondary schooling – at age 11 – further exacerbates the hierarchical nature of mathematics education. My suggestion is that primary school mathematics is largely seen as a gatekeeper to secondary school mathematics, and within this, number sense is a gatekeeper to the wider range of skills that allow one to access the wider curriculum to make success in primary school a possibility. Therefore, by conceptualising primary school mathematics as a field using Bourdieu's terms appreciate the expectations, barriers and opportunities presented by the system can be appreciated.

By conceptualising primary mathematics as a field, we can look beyond the classroom as the only site in which such skills are developed and thus have greater explanatory scope and power than the work of situated cognition. Children clearly develop much mathematical knowledge and understanding beyond the classroom, arriving at school with highly varied experiences. Whilst situated cognition begins to address the need to make mathematics learning relevant to 'real-life' it is not able to address the diverse contexts from which children are learning mathematics. In particular it is not able to explore the dissonance that children from lower socio-economic backgrounds experience between their home learning environments and that of the school. For example, the work of Street, Baker and Tomlin (2008) showed how children may have rich mathematical experiences at home, through activities like pigeon racing, but that the knowledge and experience that this provided the children was not reflected in the school environment. The Bourdieusian framework permits the competition between the recognised and the un-recognised styles of mathematics to become apparent.

Habitus

Habitus is a term used by Bourdieu to define the taken-for-granted way in which we act; a person's natural manner or disposition (Bourdieu, 1989). This is more than a set of preferences as habitus is operationalised by class, gender and race (e.g., Reay, 1998). Habitus is shaped throughout one's early socialisation and is well established by the time an individual enters education. Habitus is stable and durable, yet can be shaped, for example through education. Thus we can learn to act and operate in new ways, but our early socialisation never leaves us. Bourdieu expresses the way that early socialisation has such a powerful influence through concepts such as 'manners' or ways of acting in particular situations (Bourdieu, 1984). This is exemplified through the confidence that is acquired through 'growing up around' something, knowing 'intuitively' how to act and the confidence this brings, rather than having to learn it and being painfully aware that it is quite possible to make the wrong choice.

Considering number sense in such a framework highlights the inequalities that exist in the education system. Children who experience a home environment which is rich in number experiences – with parents who are confident and highlight numerical experiences – are likely to enter school with a greater awareness and confidence with numbers themselves. They have an apparently 'innate' confidence with numbers, which is mis-recognised as an 'innate' ability. Those children who do not have such opportunities appear as less able. Number sense is particularly suited to this explanation where it is seen broadly as the connected way of thinking about numbers, as linking different aspects of number, rather than solely elements of mathematics such as number bonds or multiplication facts. The way it privileges children becomes clear. Those children, who are used to working within the context of such number sense, used to talking about numbers in a confident way, will demonstrate 'ability' in school. Those who are not used to the language of mathematics (Walkerdine, 1989) are mis-recognised as 'low-ability' and thus excluded.

Habitus, is at home in the "field it inhabits" (Bourdieu, 1992, p. 128) thus the habitus of the middle classes, which aligns well with the expectations of the education system positions them to excel. From this Bourdieu argues that achievement becomes self perpetuating preserving the hegemony of dominant classes. Middle class discourses are largely in line with school discourses and the increased ability of such families to prepare their children for school allows them to take every opportunity offered by the education system. It is the available resources of the middle classes in Bourdieu's opinion which can readily be converted into academic achievement; such resources are considered to be capital as outlined below.

Thus, habitus can offer itself as a tool to examine the development of number sense. How does a child's habitus impact learning through development of their mathematical identity? The final tool to which I now wish to turn is cultural capital as a way to further explore how habitus can advantage and disadvantage different groups of children.

Capital

Capital is the outcome of the combination of habitus and field. Bourdieu defines different capitals of which cultural, economic and social capital are of relevance here. As stated, children bring varied experiences of learning mathematics to school with them and particular cultural experiences offer educational advantages to a child. It is the ability of those from higher socioeconomic backgrounds to utilise their economic capital to offer increased cultural capital which offers the systematic advantage such children experience in school.

What Bourdieu argues is very important in this transition from economic to cultural capital is the misrecognition of the conversion; that a child with such cultural experiences is better placed to learn mathematics is not recognised in the education system. Schools attribute being well placed to learn as being more 'able'. We know who is well placed to learn from our assessment of the children in school. Such educational assessment whilst pertaining to assess a child's 'ability' and to shape subsequent schooling, is in fact measuring wider socialisation. Habitus is exchanged for a culturally-valued outcome in the specific field, in this case achievement in mathematics, and the individuals increase their cultural capital.

CONCLUSION

A Bourdieusian analysis allows a wider conception of number sense – with number sense acting as a sorting device itself for participation in mathematics learning more generally. Thus children 'with' a habitus which fits well with the mathematical expectations of the education system are mistakenly considered able, whilst those with a poorly-aligned habitus are not. The consequence for this latter group, predominantly those from lower socio-economic backgrounds, is a message about their own 'ability' to learn mathematics and an altered curriculum which is repetitive and narrow – in order for them to 'fill gaps' in their learning. Such an approach, whilst well meant and standard practice in primary schools, is a form of 'symbolic violence' (Bourdieu, 1986) enacted upon children from lower socio-economic backgrounds. Number sense, mistakenly viewed as individual ability, shapes children's mathematical futures and potentially their life chances, from their earliest engagement with mathematical learning.

Teacher training through research in ethnomathematics

Veronica Albanese[1] and María Elena Gavarrete[2]

1 Universidad de Granada, Facultad de Educación, Granada, Spain, very_alba@hotmail.it

2 Universidad Nacional, Heredia, Costa Rica, marielgavarrete@gmail.com

Two experiences in primary school teacher education are reported. Both of them are based on Ethnomathematics understood as a tool to reflect about the ways of doing mathematics of two cultural groups. Geometric figures are built in different way by the two cultural group analyzed: a group of folk dancers of Argentina and an indigenous people of Costa Rica.

Keywords: Ethnomathematics, teacher education, cultural practice, geometric figure.

INTRODUCTION

We report two experiences performed with primary school teachers respectively in Argentina and Costa Rica, where it was proposed to use Ethnomathematics as a tool to promote professional teacher development through a process of reflective inquiry about the ways of doing and understanding mathematics (ethnomathematics) of a cultural sign of the cultural groups involved: the guild of Argentine folk dancers and the Cabecares, an indigenous group of Costa Rica.

METHODOLOGY

Both works consist in organizing a course for the training of primary school teachers, where we propose the development of Ethnomathematical Microproject (Oliveras, 1996). These include the identification and characterization of ethnomathematics in a cultural sign of the group chosen, to develop contextualized teaching activities to be presented in the classroom of primary education. The objective was to engage teachers in a research about the ethnomathematics embedded in the cultural practices in each context and to identify its relationship with academic-formal mathematics.

In both countries we organized a course for teacher training, which promotes the research on the context through micro ethnographies realized by the participants of the courses. The data collected consists of the reports of the Micro-projects and the audiovisual recordings of the course session.

SOME RESULTS

The cultural signs studied were the folk dance *chacarera* (Argentina) and the traditional conical House of the *cabécar* culture (Costa Rica). We highlight here the participants' observations about the ethnomathematics found in the cultural signs and about the relations and differences with academic and formal mathematics.

In the dance *chacarera* the participants focus on the geometric figures that outline the choreography and they observed that the circumference is associated to the movement of steps that include a turn of the body on itself for folk dancers, while in school mathematics, it is defined by an equidistance of all points in relation to a center. In fact the same steps in the figure called *avance retroceso*, which does not involve a rotation of the body on itself, are represented by a diamond, while the figure called *giro*, where a rotation is involved, is represented by a circular line; this is the evidence that the teachers provide for the hypothesis that dancers resemble the circular line to the rotation of the dancer's body by a round shape without corners. Thus we conjecture that the circumference of the guild of the dancers is conceived as a regular polygon that tends to have no angles (Albanese and Perales, in press).

The *cabécar* traditional conical house is called *Ju-Tsini* and is itself a system of cosmological representation where elements of the cultural heritage and particular geometric concepts of the group –a specific logic and a particular way of localizing- join together, since, in this ethnic group, the physical world serves as a system to represent the mythical world (Gavarrete, 2012). The participants identify the construction of the *Jú-tsiní* as a powerful and contextualized example to work with pupils concepts related to the solid corps, as symmetry (axis of symmetry and homologous points). The circle is drawn using a center pole, this means that here the conception of circle is associated to the distance from the central point. The space is represented by the union of a cone and an inverted cone, whose circular bases overlap and therefore have the same axial center, resulting in the model *Nopatkuö* which describes the three cosmic levels of the legendary tradition of the ethnic group. This specular model represents the dual opposition of elements. The principle of complementary opposition is equivalent in school mathematics to that of symmetry even if in this culture it has an added value of cosmological meanings.

CONCLUSIONS

In both countries, the research experience impacted the teachers training, as they reflected on the universality of mathematical knowledge and teaching applications, promoting teacher creativity to facilitate the developing of the mathematical curriculum in connection with the sociocultural environment.

Power-relations in participatory action research project in mathematics education

Lisa Björklund Boistrup[1,2] and Joakim Samuelsson[1]

1 Linköping University, Linköping, Sweden

2 Stockholm University, Stockholm, Sweden

The purpose of the study presented in this poster is to examine characteristics of power relations between researchers and teachers in an action research project. We position the study within a critical and social approach and pay attention to inequities that may concern power relations between researchers and teachers in an action research project (Skovsmose & Borba, 2004). We draw on Gellert (2008) who argues that if "professional development of mathematics teachers is considered a collective affair, then the concepts used to describe the teachers' actions and cognitions should reflect this perspective" (p. 94). We also draw on Atweh (2004) when we problematise "the process of research itself and critiques it in terms of power relationships between the participants" (p. 194).

Keywords: Mathematics classroom, action research, power relations.

ANALYTICAL FRAMEWORK: PARTICIPATORY ACTION RESEARCH

In our analysis we adopt a description by Atweh (2004), where participatory action research is characterised as:

— a *social activity*. This research always recognizes the broader institutional context as part of the process, for example the municipalities or colleagues etc.

— a *participatory* action research. This research engages teachers and researchers to investigate their own knowledge and actions. A consequence is that people can only carry out action research 'on' themselves. It is not research done 'on' others. Emphasised here are the conditions for the research in which teachers should be given the opportunities to fully participate in research.

— research which involves *collaboration* where teachers and researchers engage in research together. Everyone in the project strives towards developing her/his own professional competence with the support of each other. The collaboration may also include cooperation with people who are linked to, but not directly involved in, the research project.

— research which is *emancipatory*. Participatory action research may afford teachers to see and analyse the mechanisms that put limitations to their work as mathematics teachers.

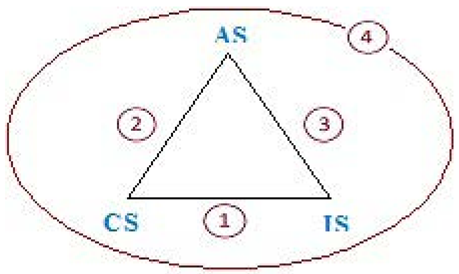
— research which is *critical*. Included here is that the research itself seeks to challenge a mathematics teaching that do not provide equal opportunities for all students to learn mathematics.

— research which is *reflexive* in that it goes in two directions. The participants in the research investigate their practice, *and* they also aim to change it.

METHODS AND FINDINGS

This is a case study where we reanalysed data from an action research project with a specific interest in power relations between teachers and researchers. The data consist of participants' logs. We also analysed audio recordings from three of the meetings in the project as well as notes from these meetings.

In the action research project, a model by Skovsmose and Borba (2004) was adopted with an addition by Björklund Boistrup and Norén (2013), see Figure 1.



CS: Current situation
IS: Imagined situation
AS: Arranged situation
1: Pedagogical imagination
2: Practical organisation
3: Explorative reasoning
4: Scrutinising the institutional context

Figure 1: (Skovsmose & Borbra, 2004) plus (4) from (Björklund Boistrup & Norén 2013)

This model frames our account of the findings that is presented on the poster while we also use the mentioned characteristics by Atweh (2004) as analytical concepts. One finding we elaborate on is how teachers went from acting as observing participants towards participatory researchers during the project, while the responsible researcher went from research leader towards a facilitating participatory researcher. Simultaneously there were constraints identified in the institutional context which affected the affordances for participants to take on new roles.

Mathematics in agriculture and vocational education for agricultures

Karolina Muhrman

Linköping University, Department of Behavioural Sciences and Learning, Linköping, Sweden, karolina.muhrman@nbg.nu

This paper presents some of the results from a research study about mathematics in agriculture and agricultural education. The purpose of the study is to investigate the role of mathematics as a professional knowledge, and how to organize vocational secondary school education so that students receive the math knowledge and skills they need for their future profession. The study is done from a curricula theoretical perspective with concepts from Bernstein (2000). The results indicate that mathematical skills are essential for a professional farmer, but according to those interviewed, many agricultural students have deficient mathematical skills for their future profession after their education.

Keywords: Mathematics, workplace, agriculture, vocational education, Bernstein.

INTRODUCTION

In Sweden it has in recent years been pointed out from various professions that vocational students do not have the desired or adequate mathematical skills for the professional life after their education. Based on that I found it interesting to study the reasons for vocational students to learn math, which math skills the professionals deem most important, how this is reflected in the school's math education and also how the students' mathematical knowledge affects their future career possibilities within their profession.

THEORETICAL FRAMEWORK

The study is done from a curricula theoretical perspective with concepts from Bernstein (2000). Bernstein's pedagogical codes, classification and framing and his theory of discourses is used to analyse how the curriculum is realized in mathematics education and how this may affect students' professional career.

METHOD

To answer the questions, I have in the winter of 2012 and the spring of 2013, done interviews with 15 professional farmers, 13 vocational teachers in agriculture, 11 mathematical teachers who teach agriculture students and 40 secondary vocational agriculture students. The students are interviewed in focus groups. The teachers and students come from eight different schools with vocational education in Sweden.

RESULTS

The results indicate that mathematics is an essential professional skill for farmers because they use mathematics all the time. Farming profession is today very advanced and as a farmer you do not only have use of practical skills. The farmers that I interviewed gave examples of 54 different job tasks that require skills of mathematics. Many of the farmers also said they do not want to hire someone who doesn´t have sufficient skills of mathematics since miscalculations can mean costly mistakes. The farmers claimed that they did not need any advanced skills but that they must have very good basic mathematical knowledge, since there is often advanced applications of the mathematics (cf. Fooreman & Steen, 1995). It is mainly the areas of percent, geometry and statistics that farmers need to have knowledge about. Farmers must also be very good at mental calculation, rough calculation and plausibility assessments.

The interviews revealed that many students did not really seem to understand the importance of learning mathematics and they claimed it to be boring. Students' lack of motivation to learn mathematics results in deficient mathematical skills to handle the calculations appearing in the profession. Lack of mathematical skills also results in that many students do not pass the professional certificates available in agriculture. To learn the required mathematics of the farming profession, many of those that were interviewed advocated that mathematics- and vocational classes should be largely integrated, and that even the professional farmers should be responsible for teaching mathematics. Students working with an integrated mathematics education say that it gives them more motivation, they learn better, and understand and remember more, when it's related to their reality. Using concepts from Bernstein, an integrated code was requested with a more a context-bound and horizontally organized mathematics teaching. But most of the schools in the study has what Bernstein calls a strong classification, where the school mathematics is clearly separated from other subjects and from work outside of school. At these schools the teachers have no or little cooperation with each other. Hierarchies and power relations described by Bernstein between different categories of teachers, were found to be prevalent. In order to enable an integrated code both the teachers and the school management must agree. An easy way to create a collaboration between vocational- and mathematics teachers, and thereby increase an integrated mathematics education, seemed to be to let these categories of teachers have a shared office space.

Discussing teaching/learning methods in a complex educational context

Alessandro Spagnuolo and Michele Canducci

University of Ferrara, Department of Mathematics and Computer Science, Ferrara, Italy, spglsn@unife.it

This paper describes the state of research concerning an international instruction collaboration between Italy and Tanzania. During the last five years of the project it has been possible to detect some of the educational aspects that might have a negative impact especially regarding mathematics. Starting from this analysis, it was elaborated a peer education proposal as a possible didactic methodology suitable to be used in the school context. Research was made and the last results show that the aforementioned methodology could be particularly useful in this specific educational environment.

Key words: African secondary education, peer education, CLIL, complexity.

INTRODUCTION

Since 2010 the Akap association (Italy), has brought together a group of researchers in mathematics education from the University of Bari, Bologna and Ferrara and teachers at Daudi Secondary School (Tanzania). Each year a meeting among these teams is organized in order to discuss and experience learning opportunities for Tanzanian pupils which respects the many interrelated factors operating within the school context.

THEORETICAL FRAMEWORK

Mathematics is recognized as important by governments all over the world. Why is it so important to teach it? Many reasons are provided and debated by influential people, both in mathematics education but also in government organisation. In many countries so-called "underdeveloped", is still frequently the opinion that school systems must teach content that in the past were decisive factors in the industrialisation of "developed" countries, without thinking on the historical, social and cultural reasons behind their inclusion. Instead it has been suggested that the goal for "under-developed" countries is not to get where "developed" countries are today, but to develop and build a educative model that is appropriate for the social organization, based on ethical values which seek the common good (D'Ambrosio, 1997).

1) The data analysis published by the Tanzanian Ministry of Education and Vocational Training [MoEVT] at the end of the first "Secondary Education Development Programme" (June 2010) showed a progressive decrease in the number of students promoted in the two main national examinations: the PSLE (Primary School Leaving Examination) and the CSEE (Certificate for Secondary Education Examination).

2) Our investigation focuses on promoting quality in the education offered within a particular context in Tanzania, characterized by specific social, cultural and political factors. Through studying the MoEVT official documents and a collection of testimonials from Tanzanian teachers and students, we became aware of the complexity[1] of the issues regarding teaching in an environment so different from the European one. Some of the issues that the teachers had to contend with were: overcrowding classes; lack of textbooks and teaching aids; English as the language of instruction instead of Swahili mother tongue; poor teacher recruitment program. Consequently, the teams developed a peer education proposal for this specific context. According to Cooperative

1 We thought that the theory of complex systems in social sciences could allow us to manage the multiple dynamics between the components of the project, through a dialectic that goes continuously from the global to the specific. The main idea is that acting on a component means acting on the whole system, with a retroactive view

Learning Theory (Johnson & Johnson, 1980), there are many reasons to investigate this methodology: improvement in all students' academic performance; increased motivation to study, due to the development of psychological well-being and a positive climate into the classroom.

MAIN RESEARCH RESULTS

The latest results show that a peer education program could be particularly useful in this school. The mathematics workshops carried out in 2014 confirm the usefulness of a teaching approach based on social mediation for Daudi Secondary School. The division of the students into groups, the organization of specific roles assigned to each member and the use of appropriate working schedules seem to overcome the problem of the high number of students in each class and to involve each pupil in all of the planned activities. The possibility of discussion within the groups has led the students to overcome language barriers related to the use of English and to develop skills in critical reasoning and understanding mathematics.

No reason to believe in numbers: Using a commercial for making ethical filtration visible

Hauke Straehler-Pohl

Freie Universität, Berlin, Germany, h.straehler-pohl@fu-berlin.de

This poster illustrates how an exercise of ideology critique can employ a commercial for making ethical filtration visible in the context of Critical Mathematics Education.

Keywords: Critical mathematics education, ideology critique, ethical filtration

CONTEXTUALIZATION IN CRITICAL MATHEMATICS EDUCATION

We are living in a mathematised world. More and more aspects of social live are penetrated by mathematics-based technologies. As Davis and Hersh (1986, p. 17) make us aware, "we should observe these developments critically, as they could do damage to all of us". This accounts *a fortiori*, as the trend of mathematisation is accompanied by a simultaneous trend of demathematisation: while mathematics becomes more and more pervasive in all spheres of life, it vanishes more and more from the surface and becomes more and more invisible (Jablonka & Gellert, 2007). The emergence of Critical Mathematics Education (CME, e.g., Skovsmose, 1992) has brought critical attention to the role of mathematics in our world. The demand for critical awareness has in the meantime grown beyond the boundaries of CME and has reached the mainstream of Mathematics Education (ME). That school mathematics *must* contribute to critical citizenship has become common sense within the field of ME (Pais, 2012). As it appears, what has been lost on the way is the care for the *limits* of mathematics for handling socially critical issues – the juxtaposition of potentially more relevant non-mathematical strategies and their sincere consideration (Skovsmose, 1992). It appears that the problematizing of socially critical issues within the mathematics classroom tends to structurally prioritize strategies that make use of mathematics. Skovsmose (2008) has described and de Freitas (2008, p. 87) has further analysed this effect as *ethical filtration*: "the agent [...] reduces the complex ethical and political situation to a set of abstract parameters which are then combined into a simplifying model primarily used for prediction. According to Skovsmose (2008), ethical filtration is built into the practice of mathematics in action". She complements that "mathematics education *actually* teaches students to enact ethical erasure so as to successfully generate solutions that seem unambiguous" (p. 88). A truly CME makes this ethical filtration visible and – where necessary – promotes support to put mathematics back to its refined place.

CONTENT OF THE POSTER

The poster suggests an activity that reverses the process of ethical filtration by carrying out an ideology-critique that problematizes the improper use of numbers – improper in this case is not meant as a use of "wrong" numbers, but that the use of numbers itself is a dead-end for the social issue under question. The poster illustrates how the philosophy of Slavoj Žižek (e.g., 2008) can serve as a means to deconstruct the improper instrumentalisation of numbers for a rankly capitalist interpellation. In a first step, the poster illustrates how cultural capitalism simultaneously installs the contradictory imperatives of a) acting sustainable and b) increasing consumption, and hereby releases an unconscious feeling of guilt within the interpellated subject. Then the poster illuminates how the commercial instrumentalises this unconscious feeling of guilt in order to be able to promise liberation from this guilt - through consumption. In a third step the poster illuminates the role of numbers in the construction of the commercial's message. It shows, how the success of the commercial is dependent on the effect that the viewer believes in the fantasy that the numbers are indeed relevant and yet simultaneously maintains a critical distance to the numbers – as taking them as actual facts that really have a meaning would lead to disintegration of the entire commercial's appeal. In a fifth step the poster proposes "over-identification" (Žižek, 2008, p. 29) as a pedagogic strategy that treats the numbers and numerical relations that are employed in the commercial as if they were *actually real.* This leads to a reversal of ethical filtration, as the initial ambiguity of the complex social problem is brought back into light and further reveals the cynicism that is implicated in the advertising campaign. Finally, over-identification is proposed as a pedagogic strategy that allows for bringing social and political issues into the mathematics classroom, without stepping into the trap of ethical filtration.

Mathematics diagnosis and support: Sensitivity of pre-service teachers to social disparities

Vivica Zweidar

University of Bremen, Bremen, Germany, vivica@math.uni-bremen.de

Mathematical diagnosis and support require a high level of professional expertise from teachers. However, profound subject knowledge and the awareness of pupils' processes of learning mathematical concepts and strategies are not sufficient for appropriate diagnosis and support. Raising teachers' awareness of hidden mechanisms of discrimination within the practice of diagnosis and support could be a valuable contribution in the struggle for more educational equity.

Keywords: Diagnosis, support, Numeracy Project, pre-service teachers, sensitivity.

THEORETICAL BACKGROUND

In the organisation of pupil-centred teaching and learning in school, diagnosis and support play a significant role. Diagnosis means for teachers that they need to recognize pupils' current knowledge and proficiencies (Wartha & Schulz, 2012), so that they can appropriately foster learning. This fostering by a teacher can be labelled 'support'. In the mathematics classroom, teachers are faced with the challenge of using mathematically and didactically appropriate methods of diagnosis and support, while at the same time bearing in mind the heterogeneity of the pupil body. This contribution focuses on teachers' reflectiveness using mathematical diagnosis and support materials from New Zealand's "Numeracy Project (NP)" in a German classroom.

In a quantitative study by Irwin and Irwin (2005), children from lower socioeconomic backgrounds were shown to benefit less from diagnosis and support with NP materials compared to children who were ranked more highly on a socioeconomic scale. My contribution focuses on how sensitive prospective teachers are to both subject-specific and generic aspects of social heterogeneity. Generic perspectives in particular, such as language or contexts in problem statements, may appear insignificant for mathematics teaching at first glance. They can, however, become relevant in mathematical diagnosis and support (e.g., Cooper & Dunne, 2000; Jablonka & Gellert, 2010), and lead to discrimination against certain pupil groups, or at least put the adequacy of diagnosis and support tools for them into question.

The overall hypothesis I adopt is that attitudes and behaviours of teachers are crucial for effective, pupil-oriented education. Against this background, not only teachers' subject-related levels of proficiency concerning tools of diagnosis and support are important, but also their awareness of potential discrimination. This discrimination within diagnosis and sup-

critical, reflecting dimension (relating to the NP materials)	high awareness of socioeconomic and social bias	SOCIOCRITICAL SENSITIVITY	MULTI-PERSPECTIVE SENSITIVITY
	no/low awareness of socioeconomic and social bias	NO/LOW SENSITIVITY	SUBJECT-ANALYTICAL SENSITIVITY
		no/low awareness of the NP material's design and goals	high awareness of the NP material's design and goals
		subject-specific (mathematical, mathematic educational, pedagogical) dimension	

Table 1

port can take place by treating unequal individuals identically as well as by treating equal individuals differently (Gomolla & Radtke, 2009).

MY RESEARCH

For the purpose of my research I conducted five guided interviews with pre-service teachers from the University of Bremen who diagnosed and taught pupils in a German school with translated NP materials.

The analysis of the interviews revealed that most pre-service teachers showed mathematics education-related sensitivity to a certain extent and at the same time almost no awareness of socioeconomic and social bias in the NP material. They were not even aware that language plays a significant role in the NP and that language can be a filter to allow access to certain practices in the mathematics classroom exclusively to particular groups of pupils. All interviewed pre-service teachers had to be placed in the 'sensitivity-matrix', as shown above, in the field of 'no/low sensitivity' or at best in the field of 'subject-analytical sensitivity'.

TWG11

Comparative studies in mathematics education

Introduction to the papers of TWG11: Comparative studies in mathematics education

Paul Andrews[1], Eva Jablonka[2], Arne Jakobsen[3] and Constantinos Xenofontos[4]

1 Stockholm University, Stockholm, Sweden, paul.andrews@mnd.su.se

2 King's College London, London, UK, eva.jablonka@kcl.ac.uk

3 University of Stavanger, Stavanger, Norway

4 University of Nicosia, Nicosia, Cyprus, xenofontos.c@unic.ac.cy

As with earlier CERMEs, TWG11 adopted an eclectic perspective in its interpretation of comparison as referring to any study that documents, analyses, contrasts or juxtaposes cross-cultural or cross-contextual similarities and differences across all aspects and levels of mathematics education. In this way, the TWG aimed to encourage critical but supportive discussion that would enable colleagues to:

- share findings and outcomes of empirical studies that adopt a comparative approach;
- outline the delineation of comparative and non-comparative research;
- develop and refine research methodologies specific to comparative studies;
- explore the interaction of macro-level survey studies and micro-level case studies;
- understand how various theoretical approaches and conceptual frameworks shape the goals and the design of comparative research;
- understand how comparative studies can inform teaching and learning practices;
- understand the role of culture in the construction of mathematics teaching and learning

A recurrent but very productive aspect of this working group has been the relatively small number of paper presentations. This year thirteen papers created space not only for colleagues to share their research in some detail but allowed participants to engage in lengthy and inclusive discussions on the nature of comparative mathematics education research and the means by which it can be meaningfully and rigorously undertaken. The papers, along with two posters, were themed in various ways, highlighting significant substantive and methodological variation. However, two theoretical papers provided an interesting and provocative introduction and conclusion to the sequence of papers. The introduction being Jablonka's "rationales for comparative classroom studies in Mathematics education" and the conclusion being Clarke's examination of "the role of comparison in the construction and deconstruction of boundaries". Between these bookends five themes were examined by means of papers and posters authored by colleagues, due to their nationality or current professional location, representing Australia, Austria, China, Cyprus, England, Finland, Germany, Ghana, Greece, Hungary, Italy, Japan, Kosovo, Poland, South Africa, Spain and Sweden.

Firstly, three papers offered differently conceptualised perspectives on how the intended curriculum is reified in official documents and school textbooks, particularly in contexts where the latter are regulated by the curriculum authorities. These were Vula and colleagues' analysis of the treatment of fractions in Kosovan and Albanian mathematics textbooks, Xenofontos and Papadopoulos' study of the ways in which the history of mathematics is incorporated into the lower secondary textbooks of Cyprus and Greece and Gosztonyi's comparison of the ways in which the "new math" permeated Hungarian and French mathematics education discourses.

Secondly, two papers and two posters confirmed that mathematics and the manner of its assessment is a cultural construction. The papers were Peng and colleagues' comparison of Swedish and Chinese teachers' perspectives on what constitute good national mathematics test tasks, Branchetti and colleagues' longitudinal analysis of the Italian national standardized mathematics tests. The posters, which were also discussed, were Lemmo's comparison of paper and pencil and computer based mathematics assessments and Bauer and colleagues' provocative appeal for teachers to unite in addressing the expectations of PISA.

Thirdly, two papers, investigating different aspects of mathematics affect, highlighted the paucity of research undertaken in African contexts and the frequent inappropriateness for use in those contexts of tools developed in the West. These were Bofah's demonstration of a reciprocal determinism between students' mathematics self-concept and achievement in five culturally diverse African contexts and Joubert's use of social media to examine the perceived causes of mathematics problems in England and South Africa.

Fourthly, two papers framed a discussion on the processes of mathematics. These were Saeki and colleagues' comparison of how Japanese and Australian students responded to a mathematical modelling intervention and Sajka and Rosiek's use of eye tracking technology to examine differences between different ability groups' approaches to mathematical problem solving.

Finally, two papers offered different methodological perspectives on the use of classroom video-recordings in comparative mathematics education research. These were Andrews and colleagues' exploitation of a foundational number sense framework to analyse learning opportunities for grade one students in Poland and Russia and Hommel and Clarke's analysis of how teachers, in four different cultural contexts, use questions to encourage students to reflect on their learning of mathematics.

In sum, the papers presented to the group reflected not only cultural diversity but also methodological pluralism, allowing a number of commonalities to emerge. Most presented studies aspired to data flexibility, with few being constrained by a priori theoretical assertions. Classroom processes have both form and function and a comparative study of one may transform the other. In comparative research the responsibility on the researcher to define adequately one's concepts and constructs is of great significance, particularly with respect to large scale tests of educational achievement. Lastly, in undertaking comparative research one should be mindful of the possibility of misapplying a set of culturally informed values.

Developing foundational number sense: Number line examples from Poland and Russia

Paul Andrews[1], Judy Sayers[1] and Gosia Marschall[2]

1 Stockholm University, Stockholm, Sweden, paul.andrews@mnd.su.se

2 Comberton Village College, Cambridge, UK

For a variety of reasons, children start school with differing number-related skills, leading to differences in later mathematics achievement. Such differences prompt the question, what number-related experiences are necessary if the first year of school is to prepare children appropriately for their learning of mathematics? In this paper, we discuss the development of an eight dimensional framework, foundational number sense (FoNS), that characterises those learning experiences. We then demonstrate the framework's analytical efficacy by evaluating episodes from two sequences of lessons, one Polish and one Russian, focused on the use of the number line. The results show that the FoNS framework is cross-culturally sensitive, simply operationalised and analytically powerful.

Keywords: Foundational number sense, grade one mathematics, Poland, Russia, number line.

INTRODUCTION

Evidence internationally shows that the depth of a child's number sense predicts later mathematical success (Aubrey, Dahl, & Godfrey, 2006; Aunola, Leskinen, Lerkkanen, & Nurmi, 2004). For example, basic counting competence has predicted later successes in, for example, Canada, England, Finland, Flanders, Taiwan and the USA respectively (LeFevre et al., 2006; Aubrey & Godfrey, 2003; Aunola et al., 2004; Desoete, Stock, Schepens, Baeyens, & Roeyers, 2009; Yang & Li, 2008; Jordan, Kaplan, Locuniak, & Ramineni, 2007). Also, under-developed number sense leads to later mathematical failure (Jordan, Kaplan, Ramineni, & Locuniak, 2009; Gersten, Jordan, & Flojo, 2005; Malofeeva, Day, Saco, Young, & Ciancio, 2004). Thus, understanding number sense and how it can be promoted seems a sensible goal.

However, despite its importance, number sense has been poorly defined (Griffin, 2004, not least because mathematics educators and psychologists work with different definitions (Berch, 2005). Indeed, "no two researchers have defined number sense in precisely the same fashion" (Gersten et al., 2005, p. 296). Over the last two years we have been working on overcoming this definitional impasse. At the same time, we have tried to develop a classroom-focused analytical framework that is simple to operationalise and sensitive to different cultural practices. In this paper, we summarise our progress before evaluating the framework, foundational number sense (FoNS), against case study lessons from Poland and Russia.

EARLIER WORK ON FOUNDATIONAL NUMBER SENSE

As indicated above, this paper draws on earlier work, including a paper presented at CERME8 (Back, Sayers, & Andrews, 2014). Since then our understanding of number sense in general and foundational number sense in particular has developed further. For example, our initial reading identified two broad conceptions of number sense. Today we argue for three, including the earlier two. The first, preverbal number sense, refers to those number insights innate to all humans and comprises an understanding of small quantities in ways that allow for comparison (Ivrendi, 2011; Lipton & Spelke, 2005). For example, young babies can discern 1:2 but not 2:3 ratios (Feigenson, Dehaene, & Spelke, 2004). The second, applied number sense, concerns those number-related competences that make mathematics sensible for all learners and prepares them for an adult world (McIntosh, Reys, & Reys, 1992). It underpins many curricular specifications and much of the material written on number sense (See, for example, Anghileri, 2000). Finally, the primary focus of this paper, is foundational number sense (FoNS). This comprises those understandings that require instruction and typically arise during the first year of school (Ivrendi, 2011; Jordan & Levine, 2009). Unlike preverbal number sense, it is something children acquire rather than possess. Unlike applied number sense, its focus is not a world beyond school but later arithmetical and mathematical competence.

When developing the FoNS framework, our intention was not to construct an extensive list of characteristic learning outcomes but a small set of simple to operationalise components amenable to cross-cultural application. Our view was that extensive lists of number sense components and typically comprising around thirty components (Berch, 2005), would be unwieldy. Consequently, we exploited the constant comparison approach of the grounded theorists. Articles and book chapters typically addressing grade one students' acquisition of number-related competence were identified. These were read and broad FoNS-related categories identified. With each new category, previous articles were re-examined for evidence of the new. This approach, placed, for example, *rote counting to five* and *rote counting to ten*, two narrow categories discussed by Howell and Kemp (2005), within a broad category of systematic counting. Among the works examined in this process were (Aubrey & Godfrey, 2003; Aunola et al., 2004; Berch, 2005; Booth & Siegler, 2006; Clarke & Shinn, 2004; Dehaene, 2001; Desoete et al., 2009; Gersten et al., 2005; Griffin, 2004; Howell & Kemp, 2005; Hunting, 2003; Ivrendi, 2011; Jordan et al., 2007; Jordan & Levine, 2009; Lembke & Foegen, 2009; LeFevre et al., 2006; Lipton & Spelke, 2005; Malofeeva et al., 2004; Noël, 2005; Yang & Li, 2008).

In this paper, we summarise these eight FoNS components before showing how they play out in two post-Soviet educational contexts. This is the third case study pilot of the emergent FoNS framework, undertaken to ensure its viability for a large scale international study. The first case study examined two teachers, one in each of England and Hungary, working with grade one children on number sequences (Back et al., 2014). The analyses, based on an earlier seven component FoNS framework, indicated not only that the original framework's categories were sensitive to culturally different classroom traditions but also that the ways in which the categories combined resonated with earlier studies' showing high levels of didactical sophistication in Hungary and, in relative terms, low levels in England. The second case study, involving two teachers, one in each of Hungary and Sweden, focused on the ways in which children were encouraged to acquire the skills of conceptual subitising (Sayers, Andrews, & Björklund Boistrup, 2014). In this case, the findings, based on the revised eight component framework, again showed a sensitivity to cultural context and highlighted well how different approaches to the same topic yield different FoNS-related outcomes, pertaining again to different levels of didactical sophistication. This paper reflects a third, and final, pilot evaluation of the framework. Before presenting the analyses, however, we present a summary of the eight components, which derived from the literature review described above. To avoid repetition and save space, each component is summarised independently of the literature on which it is based. The components of foundational number sense are:

Number recognition: Children recognise number symbols and know their vocabulary and meaning. They can identify a particular number symbol from a collection of number symbols and name a number when shown that symbol;

Systematic counting: Children are able to count systematically and understand ordinality. They count to twenty and back, or count upwards and backwards from arbitrary starting points, knowing that each number occupies a fixed position in the sequence of all numbers.

Awareness of the relationship between number and quantity: Children understand the correspondence between a number's name and the quantity it represents, and that the last number in a count represents the total number of objects, its cardinality.

Quantity discrimination: Children understand magnitude and can compare different magnitudes. They deploy language like *bigger than* or *smaller than* and understand that eight represents a quantity that is bigger than six but smaller than ten.

An understanding of different representations of number: Children understand that numbers can be represented differently, including the number line, different partitions, various manipulatives and fingers.

Estimation: Children can estimate, whether it be the size of a set or an object. Estimation involves moving between representations of number; for example, placing a number on an empty number line.

Simple arithmetic competence: Children perform simple arithmetical operations, which Jordan and Levine (2009) describe as the transformation of small sets through addition and subtraction.

Awareness of number patterns: Children extend and are able to identify a missing number in a simple.

Importantly, the eight FoNS components, while distinct, are not unrelated. This is because number sense "relies on many links among mathematical relationships, mathematical principles..., and mathematical procedures" (Gersten et al., 2005, p. 297), links that help avoid situations where children can count but not know that five is bigger than three.

METHODS AND RESULTS

The data examined in this study derived serendipitously from video-based teacher professional development programmes. However, both sets of lessons exploited the number line with grade one children and, therefore, proved amenable to a topic-based FoNS-related analysis. Both teachers, construed locally as effective, were video-recorded in ways that would optimise capturing their actions and utterances. Lessons, with transcripts, were scrutinised by at least two of the three authors with the intention of identifying episodes suitable for demonstrating a range of FoNS-related opportunities. In the following we present three episodes from each teacher's lessons as examples of the ways in which they worked with the number line.

The Russian episodes

The Russian teacher, Olga, began by sketching a horizontal line across the board, telling her class that this was a number line before asking what was missing. Over the next two or three minutes, four volunteers, with appropriate commentary from Olga, completed the number line as follows. The first drew a small arrow at the right hand end of the line to signify that numbers go from left to right also extend indefinitely. The second drew a small flag near to the line's left hand end to represent the start or zero point. The third, using what looked like a postcard, added regular intervals, as shown in Figure 1. The fourth added the integers correctly.

Figure 1: Marking the number line with an arbitrary unit

Commentary: In this first episode can be discerned several FoNS components. The use of the number line reflected an expectation that students would engage with different representations of number. The manner in which the line was constructed, using a repeated measure, implicitly addresses the relationship between a number and the quantity it represents, while the process of numbering the line, including the emphasis on the placement of a zero, highlight both number recognition and systematic counting.

The lesson now progressed to the class using this new number line. A girl came to the board and was told to show three. This she did by pointing to the flag (zero) with the index finger of her left hand and three with her right. Next, she was asked to show five, which she did in the same way. This was followed by Olga asking the girl to show how she would get from three to five, which she did by counting on two units.

Commentary: Within this episode, which was no more than two minutes in length, can be seen at evidence of least five FoNS components. The manner in which three, and other numbers, was demonstrated highlighted not only an identification of the symbol but also how three's position reflected a measure of units, essentially arbitrary, along an axis. In other words, it reflected the relationship between number and quantity. The task included an expectation that learners would count systematically, work with a particular representation of number, and engage with simple arithmetical operations.

In related fashion, the next task involved starting with seven and subtracting three. While the girl concerned initially struggled to stretch her arms sufficiently to reach seven, as shown in Figure 2, she seemed confident with the mathematics. On Olga's invitation, she counted out to seven, while keeping her left hand forefinger at the flag (zero). Next, she was invited to count back three spaces, which she did. Olga asked the class what the girl's action signified and was told that she had subtracted three from seven to get four.

Figure 2: A demonstration of seven on the number line

Commentary: Within this third episode, which lasted less than a minute, can also be discerned at least five FoNS components. The manner in which seven was demonstrated highlighted not only an identification of the number symbol but also the relationship between number and quantity. The task included an expectation that learners would count systematically, work with a particular representation of number, and engage with simple arithmetical operations.

The Polish episodes

Maria began her lesson by inviting each child randomly to the front to receive a sticker placed on his or her chest bearing a number, with Maria beginning by giving herself zero. She then asked the class to arrange itself in numerical order in a line down the middle of the room. Once this was done, she asked the class to return to their seats before asking them to repeat the task as quickly as possible. On this occasion, with great excitement, the class arranged itself within a few seconds.

Commentary: With respect to the FoNS components, Maria's actions were commensurate with her encouraging her students to recognise numbers and, essentially, count systematically. It also highlighted the extent to which the units of the number line are arbitrary and the use of the number line as a representation of number.

Later in the lesson Maria presented a number line with units but no numbers. She asked what should be placed at the end and was told zero, before being told that this should be followed by one, two and so on. At this point she asked her students to complete the number line on their sheet, as shown in Figure 3. Next she asked what would happen if the first marked point had been two and not one. This initiated a discussion on the importance of each unit being a representation of the same value with the consequence that the line would now show even numbers, 0, 2, 4, 6 and so on. Finally, in response to her asking what would happen if the first number had been three, it was agreed that the sequence would go 0, 3, 6, 9, 12, ... with each successive number being found by counting on three.

Commentary: Within this episode could be discerned five FoNS categories. At the most obvious level, Maria was attending to number recognition, different representations of number and systematic counting. Also, the introduction of the multiples focused attention on number patterns and, in the counting on of threes, simple arithmetic.

Later, Maria sketched a number line from zero to fifteen on the board. She marked a point at five, and asked her students to do the same. She then wrote 5 + 7 = before showing how the sum can be counted out, as in Figure 4. Following this she asked her students to do the same on their sheets. The students were

Figure 3: Completing the number line

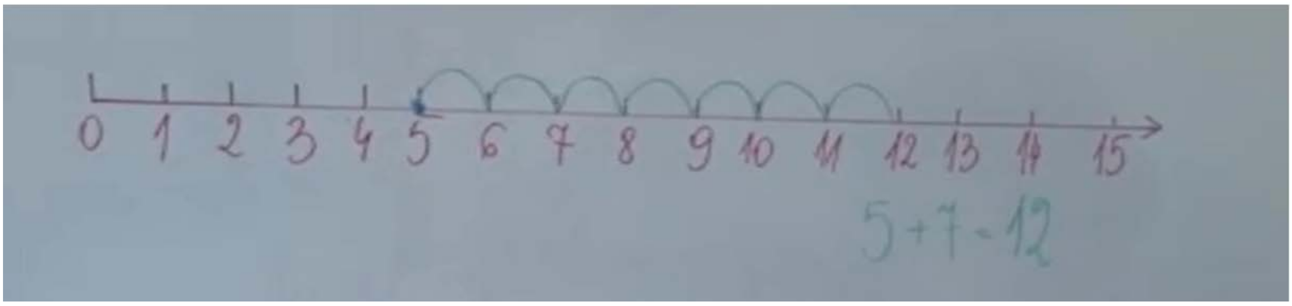

Figure 4: Using the number line to undertake simple arithmetic

then invited to repeat the process for 6 + 6 = , 14 − 9 = , 5 + 6 − 4 = . After each one, Maria repeated the process on the board, with instructions provided by different students. She counted very slowly and deliberately as she marked off each number on the way.

Commentary: In this final episode, in addition to the already familiar number recognition, systematic counting and number representations, Maria was attending to simple arithmetical operations and how they can be modelled on the number line. Interestingly, she did not just focus on addition but included subtraction and, with the third problem, both operations.

DISCUSSION

The analyses above, summarised in Table 1, indicate both similarities and differences in the ways in which FoNS was addressed. In respect of similarities, both teachers addressed, over the course of the analysed episodes, five categories. Both encouraged, throughout their respective excerpts, students' recognition of number alongside, systematic counting and awareness of different representations of number. Both also, but not to the same degree, focused attention on simple arithmetic operations. Overall, and bearing in mind the number line focus, such findings were of little surprise and, from the perspective of validating the framework, helpful – an analytical framework that failed to identify the expected would be of little use.

While it is always important to acknowledge similarities, differences are frequently more enlightening. On the one hand, Olga emphasised, through her insisting that students make a bodily link between a number and zero, the connection between number and quantity. On the other hand, through her discussion of multiples of two and three, Maria was seen to use the number line to support children's engagement with simple sequences. However, it is our view that such findings reflect not insignificant qualitative differences in the teachers' emphases. Olga's exploitation of the bodily link avoided too early a shift to working with numbers as abstract entities. This seems a more significant didactical decision when compared to Maria's emphasis on sequences, albeit a key category of FoNS in its own right. Such qualitative differences show that the FoNS framework has the propensity for highlighting, in much the way that generic learning outcomes exploited in other studies have shown, both simple analyses based on the frequencies of particular events and more sophisticated analyses based on the interactions of those events (see Andrews & Sayers 2013).

In this paper, we have shown how opportunities for students to acquire FoNS played out in two post-Soviet classrooms. This is of particular interest in the light

	Olga's episodes			Maria's episodes		
Number recognition	X	X	X	X	X	X
Systematic counting	X	X	X	X	X	X
Relationships between numbers and quantities	X	X	X			
Quantity discrimination						
Different representations of number	X	X	X	X	X	X

Simple arithmetical operations		X	X			X
Number patterns and missing numbers					X	

Table 1: the distribution of the categories across the episodes

of recent evidence that the rise of the free market had had markedly different impacts on student achievement on international tests (Bodovski, Kotok, & Henck, 2014). In this respect, Poland's PISA mathematics scores, reflecting students' real-world application of mathematical knowledge at age 15, have risen from significantly below to significantly above the international mean at a time when Russia's have remained largely static, constantly significantly below the international mean. These scores are interesting when set against Russia's grade 8 TIMSS scores, assessments of students' technical competence, has been consistently above the international mean. With respect to TIMSS grade 4, Russia has been consistently one of the higher achieving nations, while Poland has remained significantly below the international mean. In other words, and putting the case crudely, if such tests tell us anything it is that Polish students are increasingly competent on real-world mathematical tasks located in text and requiring a degree of interpretation, which Russian students are not, while Russian students are strong on mathematics tasks located in world of technical mathematics, which Polish students are not. In light of this, what do our limited analyses have to say?

Firstly, acknowledging the limited sample presented here, Olga's teaching seemed more focused on the structural properties of number and mathematics than Maria's. Not once did Olga make any number line-related reference to a world outside the classroom. Her efforts were focused constantly on a world contained solely within mathematics. Maria, on the other hand, although not reported above for lack of space, made frequent use of different representations of the number line drawn from the real world. For example, at different times she made reference to several thermometers, each of which presented a different scale and starting value, different tailors' measuring tapes, a carpenter's retractable tape, a measuring jug, various skeletons of fish and snakes showing, in particular, the regular spread of ribs. Each one elicited a brief discussion as to its purpose and relationship to the number line. On a separate occasion she based a counting activity on the use of a representation of a hotel lift travelling between the many floors of a very tall hotel. Thus, these differing emphases, essentially unrelated to the mathematics being taught, may have profound implications for students' successes on international tests of achievement. Olga's teaching seems unrelated to PISA expectations and Maria's to TIMSS. Such matters clearly require further examination.

Reciprocal determinism between students' mathematics self-concept and achievement in an African context

Emmanuel Adu-tutu Bofah

University of Helsinki, Department of Teacher Education, Helsinki, Finland, emmanuel.bofah@hotmail.com

The study tests the theoretical and methodological models of the direct feedback loop in which mathematics self-concept and achievement are specified as both causes and effects of each other using the TIMSS–2011 cross-sectional data set. The participants were students in grades 8–9 from five African countries participating in TIMSS–2011 (N=38,806, M_{Age} =15.42, SD =1.37). Using nonrecursive structural equation models, the author examined the reciprocal-effects model indicating that achievement has an effect on self-concept (skill-development model) and that mathematics self-concept has an effect on achievement (self-enhancement model). There was support for the skill-development, self-enhancement as well as direct feedback loop models. Discussion centres on the theoretical, methodological, and practical implications of the results.

Keywords: Mathematics self-concept, achievement, reciprocal determinism, TIMSS.

INTRODUCTION

Cross-national comparative studies such as the TIMSS and PISA have recently gained considerable attention. Research on TIMSS and other large-scale surveys has consistently shown strong relationship between achievement and self-beliefs across nations (Chiu & Klassen, 2010; Huang, 2012; Marsh et al., 2013; Parker, Marsh, Ciarrochi, Marshall, & Abduljabbar, 2014). Studies reporting different levels of self-belief (e.g., self-concept) across nations normally report with strong theoretical backing, a common trend of lower self-concept among Asian countries when compared to other nations (e.g., Wilkins, 2004).

Culturally, the causal relation between affect (e.g., self-concept) and achievement has been demonstrated to be valid cross-culturally, but more typically in the Western hemisphere (e.g., Seaton, Parker, Marsh, Craven, & Yeung, 2014). Moreover, other studies have shown that self-belief (e.g., self-concept) may operate differently across cultures (Chiu & Klassen, 2010; Markus & Kitayama, 1991) due to the fact that the self is highly influenced by *the frame of reference effect*—social comparison, causal attribution, and reflected appraisals from significant others (Bong & Skaalvik, 2003).

In the present study, the nature of the relationship between students' mathematics self-concept and achievement was investigated using a non-recursive structural equation models in the five African countries that participated in TIMSS–2011. The bidirectional cause–effect between affect and achievement is of practical importance because many affective enhancement programs as well as educational policy statements throughout the world are based on the fact that an improvement in affects (e.g., self-concept) will lead to better academic achievement. The full intent is to test the reciprocal relationship between affect and achievement. The study is also based on the fact that indigenous research and theorising which integrate cross-cultural perspectives are crucial to the establishment of more useful and universal theories (e.g., van de Vijver & Leung, 2000). As Chiu and Klassen (2010) put it: "Cultural differences in self-beliefs can challenge the foundations of current theories and provide new ways of looking at the self" (p. 2). Furthermore, there is a paucity of cross-cultural studies on domain-specific self-concept and achievement in the African context. The data for the present study is from TIMSS–2011, which provides a comparable open data source for these analyses.

The causal determinism of affects and achievement

Self-belief (e.g., self-concept) theories have developed into several branches (for a review, see Wang & Lin, 2008). One such branch concerns the differing relationships between self-belief and achievement (Calsyn & Kenny, 1977; M-S. Chiu, 2012). Within this context are competing hypothesis such as the *self-enhancement model*, which posits that self-belief is a determinant of academic achievement (Chiu & Klassen, 2010; Marsh & O'Mara, 2008), and the *skill-development model*, which sees self-belief as simply a reflection of performance (Chen, Yeh, Hwang, & Lin, 2013; Chiu & Klassen, 2010; Ma & Xu, 2004; Wang & Lin, 2008). Moreover, a more realistic and logical compromise between the self-enhancement and skill-development models is the reciprocal-effects model (Guay, Marsh, & Boivin, 2003; Hannula, Bofah, Tuohilampi, & Metsämuuronen, 2014; Parker et al., 2014; Seaton et al., 2014), which posits that prior self-belief influences subsequent achievement and prior achievement influences subsequent self-belief (for an in-depth review, see Guay et al., 2003).

Cross-culturally, reciprocal effect models have been found to exist. For instance, evidence has been found in Germany (Marsh & Köller, 2004), Finland (Hannula et al., 2014), Canada (Guay et al., 2003), Australia (G. Marks, McMillan, & Hillman, 2001), United States (Marsh & O'Mara, 2008), and many OECD countries (Williams & Williams, 2010) but not in the African context. However, on the relationship between affect and achievement, some studies have indicated affect as the strongest predictor of achievement (Marsh & O'Mara, 2008; Morony, Kleitman, Lee, & Stankov, 2013), whereas others have indicated achievement to be the strongest predictor of affect (e.g., Hannula et al., 2014; Ma & Xu, 2004). Other studies have found no causal relationships (e.g., Williams & Williams, 2010). Taken together, no firm conclusions can be drawn about the causal ordering of affect and academic achievement cross-culturally.

Assumptions in cross-sectional models in causal determinism

Modeling reciprocal effects with cross-sectional data sets is uncommon in mathematics-related affect studies; rather the normal approach uses a longitudinal data set. The arguments lie in the methodological challenges, assumptions and theoretical considerations associated with cross-sectional data to examine the causal ordering (Kline, 2011; Ma & Jiangming, 2004; Wong & Law, 1999). Structural equation models that are used to estimate the reciprocal relationships involving cross-sectional data are known as non-recursive models. Kaplan, Harik, and Hotchkiss (2001) indicated that data from cross-sectional designs only give a "snapshot" of an ongoing dynamic process; as such estimations of reciprocal causal effects with cross-sectional data sets require the assumption of *equilibrium*. Kline (2011 p. 108) summarized that: "any changes in the system underlying a presumed feedback relation have already manifested their effects and that the system is in a steady state. That is, the values of the estimates of the direct effects that make up the feedback loop do not depend on the particular time point of data collection". For an in-depth discussion, see Heise (1975) and Kaplan and colleagues (2001). With respect to the present study, the argument is that during the eight or nine years that these students have been in school and engaged in mathematics learning, their mathematics mastery levels and self-concept have reached a point of equilibrium where each student has formed a realistic view of their perception with regards to performing a given task (See Williams & Williams, 2010, for similar arguments).

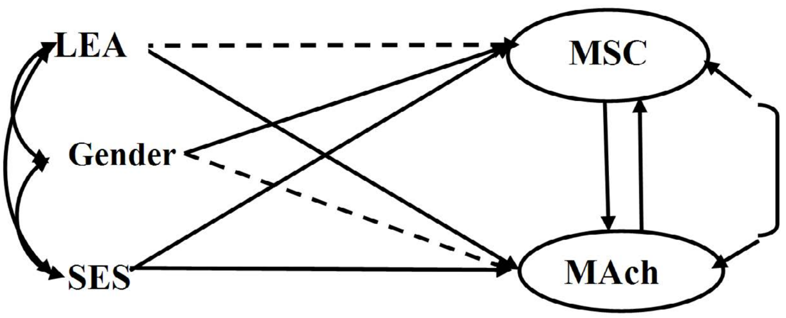

Figure 1: Reciprocal causal effects between maths self-concept (MSC) and achievement (MAch) with a direct feedback loop based on a cross-sectional design. The assumptions are shown with dotted lines. These indicate effects that were fixed to zero a priori. SES = socioeconomic status, LEA = Students' long-term educational aspirations. To avoid cluttering, only paths are shown

METHODS

The hypothesized model for the study is depicted in Figure 1. Each model was analyzed separately for each country. The result of a confirmatory factor analysis (CFA) verified a clear factor structure after incorporating the *method effect* associated with combining both negative and positive items in a survey (for similar argument see M-S. Chiu, 2012; Marsh et al., 2013). Moreover, in a multigroup CFA, measurement invariance (e.g., factorial invariance) of the MSC construct across the five educational/cultural groups was supported. Due to restrictions of space, these results are not presented here.

The students' long-term educational aspirations (LEA), gender, and socioeconomic status (SES)—measures of their home educational resources—are the exogenous variables—variables that no explanation is offered by the model; that is, no directional path point to them. In order for a non-recursive model to be identified, some parameters need to be specified a priori as such gender and LEA were assumed to have no direct influence on MAch and MSC respectively. The theoretical basis for fixing the effect of gender on achievement to zero is based on Deaux and Major's (1987) interactive approach model of gender differences which recognizes the importance of cognitive and cultural influences on gender roles, suggesting that more immediate factors, such as social and cultural patterns of discrimination, shape gender-related belief (see also gender stereotype threat: Spencer, Steele, & Quinn, 1999).

Arguing similarly as in Williams and Williams (2010), for all things being equal, the notion of males reporting higher mathematics achievement reflects a similar notion in mathematics self-concept (e.g., Nagy, Trautwein, Baumert, Köller, & Garrett, 2006). The assumption about SES is based on numerous studies that have established a firm relation between SES and achievement, and self-belief (Chiu & Klassen, 2010; Howie, 2013; Williams & Williams, 2010). The level of educational resources at home has been found to relate to students' achievement even after controlling for parental education and other factors (e.g., Teachman, 1987). However, in developing countries where large numbers of students have no access to basic educational resources, home educational resources are likely to be a more important component of socioeconomic disparity in education (Marks, Cresswell, & Ainley, 2006).

Concerning LEA, documented evidence (e.g., Gil-Flores, Padilla-Carmona, & Suárez-Ortega, 2011) suggests higher educational aspirations to be associated with higher achievement, and vice versa. With no documented evidence on the relationship between LEA and MSC, our argument is that students' mathematics self-concept mediates the relationship between LEA and MAch. Moreover, the error terms associated with the unexplained variance in mathematics self-concept and achievement were allowed to covary since they influence each other (Wong & Law, 1999; Kline, 2011).

Model evaluation and estimation criteria

The models tested in the present study were assessed by Mplus 7.2. The estimator used was the Mplus Robust Maximum Likelihood Estimates (MLR) with standard errors and tests-of-fit that are robust to non-normality and non-independence of observations (Muthén & Muthén, 1998–2012). The Mplus feature of full information maximum likelihood (FIML) was used to impute missing data. To ascertain the model fit, emphasis was placed on the comparative fit index (CFI), the root-mean-square error of approximation (RMSEA) as well as the chi-square test statistic (for informative purposes only because of it sensitivity to large sample size). The CFI is normed along a 0-to-1 continuum with values greater than .95 reflecting excellent fits to the data, and for the RMSEA, values less than .05 are indicative of a "close fit"(West, Taylor, & Wu, 2012). Due to the complex design of the TIMSS survey, the Mplus complex survey design option to account for the clustered design and to adjust standard errors was used. Students' class was used as the clustering variable, and students' sampling weights were also taken into account (*weighting variable supplied with the data*). The fit indices shown in Table 1 indicate the model fits well in all countries.

Data Source

Data were obtained from 38,806 (M_{Age} = 15.42, SD = 1.37) students who participated in TIMSS–2011 in five African countries (see Table 1). For detailed TIMSS sampling and method procedures, see Martin and Mullis (2012).

The maths self-concept scale

Maths self-concept (MSC) was measured through five items on a scale with a 4-point Likert response format: Agree a lot (1), Agree a little (2), Disagree a little (3), Disagree a lot (4). Item scales were reverse-coded to indicate higher values represent a more positive self-concept and vice versa. The items on the MSC are the following: 1) I usually do well in mathematics, 2) I learn things quickly in mathematics, 3) I am good at working out difficult mathematics problems, 4) Mathematics is more difficult for me than for many of my classmates [reverse coded], and 5) Mathematics is not one of my strengths [reverse coded]. The reliability (composite reliability) (Raykov, 2012) of the MSC ranged from acceptable in Botswana (.645) and Tunisia (.624), to low in South Africa (.557), Morocco (.526), and Ghana (.513). The maths self-concept scale was treated as a latent variable to account for measurement error. The reliability of the MSC was incorporated into the measurement model by fixing the variance of the error term to [(1- reliability)*variance]. This approach is discussed in (Heise, 1975), and a similar procedure was used in (Williams & Williams, 2010).

Mathematics achievement

TIMSS–2011 reported students' MAch in terms of five plausible values—random numbers drawn from the distribution of scores that could be reasonably assigned to each individual (Martin & Mullis, 2012).The use of plausible values has been discussed at length in the TIMSS–2011 methods and procedures (Martin, & Mullis, 2012). The composite reliability of the MAch score ranged from .969 in Botswana, .966 in South Africa and Tunisia, and .957 in Morocco, to .946 in Ghana. Mathematics achievement was treated as a latent variable and was given the same format and procedure (i.e. on the variance and reliability) as that described earlier for MSC.

Instrumental variables

Socioeconomic Status (SES). The SES scale was derived from students' reported home educational resources based on their responses concerning three home resources: Number of books in the home, Highest level of education of either parent, Number of home study supports: Own room, Internet connection. (See Foy, Arora, & Stanco, 2013 supplementary 3 for more details on the process of determining SES.)

Long-term educational aspirations (LEA). The LEA scale was a self-report asking participants to indicate the highest level of education they expected to attain on a scale ranging from (1) "Lower secondary education" to (6) "University program - Master/Doctorate." (See Foy et al., 2013 supplementary 2 for specific nationally define classifications).

Gender. The gender measure was based on students' responses to the questionnaire coded as 1 = *girl* and 2 = *boy*.

RESULTS

Overall, the results shown in Tables 1 and 2 are congruent with similar models estimated by other researchers (e.g., Williams & Williams, 2010). This lends credence to the validity of the results and supports the hypotheses. As indicated in Table 2, the causal relationship between MAch and MSC is supported in Tunisia. Furthermore, in the remaining four countries one or both of the bidirectional relationships failed. In Ghana and Botswana, only the effect of MSC on MAch was statistically significant, validating the self-enhancement model. In Morocco, the effect of MAch on MSC was statistically significant supporting the skill-development model. In South Africa, neither the self-enhancement nor skill-development model was supported. These findings indicate that the countries vary in their causal relationships between MSC and MAch.

The effect of SES on MAch was statistically significant and positive in all but two nations (Ghana and Botswana). Similarly, the relationship between SES and MSC was less consistent across the countries. A statistically significant relation between SES and MSC was found in all but two of the countries (South

Country	χ^2	*df*	S	CFI	RMSEA	Sch	Stu	Grade
Ghana	537.451	57	1.580	.991	.034	161	7,323	8
Botswana	654.534	57	1.105	.989	.044	150	5,400	9
South Africa	931.099	57	1.764	.990	.036	285	11,969	9
Morocco	642.498	57	1.359	.990	.034	279	8,986	8
Tunisia	430.827	57	1.181	.994	.036	207	5,128	8

Table 1: Measures of model fit and sample size by country. χ^2 = chi-square; *df* = degrees of freedom ratio; s = Mplus scaling correction Factor; CFI = comparative fit index; RMSEA = root-mean-square error of approximation; Sch= Schools; Stu = students (unweighted sample)

	Achievement estimates			Self-concept estimates		
Country	MSC	SES	LEA	MAch	Gender	SES
Ghana	38.519***	-2.158	2.744***	0.003	0.089***	0.071***
Botswana	-13.009***	-0.359	3.474***	0.000	0.096***	0.036*
South Africa	11.045	4.458***	3.847***	0.000	0.069***	0.012
Morocco	0.898	6.842***	1.726***	0.016***	0.098***	-0.057**
Tunisia	41.140***	2.757***	0.685***	0.015***	0.035**	-0.022

Table 2: Path Estimates by country. The absolute size of these metric estimates varies considerably because of the differences in the scales of Maths self-concept (MSC) and Maths Achievement (MAch). The effect of MSC, SES, and LEA on MAch is shown under the heading Achievement estimates. The effects of MAch, gender, and SES are shown under the heading Self-concept estimates. Socioeconomic Status (SES); Long-term educational aspirations (LEA). ***p <.001, **p <.01, *p <.05.

Africa and Tunisia). This indicates that the relationship between SES, MSC and MAch is dependent on the national context (William & William, 2010).

With regard to the effect of gender, all parameter estimates were positive and statistically significant. This indicates that males reported higher levels of MSC in all five countries. The effects of LEA on MAch were statistically significant for all the countries as well. The coefficients indicate that higher LEA predicts higher MAch in all countries.

DISCUSSION

The reciprocal determinism of MSC and MAch was validated in one of the five countries. This supports the cross-cultural dimension of the reciprocal models (Guay et al., 2003; Marsh & O'Mara, 2008; Seaton et al., 2014). Nevertheless, the analysis indicated that reciprocal determinism is dependent on the national context specific, thus supporting Williams and colleagues (2010). In South Africa, neither the reciprocal relation nor the self-enhancement model or the skill-development models were supported. Ghana and Botswana supported the self-enhancement model (Calsyn & Kenny, 1977; Chiu & Klassen, 2010; Marsh & O'Mara, 2008), whereas Morocco supported the skill-development model (Hannula et al., 2014; Ma & Xu, 2004). Moreover, the effect of students' long-term educational aspirations and gender on their MAch and MSC, respectively, also shows evidence of cross-cultural generalization, since they are all positive and statistically significant. The findings are also consistent with higher reported MSC for males (e.g., Nagy et al., 2006) and higher MAch for students' with higher long-term educational aspirations (e.g., Marsh et al., 2013). It also supports our assumptions behind the use of gender and LEA as *instrumental variables*.

The effects of SES on MAch and MSC were less consistent, but were evident in more than half of the countries. The relationships between SES, MSC, and MAch are consistent with other studies (Chiu & Klassen, 2010; Howie, 2013; Marks et al., 2006; Teachman, 1987; Williams & Williams, 2010). In countries where a relation was found between SES and MAch, governments can institute financial support schemes for low-income families in the light of our results. Moreover, upgrading schools and increasing funding for schools in low-income areas could help bridge the gap between low and high achievers (Marks et al., 2006).

The present research is one of the few cross-cultural studies on causal relationships between the MSC and MAch in an African context, and provides important new evidence regarding the generalizability of the uni- and bidirectional relationship between MSC and MAch.

A limitation of the study is the assumption behind using cross-sectional data when modeling a reciprocal analysis. For instance, the required assumption of *equilibrium*. The problem is that there is no statistical measure to evaluate the equilibrium assumption with a cross-sectional data set; *it must be argued substantively* (Kline, 2011, p. 108). Moreover, others have argued that the equilibrium assumption does not justify using cross-sectional models for bidirectional determinism, because cross-sectional models are miss-specified due to the fact that they do not take time lags into account (Gollob & Reichardt, 1987; Wong & Law, 1999). However, others have argued for the importance of cross-sectional data to test reciprocal models because in most situations cross-lagged effects are virtually impossible to obtain (Wong & Law, 1999). As we have seen, "causal attribution is not an automatic process; useful causal conclusions are the product of careful thought, high-quality data, and sound data analysis" (Rogosa, 1979, p. 301).

The findings of this study clearly challenge some of the foundations of current theories on self-belief, and provide new ways of looking at the self (Chiu & Klassen, 2010). Reciprocal determinism was found in some countries and was non-existence in others. The data shows the degree of cross-cultural variations on the reciprocal determinism between affect and achievement. The author could not provide sound cultural theory to explain these phenomena. Moreover, it is important to bear in mind that the analysis may not represent the dynamics of the feedback loop between math self-concept and achievement because the findings represent a static view of an ongoing dynamic system and may vary based on when the system is observed as it moves toward equilibrium (Kaplan et al., 2001).

This paper presents a longitudinal analysis of the outcomes of the Italian national standardized mathematics tests. By intertwining quantitative and qualitative methods, we selected and analysed a set of linked questions among the tests administered to the same cohort of students first in grade 6 and then in grade 8. In particular, we focus on poor knowledge students and we argue an example of the analysis of two linked questions about graphical representation of fractions. The comparison between the two questions allows us to interpret some difficulties of students and to expect possible future behaviours.

Keywords: Standardized mathematics tests, longitudinal analysis, fractions, qualitative and quantitative analysis.

INTRODUCTION

This paper presents an "in progress" research developed within the *Ideas for the research* project, funded by the Italian national institute for the educational evaluation of instruction (INVALSI). This project asks for new qualitative interpretative tools with the aim to integrate the statistical ones with them. These tools can be used by teachers to point out some groups of questions (in different grades) that could identify *poor knowledge students* (see the next section for a definition of this set) in specific mathematics contents. Our study focuses on a longitudinal analysis of mathematics standardizes tests outcomes collected by INVALSI in 2011 and 2013 respectively in grade 6 and 8 (therefore we analyse the same cohort of students who faced the INVALSI tests in grade 6 and 8). The aim of this analysis is to identify questions in which poor knowledge students have difficulties and, observing their behaviours, to describe possible causes of these difficulties. Such causes are going to be the object of our future analysis in classroom activities.

We carried out an analysis that intertwined qualitative and quantitative interpretative tools in a longitudinal study: in particular, we analysed items of the INVALSI tests focusing both on the mathematical contents involved and on the solution strategies developed by students to face the tasks (qualitative analysis), and using the information given by a statistical analysis of the national sample results (quantitative analysis). We expect this study to be an useful tool for teachers because the outcomes of the research could help teachers in identifying students' difficulties in longitudinally linked items. These information could be used to implement educational activities aimed to avoid the persistence of wrong behaviours of students, similar to the ones observed in the research, and future failures in mathematics.

In the next phase of our research some of the items, selected from the INVALSI tests and analysed in the first part of our study, will be administered again during classroom activities in order to give empirical support to the analysis presented in this paper.

THEORETICAL LENSES

The INVALSI test is designed by Italian teachers selected by INVALSI according to their experience and education. INVALSI framework is based on to National Standards Ministero dell'Istruzione, Università e Ricerca, 2012). In our study, we take into account INVALSI framework but we integrate it with specific theoretical tools taken from the literature in mathematics education.

The items are presented in a written form with multiple choice questions, open questions, true or false and closed. As the topics are many and the test is faced by a large amount of students, we conjecture that the most frequent difficulties described in literature appear in students' answers. For this reason, we create a list of difficulties found in literature for each topic. For instance, in this paper, we analyse two questions about fractions. Our theoretical framework on educational studies about fraction refers to the research carried out in the last thirty years and summarized in the Encyclopaedia of Mathematics Education (2014). In particular, Demetra Pitta-Pantazi describe some recurring misconceptions, for example:

Students often do not interpret fractions as numbers but view fractions as two numbers with a line between them. When adding fractions, they often add the numerators and denominators or are unable to order fractions from smaller to larger (e.g., Behr et al., 1992). (Encyclopaedia, 2014, pp. 470–476)

We use also the study of Fandiño Pinilla (2007) who offers a wide review about difficulties in fractions domain. These researches gave us the tools to identify and to interpret students' answers to the INVALSI test items. In this paper, we analyse students' answers identifying some common difficulties and errors linked to the concept of fraction: (M1 – Divide in non-equivalent parts: count-and-match misconception) the "Epistemic" misconception of fraction as a part but non-equivalent to the others; (M2 – Answer d – n instead of the total d) the mistake in identifying the fraction numerator and denominator when students analyse some coloured parts in a grid of equivalent parts of a figure and considering the coloured part as numerator (n) and only the rest (d–n) as denominator, not the total amount of parts (d); (M3 – Divide in equivalent parts and take some parts) Student implicitly suggests that "some" cannot be "all"; it becomes easily an obstacle for the fractions equivalent to the unit. The INVALSI items are given to students in written form, but words are often mixed with images, tables, graphs and other representations. For this reason, some students' difficulties could be related to semiotic representations management. Indeed, we need a theoretical tool of analysis to figure out possible obstacles arising from this semiotic richness. We use semiotic approach proposed by Duval: "there are always many possible semiotic representations of the same object. The higher process of thought, and especially mathematical activity, are based on this plural semiotic object representation" (Duval, 1993; 2008). Even if a richness of semiotic representations is necessary to conceptualize mathematical objects, in the very first steps of learning or for poor knowledge students coordinating many registers and connecting representations can be an obstacle. Different students errors in INVALSI tests can be interpret as a failure in verbal-graphic conversion, in the decoding of the text or in expressing a right solution in another register. In the examples argue below the students mistakes could be caused by a wrong transformation of the fraction verbal representation in the right graphic one or vice versa (S1) or in a incorrect transformation of the graphic results in the fractions' register (S2).

Our research question is: what kind of information, emerging from the analysis (both quantitative and qualitative) of the 8th grade items, are useful for the interpretation of the outcomes of the analysis of the 6th grade questions?

We conjecture that a longitudinal analysis of the answers of the same cohort of students, carried out through the comparison between the two data sets from different years, could be useful to better interpret the 6th grade outcomes in terms of the analysis of 8th grade items. Unfortunately, by means the analysis of the statistical data, we cannot follow the specific test outcomes for each student in different years; for this reason we need a criterion to link questions from different grade tests. In particular we decided to select questions that deal with longitudinal topics, identified in the National Standards - Indicazioni Nazionali (2012), and which can be solved using the same *scheme*, namely the same sequence of actions, controls, operational invariants and so on (Vergnaud, 2009).

METHODOLOGY

A longitudinal analysis of the tests, administered to the same cohort of students in different years has been performed integrating qualitative methods with quantitative ones. Starting from 2013 INVALSI test for grade 8 students, we consider 2011 test for sixth graders.

As concerns the qualitative analysis we analysed all the items of the INVALSI test for grade 8 and grade 6 focusing on some longitudinal contents: e.g., fraction and decimal representations of rational numbers and equivalent polygons. In this paper, we analyse items that deals with the fractions of a square area.

The INVALSI team verifies the consistency of the whole test by Classical Test Theory tools (Cronbach alpha, point-biserial correlation coefficient). Then using an Item Response Theory approach (Van der Linden & Hambleton, 1997) the estimation of item characteristic parameters is carried on.

In our work we use some INVALSI test results to investigate the behaviour of the items. First we apply a latent class analysis [1] to classify students and to judge the item characteristics. This statistical method gives a classification of students in a fixed number of groups characterized by different levels of performance. The classification is based on the estimated probability of correct answer of each item. Chosen the best number of groups, it is possible to interpret them (for example, the group with the worst performance, the group with the best performance and so on) and to investigate the probability of a correct answer for all items within each group. In this way items that show a particular response behaviour could be identified. Most items included in the test are unordered categorical (nominal) multiple-choice items. The statistical analysis and specifically the latent class analysis were conducted on dichotomous items, i.e. correct/incorrect response. The analysis of the national sample (i.e., the students of the same cohort in grade 6 in 2011 and in grade 8 in 2013) showed the presence of groups/classes of students with a lower probability of correct answers in comparison with the results of the whole of students' answers to all the items of the INVALSI test. Analysing the results obtained by the group with the lower performance, we selected some items in which the 'weaker' group had the lowest probability of correct answer compared to all the students who faced the same test. In our data we identify five groups/classes [2] which consist of students with a similar response probability for the same items. We analyse the results on a national sample of about 28000 grade 8 students.

Class 5 (about the 23% of the students) is the class with the lowest outcome probabilities so we consider it as the set of *poor knowledge students*. Comparing class performances item by item, a set of questions in which only class 5 has low performances can be observed (Figure 1). In particular, we gather the items in which the success probability for class 5 is less than half of outcome probabilities for the other classes. Item D25 (Figure 1) has the maximum ratio, equal to 0.46, indeed the probability of class 5 right answer is 14% instead of the other classes whose outcome probabilities are a range from 30% to 81%. This item seemed to be a good candidate to study the possible difficulties face by poor knowledge students in INVALSI test. It was identified through the interweaving of qualitative and quantitative analysis: this is meaningful both as regards the contents and schemes involved (it concerns

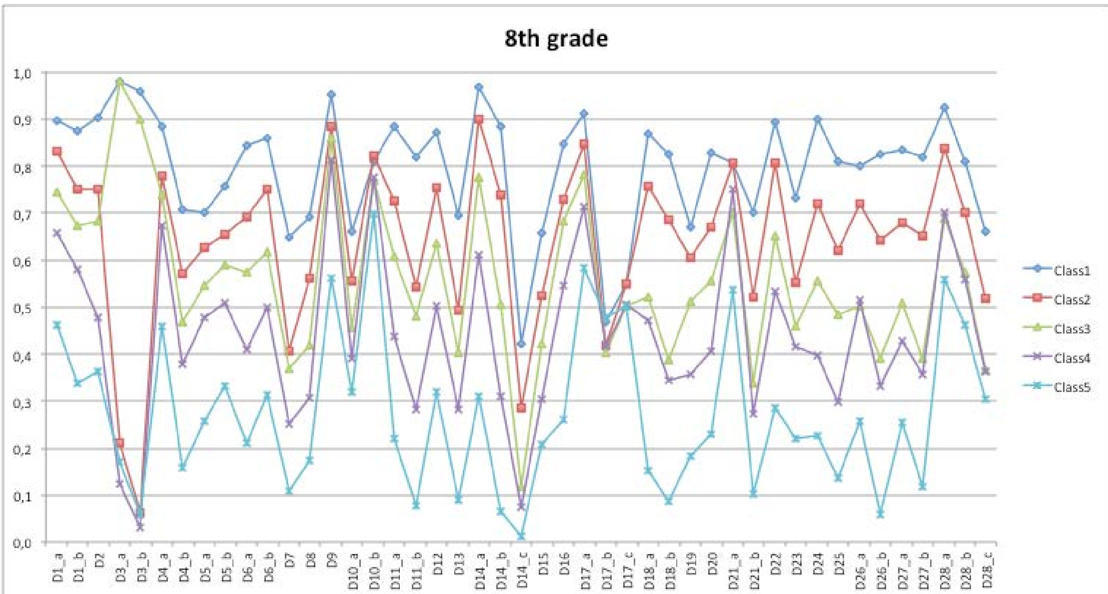

Figure 1: Classes' outcomes probability of correct answer in 8 grade test

the identification of relationships between areas of polygons), and the results on the national sample.

AN EXAMPLE OF ITEMS ANALYSIS

Using Latent Class analysis on data from grade 8 test of 2013, we select a set of questions with low performances in particular for poor knowledge students. To give an example of our analysis we consider question D25 (Figure 2).

This is a multiple choice question with four options and only one right answer. The correct answer is Option D. Option A considers the number of all pieces as denominator, so it could be chosen by students who do not take in account the different areas of the pieces (M1); Option B may be selected considering only half of the Tangram maybe because of a wrong calculation of the area of the triangle not dividing by 2; Option C is selected by students that correctly divide in equivalent parts the square, but take 1 as numerator and the difference between total and 1 (16−1=15) as denominator (M2).

Looking at data, 42% of the students answer correctly and few students choose Option B and C (respectively 8.0% and 11.3%). A relatively high percentage of students, about 35%, chooses Option A.

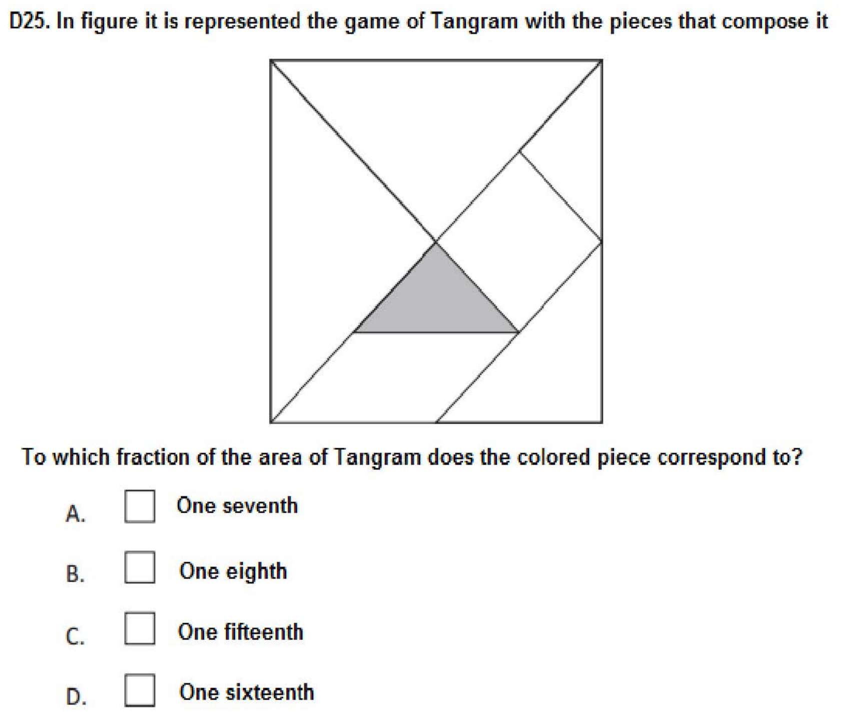

Figure 2: Question D25 from the grade 8 INVALSI test administered in 2013 [2]

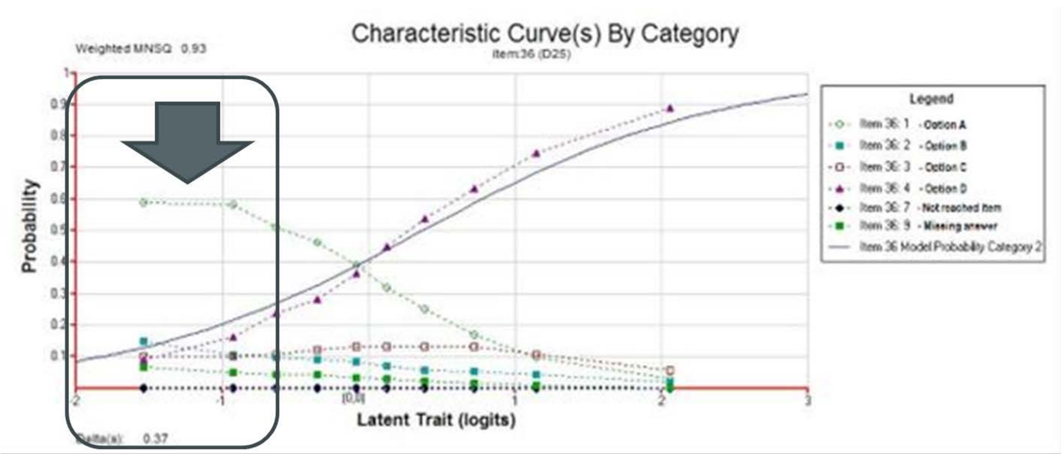

Figure 3: Characteristic Curve of question D25 from the grade 8 INVALSI test, 2013. The probability of options choice is shown on the vertical axis, while the corresponding ability estimate is shown on the horizontal axis.

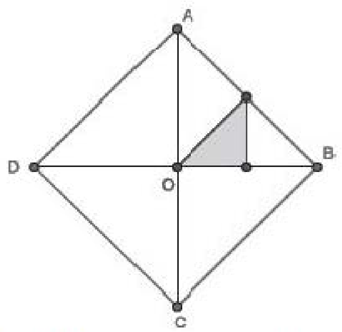
In the Figure 3 on the abscissa of the graph we can read the measure of the ability of the students in the test (Latent Trait), and on ordinate there are the probabilities of options choice. Each option choice is represented by a different Characteristic Curves (see the Legend in Figure 3). Analysing Characteristic Curve (Figure 3), we can notice that students with lowest performances, among which we expect to find poor knowledge students, have 60% of probability to choose Option A and less than 20% of probability to choose the others (see the framed region indicated by the arrow in the Figure 3). We link the question of grade 8 test, D25, to question D2 of grade 6 (Figures 4–5).

There's a very good relation between the two questions in terms of statistic trends. Moreover the task is similar and the strategies developed to answer can be compared. We have to stress that the two questions, even if similar, are different. The grade 6 question asks to cover while the grade 8 one to find a fraction, but in both the cases the operation to carry out the solution is the same: to compose the square using triangles equivalent to the coloured one. In item D2, the percentage of correct answers is 55.3%; since the question is not a multiple choice one, the Characteristic Curve gives information only in terms of "right-wrong" answer. In this case, students belonging to the lowest performances in the graphic have a probability about 10% to provide a correct answer, with more than 70% of failure. The percentages given by national results didn't help us to understand which kind of errors students made because, in open questions, we can know only how many students gave the right answers (and how many students gave the wrong ones). In order to identify the possible wrong answers, we collected a sub-sample of 74 tests from the national survey of 2011 and we analyse the students' answers. Obtained data are summarized in Table 1.

D2 In the square ABCD the middle points of side AB and segment OB are connected



How many triangles, as the colored one, can we exactly cover the surface of the squ ABCD with?

Figure 4: Question D2 from the grade 6 INVALSI test administered in 2011 [3]

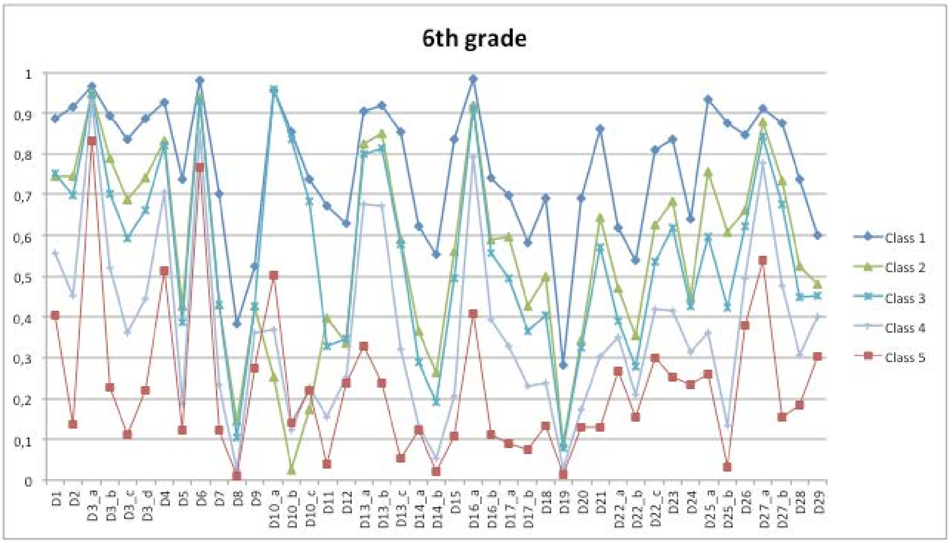


Figure 5: Classes' outcomes probability of correct answer in 6 grade test

Answer	16	12	8	4	3	other	missing
Percentage	52.7%	10.8%	5.4%	6.8%	4.1%	6.8%	13.4%

Table 1: 74 students' response to D2: answers (16 is the right answer, the others are wrong)

The percentage of right answers of this sub-sample is coherent with the national sample. Analysing wrong answers in Table 1, it is possible to identify some results that can be the outcome of the same students' solution schemes captured by the options of the D25 in 2013: therefore we conjecture a link between these difficulties observed in grade 8 and grade 6 results. As a matter of fact, students who answer 12 maybe look at triangle AOB as composed by three triangles, even if they are not equivalent (M1), and repeat this procedure in all the quarters of the square. This attitude could be linked with students who answer 3. They probably consider the three triangles but do not extend the procedure to the others. Another interpretation of this phenomenon is that students could individuate the right number of triangles composing AOB, but do not consider in the calculation the grey one and count 3 triangles or 12 in the case of extending procedure for the whole square (M2). Students that answer 8 probably do not consider the grey part and count only the white pieces of AOB, then multiply by four (M2+M1). Who answers 4 maybe does not reach the instruction and refers to AOB instead of the grey triangle or just focus on AOB's pieces (S3). As a matter of facts, same codes are present in both questions' analysis. This fact allows us/makes us able to link difficulties in the two questions longitudinally. In particular, students who answer 12 in D2 can behave as students who choose Option A or C. For instance, M1 refers to students who consider non-equivalent pieces and count 12 triangles in D2 (or 3 in the case in which do not extend the procedure to the whole square) and "one seventh" in D25. Otherwise, if we consider the second interpretation (M2), it is possible to link this attitude with the choice of Option C i.e. who does not consider the coloured triangle in counting. From the semiotic point of view, in both questions students have to recognize verbal, graphic and symbolic representations of fraction and to switch from one to the others. Indeed, one of the students' difficulties could be found in conversion between registers (S1–S2).

An interesting difference we have to take in account is that the multiple choice question obliges the student to coordinate graphical register with the verbal one, because using written verbal register to represent fractions is quite unused in Italian schools for the solutions. Probably some wrong answers are due to a combination of these difficulties. It will be possible to validate this conjecture only in the second part of the project, that will be carried out through interviews and classroom experiments – on the qualitative side – and correlating sets of data from the same sub-sample of students in the two grades. Comparing the percentage of correct answers, we notice that from grade 6 to grade 8 it decreases of 13 percentage point (from 55% to 42%), thus there is a significant group of students that is able to give a correct answer to D2 question but not to D25, even if the operations required to give the right answer are the same. Indeed, there is a peculiar feature of D25 which make this question more difficult and the main difference can be identified in the presence of a direct reference to fractions.

CONCLUSION AND FUTURE PRESPECTIVE

In this paper, we show an example of longitudinally linked items (these can be seen as paradigmatic examples of questions) that can identify poor knowledge students in specific tasks. From the methodological point of view we selected these questions both using quantitative and qualitative methods intertwined. In particular statistical analysis on a big amount of data allowed us to focus our attention on a group of students, and starting from their performances we could select a set of items of interest for our aim. The opportunity to use data about the same cohort of student in different grades has been exploited linking the selected questions from 2013 test to questions of the 2011 one. This connection is achieved through a qualitative study focuses on the epistemological, cognitive and educational aspects: i.e. we analyse the concepts involved, the representations and schemes (Vergnaud, 2009) developed by students in order to face that the task, and the possible difficulties arising from conversion among different semiotic representations (Duval, 2003).

The comparison of the linked questions outcomes strengthens the a priori analysis of possible students' difficulties facing these items. We identified the same coded difficulties and the percentages in outcomes are similar. The qualitative analysis of the grade 6 item allows us to formulate hypothesis for the selection of options in grade 8 item; it is reasonable to assume that grade 6 question outcomes can have a predictive power for the grade 8 ones, but only the classroom experiment can confirm it. In particular, as concerns the analysed questions, we can assume that the students who have difficulties in dividing a figure in equivalent pieces in grade 6 will tend to consider non-equivalent parts in graphical representation of fractions in grade 8. Similarly, the students who do not consider all the parts in a figure (in our example, the grey part) will be inclined to convert graphical representation of fraction in symbolic or verbal ones with a wrong denominator. Further interviews can confirm if students that have a difficulty in one of the questions have the same difficulties in the other. These interviews could be integrated with a correlation analysis of outcomes within already collected data.

The next phase of the project is going to involve some schools to identify students with peculiar difficulties on the selected items and to analyse their behaviours. We can show how our analysis points out some groups of questions (in different grades) that could identify poor knowledge students in specific mathematics contents. We would like to share with the teachers involved both our theoretical tools and the analysis of the data. It is important for us to understand if the tools produced are usable by the teachers.

These qualitative analysis of the items could be also useful for the teachers who design the test items because it shows some elements that can discriminate in the assessment of poor knowledge students.

From a statistical point of view, future developments of this work could include the implementation of a multilevel latent class analysis (Vermunt, 2003; 2008). In fact, traditional latent class analysis assumes that observations are independent while a hierarchical structure could be present (e.g., students nested within classes or schools). The multilevel latent class analysis could account for the nested structure of the data by allowing latent class intercepts to vary across groups (level 2 units) and by investigating if and how the groups affect the level 1 latent classes. In our study, this analysis would allow to examine how the probability of belonging to a particular performance group could vary across level 2 units (classes or schools). Finally, covariates could be introduced at level 1 and level 2 in order to predict the probability of belonging to a certain latent class.

The role of comparison in the construction and deconstruction of boundaries

David Clarke

University of Melbourne, Melbourne, Australia, d.clarke@unimelb.edu.au

This paper addresses comparative research from the perspective of boundary crossing and argues that all research is intrinsically comparative and, as such, continually engages in the useful and productive activity of constructing and reconstructing boundaries. Recognition of the significance of acts of comparison in both boundary crossing and boundary construction foregrounds comparison as a key tool in the essential act of boundary deconstruction. International comparative research in mathematics education provides the examples illustrative of the points being made. It is incumbent upon researchers in mathematics education to consider what boundaries they invoke in their comparisons and to examine critically the form of boundary crossing implicit in their particular comparison event.

Keywords: Comparative research, boundary construction, boundary crossing.

COMPARATIVE RESEARCH AND BOUNDARIES

It is the assertion of this paper that it is the business of research to continually engage in the useful and productive activity of constructing boundaries. It is also true that some of the least useful and most harmful boundaries are also products of research. I would further argue that there is a fundamental redundancy to the expression "Comparative Research," since comparison is implicit in all research. Nonetheless, this paper will continue to employ the expression "Comparative Research" to refer to those research designs for which the focus is on specific, differentiated objects, communities or systems about which an act of comparison is to be undertaken. By contrast, a longitudinal study of evolving practice in a single classroom would not conventionally be thought of as a comparative study, yet the comparison between current and recent practice is continual in such a design. At the heart of this paper is the argument that acts of research comparison necessarily construct boundaries that distinguish between the objects, groups, communities, settings or systems that are compared. These boundaries are important. Without them, our acts of comparison are futile. As a consequence, boundary construction is an inevitable entailment of all research activity.

RESEARCH AS COMPARISON: THE RIGHT TO COMPARE

A paper presented at the previous CERME conference, posited the Validity-Comparability Compromise as a central consideration in cross-cultural research in mathematics education (Clarke, 2013a). In this earlier paper, commensurability was interpreted as the right to compare. And the central assertion was that this right to compare cannot be assumed, but is contingent on our capacity to legitimise both the act of comparison and the categories through which this act is performed. This earlier paper identified key considerations affecting the conduct and utility of international comparative research. It posited as central to research design the dual imperatives of validity and comparability and argued that these imperatives are inevitably in tension. The paper identified, illustrated and discussed those tensions, utilising very specific examples from current international comparative research. It was argued that any value that might be derived from international comparisons of curricula or classroom practice is critically contingent on how the research design addresses the dual priorities of validity and comparability. It was further argued that since these priorities act against each other, researchers undertaking international comparative research must find a satisfactory balance between these competing obligations.

Since it can be argued that all research involves acts of comparison (or "comparison events" from the perspective of Verran (2011)), any examination of the principles and contingencies which frame international comparative research will have implications for research in general. Those research designs currently associated with Comparative Research provide rich and fertile ground in which to speculate about the association between boundary construction and the acts of research comparison. The previous paper (Clarke, 2013a) questioned the assumptions we might make about our right to compare and attempted to foreground the decisions and obligations confronting a researcher undertaking particular types of comparison. This paper examines the nature of the boundaries constructed through our acts of comparison, the status that might be accorded to those boundaries, and our responsibilities as researchers to acknowledge our role in boundary construction. Further, making a virtue of necessity, I argue that sensitivity to the entailments of our comparative acts can assist us in the deconstruction of those boundaries created by our research. Such deconstruction would then better equip us to celebrate the useful work performed by those boundaries, while sensitising us to possible dangers, such as unwarranted extrapolation or generalisation, reification, segregation, stagnation or sanctification.

COMPARATIVE RESEARCH AS BOUNDARY CROSSING

If all research involves comparison, and all comparisons invoke or create boundaries, then my further proposition is that all research, and Comparative Research in particular, involves acts of boundary crossing.

It is useful at this point to consider the proliferation of boundary-related terms pervading educational literature at the moment: boundary crossing, boundary object, boundary interactions, boundary practices, and boundary zones (see Akkerman & Bakker (2011) for a useful discussion). Underlying all these terms is an inevitable uncertainty about what the term "boundary" actually refers to; inevitable, because its use and referent will vary from study to study. Boundaries are constructions, built of language through discourse. However, we respond to boundaries in different ways. Sometimes the boundary appears as a natural feature, like a river, separating one habitat from another; sometimes, as an artefact, like a wall, constructed to enclose or to separate; and, sometimes, as the principles by which the members of a club or society are distinguished from non-members [1]. Given such variation, the nature of boundary crossing itself must take different forms. The remainder of this paper addresses possible different approaches to boundary crossing and attempts to illustrate its points with examples relevant to mathematics education. The lead question, to structure this discussion, is "How do you cross a boundary?" Sometimes, the answer to this question can provide significant insight into the nature of the particular boundary. Each method of boundary crossing comes with its own caveat.

METHODS OF BOUNDARY CROSSING

One way to cross a boundary is to abolish it

> The insertion of cultural artifacts into human actions was revolutionary in that the basic unit of analysis now overcame the split between the Cartesian individual and the untouchable societal structure (Engeström, 2001, p. 134).

In this instance, the boundary between the individual and the physical world was abolished as a matter of theoretical dictate. In the field of research, the redefinition of metrics can significantly reconstruct boundaries. As a case in point, between the 2000 and 2003 administrations of PISA, Australia moved from "low equity" to "high equity" status without apparent change in practice, but through "slight variation in the way 'equity' was measured in PISA" (Gorur, 2014). In such cases, boundaries are re-drawn without additional evidence and a school system may cross from one grouping to another as a matter of legislation, rather than any change in either practice or outcome. Political examples of such boundary crossing by proclamation are extremely common.

Every act of boundary crossing can be associated with at least one potential danger, represented in this paper as a caveat.

CAVEAT: the abolition of boundaries can deny the recognition of diversity.

Each abolished boundary assigns an integrity or connectedness to otherwise distinguished entities (students, teachers, school systems, or task types) as members of a unified aggregate that conceals diversity. These concealed diversities may disempower the communities now integrated and may deny the researcher both explanatory alternatives and possibilities for advocacy of action. A particularly obvious example is the national aggregation of student achievement scores across category distinctions of ethnicity or socio-economic status that, once dissolved, no longer offer avenues for researcher comparison, explanation, advocacy or political action (e.g., Berliner, 2001; see also Clarke, 2003).

Another way to cross a boundary is to demolish it

The distinction between abolition and demolition for me is one of theoretical dictate vs empirical demonstration. Theory or simply accepted wisdom (entrenched belief) may treat a boundary as well-established, in that it distinguishes two categories of occurrence or situational domains that are conceptually distinct in a useful way. However, if empirical evidence pertinent to the characteristics held to distinguish the bounded domains is not consistent with the posited difference, then the boundary must be considered demolished (or at least destabilized) on evidential grounds. This destabilizing of boundaries can be highly productive. The lack of evidence of difference, where difference might be expected, should lead us to interrogate the original assumptions on which that difference was posited.

As a case in point, PISA student achievement performance is commonly invoked as providing evidence of curricular or pedagogical difference. The inability of PISA scores to distinguish between Korea and Finland, therefore demolishes a putative boundary that would have those two school systems in distinct domains, while calling into question the evidential value of similar distinctions that appeared to reify expected boundaries between other school systems (Clarke, 2013b). To labor this point: the distinction between high-achieving and low-achieving countries, as identified through either PISA or TIMSS performance, has been interpreted as indicating associated pedagogical differences that should inform educational change in less successful school systems. Research in classrooms in Korea and Finland problematize any simplistic clustering of Korean and Finnish school systems as pedagogically similar. Similarity seems limited to the comparable (measurably equivalent) success of their students on international tests of student achievement. The comparability of Korea and Finland in one respect usefully destabilizes generalized assumptions of difference with respect to the compared systems, but also (because of differences known from other measures/studies) suggests that the dissolution of boundaries is highly specific and cannot be simplistically generalized. It does, however, suggest the particularly useful question: "For what educational attributes might Korea and Finland be considered to reside in the same domain?"

CAVEAT: The demolition of a boundary can create a misleading appearance of homogeneity. Boundaries are situated constructions of prescribed conceptual tenure.

Yet another way to cross a boundary is to build a bridge

What is the work of a bridge? A bridge conveys individuals, groups, ideas or artefacts between domains. It does not interact with the boundary, but passes over it. When attempts are made to measure a construct like "Civic Principles" with sub-constructs such as equity, freedom, and social cohesion (IEA Civic Education Study, Shultz & Sibberns, 2004), the assumption that the construct can be defined in a commensurable fashion across two school systems builds a bridge between those school systems. Emergent empirical differences reify the boundary without necessarily interacting with or interrogating it. In the same way, assumptions of curricular comparability with respect to mathematics, such that mathematical performance is commensurable across various political and cultural boundaries, then generate differences, which retrospectively consolidate the boundary and the respective domains being compared.

We know from comparative analyses of mathematics curricula that different school systems do not organize their mathematics content in the same way (see Figure 1). Figures 1 and 2 show the results of comparative analyses of the Australian, Chinese and Finnish national mathematics curricula for the years of compulsory schooling. The categories employed in both analyses are adapted from the work of Porter and his colleagues (Porter & Smithson, 2001; and see Xu, Kang, & Clarke, 2011).

As can be seen from Figure 1, both the content and its sequencing differ significantly between the three countries. Perhaps, as importantly, the types of mathematical performances (levels of cognitive demand) specified in the three curricula also differ significantly (see Figure 2). Figures 1 and 2 demonstrate profound differences in not only the nature of the mathematics considered essential but in the types of

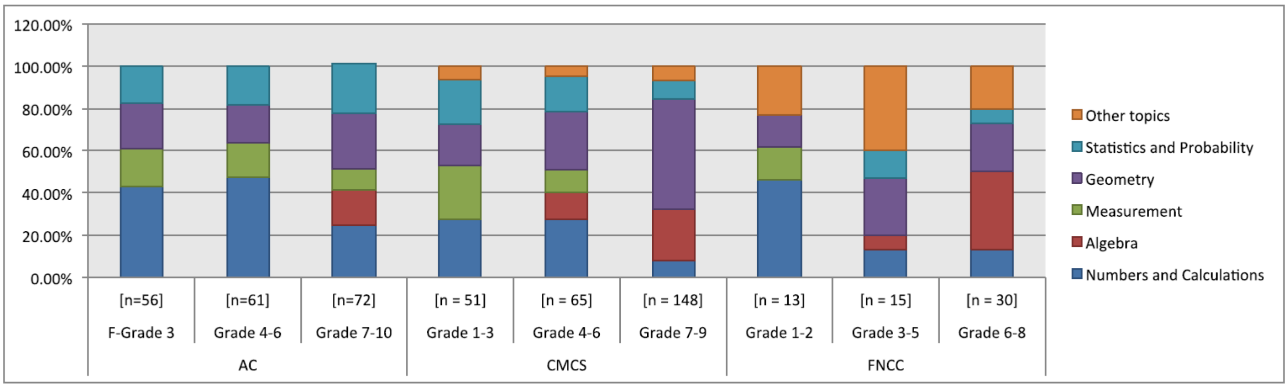

Figure 1: Comparison of Australian, Chinese and Finnish Mathematics Curricula by Content Category

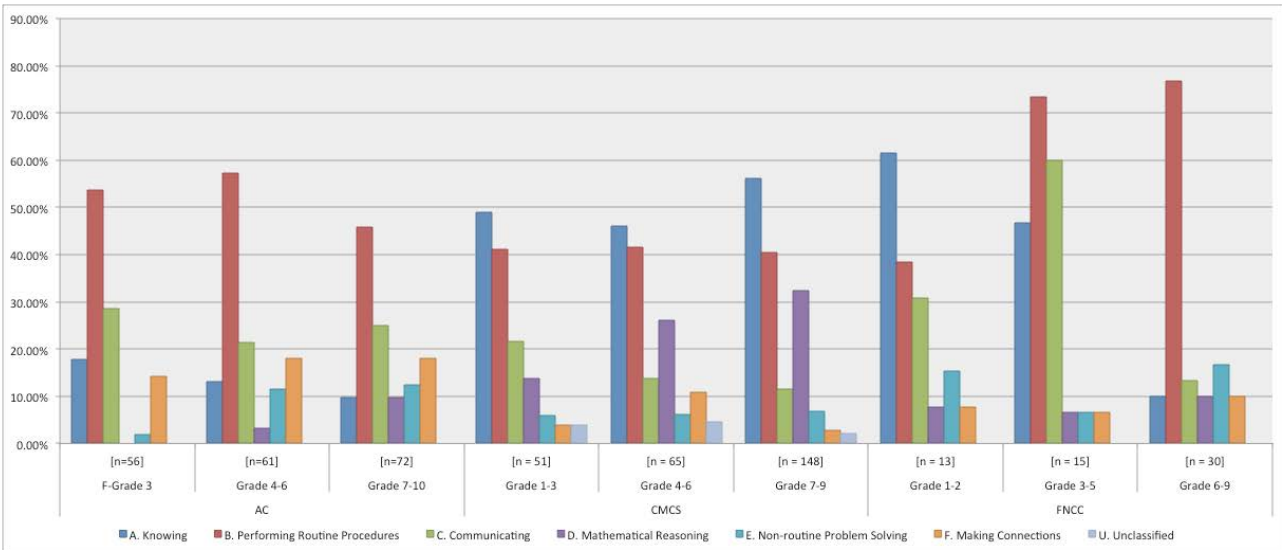

Figure 2: Comparison of Australian, Chinese and Finnish Mathematics Curricula by Performance Type (Cognitive Demand)

student performances promoted in relation to this content.

The measurement of student mathematical achievement on international tests such as PISA or TIMSS constructs a bridge between the mathematics curricula in the participating countries that affords comparison with respect to the performances attributable to students benefiting from the various curricula. The institution of international testing provides the bridge for this form of border crossing and reifies through the international acclamation of its findings the boundaries its acts of comparison have simultaneously surmounted and invoked.

CAVEAT: Bridges can institutionalize both difference and the defining boundary, differentiating what is being connected.

Bridges such as international testing regimes, university ranking schemes, and school comparison metrics (see, for example, the Australian *My School* website: http://www.myschool.edu.au) institutionalize the measures they document and the differences arising from their comparison. The paradox of simultaneously differentiating what is being connected through the act of comparison is at the core of the activity of research comparison. As was discussed in the previous CERME paper (Clarke, 2013a), we must scrutinize the legitimacy of the act of comparison because its consequences can consolidate the boundary it appears to transcend: both constructing and concealing difference (Clarke, 2013b).

A fourth way is to find objects to which the boundary is permeable

A truly impermeable boundary would prevent all possibility of comparison. Another way to say the same thing is that there would be no objects pertaining to one domain that had meaning within the other domain and nothing, therefore, that could serve as the basis for comparison. In one form of contemporary boundary-speak, there would be no possibility of a "boundary object" (Star & Griesemer, 1989). I do not propose to make continued use of the term "boundary object" in this paper. The term is sufficiently widely used to have become ill-defined or at least variously defined and my metaphor of permeability will serve my purpose without the added burden of any possible misunderstandings of another multi-faceted term.

To provide a contemporary context for this form of boundary crossing, I would like to situate the discussion around the acronym "STEM." The acronym STEM has achieved recent popularity and is simultaneously invoked to affirm a perceived distinction between STEM and non-STEM disciplines, the implicit integrity of a knowledge domain designated by STEM, and the independent integrity of the constituent elements of STEM, that is, Science, Technology, Engineering and Mathematics [2]. In fact, it seems that STEM is invoked in educational discussion as frequently to distinguish its constituent knowledge domains as it is to affirm their connectedness. This simultaneous invocation of integration and distinction makes STEM an ideal site to employ "boundary crossing" as an interrogative tool.

We have become so accustomed to the subject grouping for which STEM is the acronym, that it is difficult to recognize that STEM could be the name for a fairly monumental category error. One approach is to consider the nature of the truth claims characteristic of each discipline and the authorities to which these might appeal:

Science – empirical consistency

Technology – tool utility

Engineering – built viability

Mathematics – logical coherence

This approach demonstrates just how fundamental are the differences between STEM disciplines. If STEM, as representative of some unitary aggregate or assemblage, is to be of value in educational (or other) settings, then we need a mechanism to enable boundary crossing between the STEM disciplines. In this fourth approach to boundary crossing, we examine those constructs to which the boundary walls of the STEM disciplines seem most permeable. What we need to identify are constructs that demonstrably do explanatory or at least classificatory work in more than one domain within STEM.

How permeable are the disciplinary boundaries within STEM? And to which constructs are they permeable? Here are four contenders [3]:

Discourse – reasonable speech

Artefacts – constructed objects

Reasoning – purposeful thought

Evidence – objects of justification

Take "Evidence" as a construct having currency in each of the STEM disciplines. What qualifies as evidence in the domain of mathematics may be differently conceived than in science. Yet the function of evidence remains arguably the same in each domain: the validation of truth claims. Research seeking to compare phenomena across the STEM disciplines can do useful work by addressing how constructs such as Evidence are employed. How are these constructs transformed in their passage between STEM cells? Do we find conservation of function accompanied by transformation of form? Are the differences between STEM and non-STEM domains with respect to either the function or form of Evidence so disjoint that our act of comparison, legitimized by the existence of a construct (Evidence) to which the STEM to non-STEM boundary is permeable, retrospectively amplifies the STEM non-STEM distinction and consolidates that same boundary?

CAVEAT: How are these objects transformed in their passage through the boundary? Does conservation of function but transformation of form maintain object identity and consequently comparability?

We start to hear echoes of the Validity-Comparability Compromise (Clarke, 2013a), as the empirically-driven opacity (impermeability) of the boundary undermines the legitimacy of the very comparison that is rendering it more opaque. I suggest that the status of our "boundary object" as "boundary object" is critically dependent on the balance between sufficient similarity to support comparison and sufficient difference to sustain the boundary.

A fifth way to cross a boundary is to federalize the collective of bounded regions into a structured unity

STEM also provides an example amenable to our fifth method of boundary crossing. If we consider STEM to be a confederation of states subject to the same legislative and constitutional principles, but independently organized for many practical purposes, then boundary crossing is achieved through the identification or articulation of those constitutional (and constituting) principles. Not only does this approach constitute a form of boundary crossing by transcending intercellular STEM boundaries, but it also holds the capacity to regulate the process of boundary crossing by legislating which responsibilities are shared and which are the specific province of each domain. For example, is Evidence universally invoked, but Proof restricted to the domain of Mathematics? The mechanism whereby such principles of intellectual trafficking are laid down will reflect the relative agency and voice given to the constituent entities in the federated states of STEM. Dominance of any particular voice in determining the principles of exchange (e.g., the standards for evidence-based practice) would constitute an act of colonization.

CAVEAT: Federation is a commendable aspiration provided it does not become colonization. Who speaks for each bounded region?

Again, we find echoes of the concerns expressed by Clarke (2013a), elaborating the proposition: "Comparison must not be unilateral" (Stengers, 2011). In the context of international comparative research, any construct employed for the comparison of the classroom practices of Confucian-Heritage-Cultures and "Western" cultures must be sanctioned by each conglomerate community as legitimately typifying some shared aspect of both. Such shared aspects cannot be identified unilaterally (Clarke, 2013b).

A sixth way to cross a boundary is to accept responsibility for its construction (and deconstruction)

Each act of comparison simultaneously achieves the researcher's creation of the domains that are the subject of comparison and the boundary by which the domains are defined and distinguished. Each research report solicits the reader's complicity in these acts of construction and distinction. As already discussed, the event of comparison may be predicated on a presumption of difference that provided the warrant for comparison, but the consequences of the comparative activity may provide evidence that could either consolidate or destabilise the boundary on which the legitimacy of the comparison was predicated.

From this perspective, boundaries must be seen as fragile entities, ephemeral, continually changing and immensely useful. Eugene Ionescu once stated, "Only the ephemeral is of lasting value" (see Rothenburg, 1993). Whatever ideological commitments we might all feel to inclusivity, our practice as researchers acts to divide, to create boundaries. We do this most visibly in Comparative Research, where acts of comparison are foregrounded, as are the domains across which we compare. As has been argued, these acts of comparison have the inevitable outcome of constructing boundaries. Our obligation as researchers is to acknowledge this activity and engage simultaneously in both the construction and the deconstruction of these boundaries. In this way, by accepting our role in boundary construction, we position ourselves across (on both sides of) the boundary, not only able to make comparison but also to examine the implications of that comparison for the boundary it presumes. This examination will require the deconstruction of the boundary, providing insight into its utility, its fluidity and what I have called its conceptual tenure.

SUMMATIVE DISCUSSION

Boundaries are constructions, built of language through discourse. They are inevitably purposeful and can be both useful and affirming. They must also be fluid, in the sense that they must always be subject to contention, to destabilisation, and, consequently, open to deconstruction and reconstruction.

In this paper, I have foregrounded the role of comparison (in Comparative Research and in research in general) in creating and crossing boundaries. Viewing the various events of Comparative Research from the perspective of boundary crossing sensitizes us to the role research plays in creating boundaries and to the implications for our research of both the possible nature of these boundaries and of the process of boundary crossing that is also intrinsic to our research activity.

International comparative research in mathematics education can both create and destabilize boundaries in ways that enhance or impede our ability to benefit from the practices of mathematics classrooms and school systems elsewhere. The boundaries we construct should clarify our understandings, not impede their application. Equally, our destabilisation of existing boundaries should result from our demonstration that some boundaries do no useful work, but rather inhibit our consideration of alternative ways to conceptualise our discipline, our pedagogy, and even our research.

ENDNOTES

1. It is important to note the dangers of specific instantiations of a more generalized construct: a river, a wall and a set of principles can all serve as boundaries; but a river can connect, a wall can protect and a set of principles can empower. The illuminating illustration can also mislead and we need to be sensitive to entailments of such examples that are no part of the boundary function for which they were invoked.

2. In fact, it is arguable that STEM encompasses many more knowledge domains than simply Science, Technology, Engineering and Mathematics; each of which (as we have seen for mathematics) cannot be treated as consensually defined. Bioinformatics provides a useful example of a STEM discipline that is both additional to and a hybridization of the 'primary' STEM domains.

3. More detailed discussion can be found in (Clarke, 2014).

The 'New Math' reform and pedagogical flows in Hungarian and French mathematics education

Katalin Gosztonyi

University of Szeged, Bolyai Institute, Szeged, Hungary
University Paris Diderot, Laboratoire de Didactique André Revuz, Paris, France, katalin.gosztonyi@gmail.com

In this paper, I present my PhD research (in progress) focusing on the mathematical reform movements of Hungary and France in the 1960s and '70s and their origins: especially how much they were influenced by the international "New Math" movement, and by the mathematical and mathematics education traditions of these countries. I consider different aspects of the reform: curricula, textbooks, teaching practices. I look for their general characteristics, in the sense of the Pedagogical Flow approach (Schmidt et al., 1996), the leading principles behind these characteristics and the historical-cultural origins of these principles. In this paper, I present elements of this research, focusing on the example of the Pythagorean theorem.

Keywords: Pedagogical flow, New Math, Pythagorean theorem, textbook analysis, comparative research.

INTRODUCTION

Although the reform introduced by Tamás Varga during the 1960s and '70s is generally recognized by the Hungarian mathematics education community as a key moment in the history of Hungarian mathematics education, having an important influence and keeping its values until today, its detailed historical or didactical analysis is lacking [1]. In my research, I consider Varga's work in its international context, comparing to the French "Mathématiques Modernes" reform of the same period: one of the most influential reforms during the international "New Math" movement, and also one of the well described ones, thanks to French historians of mathematics education (e.g., d'Enfert & Kahn, 2011). I attempt to describe general characteristics of these reforms, looking for coherent aspects between their different elements. Beyond common characteristics of the two countries' reforms, issued from the international discourse, I attempt to underline differences, and to show how they ensue from cultural traditions of the countries in question. I focus especially on mathematicians' conceptions about the nature of mathematics and its teaching.

I apply the term "pedagogical flow" in accordance with (Schmidt et al., 1996), where the international research group preparing the TIMSS studies introduces it to describe general characteristics of the mathematics educational system of a country which are present in different elements of mathematics education (as in curricula, textbooks, teaching practices). However, the cultural background of these characteristics, even if supposed, is hardly explored in (Schmidt et al., 1996); and the general model used by this research, the model SMSO which presents interrelations between the different levels of an educational system in detail, does not take into account the cultural, political, social or scientific background. Another model, the levels of codetermination of Chevallard (2002) takes these aspects into account, but integrates them into one hierarchical and linear system, and supposes that broader institutions like society or the scientific community of a country determine the lower levels of the system, such as the teaching of mathematics, for example.

In my research, I take into account complex interrelations between different elements (e.g., political, social, scientific and cultural) of the historical context, and the characteristics of the reform in each country. I focus more in detail on the epistemological background of mathematics and its teaching, expressed by a community of mathematicians in each studied country (communities which were particularly influential in the "New Math" period, as it is showed in the historical part of the study). By analysing written documents of the reforms: curricula, textbooks, teachers' handbooks and also the teaching practices suggested by these documents, I try to show how the conceptions expressed by mathematicians about mathematics and its teaching appear in the didactical characteristics of the reforms. In this paper, I focus on the example of the geometry curricula and, in particular, the Pythagorean theorem.

The "New Math" reform period is particularly suitable for this kind of research for several reasons. First, the "New Math" reforms are profound reforms, transforming curricula, resources and attended teaching practices in a coherent way, in accordance to some leading principles [2]. Secondly, exactly because of the profound changes, characteristics of the reform and the underlying principles are often explained in detail to inform the teachers and the society. Thirdly, the wide international discourses of the period make the comparison easier.

Finally, even though the "New Math" period is already history, it is not very far-away, and has its influence until today. Comparison of the present research to some more modern studies about "pedagogical flows" (e.g., Schmidt et al., 1996, for France; Andrews & Hatch, 2001, for Hungary) allows us to suppose a certain continuity. In this sense, the research on the "New Math" reform of Hungary and France can contribute to a better understanding of the historical, cultural and epistemological background of pedagogical flow in these countries.

METHODOLOGY

The research consists of three major parts: a historical, an epistemological and a didactical part. The first part of the research, concerning the history of mathematics education, is based on existing historical studies about France and about the international discourse of the "New Math" period. Concerning Hungary, general works on the history of pedagogy, original official sources, as well as written and oral memories of Varga's colleagues are used.

For the second, epistemological part, writings of mathematicians influencing the reforms are analysed: publications and lectures about mathematics education, mathematics popularisation books and correspondences. I look for characteristics of these mathematicians' conception about mathematics, and their main principles about its teaching.

The third, main part of the research is based on analytical tools provided by French theoretical frameworks of mathematics education research. After a general analysis of the content and of the structure of the curricula, three chapters are chosen from the first 8 grades in Hungary, and from the first 9 grades in France (primary and middle-school in each case). The analysis contains 1) an analysis of the place and role of the chosen chapter in the curriculum, based on the "ecological approach" of the Anthropological Theory of Didactics (Artaud, 1997); 2) a structural, rhetorical and linguistic analysis of the textbooks and teacher's handbooks; 3) an analysis of the teaching practices suggested by these resources, based on the Theory of Didactical Situations of Brousseau (1998).

THE HISTORICAL CONTEXT

During the 1960's and 70's, the international "New Math" reform movement, starting from the US and from some countries in Western Europe, influenced mathematics education in many countries of the world. France was one of the leading countries in this movement. International and French research studies underline the role of the technological competition of the Cold War, of mathematicians' efforts to integrate elements of modern mathematics, of the psychological discourses (first of all around Piaget), of the development of the educational systems and of society in the "New Math" reforms (e.g., d'Enfert & Kahn, 2011; Kilpatrick, 2012). Similar processes can be shown concerning Hungary.

The French reform called "Mathématiques Modernes" was introduced in 1969 for secondary, and in 1970 for primary education, following the work of a national committee led by the mathematician Lichnerowicz, but also vivid debates in teachers' associations and different, mostly short term experimentations. A modification of the reform took place in 1977.

In the same period in Hungary, a reform project was led by Tamás Varga, inspired by experiments of different countries but also by some Hungarian mathematicians and psychologists, and based on a long experimentation process since 1963 (Varga, 1975). This project was selected by a ministerial committee as basis of the reform of mathematics education, and the new official curriculum was introduced in 1978.

MATHEMATICIANS' DISCOURSES ON MATHEMATICS EDUCATION

In the "New Math" period, mathematicians participated actively in influencing mathematics education. In France, several mathematicians, often members of, or near to the Bourbaki group, expressed their opinions (e.g., Dieudonné, Choquet or Lichnerowicz, the leader of the committee preparing the reform). They emphasize the importance of modern, unified formal language, abstraction, structures and the axiomatic-deductive method in mathematics education. According to them, structures of modern mathematics correspond perfectly to the structures of human thinking; therefore they suggest that students should be introduced as quickly as possible to the use of this language and methodology (see, e.g., Piaget et al., 1955) [3].

In Hungary, mathematicians also took an active role in the reform movement of the period in question. In my present research, I focus on a group of first-rate Hungarian mathematicians who were interested in education since the 1940's and had important influence on the later reforms: first of all L. Kalmár, R. Péter, A. Rényi, L. Surányi, but also Hungarian thinkers living abroad: G. Pólya and I. Lakatos.

The analysis of their diverse writings (Gosztonyi, 2012) shows that these Hungarian mathematicians' image of mathematics is in deep contradiction with the one represented by the Bourbaki-school. They see mathematics as a constantly developing and changing creation of the human mind, and this development is guided by series of problems. According to them, the source of mathematics is intuition and experience; mathematical activity is basically dialogical and teaching mathematics is a joint activity of the students and of the teacher, where the teacher acts as an aid in the students' rediscovery of mathematics. Excessive formalism is discouraged; formal language being also seen as a result of a development. Mathematics is presented as a creative activity closely related to playing and to the arts.

DIDACTICAL ANALYSIS OF THE REFORMS

The content and the structure of the curricula

Concerning the curricula, both reforms aim to introduce new chapters from modern mathematics (such as set theory, logic, topology etc.), and to present mathematics as an integrated science (not "counting and measuring" as before the reform). But the way of realising this, the structure of the curricula is very different in the two countries; while the French curriculum is strictly hierarchic and linear, based on set theory, the Hungarian curriculum contains five big topics which are present in parallel during all the curriculum and interact with each other in a dialectic way: 1) sets and logic 2) arithmetic and algebra 3) relations, functions and series 4) geometry and measure and 5) combinatorics, probability and statistics.

In the followings I briefly present the case of the geometry curricula and that of the Pythagorean theorem.

In the French geometry curriculum of 1969 and 1970, an important break is marked between the lower grades (until 7th grade) and the last two years of the middle-school (8th and 9th grade). In the lower grades, geometry has minor importance, and is not recognised as 'veritable mathematics': the related chapters of the curriculum are named "observations of physical objects" and "practical exercises". The curriculum underlines that the study of 'veritable geometry' starts from the 8th grade, as an example of axiomatic thinking. Axioms and notions have to be introduced via physical observations, but once they are admitted, they have to be clearly distinguished from the physical word and every further theorem has to be deduced by formal demonstrations.

The study of geometry follows the axiomatic construction of real numbers, and is based on this last notion. Classical synthetic geometry is completely eliminated: the main aim of this geometry curriculum (in accordance with Bourbaki's construction of mathematics, where geometry is not an autonomous domain but part of topology) is not to study geometrical figures but to construct an algebraic tool to describe first the affine, then the Euclidian plane and space. Principal notions are projections, vectors, frames, transformations etc.

In this French curriculum, the Pythagorean Theorem is of limited importance: it is integrated in a bigger chapter about the Euclidian plane, as an algebraic consequence of a property of the orthogonal projection, and contributes to the construction of the notion of an orthogonal frame [4].

The Hungarian curriculum links geometry to other domains of modern mathematics (e.g., to set theory; to functions by transformations treated as movements; to combinatorics by discrete geometry), but not in a hierarchic, rather in a dialectic way. The visual nature of geometry plays an important role: geometry offers intuitive examples to treat problems of the other above mentioned domains. Although coordinate-systems are introduced, the studied geometry is mainly synthetic and concerns figures and their properties, transformations and symmetries.

The curriculum emphasises continuity; physical world experiences are present until the end of the middle-school, in a dynamic relation with argumentations and proofs on ideal figures. There is no completely axiomatic geometry in the Hungarian curriculum.

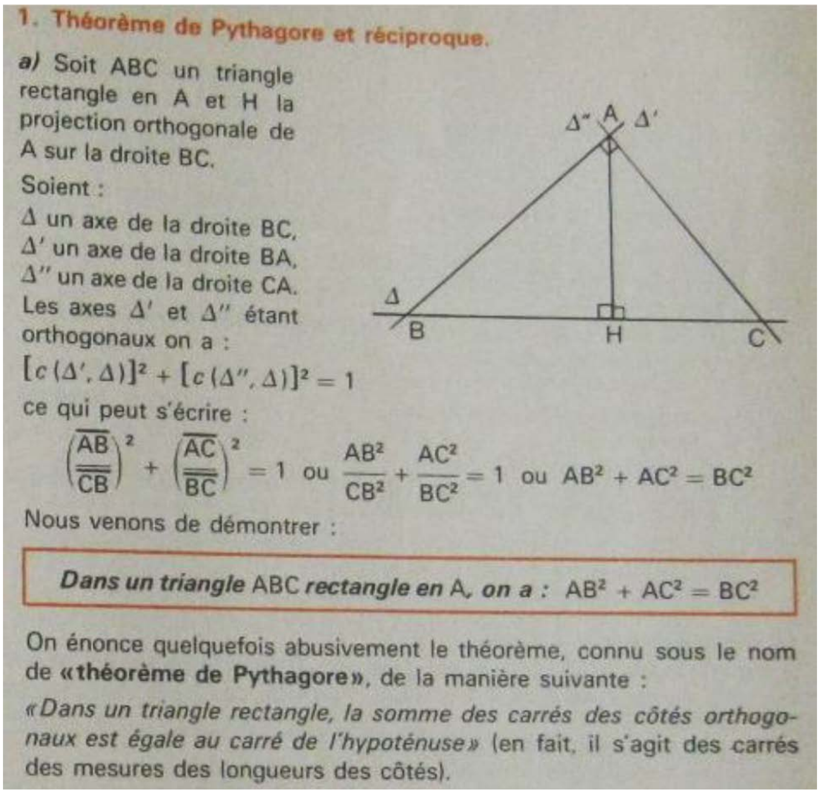
The Pythagorean theorem plays a significant role in this curriculum, not only as an important and useful property of right-angled triangles, but also as one of the first theorems, where students can discover the significance of proving.

The textbooks, teacher's handbooks and the attained teaching practices

In France, there is a great diversity of textbooks and of related handbooks, but some general tendencies can be observed. In Hungary in the period in question, there is only one obligatory series of textbooks. Here I present some structural, rhetorical and linguistic characteristics of middle-school textbooks, their suggestions about teaching practices; treating the example of the Pythagorean theorem in detail.

French middle-school textbooks, according to the curriculum, emphasise the initiation of students in the precise use of mathematical language. The first two years' books give also some natural language examples and describe some physical experiments; the second two years' books contain mainly formal mathematical discourse in an axiomatic-deductive form, followed by some "exercises" at the end of each chapter.

Figure 1 illustrates a typical treatment of the Pythagorean theorem in one of the French textbooks of the period. The demonstration is purely algebraic, requires developed formal and theoretical knowledge. The figure is only an illustration and what it represents is not really a triangle, rather three lines projected on each other. The textbooks, in accordance with the curricula, present the Pythagorean theorem as an element of a big theoretical system, constructing an algebraic tool to describe the plane and the space.



1. Théorème de Pythagore et réciproque.

a) Soit ABC un triangle rectangle en A et H la projection orthogonale de A sur la droite BC.

Soient :

Δ un axe de la droite BC,
Δ' un axe de la droite BA,
Δ'' un axe de la droite CA.

Les axes Δ' et Δ'' étant orthogonaux on a :

$[c(\Delta',\Delta)]^2 + [c(\Delta'',\Delta)]^2 = 1$

ce qui peut s'écrire :

$$\left(\frac{\overline{AB}}{\overline{CB}}\right)^2 + \left(\frac{\overline{AC}}{\overline{BC}}\right)^2 = 1 \text{ ou } \frac{AB^2}{CB^2} + \frac{AC^2}{BC^2} = 1 \text{ ou } AB^2 + AC^2 = BC^2$$

Nous venons de démontrer :

Dans un triangle* ABC *rectangle en* A, *on a : $AB^2 + AC^2 = BC^2$

On énonce quelquefois abusivement le théorème, connu sous le nom de **«théorème de Pythagore»**, de la manière suivante :

«Dans un triangle rectangle, la somme des carrés des côtés orthogonaux est égale au carré de l'hypoténuse» (en fait, il s'agit des carrés des mesures des longueurs des côtés).

Figure 1: (Fauverge, Jeanmot & Rieu, 1976, p. 163) Handbook for the 9th grade

This purely mathematic, deductive treatment corresponds to a lecture form in education: a direct transmission of institutional knowledge by teachers, and passive understanding by students (as we can understand from several textbooks' introduction). Although the introductions of the textbooks emphasise the importance of modern pedagogical methods and students' activity, they give only some general pedagogical indications and little help to concrete pedagogical practice. From the point of view of Brousseau's theory, these textbooks offer little *adidactical potentiality*: occasions to situations when students would engage in the construction of their own mathematical knowledge.[5]

Hungarian middle-school textbooks of the period are different from the presented French ones in several aspects. As we can see in the example presented below, the books contain a number of non-mathematical illustrations and didactical signs (the STOP sign means for example, as it explained in the introduction, that the reader should stop and think about the asked question). They also contain, in every grade, fictive dialogues of students to introduce new knowledge. The related teacher's handbook proposes to provoke similar discussions in the class. The dialogues are guided by a series of problems.

In the case of the Pythagorean theorem (see Figure 2), the first problem concerns the length of a rope stretched across the classroom, so that a student with a given height could stand under it. Students first estimate the result, and then solve the problem by experiment and measurements. The second problem is similar, but instead of the classroom, it concerns the bigger sports hall where students can't perform real experiments. The question is whether the difference between the length of the cord and that of the hall is bigger or smaller than in the case of the first problem. They first try to solve the problem by modelling and measuring, but the approximate result obtained this way isn't precise enough to answer the original question. Then they look for another method to solve the problem, "only with the help of calculations".

At that point, the handbook suggests finding a relation between the sides of a right-angled triangle, and introduces the figure of a classical geometrical proof of the Pythagorean theorem. Even the proof of the theorem is problematised, interrupted by questions and by discussions of students studying the figure. Finally, the theorem is applied to solve the original problem, as well as other problems.

The teaching practice suggested by the teacher's handbook and illustrated in the dialogues of textbooks is a kind of "guided discovery" process: students are guided through a series of problems, while continuing a dialogue between each other and with the teacher about the problems. Intuition, visuality and experiences play important role in this discovery process.

From the point of view of the theory of Brousseau, it is difficult to determine whether this work of students can be called *adidactic*: they rarely work autonomously, without the teacher's intervention (which is a necessary condition of the classical notion of an adidactical situation); nevertheless they take important responsibility in the process of constructing mathematical knowledge. So, the "guided discovery" teaching practice can be interpreted as involving an adidactical character of student's work, even if it doesn't correspond exactly to the classical notion of adidacticity.

CONCLUSION

The different presented aspects of mathematics education: the content and the structure of the curricula, the form of textbooks, and the attended teaching practices show great coherence both in the case of Hungary and of France. This observed coherence allows us to talk about "pedagogical flows" in the sense of (Schmidt et al., 1996).

Some common characteristics of the two reforms can be observed which may take their origin from the international discourses of the New Math period (like the ambition to present mathematics as a new, coherent subject; the emphasis on 'mathematical thinking'; new topics introduced like set theory or logic; the use of manipulative tools, especially in primary school). But there are also some important differences between the two countries, and the analysis of the mathematicians' principles let us suppose that they can be traced back to some mathematical traditions of these countries.

In France, such characteristics are the focus on big theoretical systems and on the strict hierarchical structure of mathematics, the emphasis on the axiomatic-deductive method and on the formal language

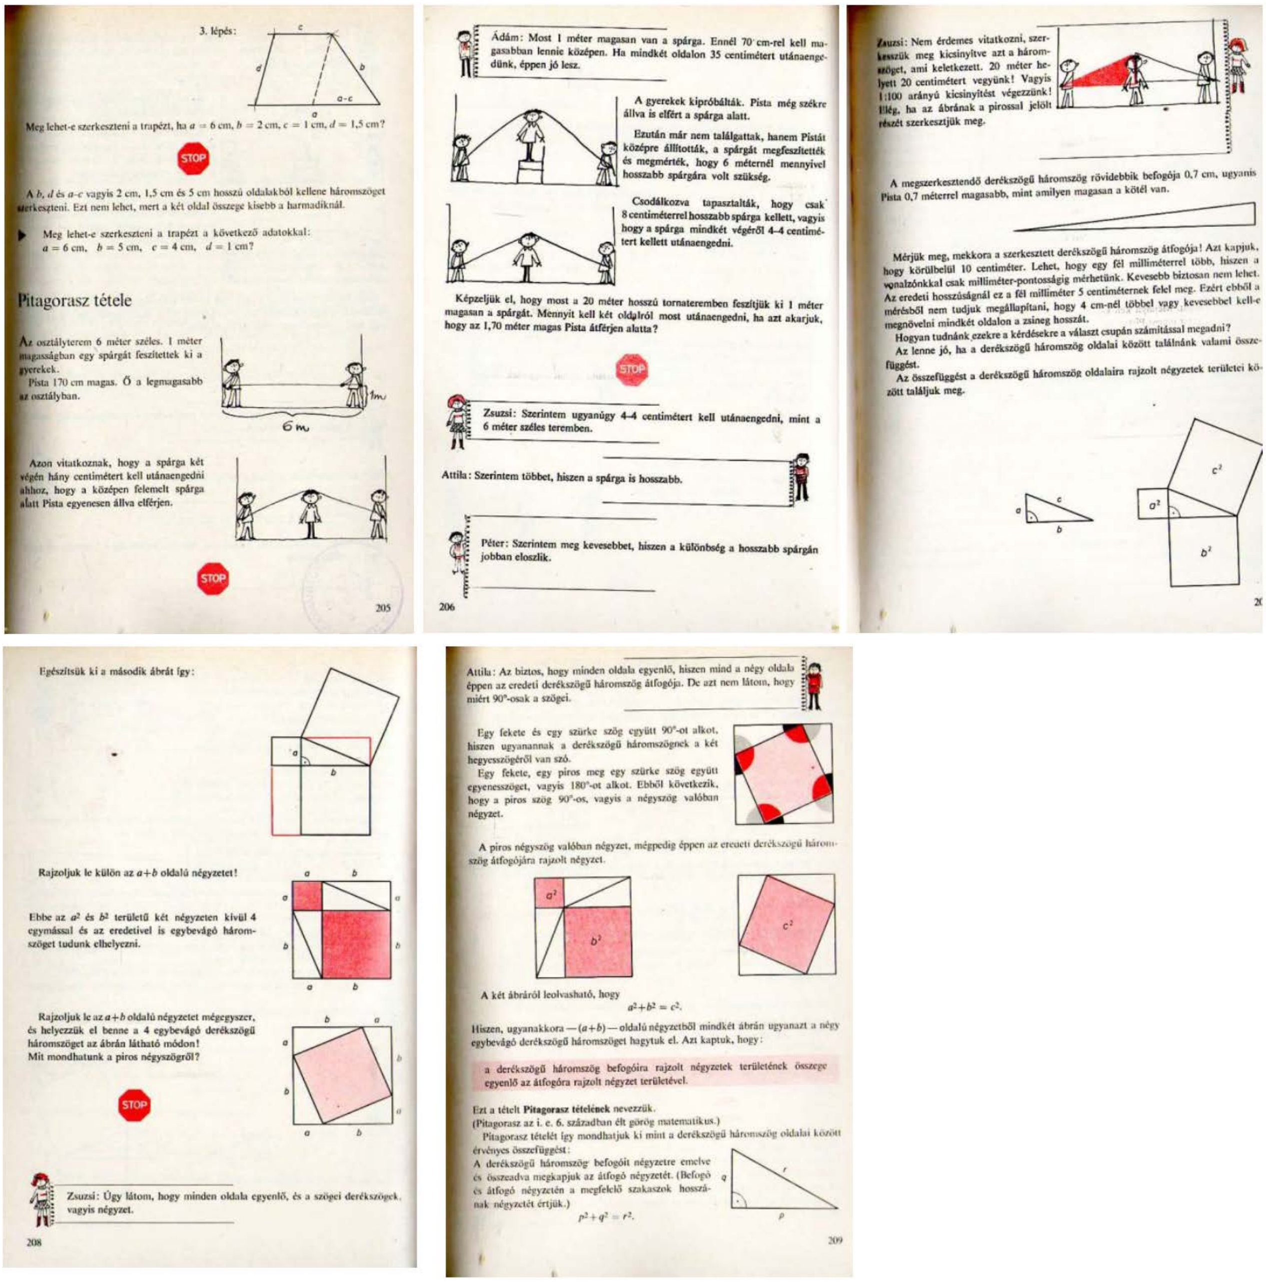


Figure 2: (Kovács, Sz. Földvári & Szeredi, 1980 pp. 205–209.) Handbook for the 7th grade

of mathematics. A principal aim of mathematics education is to initiate students into the knowledge and the methodology established by 'modern mathematics', considered as an ideal of human thinking. A tension can be observed between mathematical and pedagogical ambitions: although teacher's handbooks suggest to middle-school teachers to use some modern methods of active pedagogy, they offer little concrete suggestions to their realisation; the textbooks mostly correspond to the lecture form as a typical teaching practice.

In Hungary, the emphasis is more on the natural development of students' mathematical thinking and problem solving skills. The curriculum content is diversified and different topics interact dialectically, presenting the developmental, rather than the hierarchical nature of mathematics. Varga's curriculum is very careful with introducing formal language, and relies on empirical knowledge and on manipulative tools even on higher levels of mathematics education. A typical teaching form is the dialogue between the teacher and the students while they participate in a common discovery process based on series of problems.

To summarize, the "New Math" reforms of the two countries represent two, almost paradigmatic cases of mathematics education, related to different mathematical traditions and different epistemologies: a "bourbakist" view in the French case and a "heuristic" or "lakatosian" view in the Hungarian case.

The "New Math" is already history, and this research couldn't even attempt to have access to practices in ordinary classes. Curricula and resources changed in important ways in both of the countries since the 1970s, following social debates and didactical research among other factors (actually, the changes seems to be even more important in the French than in the Hungarian case). But, as I mentioned above, a comparison with results of other research works based on current classroom observations, confirms that several observed characteristics remain present both in French and in Hungarian mathematics education (see, e.g., Schmidt et al., 1996; Andrews & Hatch, 2001). The analysis of the "New Math" reforms may complete these existing observations, provide basis for further ones, and contribute to understanding the complex interrelations within a country's pedagogical flow more profoundly.

ENDNOTES

1. Short commemorations with his colleagues are accessible, e.g., in the proceedings of the yearly organised 'Varga Tamás Days' (http://mathdid.elte.hu/html/vtn.html). In English see for example, Szendrei (2007).

2. This research takes into account the *intended* and *potentially implemented* curricula, described in the official documents and in the textbooks and teacher's handbooks. I don't consider the *implemented* curricula, the practice of ordinary teachers in the period, which can be fundamentally different from the intended practices.

3. At the same time, the teachers' association, also influential in the debates around the reform, and convinced by the importance of reforming the content of the curricula, emphasises also the use of modern, active pedagogical methods.

4. The next French curriculum, of 1977, doesn't ask the complete axiomatic construction of real numbers or geometry in the middle-school any more, and emphasises the practice of proof rather than axiomatisation. The mathematical organisation of the geometry curriculum remains similar to the preceding one, however the curriculum provides broader liberty in the organisation of textbooks and in the practice of teachers.

5. This contradiction between pedagogical ambitions and their realisation can be interpreted in the con-

text of the debates mentioned in note 3. The observed tension between mathematical and pedagogical ambitions probably contributes to the emergence of French didactical researches during the 1970's. The textbooks related to the new reform of 1977 follow the development of the debates: although some of them remain similar to the preceding ones, new textbooks appear with more developed pedagogical suggestions, e.g. in problem solving, and with a more classical treatment of geometry, among other things.

Reflection and questioning in classrooms in different cultural settings

Mandy Hommel[1] *and David Clarke*[2]

1 TU Dresden, Faculty of Economics, Chair of Business Education and Management Training, Dresden, Germany, mandy.hommel@tu-dresden.de

2 University of Melbourne, Melbourne, Australia, d.clarke@unimelb.edu.au

Reflection in classroom learning leads to a deeper understanding and helps to connect knowledge with application situations. Socially initiated reflection can be observed as a lesson event embedded in Review, Elaboration, and Summarization. Questions constitute a primary catalyst for stimulating reflection, particularly in classroom settings. This study[1] *investigates reflection events and related questioning behaviour of students and teachers by undertaking a comparative analysis of video data from the Learner's Perspective Study (LPS; Clarke, Keitel, & Shimizu 2006) in classrooms in Australia, Germany, Japan, and the USA.*

Keywords: Reflection, questions, patterns of question sequences.

INTRODUCTION

Already Dewey has pointed out, that reflective thought "... alone is truly educative in value..." (1910, p. 2). The importance of reflection in facilitating and shaping learning processes is broadly accepted. Reflection creates the conditions for the utilisation of new information in several types of action situations. One key function of reflection is the connection, integration or synthesis of existing knowledge. Without reflection, an individual's newly constructed concepts might remain abstract and isolated. If there is no connection to prior knowledge and to ways of action, new knowledge is useless, lacking either conceptual foundation or the connection to contexts in which it might be employed.

Processes of reflection in classrooms are frequently initiated by questions (White, 1995). Questions typically communicate a specific purpose related to identified content and context, and are usually intended to elicit an answer. But additionally, a question also conveys a more general indirect request (Searle, 1969). This indirect request implies: Think about it! That is, reflection can be triggered through the use of questions. An individual's response to the attempted initiation of reflection depends on situational factors and individual conditions, such as prior experiences and knowledge. With the help of questions, teachers can invite students to follow and even participate in the teacher's externalised way of thinking and thereby model both reasoning and reflection (Walsh & Sattes, 2011, p. 69), approaches to solving a problem, and the generation of insight by the elaboration of information. Nevertheless, recognising the individual character of reflection as a cognitive process (function), it has to be supposed, that students' respond differently to attempts to stimulate reflection in classroom learning situations. Classrooms all over the world are embedded in different cultural settings and it has been shown that teaching and learning are influenced profoundly by culture (Clarke, Emanuelsson, Jablonka, & Mok, 2006; Stigler & Hiebert, 1999, p. 87). It is certainly possible that cultural influences might have an effect upon both questioning and reflection, leading to similarities and differences in the performance of both in classrooms.

To get more insight into reflection in classroom learning, this investigation focused on observable indicators and patterns for such processes in classrooms. In addition to the consideration of questions as initiators of reflection, observable phenomena related to conducting reflection in classrooms (methodical forms like question-answer processes between stu-

1 The project was supported by DFG (German Research Foundation, HO 5092/1-1).

dents and/or between teacher and students, a mind-map, or a task situated in a real-world context) have to be documented. Importantly, reflection phenomena must be studied in classrooms in different countries in order to know about the role of reflection in classroom learning in different cultural settings. That is, in undertaking cross-cultural comparison of reflection as a socially-initiated process in classrooms, it is important to attend to both the form and the function of reflection in the different cultural settings.

THEORY OF REFLECTION AND QUESTIONING

Referring to White (1995), reflection can be thought of as initiated by questions and this may occur both as self-interrogation by an individual as well as by means of a socially performed process. Skovsmose (2006, p. 327) emphasized the importance of questions as facilitator and initiator of reflection. In classroom learning these questions could be raised by teachers, but also by students themselves. The assumption is that questions can be employed as the first observable indicators of the occurrence of reflection. The use and the effects of questions in learning have been investigated in many studies. Previous research has shown that most questions in classrooms are asked by teachers (Wragg & Brown, 2001). "It is normal for students not to ask questions" (Dillon, 1988, p. 12). To change this state, it would be necessary to get more into a "habit of reflection" (Costa & Kallick, 2000, pp. 60 ff.; Walsh & Sattes, 2011). To get into such a habit of reflection would constitute a significant change not only for students but also for teachers and schooling in many school systems and cultural settings (Costa & Kallick, 2000). Thought-provoking teacher questions as well as student-generated questions can be utilised to initiate reflection. Because students may not be accustomed to generating questions, it could be necessary to scaffold them with the help of question stems (King, 1992; Hommel, 2012). Such guided student-generated questioning supports to higher level questioning (King, 1992). Extensive analyses by Clarke and his co-workers of video records of large numbers of mathematics lessons in China and Korea revealed a complete absence of student-initiated questions (Clarke, Xu, & Wan, 2013). Such a uniform absence suggests a well-established history of pedagogic practice wholly reliant on the teacher as the source of all classroom questions. It is possible that the contemporary dissatisfaction among Chinese and Korean educators with the capacity of school graduates for innovation and novel problem solving may be a consequence of less well-developed habits of inquiry and reflection. Certainly, recent reforms in curriculum and pedagogy in both China and Korea seem directed towards more interactive and interrogative modes of classroom participation by students. Teacher questions promoting reflection, together with the opportunity for students to replicate such questioning in classroom interaction, may provide the means to realise not only contemporary Chinese and Korean educational aspirations, but also the aspirations of communities where student-initiated questions already occur, but are not promoted to best effect.

The concept reflection can be differentiated in content-oriented reflection and self-reflection. Beside self-reflection, Lengnink (2005) refers to different forms of content-oriented reflection: reflection of situation, reflection of sense, model-oriented and context-oriented reflection (p. 247). The focus of this study is socially-enacted, content-oriented reflection in classroom learning processes. That is, reflection as it is associated with the actual learning of content, application possibilities, and the further use of the learned content in the student's participation in various communities and contexts (Skovsmose, 2006, p. 328). Based upon the outline above, reflection can be defined as the process of further meaning-making and the deepening of an individual's understanding of their existing knowledge, drawing connections to other experiences and prior knowledge, as voluntary, conscious, systematic; embedded in social context, requiring attitudes of willingness, openness for novelty, interest, and the acceptance of responsibility for learning and for the outcomes of learning. Defined in this way, reflection in classroom learning is part of "student content engagement" (Mullis, Martin, Foy, & Arora, 2012 [TIMSS 2011]). The students' embodied "in-the-moment cognitive interaction with instructional content" (Mullis et al., 2012, p. 358) contains, beside other processes, precisely this "reflection in classroom learning." Without reflection, new information could remain disconnected from prior knowledge and ways of action.

RESEARCH QUESTION

Is there empirical evidence for the assumption that reflection processes in classroom learning are associated with questions? Are there commonalities and differences of observable reflection phenomena in classrooms in different cultural settings? It seems reasonable to expect that the variable "culture" is also influencing the occurrence and nature of reflection. For this reason, this study analysed selected classrooms of different countries to obtain an indication of this kind of influence.

METHOD

This investigation is based upon video data drawn from the international comparative Learner's Perspective Study (LPS). The LPS data set comprises lesson data from eighth grade mathematics classrooms in different countries (Clarke, Keitel, & Shimizu, 2006; Clarke, Emanuelsson, Jablonka, & Mok, 2006). The investigation reported here accessed data from classrooms in Australia, Germany, Japan, and the USA. All LPS teachers were recruited on the basis of their competence as judged by local criteria. Twelve lessons were selected. Three consecutive lessons for one teacher from each country were analysed[2]. This sample provided both the opportunity to gauge consistency of practice for each teacher across the three lessons and a sufficient database to facilitate comparison of practice between the classrooms situated in the four countries. Selection of teachers for this analysis was based on the existence of a coherent three-lesson sequence addressing an identifiable sub-topic within the lesson sequence recorded.

For the empirical identification and analysis of *reflection* in classroom learning, it has to be considered first, when and in which form reflection could occur. Reflection events can assumed to be embedded in different "lesson events" (Clarke, Emanuelsson, Jablonka, & Mok, 2006). The following stratified forms of reflection are assumed to be observable, in the order of their occurrence within the course of a lesson: Review, Elaboration, and Summarization. With '*Review*,' Mesiti and Clarke (2006) describe one of the dominant components in the beginning of the lesson as reflection activities related to the content of prior lessons and also to the prior knowledge of students (p. 51). These activities could be whole class activities, involving either review of previous lesson content in form of teacher led discussions, or question-answer situations for repetition of prior knowledge, or the comparison of student solutions to homework tasks. '*Elaboration*' is a form of reflection, which can occur at the end of a lesson, but also during the whole lesson. It implies a deep processing, while a systematization and abstraction relating new concepts and existing knowledge takes place. During this further processing, facts and concepts will be clarified and corrected. The third form, '*Summarization*', normally occurs at the end of a topic or a lesson. In Japanese classrooms, this lesson event is known as "Matome" (Shimizu, 2006). The core functions of Matome are highlighting and summarising the main point in the lesson, promoting students' reflection on what they have done, setting the context for introducing a new mathematical concept or term based on previous experiences, and making connections between the current topic and previous one (Shimizu, 2006, p. 141). The authors' experience of contemporary classrooms suggested the pessimistic hypothesis that Review and Summarization occur most frequently in classroom learning and that Elaboration, as the most desirable form of reflection on the basis of the depth of processing, would be the least frequent.

Following the assumed association between questions and reflection, questions need to be coded. To create an objective, comparable, and reproducible taxonomy, amenable to low inference empirical application, it should be useful to anchor the categories of *questions* to cognitive processes. The "Taxonomy for learning, teaching, and assessing" (Anderson & Krathwohl, 2001) offers a suitable frame. The developed category system consists of Rote (or Recall) questions (remember), Comprehension Questions (understanding), and Elaborative Questions (elaboration in the sense of apply, analyse, evaluate, and create) asked by teacher or students. Rote questions could be further distinguished into Single answer questions and Remembering questions. Single answer questions could be (theoretically) answered with 'one' word (e.g. yes, no) or the recipient is requested to name something. These kind of questions merely require a single (not a simple) and short answer. Single answer questions could be differentiated further into "organizational" (coded SAO) and "learning content" (SAC) regarding the content focus of the questions. Remembering Questions (REC) require an answer more than one word. In this case, the requested answer

2 Overview about the learning content: Australian lessons: area concept, area of a triangle, area of a rectangle; German lessons: binomial formulae; Japanese lessons: equations; U.S. lessons: positive and negative exponents, prime factorization. For details see (Shimizu, Kaur, Huang, & Clarke, 2010; Mesiti & Clarke, 2010).

exceeds only a single-word answer and consists of naming a concept, recalling a procedure or definition. Comprehension Questions (COQ) refer to eliciting a meaningful understanding of facts, concepts and procedures and thereby leading to broader learning than rote questions do. Students' need to have already understood the concepts and procedures the question is addressing in order to answer this kind of question. Elaborative questions (ELQ) are associated with a more deep and intensive form of processing than the previous question types. They refer, for example, to applying a procedure, analysing a relationship or explanation, or to evaluating or creating something. Irrelevant Questions do not have a conceptual connection either to the topic content nor the actual learning task. We decided to consider only questions which really required an answer. Utterances like rhetorical questions (e.g., "Isn't this great?", "We said that's a prime, right?"), in which the person who is asking the question does not actually expect a reply, explicit requests to students to do something, or questions which are answered immediately by the speaker himself, are not targeted.

The development of the coding system followed two steps. First, a deductive approach, based on a literature review and second, an inductive approach, within the coding progress, in discourse with other researchers. The validity of the coding system was proofed by means of intra-coder reliability (Kendall's Tau $\tau = .926$, $\alpha \leq .01$) and inter-coder reliability ($\tau = .875$). Reliability could be further improved by generating a detailed coding handbook with question examples as indicators for the different categories. For the purpose of this study the reliability was sufficient.

The investigation relies upon video-based observation. Of particular interest are observable reflection phenomena and the assumed association with questioning behaviour in classrooms. The unit of analysis for this investigation consists of "lesson events" (Clarke, 2003). "A Lesson Event is intended to connote a form of classroom interaction occurring within a lesson, but at a level of social complexity greater than just a statement or action taken by an individual" (Clarke, 2003, p. 10). Some regularity and recurrence are necessary to label a phenomenon as a lesson event. Reflection as *form* is assumed to be an identifiable recurrent phenomenon in the classroom. Lesson events involving reflection are related to a specific topic, task, problem or/and situation. As an individual process, reflection has the *function* of deepening understanding and elaboration. Whether a student responds effectively to the offer provided by a reflection initiation depends on several situational and individual factors (like emotion, motivation, prior experiences and knowledge). Individual reflection can occur within the socially-performed instructional form of teacher-orchestrated reflection, but is, of its nature, individual and regrettably mostly non-observable during the lesson. Beside, being an individual process in each student's mind, reflection as a socially-performed instructional form occurs with sufficient regularity to be defined as a particular type of lesson event. Observable indicators for these events of further meaning-making, deepening understanding, and drawing connections are also associated with questioning. Questions and the following question-answer sequences can give insights into externalized processes of reflection.

For analysing the lessons, the following forms of research data were used: classroom videos providing different perspectives (teacher, students), videos and transcripts of the post-lesson interviews with several students, lesson tables providing an overview about time, progress, content, and social-interaction form within the lesson; transcripts (original language and transferred into English). The various forms of data were analysed with respect to the research questions, using the forms of reflection and question categories identified from the research literature. Within the coding process, all questions occurring within the selected lessons were coded and the lesson events involving reflection (in the form of review, elaboration, and summarization) were identified and the associated question behaviour identified and documented. The data analyses included quantitative and qualitative procedures.

RESULTS

Over the 12 lessons, 43 reflection events were identified (Table 1).

All reflection events belong to a specific task, content, relationship or procedure and were initiated by a first question. The reflection events showed 21 phenomena of review, 18 elaborations, and 4 events of summarization. The highest amount of reflection initiating questions (21) belonged to *Review* in the beginning of a lesson. Most of these (18) were rote questions (ROQ)

	Review	Elaboration	Summarization
Australia	7	3	0
Germany	3	4	0
Japan	3	3	3
USA	8	8	1
Sum	21	18	4

Table 1: Reflection events in Australian, German, Japanese, and USA-lessons

(Table 2). Events in this category of reflection events were only initiated by teachers, for example:

J1-L03 So, let's take a look and try to remember what we did last time, and go over it before we go on. Um, do you all remember the equations, those we talked about in class yesterday, um, let's share them with the class. What kind of equations we had? (REC)

Student questions were all at the elaborative level and consisted of three questions:

A1-L12 By that couldn't a rectangle be a special kind of square? (EAN)

G1-L05 And what do you need ... what's the practical application? (EAP)

Elaboration events in sum were observed 18 times during the lesson (initiated 3 times by student questions and 15 times by teacher questions). Elaboration did not occur at the end but during the lesson. For the observed elaboration events, initiating teacher questions were found at every level of question. So, it could be suggested that the level of the first initiating question was not crucial for the elaboration progress itself. Rather the subsequent questions-answer process determined the progress of stimulating and scaffolding reflection in the classroom.

The most frequent instances of Summarization were observed in the Japanese Lessons, for example:

US1-L05 Let's - quickly guys, let's quickly do this. What would be, then, a good way to go ahead and sum up then what exactly is a composite? (REC)

Other than in the Japanese classroom, there was only one event of Summarization, which occurred at the end of one of the USA lessons. Summarizations during the lesson that might have been assumed to take place at the end of one topic were not observed. Summarization events were exclusively initiated by teacher questions at the level of rote questions. The distribution (Table 2) could indicate some support for the researchers' initial hypothesis of a theoretically-based hierarchy of reflection, with summarization associated with the lowest (least sophisticated) form of reflection, below review, and with elaboration as the deepest (most sophisticated) form of reflection. The observed "reflection events" provide support for the assumption, that reflection processes are associated with questions. From a practical perspective,

Question Level	Review	Elaboration	Summarization
SAO	1	0	0
SAC	6	2	3
REC	11	0	1
COC	1	8	0
EAP	0	3	0
EAN	1	5	0
EEV	1	0	0
ECR	0	0	0

Table 2: Distribution of initiating questions for reflection events

questions provided the primary observable indicators of reflection.

Within the qualitative analysis of the reflection phenomena in the Australian classroom, intensive recap activities were observed in the beginning of the lesson. But the Australian classroom did not show recurrent reflection activities at the end of a lesson. Rather, the Australian teacher used the specific characteristics of a situation within the lesson, for example a student question, to foster reflection.

The first German lesson (new content: binomials) started without the typical recap activities for German lessons as reported by Stigler and Hiebert (1999, p. 81). Further, the new content was practiced in group work, followed by comparing solutions. Group work was the predominant social-interaction form in the three German lessons. In fact, group work provided the context in all three German lessons for the majority of student questions. Compared to the Australian, Japanese and USA-classrooms, the most student questions were observed in the German classroom.

In contrast with the German classroom, the low frequency of student questions in the Japanese classroom is remarkable. Student utterances were rarely self-initiated. Similarly, Kawanaka and Stigler describe a proportion of 90 per cent teacher spoken words compared to 88 per cent in the USA and 76 per cent in Germany (1999, p. 261). Mostly students only spoke in response to a teacher request.

The three USA lessons started with a few written tasks for the students to solve. A remarkable characteristic was the high frequency of teacher questions as well as question sequences. To understand the process, we added a qualitative analysis of question sequences. Question sequences related to a concrete situation provide a deeper insight into the process. In this analysis, question sequences were defined as three or more subsequent (but not instantaneous) questions belonging to an interaction about a specific content in a delimitated situation.

Observing reflection behaviour in the lessons, three particular patterns of question sequences (Table 3) were identified: sequences of questions belonging to an equal level of cognitive dimensions, sequences of alternating question levels. A third possibility, the funnel pattern (Bauersfeld, 1980): sequences of questions getting a more narrow range of required cognitive dimensions in progress, was not explicitly found in the data. Instead, we found the opposite: sequences of questions leading from a single answer level to an elaborative level (inverted funnel pattern).

CONCLUSION

The initial assumption of this study was that reflection in classrooms is facilitated by questions. The data support the association between questions and observable reflection processes. However, a student's reflection process can only be observed once it is externalized in some way. This form of externalization can frequently be associated with the occurrence of a question. The association between questions and reflection does not allow the conclusion that the externalized question is actually the first incident of an individual reflection. The question could reflect a student's sudden idea or cognizance, the result of a preceding internal (unobservable) process.

This investigation analysed reflection in classrooms in different cultural settings. But the observed phenomena also reflect the specific instructional behaviours of the teachers. Observed differences between the four different teachers might suggest cultural differences but cannot be generalized to represent cultural patterns. The different forms: Review, Elaboration, and Summarization were not observed in equal measures in the twelve classrooms. The reflection events of Review in Australian, Japanese and USA-classrooms, the Elaboration in the German and

	Review	Elaboration	Summarization
equal level	13 (5 AU, 3 GE, 3 JA)	3 (1 GE, 2 JA)	3 (2 JA, 1 US)
alternating levels	7 (2 AU, 1 GE, 4 US)	10 (2 AU, 8 US)	0
inverted funnel pattern	1 (US)	1 (GE)	0
	21	14	3

Table 3: Reflection events in Australian, German, Japanese, and USA-lessons

USA-classrooms, as well as the Summarization of the Japanese classrooms could be employed to increase reflection for supporting students' learning in classrooms all over the world.

Why look into mathematics classrooms? Rationales for comparative classroom studies in mathematics education

Eva Jablonka

King's College London, London, UK, eva.jablonka@kcl.ac.uk

Larger comparative studies of mathematics classrooms became most prominent as an appendix of international achievement studies. With the advance of video technology and the potentials it offers for researchers, however, comparative classroom observation studies became attractive and feasible also for smaller scale and low budget projects. This paper intends to provide a basis for discussing rationales for comparative studies of mathematics classrooms. It is suggested that the affiliation of classroom observation with school inspection on the one hand, and ethnographic research on the other hand, lingers on in comparative classroom research. The paper provides a narrative, illustrated by examples, that exposes this tension between evaluation and documentation inherent in the field.

Keywords: Classroom research, mathematics education, international and comparative education, teacher evaluation.

INTRODUCTION

There is no shared set of specific goals or methodologies that would justify characterising 'comparative studies of mathematics classrooms' as a sub-field, other than reference to the classroom as a focus of interest and 'comparative' as a research strategy. One might contemplate what constitutes a classroom as a unit; for example, the fact that all inside happen to gather in the same 'room' [1] in the presence of a teacher, or that there is a common practice in which all engage? The latter is not the case for individualised instruction or when students work on-line and access different sites, even if they are in the same room. Further, one can look at classrooms as micro-cultures, as reflecting school culture and schemes of work, as sites for teachers enacting broader curriculum traditions, as sites for transmitting norms and values of larger communities, or as sites for differential distribution of curricular knowledge, amongst others. The 'unit of comparison' [2] will be different in each case. Not all of these interpretations are featured as comparative studies in the mathematics education literature. These are usually comparisons across (groups of) countries, regions or districts. While comparative studies of mathematics classroom practice are driven by diverse interests and methodologies, all assume that classrooms are an obvious site to look at.

The range of comparative studies of mathematics classrooms presented in this working group at previous CERME conferences highlights well the diversity of goals pursued [3]. The intention of this paper is neither to provide a comprehensive review of comparative classroom research nor to present its history in terms of research traditions, but to offer a narrative that exposes the tension between documentation and evaluation inherent in the field.

SCRUTINISING THE QUALITY OF EDUCATION

There is a long tradition of carrying out comparative classroom observations that seek to identify how pedagogy and curriculum relate to students' learning, with the aim of scrutinising the quality of pedagogic practice. In 1891–92, Joseph Mayer Rice took stenographic notes from lesson observations in classrooms in primary and grammar schools in 36 United States cities (East Coast and Mid West). In addition to lesson observations, he talked to teachers, parents and staff in education authorities, visited teacher education institutions, collected student productions and also tested year-3 pupils in arithmetic, amongst others. He classified schools into 'classes' of excellence, ranging from a mechanical 'antiquated' drill-and-practice to a 'scientific' approach. Further, he argued that the differences between the two higher 'classes' of practices can be brought out more effectively by a method of comparison. Accordingly, he summarised commonalities and differences that accounted for his ranking: In the schools of the two 'higher classes', teachers aimed at children's development in all faculties, took into account their 'developmental stage' and made the work interesting. In addition, he observed an 'excellent spirit' amongst the teachers, who treated the children kindly, were enthusiastic and constantly strived to increase their professional strength. The schools in the highest class differed in their practice of integrating school subjects in an 'attempt being made to teach the subjects in their natural relation to each other' (Rice, 1893, p. 222). Further, he notes a strong focus on having children express their ideas in written form in all subjects as a distinguishing feature of the highest class. He also reports that the supervision in these districts takes the form of guidance, instruction and inspiration rather than inspection.

Notably, Rice took the school as his unit of analysis and occasionally included the local policy context as well as the economic conditions of the schools' district in his report. For example, he observed the 'poorest' teaching as regards 'methods and tone' (Rice, 1893, p. 131) in a primary school in one of the poorest neighbourhoods in Boston. [4] This points to another feature of his report, namely the assemblage of impressions on curriculum and authority relations from classroom observations across a range of school subjects.

The report is explicitly evaluative and critical, with clear preferences for a 'progressive' curriculum and pedagogy as outlined in the introduction (notably the labelling of the preferred pedagogic practice as 'scientific'). However, the principles for compiling his notes and the collected student work remain largely implicit. The writing style is journalistic and often scathing, which might be partly motivated by Rice's trip being financed by the magazine *The Forum* that first published part of his report as a series of articles and later financed a second study trip. His overall approach to data generation could be classified as ethnography, while his goal clearly is critical evaluation. Hence he engaged in two different activities.

Around 120 years later, comparative classroom studies produce large data sets due to an increased level of methodological differentiation, such as refined multi-camera video observation, complex scaling and other statistical techniques for constructing reliability and validity of a range of measurements, inclusion of a variety of context variables, systematic procedures for 'coding' segments of classroom video footage, often embedded in research processes characterised by a division of labour in academic work (e.g., coders/report writers). These large studies are affiliated with educational psychology and its tradition of measurement. On the other hand, there are many smaller projects, mostly within a tradition of ethnographic classroom research. The distinction between the activities of evaluation and documentation, however, does not necessarily specialise studies into these two forms. The picture looks more complex.

COMPARING AND MEASURING THE QUALITY OF TEACHING

Comparing and measuring the quality of teaching can be seen as an elaboration of strategies that have been used in many places for assessing teachers during classroom visits, including judgment of the level of teachers' subject-related knowledge and appropriateness of pedagogic strategies, in addition to curriculum coverage and classroom management. Instead of a holistic evaluation based on largely implicit performance criteria (practiced in many places by school inspectors), coding of lessons is based on developing a list of relevant aspects and identifying specific performances that relate to these aspects. Presence/ absence or proportion of lesson time spent on different activities, are then used as a basis for numerical measures, but for lack of theory also expert ratings for each aspect are conducted ('high-inference' coding). The latter leaves the criteria for the 'marks' on each aspect implicit. Scales based on ratings of a range of aspects of teacher performance are increasingly employed in the USA for formative teacher assessment, evaluation of curriculum policy and professional development (Hill et al., 2012). Sapire and Sorto (2012 used adaptations of such a scale (the Mathematical Quality of Instruction - MQI score) for comparing teaching quality in Botswana and South Africa, where teaching appeared much less complex in terms of pedagogical techniques and use of resources than in the USA, which renders the application of the measure questionable. They complemented the measure with curriculum coverage and other codes. In this context, with reference to (Knight & Sabot, 1990), Carnoy (2012) uses the term 'natural experiment' for the situation where national social conditions are similar but policies and outcomes differ. Even though measures of instructional quality originate in the idea that students' scores on mathematics tests are not an appropriate measure of the quality of teaching and hence classroom teaching practice needs to be looked at, correlations with some measures of student achievement are still often incorporated in studies that use such measures and are sometimes used as an argument for their validity. Comparison and evaluation become intertwined.

Studies that aim at comparing instructional effectiveness of different teaching approaches by means of randomised controlled trials have not (yet) been associated with comparative studies in mathematics education. These studies reflect a comeback of experimentalism, asserting it a position of scientific superiority for identifying 'what works'. They occasionally include classroom observation in order to check the fidelity of the teachers' dispending of the intervention (treatment), or to complement measurement of gain scores with scores from classroom observations (e.g., Clements, Sarama, Spitler, Lange, & Wolfe, 2011). Classroom observation in these studies is asserted an auxiliary role, as the classroom is only relevant in relation to the statistical regularity the black box produces as its achievement outcomes. Hence these studies do not qualify as comparative studies of mathematics classrooms.

RELATING INTERNATIONAL ACHIEVEMENT RANKINGS TO TEACHING APPROACHES

The international comparative measurement of average outcomes, which may include affective co-productions (e.g. attitudes) in addition to academic achievement, preceded international studies that included mathematics classroom observations. As a result, in many classroom observation studies, the nominal unit of comparison is countries and administrative units, or larger units defined by shared cultural traditions (such as the 'Confucian Heritage Culture' or CHC), with the aim of identifying characteristics of representative mathematics teacher practice based on random samples of lessons. This is motivated by an interest in high achieving countries (e.g., Hiebert et al., 2003). Comparisons of teacher practices in countries at the bottom end of the achievement rankings rarely attract wider than local interest.

In reflecting upon experiences with the video surveys from the Third International Mathematics and Science Study (TIMSS) and its follow-up study (TIMSS-R), Stigler, Gallimore and Hiebert (2000, p. 87) noted that "the most obvious reason to study classrooms across cultures is that the effectiveness of schooling, as measured by academic achievement, differs across cultures (e.g., Peak, 1996)". A similar observation by the Under Secretary of State for Education recently prompted the invitation of 60 Shanghai teachers to give workshops for teachers in England. Stigler and colleagues (2000), however, also mention the illuminating effect of making the familiar look unfamiliar when confronted with other cultural practices as a rationale for the TIMSS video studies, which does not suggest replanting of teaching practice. They describe the TIMSS video surveys as 'integrating' the tradition of ethnographic classroom research with a survey tradition of schools and classrooms that aims at allowing generalization to a wider population.

As 'comparing' only rests on generating analytical categories to find commonalities and specialising these for describing differences or variations, there is no restriction to the level of detail to which this strategy can be applied; neither is there any restriction to what could be usefully looked at in mathematics classrooms. Lesson structure, based on low-inference codes for time spent on a range of activities, has been a focus of many studies. In doing so, lesson structure ('script', 'pattern') is taken as both an unconscious routine (e.g., Hiebert et al., 2003) or as an outcome of a more conscious act of teachers' planning (e.g., Leung, 1995; see also the discussion in Clarke et al., 2007). Generally, it is not much looked at how instruction is constrained by traditions of classroom management other than through interpreting differences in student behaviour in terms of culturally typical inclinations, e.g., of Chinese students being obedient, a form of analysis, which Jablonka (2013) sees affiliated with cultural essentialism. Wong (2004) is critical towards attempts of interpreting differences in terms of culturally typical behaviour of Chinese students.

As the achievement measures are reported in the form country/region averages, relating classroom teacher practice directly to these measures can only be suggestive. In the first TIMSS study, the classroom samples for the achievement test and the video samples did not overlap in Japan and US, but only in Germany. Klieme and Bos (2000) found a differential item function on the Japanese test results in the achievement test for the type of mathematical tasks they observed in the lessons. For the German videos, relations between teaching practice and achievement were explored through high-inference ratings of some aspects of teaching quality with not much significant outcome. Clarke and colleagues (2007) observed more variability in lesson structure than reported in the TIMSS video study, and see the location of the lesson in a topic sequence as a key influence on a lesson's structure. The TIMSS video studies have not only been criticized for taking single lessons as analytical units, but also for not exploiting the potential of their rich qualitative data sets (Stigler et al., 2000; Andrews, 2007; Clarke et al., 2007). Other studies reported more consistent patterns in lesson structure in some places, as for example in China (Beijing) and also included a wider range of analytical categories than the TIMSS (Leung, 1995). In a random sample of lessons from Finland and Iceland (20 each), Savola (2010) found that the Finnish lessons followed a 'conventional' review-lesson-practice script, whereas more than half of the Icelandic lessons exhibited versions of individualized learning. When looking at the range of codes employed for characterising lesson structure, a major challenge appears to be the apparent embeddedness of instructional and regulative discourse [5]; hence categories for coding tend to include 'mixes' of privileged teacher-student relations and mathematical knowledge structures.

Relating characteristics of teaching practices to national achievement levels did not work for the TIMSS-R video studies either. The official executive TIMSS report (National Center for Education Statistics, 2003) is not explicitly appreciative of any practice, but the mentioning of the achievement levels of the countries implicitly suggests a ranking of some aspects identified in high achieving regions: "Results from the 1999 study of eighth-grade mathematics teaching among seven countries revealed that, among the relatively high-achieving countries, a variety of methods were employed rather than a single, shared approach to the teaching of mathematics." (p. 11). The Pythagoras Study (Klieme, Pauli, & Reusser, 2009) set out to further investigate relations between characteristics of teaching practice and student achievement as well as motivation in 20 classrooms from Germany and Switzerland each, covering a broad range of achievement levels. They focussed on particular topics (the Pythagoras Theorem and algebra 'word problems'), including some briefing for the teachers about how to approach these. This study, then, departs from the ethnographic tradition mentioned by Stigler and colleagues (2000) and moves towards an intervention and evaluation study. It included a broad range of methodological questions and produced a range of publications with detailed analyses. These studies are affiliated with educational psychology usually associated with measurement and with a conception of the curriculum as socially and culturally neutral content delivered in different ways by teachers.

As to the PISA, there is a limit in identifying the schools and classrooms that were chosen for further research. Hence, the use of the available contextual school data for comparative classroom studies is restricted. There is anecdotal evidence, however, that some complementing video studies are planned by the OECD. All attempts at relating regularities of teacher practice to a country's average achievement are further hampered by severe methodological problems in the production of achievement rankings, including sampling problems. Also, different international achievement measures privilege different forms of mathematical knowledge (Wu, 2010), which are balanced differently in national curricula (Cai & Howson, 2013).

This does not derogate the value of looking at larger samples of classroom videos. Most of the reports, however, are ignorant of the socio-political contexts, in which these classrooms are situated. Not much is said, for example, about practices of streaming and selection based on educational credentials, school fees, accountability regimes or working conditions of teachers. The highly competitive nature of the college entrance test in China or the amount of private tutoring in some places (cf. Bray & Kwo, 2014) are rarely mentioned in reports. In addition, classrooms are featured as culturally and socially homogeneous conglomerates, and one is left in the dark about the student intake and neighbourhood of the schools.

EXPLORING REGULARITIES IN MATHEMATICS CLASSROOMS WITHIN AND ACROSS DIFFERENT CURRICULUM TRADITIONS

A range of comparative observation studies are more in line with an ethnographic tradition or interpretive sociology (e.g., Kaiser, 2002; Knipping, 2003). Rather than analysing random samples of classrooms, typicality is achieved through selecting classrooms of experienced teachers judged locally as competent (Clarke, 2006). The practices of these teachers and students can then be seen as representing a range of pedagogic discourses in different curriculum traditions. Identification of regularities and exposure of similarities and differences facilitates interrogation of assumptions and so opens up possibilities for theoretical differentiation and practical innovation that might not otherwise be recognised. Exploring regularities of classroom practice can also be aided by use of statistical techniques (e.g., Andrews, 2009).

The Learner's Perspective Study (LPS) (e.g., Clarke, Keitel, & Shimizu, 2006a) views classroom practice as co-constructed by teachers and students and so included student video-stimulated reconstructive interviews and a camera focussing on changing groups of students (during ten lessons), in addition to a teacher camera and a whole-class view, which affords considering multiple points of view. This is a reminder of the insight that different techniques for producing video data reflect different analytical gazes (cf. Hall, 2000). The variety of analyses conducted by different research groups and teams composed of insiders and outsiders is reported in a series of volumes (Clarke et al., 2006a; Clarke, Emanuelsson, Jablonka, & Mok, 2006b; Shimizu, Kaur, Huang, & Clarke, 2010; Kaur, Anthony, Ohtani, & Clarke, 2013) and other publications. This demonstrates the productivity of a departure from the search for 'best practice' and shows how a substantial data set can be used for iteratively developing languages of descriptions ('theories') as well as for complementary analyses. The advantage of publishing reports that contain transcripts, student work and examples of teaching material is that the audience can engage in their own interpretations.

DEPARTURES AND POSSIBILITIES

While classroom practice also produces valued learning outcomes not captured by the examination system, curricular choices might appear most aligned with external examination specifications or with criteria derived from other policies (e.g., school inspection regimes). In systems with strong regulation there is very limited space for teachers to act upon curriculum. Weaker regulation affords more diversity in classroom practice and more adaption to apparent needs of different categories of students. Hence it would seem reasonable to analyse classroom practice with reference to a level where teachers and schools make deliberate decisions about curriculum, which clearly differs in different socio-political contexts. This strategy departs from attempting to uncover taken-for-granted lesson scripts, patterns or rituals.

Cross-subject studies with the same students or the same teacher would allow to create differentiated accounts of regulative principles of instruction and behaviour in relation to teacher authority and mathematical knowledge structures. Comparison is then a methodological strategy for creating substantial variation in the empirical data as a starting point for developing a language of description (see Gellert & Jablonka, 2009; Knipping, Reid, Gellert, & Jablonka, 2008). Studies with a broader conception of curriculum that illuminate issues of power, identity and subjectivity are still almost absent amongst comparative studies of mathematics classrooms.

Irrespective of the substantial amount of work produced by comparative mathematics classroom studies, those that employ quantifications, in particular for establishing descriptive causality ('findings') between characteristics of teacher practice and some 'student outcomes', still (or again) earn more scientific respectability, despite their often antiquated mechanistic conception of curriculum.

ENDNOTES

1. Including, for example, open-air arrangements found in rural areas in periphery countries or in refugee camps.

2. The distinction between unit of analysis and unit of comparison has been discussed in the working group on comparative studies in mathematics at CERME 7.

3. These are published in the CERME proceedings. For lack of space for an extensive bibliography, the examples mentioned in this paper will remain limited.

4. It needs to be pointed out that Rice did not comment on the racist nature of some student writing assignment, which he collected from a grammar school.

5. The notion of 'embeddedness' of these two discourses is taken from Bernstein (e.g. 2000).

The perceived causes of the (assumed) mathematics problems in England and South Africa: A social media experiment

Marie Joubert

African Institute of Mathematical Sciences, Cape Town, Republic of South Africa, mariervjoubert@gmail.com

This paper presents an exploratory study, using a methodology based on the idea of building knowledge through the use of social media such as blogs, discussion forums and twitter. The study builds on work carried out in the UK, collecting and synthesising reports related to mathematics education, and from this developing research on the perceived causes of the (assumed) problems with mathematics education in the UK. It develops the research to take account of the South African context, and investigates the same question in this context. The results are compared, and findings include the fact that in both countries 'negative attitudes' towards mathematics are seen as a major cause. The paper concludes by reflecting on the methodology adopted.

Keywords: Negative attitudes, poor teaching, nature of mathematics, social media.

INTRODUCTION

This paper presents an exploratory study, which draws on, and extends, my previous work on the use of social media (e.g., twitter, blogs, wikis) in research (e.g., Joubert & Wishart, 2012; Joubert, 2011). I constructed a blog in which I collected and synthesised over 50 'official' reports broadly about mathematics education, published in the UK after January 2011. The blog can be found at https://mathsreports.wordpress.com. The reports were commissioned by a range of governmental and non-governmental organisations, such as, for example, the Advisory Committee for Mathematics Education (ACME), whose membership includes researchers and practitioners in mathematics education and which aims to advise policy, the Royal Statistical Society and the Nuffield Foundation. Naturally the reports can be seen to reflect the interests of these organisations. Many, but not all, of the reports make generalised statements without reference to empirical research, raising questions about where these statements came from and what the status of the reports is; there is much more discussion about the reports on the blog.

I used social media such as twitter and online discussion forums to invite the mathematics education community and others (anyone who was interested and was willing) to help me understand more about these reports, by making comments on the blog. For example, what did they aim to achieve? Why were they commissioned? Whose interests did they serve? What is their role in shaping – or reflecting - a collective mindset?

On moving to South Africa in mid-2014, I aimed to carry this work forward but within the South African context. The work is at a very early stage but it is nevertheless perhaps interesting to compare initial results with the findings emerging from the UK. Of course the context is very different and one might expect there to be some differences; the value of any findings is under review.

The research has two distinct focus areas: the use of social media in research and the reported state of mathematics education. In this paper, I focus on one aspect of the latter, (the perceived causes of the perceived problems in mathematics education) and comment on the former.

BACKGROUND: PROBLEMS WITH MATHEMATICS EDUCATION?

In both countries there seems to be a belief that mathematics education is problematic, in terms of, for example, low levels of achievement on international benchmarking tests and low take-up of mathematics at post-compulsory levels. The extent to which these problems actually exist or could be said to be similar is of course debateable, but for the purposes of this paper the so-called problem is assumed. Perhaps the most compelling symptom of the (assumed) problem is that in both countries employers and higher education claim that the mathematical knowledge of school leavers falls short of what they require (ACME, 2011a; British Academy, 2012; The Centre for Development and Enterprise, 2013).

It could be argued that the commissioning of the UK reports is in itself a response to the assumed problem and a number of reports claim that a problem exists (ACME, 2011a; Harris, 2012; Vorderman, Porkess, Budd, Dunne, & Rahman-hart, 2011).

In South Africa, education generally is troubled (Spaull, 2013) but it seems that mathematics is particularly problematic (Howie, 2003; Human Sciences Research Council, 2011; Mji & Makgato, 2006) with, for example, South Africa at the bottom of the league table in mathematics in the 2008 international benchmarking tests, TIMSS. Even the highest achievers in South Africa performed less well than the average students in top performing countries (Human Sciences Research Council, 2011).

A second, related, problem in both countries is a reported shortage of young people with appropriate skills in mathematics and so-called STEM subjects. (ACME, 2011a; British Academy, 2012; Southern African Catholic Bishops' Conference, 2012).

The problems, it seems, are similar although the extent of the problem is perhaps not. The focus of this paper, however, is on the causes of the problems rather than the differences in the extent of the problems. If the causes are well understood, then governments might be in a better position to target interventions; and if the causes are similar in both countries, then it could be that recommendations or successful interventions in England might be applicable in South Africa and vice-versa.

THE CAUSES OF THE PROBLEMS

Many of the reports collected on the blog suggest the causes of the problems, which fall into three broad areas: young people's (and adults') mathematical activity; the curriculum, qualifications and assessment; and teachers, teaching and schools.

In terms of young people's mathematical activity, negative attitudes are widely seen as a cause for the problems. The term 'negative attitudes' includes a general dislike of mathematics and a cultural acceptability of 'I can't do maths'. For example, the Royal Society mentions 'a distinct general lack of warmth towards science and maths' (2011, p. 55). It is further reported that not being good at mathematics is generally seen as acceptable and leads to low levels of post-compulsory participation (ACME, 2011b; Harris, 2012; National Numeracy, 2012; Vorderman et al., 2011). Harris sums up the claim, stating that:

> It seems that the UK has a culture where being less skilled in mathematics and numeracy is perceived as acceptable and not uncommon.... learners do not see the need to increase their mathematical skill. (p. 11)

The argument seems to be that because it is acceptable to be bad at mathematics, young people think that they do not need to study mathematics.

The curriculum is sometimes seen as a cause of problems in (mathematics) education. In 2011 the then secretary of state for education announced a review of the national curriculum, stating that 'The previous curriculum failed to prepare us for the future. We must change course.' (Department for Education, 2011). This announcement seems to imply that the Government believed that a different (better?) curriculum would drive standards up.

The ACME report, *Mathematical Needs of Learners*, stated that 'it is not necessarily mathematics itself that is problematic, but rather the nature of the curriculum and the teaching methods and assessment regimes'(ACME, 2011b, p. 8). It went on to say that 'the current curriculum is seen as being fragmented' (p. 6). As described by ACME, the curriculum is linear and lists topics and skills which should be taught and tested in order. This approach can mean that, for students, learning in mathematics is 'fragmented and incoherent' (p. 17).

Assessment is widely mentioned in the reports and there seems to be general agreement that it needs to be improved. However, assessment is not frequently cited as a cause of the mathematics problems. Where it is given as a cause, this is in terms first of the content of some assessments and second the 'assessment regime'.

In terms of the content, there appears to be a tension between promoting mathematical thinking within, for example, extended investigative projects or problems solving, and the ways in which mathematics is assessed. The claim is that examination questions tend to be routine and familiar, and the only mathematical thinking that is assessed is that which is easy to test, and reliability of assessment tends to be highly valued possibly to the detriment of validity. (ACME, 2011b; Norris, 2012; Vorderman et al., 2011). As ACME says:

> GCSE and A-level examinations are dominated by routine procedures and familiar applications. There is strong agreement among teachers, educationalists and Ofsted inspectors that unless all aspects are assessed they will not be given significant teaching time and resource in schools and colleges. (2011b, p. 6)

A bigger concern than the content of the assessments seems to be the 'assessment regime'. Many reports suggest that assessment takes place within a 'culture of performativity' (Norris, 2012, p. 11) driven by the annual publication of league tables and that operating within this culture maybe at the expense of the best mathematical experiences for pupils (ACME, 2011b; Norris, 2012; Ofsted, 2012; Vorderman et al., 2011).

It appears that there are two main causes of the mathematics problems which are directly related to teachers and teaching. First, there is a shortage of specialist mathematics teachers (Parliamentary Office of Science and Technology, 2013; Royal Society, 2011; Vorderman et al., 2011). Second, teacher knowledge is sometimes limited; there is much within the reports to imply that poor or inadequate teaching is the cause of much of the mathematics problem although this point is not always made explicit.

Where teaching is given as a reason for the problems in mathematics, it is argued that the approaches which are often privileged in classrooms are over-simplified and mechanistic and that students do not benefit mathematically from these (ACME, 2011a, 2011b; Norris, 2012; Ofsted, 2012; Vorderman et al., 2011). A number of reports claim that there is tendency to 'teach to the test' avoiding innovative teaching approaches, and using methods that are unlikely to lead to anything more than superficial learning (ACME, 2011a, 2011b, 2012; Harris, 2012; NFER, 2013; Royal Society, 2011). It seems that increased accountability (performance tables and inspections) has a role to play in this (Ofsted, 2012).

It is difficult to find South African reports equivalent to those cited above. However, the South African research literature suggests a range of causes for the problems. For example, Spaull (2013) identifies factors such as teacher education, parents' education and speaking English at home as being strongly associated with mathematics performance. Howie (2005) explored the relationships between background variables and mathematics achievement at the school level and the classroom level. She found that the variables at the combined school and classroom level most strongly associated with mathematics performance were the community where the school was located, size of classes, attitudes, beliefs and commitment of the teachers including dedication towards lesson preparation and the workload of the teacher. In a separate earlier study (Howie, 2003), she also explored the relationship between language proficiency and mathematical achievement and found that students who spoke English or Afrikaans at home, and those coming from classrooms where these languages were mainly used, overall gained higher scores in mathematics. In this same study, she also found that there was an association between achievement in mathematics and socio-economic status of the student, their 'self-concept' in terms of finding mathematics difficult and their perception of the importance of mathematics (their own perception as well as those of their mothers and friends).

Research by Mji and Makgato (2006) investigated the causes of poor achievement in mathematics and science by seeking the views of teachers and learners in a small number of schools. They found direct influences such as teaching strategies, content knowledge and understanding (of teachers), motivation and interest (of both teachers and learners) and non-completion of the syllabus; and indirect influences such as parental role and language.

Whereas research such as Spaull's and Howie's, and the reports produced in the UK, can be seen to take a top-down approach, the approach used by both Mji and Makgato and within this research is perhaps more 'bottom-up' or grass-roots. Building a comprehensive understanding may require both.

METHODS

As discussed above, this research draws on previous experience of using social media and web 2.0 within research, from which the principle of quick and easy data collection was derived. A very short online questionnaire was devised, which begins by stating 'Too many of our young people leave school with mathematical understanding which falls short of the needs of employers and higher education' and then asking 'Why?'.

Five possible causes were tested in the UK. These were derived from the UK reports and discussion points made on the online forums mostly by teachers and parents: assessment focuses on the wrong things; the curriculum is not fit for purpose; societal attitudes towards mathematics are negative; teaching is not good enough; and 'mathematics is hard'.

The same questions were used for the South African audience, and to take account of the South African context two further causes were included. The first, 'Too many learners opt for maths literacy' because of obvious concern amongst the mathematics education community about it (see for example Southern African Catholic Bishops' Conference, 2012). Mathematics literacy was introduced in South Africa 2008 as an alternative to pure mathematics and was designed to provide functional mathematical learning to address the needs of the workplace. However, it is generally seen as an easier version of mathematics rather than an effective preparation for the workplace, as explained by Spaull (News 24, 2014). The second additional cause, 'The language of learning and teaching (LoLT) is not the home language', takes into account the findings by Spaull, Howie and Mji and Makgato, see above.

Respondents were asked to rate each of the causes in terms of a) a key reason b) having some influence and c) not a reason. They were also provided with an opportunity to add 'your longer comment' in recognition of the fact that these five or seven 'causes' are somewhat over-simplified and the list is almost certainly not exhaustive. It also allows respondents to disagree with the 'causes'. Respondents were also asked for their main interest in mathematics education, to allow for an analysis of the responses of different groups (if needed). Further this provides some sort of understanding of the demographic profile of the respondents.

FINDINGS

There were 101 and 62 responses to the questionnaire in the UK and South Africa respectively. Figure 1, below, gives the breakdown of the respondents' main interest in mathematics education in the two countries. This has been included to demonstrate that in both countries responses come from a mixed demographic, with the majority of respondents being teachers.

In both countries, negative societal attitudes are seen as a major cause of the problems in mathematics; in both countries fewer than 10% of the respondents gave this as 'not a reason' and in both almost 50% gave it as a key reason.

For assessment, similar proportions in both countries (about 20%) stated this was not a reason. There is a relatively big difference, however, in whether it is a

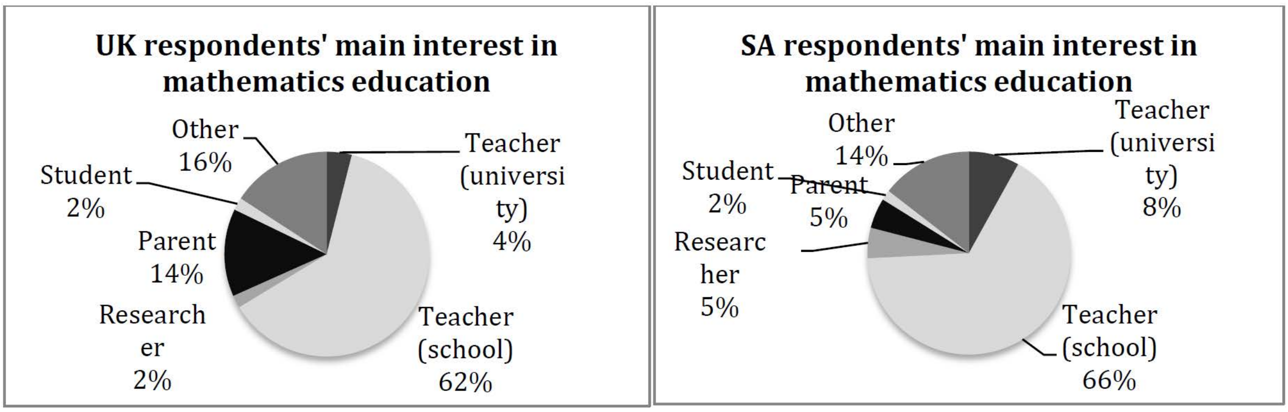

Figure 1: Main interest in mathematics education

key reason; in the UK the figure is over 30% while in South Africa it is under 15%.

In terms of the curriculum, the biggest difference in the two countries is in the numbers stating that it is not a reason, with under 20% in the UK making this choice in comparison to just over 40% in South Africa.

In the UK, under 20% gave 'teaching is not good enough' as a key reason, in contrast to 50% for South Africa. Just under 30% in the UK stated that they did not think it is a reason, whereas fewer than 10% said this in South Africa.

Finally, for 'maths is hard', fewer than 10% chose 'key reason' in the UK, whereas almost 30% made this choice in South Africa. In both countries about 40% chose 'has some influence' but the figures for 'not a reason' are 50% and just over 30% in the UK and South Africa respectively.

For South Africa, for mathematics literacy, just under a third of the respondents chose key reason (28%), just over a third chose 'has some influence' and about a third (32%) chose 'not a reason'. For the language of learning and teaching, however, almost 50% stated that this is a key reason with under 20% stating that it is not a reason.

Almost all respondents also provided longer answers sometimes adding further causes, such as a lack of commitment by the students in both countries (twelve comments). A number (seven) of responses from the UK mention accountability, 'excessive' monitoring, a target-driven approach and the need to see constant progress. In contrast, South African responses give reasons such as lack of accountability, unsafe schools and large classes. In both countries home life is given as a reason. Five UK respondents made comments to this effect, suggesting, for example, that parents do not support the students or that they 'have rotten home lives'. Six comments from the South African survey suggest that home life and parents cause problems in mathematics learning. Of these, four suggest that parents do not support their children in their school work, sometimes explaining how difficult it is for parents:

> 'Majority of our learners have no support at home and therefore have no culture of learning. Parents are too busy trying to make a living and do not have time to check up on their children's progress or lack thereof. The learners only do the Mathematics during the Mathematics period and do not consolidate/practice/do homework, at home.'

Two further comments explain that children are hungry and lack the basics in life.

DISCUSSION

The sample for this research was an opportunity sample of 101 in the UK and 62 in South Africa, very many of whom are teachers. Some of these people were invited directly to complete the survey but most responded to invitations on social media which implies at least that they had access to the Internet and excludes those without Internet access. It probably cannot be seen as a representative sample and I do not claim that the results reported above hold true for the whole population. However, the findings of this study do seem to indicate that there are differences in the two countries with respect to the perceived causes of the (assumed) problems with mathematics education. This is hardly surprising as the contexts are so different. What is more interesting, perhaps, is what the differences and similarities are.

In terms of the findings, in both countries the reason 'negative societal attitudes' was selected as a key reason or as having some influence by very many respondents, with almost half the respondents selecting it as a key reason. This is the only reason where there is strong similarity in the responses in the two countries. Of course, 'negative societal attitudes' over-simplifies the issue, which has many facets and could be seen as related to 'maths is hard' in complex ways. However, the point is that a) this is seen as the 'biggest' cause by the samples in each country and b) that there is agreement between the two respondents from the two countries. In the UK, this cause is well recognised and attempts are made to tackle it (e.g., setting up the charity 'National Numeracy'). The extent to which these attempts are successful is difficult to gauge, but it could be that South Africa might learn something from the UK's example.

A key difference between the responses from the two countries is in terms of teaching. For the South African respondents this cause was selected as a key reason or as having some influence by as many people as selected negative societal attitudes, whereas the figure for the UK is considerably lower. The biggest difference, however, is in the numbers selecting it as a key reason. It seems that the standard of teaching is a major concern in South Africa. One major factor contributing to the poor teaching, across all subject areas, could be the lack of accountability reported above (Spaull, 2014). However, in the UK accountability does not seem to work well, also reported above as a cause of the problems. It is not clear how or whether either country could learn from the other.

There is also a difference in the responses from the two countries related to the cause 'maths is hard' where the proportion of South Africans selecting this as a key reason is over double the proportion for the UK. There is no obvious explanation for this although it may be related to the language of learning and teaching.

Finally, for South African respondents the fact the language of learning and teaching is not the mother tongue appears to be a major cause of the problems. Whereas this is probably the case across all subject areas, in mathematics it is possibly more acute as many of the African languages do not have words for mathematical concepts (e.g., there is no word for 'parabola' in Zulu).

CONCLUDING COMMENTS

The mathematics education landscape is highly complex in the UK as is perhaps evidenced by the large numbers of reports produced on the topic. It seems clear that there is no 'quick fix' (such as a review of the national curriculum) for the problems although there does appear to be some general agreement about what needs fixing (attitudes mainly).The landscape in South Africa, however, is perhaps even more complex, and it is less clear where to put efforts in; negative attitudes, poor teaching and LoLT are all seen as major causes.

It would be unrealistic to expect research of this kind to capture the complexity of the situation in either country but the research does, perhaps, begin to reveal something of the causes of the problems. Learning from this research, further work in the area will pay more attention to the school environment, policy and accountability.

The research approach is experimental and I conclude with a review of its success. To some extent the blog can be seen as successful as it has had over 11 500 views (at January 2015) from all over the world. However, the number of comments, and the level of debate, is perhaps disappointingly low. The comments did not help me answer the questions posed at the start of this paper, but in a sense that is not relevant to this paper which has a different focus. The online forum activity generated active discussion which was useful in informing the questionnaire design. The micro-blogging (twitter) attracted some visitors to the blog and the questionnaire.

As remarked above, the respondents and commenters were essentially a self-selected opportunity sample, mostly anonymous (although some provided email addresses). These were people who volunteered to contribute, and, for the questionnaire, many of them gave substantial responses to 'your longer answer'. In my view, the data collected is interesting and worthwhile and justifies the approach adopted. However, I would like to explore further about how to use web 2.0 and social media approaches more effectively.

Swedish and Chinese teachers' views on what constitutes a good mathematical test task: A pilot study

Aihui Peng[1], Håkan Sollervall[1,2], Erika Stadler[3], Yueqiang Shang[4] and Li Ma[1]

4 Southwest University, Beibei, China

Mathematical tasks in tests are central to students' learning. Research shows that there is a significant gap between mathematical tasks in national tests and teacher-made tests. In this pilot study, we examine nine Swedish and nine Chinese teachers' views on what constitutes of a good mathematical test task at the lower secondary school level. E-Mail Interviewing is conducted by presenting seven mathematical tasks from national tests in Sweden and China, respectively. The preliminary results show that Swedish and Chinese teachers hold some common views on the characteristics of good mathematical test tasks, but they also show different views on some mathematical tasks with high level of abstraction. Implications of the results and the methodology informed by the pilot study are discussed.

Keywords: Abstraction, assessment, mathematical task, pilot study, teacher belief.

INTRODUCTION

This study is motivated by the observations of a significant gap between tasks in teacher-made tests and national tests. Palm, Boesen, and Lithner (2011) investigated the mathematical reasoning required to solve the tasks in the Swedish national tests and a random selection of Swedish teacher-made tests, and found that most of the tasks in the teacher-made tests did not require the students to produce new reasoning and considering the intrinsic mathematical properties involved in the tasks, findings that were contrasted with the national tests that included a large proportion of tasks for which memorization of facts and procedures were not sufficient. Senk, Beckman, and Thompson (1997) examined the kinds of assessment tasks used in 19 mathematics classrooms in the United States, and found that, in general, teachers selected low-level abstract tasks that did not reflect the aims of reform curricula. Tasks in teacher-made tests generally were low-level, were stated without reference to a realistic context, involved very little reasoning, and were almost never open-ended (ibid). Chen (2013) investigated a group of Chinese teachers' views of the tests made by them, and found that the tasks in the teacher-made tests were mostly adapted from previous tasks in different levels of tests, and a small portion of them were simplified from tasks in mathematical competitions, in general, tasks in Chinese teacher-made tests were predictable and therefore did not require students to produce new reasoning. Researchers state the urgency to investigate the potential different factors that result in the gap between teacher-made tests with mostly routine tasks and national tests with a larger proportion of creative tasks, so as to gain further insights into necessary and sufficient conditions under which teacher-made tests can be improved (Palm, Boesen, & Lithner, 2011). Our study presented here aims to make such a contribution.

Assessment has become a central issue in the discussion of ways to improve mathematics education. Teacher-made tests are an important constituent of assessment. Mathematical test tasks are central to students' learning because what students learn is largely assessed by the tasks they are given. The characteristics of mathematical test tasks in teacher-made tests are influenced by different factors including teachers' knowledge and beliefs, as well as the content and textbook of the course (Senk, Beckman, & Thompson, 1997), but the mathematics teachers' beliefs are so instrumental in shaping their final decisions concerning what tasks to include in a test (Nathan & Koedinger, 2010). Accordingly, teachers' beliefs on what constitutes a good mathematical test task to a great extent determine the characteristics of mathematical tasks in teacher-made tests. In this study, we investigate this issue by comparing Swedish and Chinese teachers' views. We focus on Swedish and Chinese teachers because Sweden and China run totally different educational systems and the assessment of mathematics education in both countries are differently practiced by that, one has a long traditionally high-stakes assessment culture whereas the other has not. This leads us to consider whether teachers' views on mathematical test tasks may be different or common across the two educational systems. We specifically address the following questions: What constitutes a good mathematical test task from a teacher perspective? What are the commonalities and differences between Swedish and Chinese teachers' views on the characteristics of a good mathematical test task?

Our current study is a pilot study, which forms the foundation of a larger study that aims to develop a framework for examining good mathematical test tasks. A pilot study is defined by Wiersma and Jurs (2008) as:

> A study conducted prior to the major research study that in some way is a small-scale model of the major study: conducted for the purpose of gaining additional information by which the major study can be improved – for example, an exploratory use of the measurement instrument with a small group for the purpose of refining the instrument. (p. 427)

It is widely accepted that pilot studies precede the main study and form an important component of the research design. Therefore, we have a dual purpose of the current study, one is to address the research questions stated above, and the other is to examine the methodology of the study.

LITERATURE REVIEW

In this section we give a brief literature review on the nature of mathematical tasks and the attributes of a good mathematical test task, which helps to identify the potential contribution of the current study.

The nature of mathematical tasks

A mathematical task is defined as a set of problems or a single complex problem that focuses students' attention on a particular mathematical idea (Stein, Grover, & Henningsen, 1996). According to the different purposes, researchers classified mathematical tasks into different types. For instance, Yeo (2007) classified them into mathematically-rich tasks, such as analytical tasks and synthesis tasks that can provide students with opportunities to learn new mathematics and to develop mathematical processes such as problem solving strategies, analytical thinking, metacognition and creativity; and non-mathematically-rich tasks, such as procedural tasks that can only provide students with practice of procedures. Sullivan, Clarke and Clarke (2013) classified three types of tasks, namely, purposeful representational tasks, contextualised tasks and content-specific open-ended tasks, and highlight the importance of providing a wide range of types of tasks in a variety of different sequences:

> ... allow students opportunity to have a sense of control by allowing them to make decisions, are interesting to the students, incorporate a rationale for them to engage, provide some challenge, reduce the risk of failure, and for which success provides the motivation for further engagement. (p. 10)

In reference to Sullivan, Clarke and Clarke's work, Foster (2013) claimed that the most powerful task type presented was the content-specific open-ended one, which accommodates tasks that are "accessible by students, able to be used readily by teachers, foster a range of mathematical actions, and contribute to some of the important goals of learning mathematics" because "such rich tasks would seem to offer students deep opportunities for learning mathematics". As we can see, the different types of tasks have explicitly or implicitly implied some features of a good mathematical task. However, a good mathematical task might be not necessarily a good mathematical test task. Below we address what makes a good mathematical test task shown in the literature.

Attributes of a good mathematical test task

Our literature survey shows that there are only a few studies that focus on the attributes of a good mathematical test task. These studies can be classified two types: one is from a researcher perspective and the other from a participant perspective. For the former, Kin (2010) suggested three characteristics that a mathematical test task should have, firstly, the correctness and rigour (mathematically sound, correct, and accurate); secondly, must be set within the scope of the stipulated syllabus; thirdly, possess a respectable amount of beauty (in the form of neat formula, symmetry of the situation, beautiful link with a few topics, or ingenuity of ideas). For the latter, Kontorovich (2011) argued that in the case of competition problems there is a "built-in kernel" which has the potential to be appreciated by the intended solvers. And therefore he investigated 22 adult participants' perception of an interesting mathematical problem in mathematical competition and identified four characteristics of those interesting problems, which are as follows: consisting of meaningful mathematics beyond the problem, the misleading problem situation image, A-typicality and novelty of problem's formulation, and the dilemma on the problem's "wrapper". Building on the previous studies, our study aims to contribute to better understand the attributes of a good mathematical test task from a teacher perspective.

METHODOLOGY

Participants

The participants consisted of 9 Swedish and 9 Chinese teachers, from two Swedish schools and two Chinese schools and teaching mathematics in grades 7–9. Most of them hold a Bachelor's degree in Mathematics Education. They participated in the study through our contact of a liaison person who was one of their colleagues. Their participations were voluntary. They were informed about the purpose of the study, that all information they provided would be kept confidential, and that only the collective results would be shared.

Material and its translation

To avoid our study resulting in general claims by just asking the teachers "what constitutes a good mathematical test task", we adopted a task-based interview that attempted to elicit specific and detailed responses about their views on characteristics of good mathematical test tasks. Mathematical tasks, selected from national tests in Sweden and China, served as a foundation of the current study. Based on researchers' views on good mathematical tasks in national tests, and having considered both the coverage of different mathematics topics and the representativeness (or typicality) of tasks in each country, fifty tasks were firstly identified. Next, to ensure tasks from each country could be adapted to the other country, we discussed further with mathematics educators from both countries about each task and finalized seven mathematical tasks from each country.

In a cross-national study, the equivalence of the two language versions of the instruments is an important issue (Andrews & Diego-Mantecón, 2014). In our study, the mathematical tasks presented to teachers were the main research instruments. In order to produce equivalent information in the different language versions of the tasks, both the Swedish and Chinese tasks were first translated sentence by sentence from their original language to English. Only the names of persons in the tasks were changed to those, which were familiar to teachers in their culture. An English version of the fourteen mathematical tasks was formed and tested by oral interview with two Swedish colleagues and a Chinese colleague. In the end, the Chinese teachers were presented with the original mathematical tasks from China and a Chinese version of the mathematical tasks from Sweden. The Swedish teachers were presented with English versions of the mathematical tasks from both China and Sweden. During this process, the first author who is proficient in Chinese, English, and basic Swedish, checked whether the two versions of the instruments were equivalent.

Data collection

As a pilot study, we choose E-Mail Interviewing as a main method to collect data. We chose this method as it cost considerably less to administer than telephone or face-to face interviews, and it also allowed us to invite participation of geographically dispersed samples from both Sweden and China (Meho, 2006). Furthermore, the participants also showed their preference to use E-Mail Interviewing because it saved time for them compared with arranging face-to face interviews, and also allowed them to allocate enough time to read and think about the mathematical tasks as an important precondition to answer the interview questions in this study.

Through the contact of the liaison persons, every teacher in his/her school got a copy of the task-based interview questionnaire consisting of the fourteen mathematical tasks in the order of tasks from their own country and followed by those from the other country. In the beginning of the questionnaire, there were instructions about the interview where they were specifically informed to consider the tasks from the perspective of assessment, and after every mathematical task, there were specific interview questions "do you think this is a good mathematical test task? If so, clarify the reason; if not, clarify the reason". After having finished the interview questions, the liaison persons collected all the questionnaires and sent back to us by emails.

Data analysis

Our data coding was inspired by grounded theory (Corbin & Strauss, 2008) to understand the differences and commonalities of the teachers' views on good mathematical test tasks. The data was coded in the original languages, Swedish and Chinese, respectively. The coded data was translated into English. Finally, the data was scrutinized by two steps: 1) identify the good mathematical test tasks recognized by teachers, and 2) identify recurring themes on how the teachers viewed the selected mathematical tasks. Disagreements were resolved through discussion between the researchers.

RESULTS AND DISCUSSION

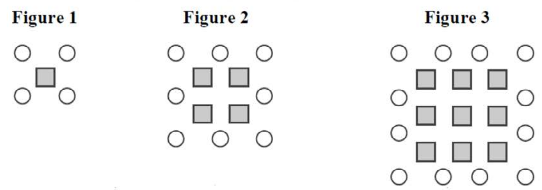
Good mathematical test tasks as identified by Swedish and Chinese teachers

The results show that teachers differ in their views on the 14 mathematical tasks. For some tasks, more teachers regard them as good mathematical test tasks, but for some tasks, only a few regard them as good mathematical tasks. The task that was identified by the highest number of teachers as a good mathematical test task was one of the Swedish tasks (S6 – Figure 1). This task is about looking for patterns, inductive reasoning and generalisation, which is regarded as "A good mathematics test task because it provides a figure with a clear visual representation, with subtasks ranging from simple to complex, and it also has strong regularities and suitable level of difficulty (CT2)."

The task that the lowest number of teachers identified as a good mathematical test task is one of the Chinese tasks (C7). C7 is a task with a similar knowledge background as S6, but it is regarded as "too difficulty for students".

C7: As shown by the figures (Figure 2), in the rectangular paper ABCD, $AB = \sqrt{6}$, $BC = \sqrt{10}$. Firstly, fold the paper to overlap point B and point D, where O_1 is the intersection of the crease with BD and denote by D_1 the middle point of O_1D. Secondly, fold the paper to overlap points B and D_1, where O_2 is the intersection of the crease with BD and denote by D_2 the middle point of O_2D. Thirdly, fold the paper to overlap points B and D_2, where O_3 is the intersection of the crease with BD, and so on. Assume the intersection of n^{th} crease with BD is O_n. Then BO_1 = ___, BO_n = ___.

S6: In a fruit plantation there are some mango trees (■) surrounded by orange trees (○) as shown in the figures.



a) How many mango trees and how many orange trees would there be in figure 5?
b) How many mango trees and how many orange trees are there in figure n?
c) In figure 2 there are twice as many orange trees as mango trees. Investigate in what figure there are twice as many mango trees as orange trees.

Figure 1

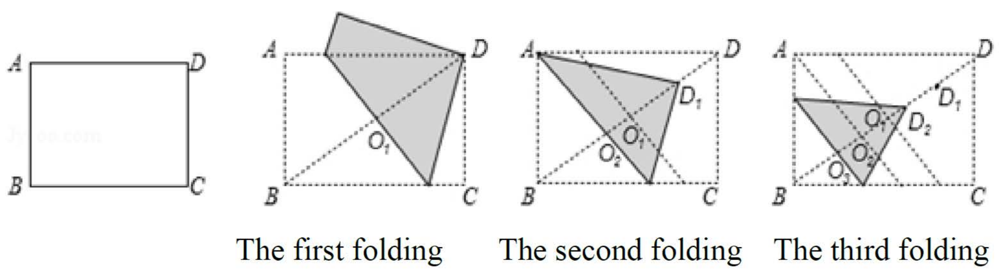


Figure 2

In generally, the Swedish tasks were more appreciated by the teachers than the tasks from China. Table 1 shows the number of teachers from each country (#CT = number of Chinese teachers, #ST = number of Swedish teachers) that considered the specific task (C1-C7: Chinese tasks, S1-S7: Swedish tasks) as a good mathematical test task.

Commonalities of Swedish and Chinese teachers' views on characteristics of good mathematical test tasks

Two recurring themes regarding the characteristics of a good mathematical test tasks commonly held by both Swedish and Chinese teachers emerge in our analysis. These are having connections with real life, and being accessible to average students.

Our results show that both Swedish and Chinese teachers highly recognized real life context as a characteristic of a good mathematical task. With an increasing emphasis being placed on the applications of mathematics in real-life situations in school mathematics curriculum in most countries for various motivations, for instance, real life tasks are often familiar enough and imaginable to students and can therefore serve as a stepping-stone for thinking about important mathematical concepts (Yeo, 2007), as the enactors of curriculum, it is understandable that teachers also commonly recognize the value of tasks has collections with real life. Below are quotations from both Swedish and Chinese teachers:

ST3: The pupils can relate to it when they go for a trip.

CT4: It is a good task because it has close connection with everyday life application, which reflects the idea that mathematics comes from real life and has the function of serving for real life.

A basic function of test is to assess students' learning. Therefore, the accessibility to average students is an important indicator for mathematical test tasks, which is commonly shared by Swedish and Chinese teachers. Below are some selected comments from the teachers.

ST6: They (the Swedish tasks) all have a reality in which students can, without having lots of theoretical knowledge of mathematics, see a "picture" of the task and solve the task and think about the answer reasonably.

CT8: The task is not very hard, can be solved by average students.

Differences of Swedish and Chinese teachers' views on characteristics of good mathematical test tasks

Two recurring themes regarding the differences of Swedish and Chinese teachers' views on characteristics of good mathematical test tasks emerge in our analysis, which is, students' mathematical competency is emphasised by the Chinese teachers but is not visible in the Swedish teachers' responses, and that Swedish and Chinese teachers have different views on some mathematical tasks with high level of abstraction.

Different from the Swedish teachers, when arguing the characteristic of good mathematical tasks, the Chinese teachers always refer to students' mathematical competency that is expected to have in order to solve the tasks successfully. Niss (2003) defines that mathematical competency means the ability to understand, judge, do, and use mathematics in a variety of intra- and extra-mathematical contexts and situations in which mathematics plays or could play a role. And he categorizes eight different types of mathematical competencies. In our study, the Chinese teachers continuously mention different mathematical competencies such as computational competency, imaginative competency, observational competency, inductive competency, etc., which is not visible in the Swedish

Task	C1	C2	C3	C4	C5	C6	C7	S1	S2	S3	S4	S5	S6	S7
#CT	6	5	5	5	8	2	1	7	6	4	6	5	7	5
#ST	4	5	1	4	0	1	1	6	4	5	5	5	7	7
Total	10	10	6	9	8	3	2	13	10	9	11	10	14	12

Table 1: Number of teachers considering the task as a good mathematical test task

teachers' responses. We interpret this difference by referring to mathematics education in China, where there is a long heavy tradition on emphasizing the two basics, basic knowledge and basics skills, which forms the foundation for any further study in mathematics and students' mathematical competency development. And this tradition is deeply rooted in Chinese teachers' beliefs in their mathematics teaching practice, therefore it. Below are the Chinese teachers' responses on their perspectives on the Swedish and Chinese tasks by phrasing some mathematical competencies.

CT6: The Chinese test tasks aim for cultivating students' problem solving competency, which is a little bit far from reality. And most of the Swedish tasks relate to every life, which could have the realistic significance for students' development.

CT2: The Swedish tasks are simpler, but they focus on the application of mathematics, which is close to real life. And the Chinese tasks examine students' synthesis competency.

For some mathematical tasks with high level of abstraction, the study shows that Swedish and Chinese teachers have different views. As seen from Table 1, there are gaps between Swedish and Chinese teachers' views on two tasks (C3 and C5), which Swedish teachers do not regard as good mathematical tasks, but Chinese teachers regard as good ones. Below are some comments from the teachers.

ST5: The Chinese task has a much higher level of abstraction and students need to have much more theoretical mathematics.

CT6: This task reflects the category idea; such tasks are very helpful to cultivate students to form a mind of thinking comprehensively.

As Kin (2010) suggests that a good item must be set within the scope of the stipulated syllabus, Swedish and Chinese teachers differ in their views on mathematical tasks with high level of abstraction could be explained from this perspective. Mathematics curriculum standards (or syllabus) in Sweden and China are different with different requirements for students, the mathematical knowledge and competency covered in those mathematical tasks with high level of abstraction might be covered in curriculum standards in China but not in Sweden, therefore, Chinese teachers value them but Swedish teachers do not. Another interpretation for this difference might be connected to the different cultural profiles in mathematics education. Grønmo (2013) stated that the Nordic and English-speaking countries has the profile of applied mathematics that can be referred to as mathematics applied to solving problems in everyday life, whereas the East Asian and East European countries has the profile of pure mathematics that is an abstract world with well-defined symbols and rules. Obviously, mathematics education in Sweden has the applied mathematics profile and whereas in China it labelled as pure mathematics, therefore, mathematical tasks with high level of abstraction are appreciated by Chinese teachers but not Swedish teachers.

CONCLUSIONS

Our study has contributed to our better understanding on characteristics of good mathematical test tasks from a teacher perspective. To be a good mathematical task in tests, both the features of the tasks and the expected difficulties of the tasks for students need to be considered. Through the comparison between the Swedish and Chinese teachers, we uncover some common beliefs they hold and their different views on characteristics of good mathematical test tasks, which provide helpful insights for our reflections on mathematics education in Sweden and China.

Furthermore, the pilot study presented in this paper illustrates that there are several potential flaws in the instruments and in the procedures. Firstly, we would like to address the task selection. Surprisingly, although the researchers consider the tasks used in the interviews as good mathematical test tasks, not all of them are recognized as good ones by the teachers. Therefore, a pre-interview with schoolteachers might be helpful to ascertain whether the tasks are good. Secondly, we address the task organization. In the interview, tasks are labelled by their sources either from Sweden or China, which may produce a priori prejudice for teachers when making their judgements, as we see from teachers' comments on their view on differences of mathematical tasks in Sweden and China. This could be avoided if we remove the information on the exact sources of the mathematical tasks. Thirdly, the E-Mail interviewing doesn't allow for further prompting and clarification of responses, for such a reason we lose the opportunity to achieve deeper understanding of teachers' valuable insights. In all, the feedback obtained from this pilot study enables us to make revisions aimed at overcoming these identified weaknesses and improve on the design for our main study. Additionally, data analyses suggest that the research findings from the main study would be fruitful and likely to make valuable contributions to the knowledge in both characteristics of good mathematical test tasks and teachers' different perspectives across educational system.

Examining the heart of the dual modelling cycle: Japanese and Australian students advance this approach

Akihiko Saeki[1], Akio Matszaki[2], Takashi Kawakami[3] and Janeen Lamb[4]

4 Australian Catholic University, Brisbane, Australia, janeen.lamb@acu.edu.au

The aim of this study is to compare how Japanese and Australian teachers utilise opportunities to promote students' switching between mathematical modelling cycles based on the dual modelling cycle framework (DMCF). This study found that teachers need to change how they assist students when transitioning from one modelling cycle to another not only based on differing levels of student ability, but to account for differences between countries as well. The Japanese students had more sophisticated visualisation skills than the Australian students when working with the geometric structure of an ordinary helix on the side face of a cylinder. However, both groups of students benefited from use of the DMCF to develop their understanding of the mathematical problem as they moved between modelling cycles.

Keywords: International comparisons, dual modelling cycle framework (DMCF), ordinary helix, modelling teaching, mathematics education.

INTRODUCTION

Problem solving in the traditional mathematical classroom has tended to be an individual task. Students work in isolation as they go about problem solving. When teaching problem solving skills, teachers have relied on the work of Polya (1945). His approach included the hermeneutic of solving a similar, simpler problem which provided each student with an approach that they could use to find a solution for their problem. In more recent years there has been a realisation that to effectively function in society students need to develop the skills of being more flexible and creative problem solvers. Mathematical modelling provides an opportunity to develop these skills, as it is designed for group work that promotes collaborative interactions. This approach is usually set in the context of real world problems where information is incomplete or ambiguous, promoting questioning and the posing of conjectures (Brown & Walter, 2005). As a result it allows for multiple solution paths, permitting discussions around the *best* solution rather than *the* solution. In these situations research indicates that modellers' attempts to find a solution usually results in their shuttling between the real and mathematical worlds (e.g., Stillman, 1996; Stillman & Galbraith, 1998; Borromeo Ferri, 2007; Matsuzaki, 2007, 2011). According to Busse and Kaiser (2003), modellers construct their own *subjective figurative context* from the modelling task, and the modellers' perception of the task context can affect their modelling progress. When the modellers' modelling processes have stalled, evidence suggests that students move from their initial modelling task to a similar and simpler modelling task where some traction is considered possible. In this paper, we explore a theoretical extension to this approach to mathematical modelling, as limited research exists on how to facilitate the teaching of mathematical modelling when responding to a diversity of modeller abilities.

Saeki and Matsuzaki (2013) proposed a new theoretical modelling framework called the *dual modelling cycle framework (DMCF)* (see Figure 1). This DMCF re-conceptualises the modelling cycle explicated by Blum and Leiß (2007). In the case of solving an initial task located on the first modelling cycle, one modelling cycle is enough if modelling is proceeding successfully. If problem solving is unsuccessful or the

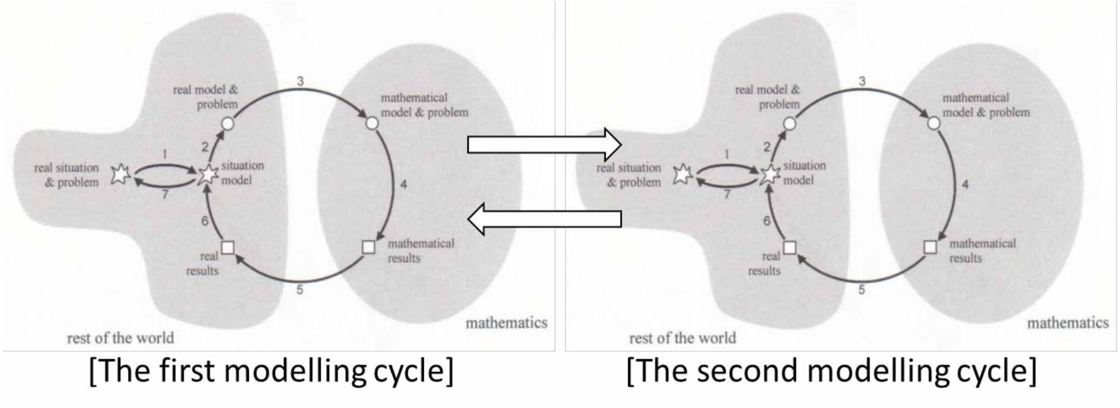

Figure 1: Dual modelling cycle diagram (Saeki & Matsuzaki, 2013, p. 94)

modeller does not know enough to solve the task, the modeller can be assisted by trying to solve a similar task as was proposed by Polya (1945) in his earlier work. One rationale for using two separate modelling cycles when changing from an initial modelling task (TASK1) to a similar and simpler modelling task (TASK2) is that there may be cases when doing so leads to more success.

Research by Saeki and Matsuzaki (2013) has identified that to support successful outcomes for all modellers using the DMCF, the most important point is for teachers to support switching between the first modelling cycle and the second modelling cycle by providing a similar and simpler task. Matsuzaki and Saeki (2013) implemented experimental modelling lessons for undergraduate students in Japan and identified three stages: transition from the first modelling cycle to the second modelling cycle, modelling within the second modelling cycle, and transition from the second modelling cycle back to the first modelling cycle. Kawakami, Saeki and Matsuzaki (2012, 2014) implemented DMCF-based modelling lessons with Year 5 elementary school students in Japan and classified six types of students' responses. They also described modelling lessons in terms of a first trial of two tasks, one in each modelling cycle; a second trial of TASK1 based on TASK2, and a final trial of TASK1 through classroom discussion. DMCF-based modelling lessons were also implemented with Year 6 students in Australia (Lamb, Kawakami, Saeki, & Matsuzaki, 2014), permitting international comparisons. The aim of this paper is to compare how teachers can assist students in switching between modelling cycles while supporting a diverse range of student capabilities within two different countries.

CHARACTERISTICS OF MATHEMATICS LESSONS IN JAPAN AND AUSTRALIA

In this paper, we explain the differences in mathematics teaching in Japan and Australia in order to make international comparisons between the two modelling lessons. Some of these differences are based on work by Mok and Kaur (2006), where characteristics of mathematics lessons are explained with a focus on the '*learning task*'.

The teaching strategy used by Japanese teachers is one that supports each student's level of ability. Teachers lead lessons by considering the needs of each student and providing a variety of activities to suit. Furthermore, many Japanese teachers have adopted problem-discovery oriented teaching methods based on Yamamoto's (2007) work, which outlines three stages when detailing such methods: (1) initial learning activities, (2) discovery of a problem that must be solved, and (3) solution of the problem. A characteristic of this method is to emphasize the children's change of awareness. Consequently this style of lesson can be challenging for the teacher. Thus this view of mathematics teaching matches the modelling teaching practice described above (Kawakami et al., 2012, 2014).

On the other hand, the teaching strategy adopted by Australian teachers relies on mathematical tasks based in daily-life contexts where students make links to their daily life activities (Mok & Kaur, 2006). Supporting this Australian teaching strategy, Stillman, Brown, Faragher, Geiger and Galbraith (2013) analyzed the goal of mathematics by analyzing textbooks and curricula in secondary classrooms in Australia from a socio-cultural perspective. This led to three findings: (1) textbooks were used as a foundation for teaching materials, (2) teaching materials were based

Figure 2: Oil tank image URL<http://blog.goo.ne.jp/kobeooi/e/b021c971381154725 fc3ee4a3d645aa8> [18 Mar 2014] (Note: Picture reversed in class)

in contexts that enhanced students' understanding of the world, and (3) assisted the development of a critical disposition towards the surrounding world that requires decisions to be made. Thus teaching tasks emphasized daily-life contexts that evoked a need for decision making. With this in mind we were conscious of the need for context based problem-solving in Australian schools and we found data for this perspective (Lamb et al., 2014).

EXAMINING THE HEART OF THE DUAL MODELLING CYCLE FRAMEWORK

We developed DMCF-based teaching material for elementary school students to assist them in understanding the geometric structure of an ordinary helix on a side face of a cylinder. The students were initially provided with a picture of oil tanks with differing diameters (see Figure 2). The students were then provided with an *Oil tank task* (TASK1) and a *Toilet paper tube task* (TASK2), displayed in Figure 3.

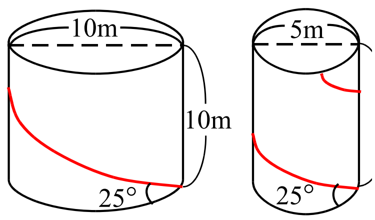
In our earlier research using the same task as above, we found that modellers who could not solve TASK1 were able to advance their modelling of this task by modelling a similar but simpler task, TASK2 (Kawakami et al., 2012; Lamb et al., 2014). Students who could solve TASK1 but were encouraged to engage with TASK2 developed a more advanced understanding of TASK1. By actively switching between TASK1 and TASK2, most students were able to solve TASK1 (see Kawakami et al., 2012; Lamb et al., 2014 for details). These tasks helped students understand the geometric structure of an ordinary helix on the side face of a cylinder. This structure is important because it forms the foundational knowledge necessary to solve the oil tank task in higher grades (using either the Pythagorean theorem or trigonometric ratio). Student investigation of the 3D model leads to understanding the rectangle model and the parallelogram model (see Figure 4).

The DMCF aims to deepen students' mathematical understanding by switching between two modelling cycles, as indicated in Figure 5. There are two kinds of switching that lead to in-depth engagement in the tasks.

The first is a teacher's intentional switching to facilitate student understanding. It is therefore very important for teachers to design an approach to switching through the use of teaching material before implementing the lesson. Teacher's intentional switching is done twice. The first instance of switching is the transition from the first modelling cycle to the second modelling cycle. In this transition, the teacher used the toilet paper tube to present an opportunity for students to work with a concrete object. The second instance of switching uses feedback from the second modelling cycle to return to the first modelling cycle. In this transition, it is necessary for all students to recognize that they have returned to TASK1. Therefore

***Oil tank task* (TASK1)**

There are several types of oil tanks. Their heights are equal but their lengths of diameters are different. Is the length of the spiral stairs on these oil tanks equal or not? As conditions, angles to go up spiral banisters are all the same.



***Toilet paper tube task* (TASK2)**

It is impossible to open along the actual spiral stair of the oil tank. We can use a toilet paper as a similar shape to an oil tank as it can be opened along its slit to show the 2D shape. Con

Figure 3: Teaching material based on DMCF

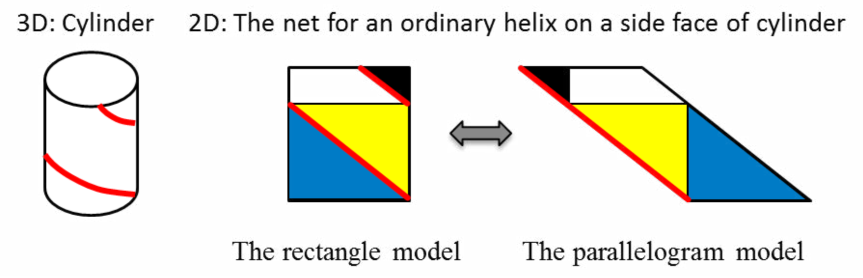


Figure 4: The geometric structure of an ordinary helix on the side face of a cylinder

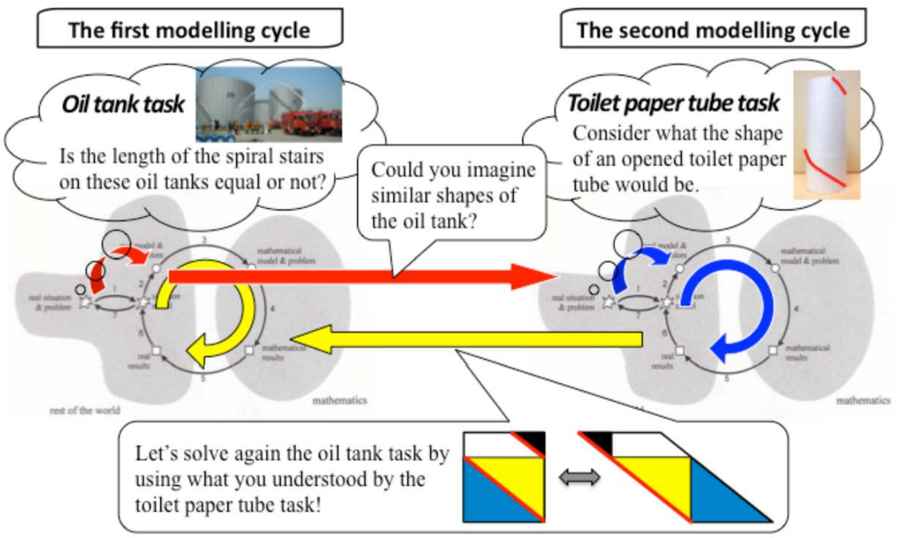

Figure 5: Dual modelling cycle diagram of switching between two modelling cycles

we offered the information of TASK1 to students again and let them predict whether the spiral stairs would be the same or not. It is necessary for the teacher to prepare methods of switching that accommodate differing levels of student ability. In the case of the Australian school, significant student difficulties necessitated a substantial change in the switching methods used (see description on pages 7 and 8).

The second is students' intentional switching to solve TASK1. This switching is important as it provides an opportunity for students to develop ideas by themselves. Hence, teachers have to prepare a range of alternative approaches to stimulate the transition between modelling cycles that correspond to differing student needs. It is important to note that one of the problems in this process is that some students lose track of which modelling cycle they are in. When this is the case it is necessary for teachers to guide students in understanding their position in the modelling sequence and the correct direction they need to take to move to TASK2 or back to TASK1.

THE MODELLING LESSONS IN JAPAN AND AUSTRALIA

Case of Japan

The Japanese experimental class consisted of three 45-minute lessons (see Kawakami et al., 2012). The class included 33 Year 5 students (aged 10 or 11) from a Japanese private elementary school.

Showing the Oil tank task

At the beginning of the lessons, the teacher showed photographs of two oil tanks and asked the students if the length of the spiral stair was equal or not (see the oil tank photograph, Figure 2). In order to simplify the *Oil tank task* (Figure 3), the teacher asked which part of the spiral stair should be measured, its banister or its steps. Through discussion with the students they agreed to measure the length of banister at the side of the oil tank. Then the teacher showed 3D models of the oil tanks displayed in Figure 3 and asked students what they could do to solve the *Oil tank task*. The students responded by producing 2D drawings.

Seventeen students (52%) were able to draw the mathematically correct 2D rectangle models of the oil tanks from the 3D models, representing the spiral staircase as straight lines on their models (see Figure 6). The remaining students were not able to draw the mathematically correct models, as the representation of the staircase was not connected on their models (see Figure 7). Some students rounded their paper to check whether the staircase would be connected or not. However they did not make the full link to the mathematical structure of the spiral shown in Figure 4.

Teacher's intentional switching (1):

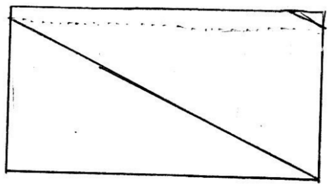

Figure 6: Mathematically correct models

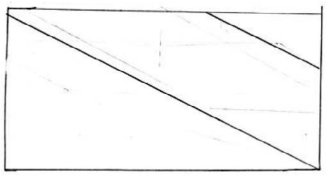

Figure 7: Mathematically incorrect models

Guiding to the Toilet paper tube task:
At the beginning of the second lesson, in order to switch from the first cycle of the *Oil tank task* to the second cycle of the *Toilet paper tube task*, the teacher asked the students to consider what objects were similar in shape to the oil tank, but smaller in size. The student responses included pencils, toilet paper tubes and so on. The teacher provided an actual toilet paper tube for each student and asked them to open the toilet paper tube. The students were asked to compare the length of each staircase and to produce a 2D drawing of the toilet paper tube (see the *Toilet paper tube task*, Figure 3). Almost all the students identified cutting the tube along the slit and were able to subsequently draw the parallelogram model.

Teacher's intentional switching (2):
Returning to the Oil tank task:
At the beginning of the final lesson, in order to switch from the second cycle of the *Toilet paper tube task* back to the first cycle of the *Oil tank task*, the teacher asked the students to compare the length of the staircase with reference to findings from the *Toilet paper tube task*. The students tried to solve the *Oil tank task* independently. Fifteen students made the parallelogram model of the oil tank and tried to calculate the length of the staircase.

During the final lesson, the teacher observed four different methods used to find solutions: (1) calculating the length of spiral stair (five students), (2) measuring the length of spiral stair in rectangle models and parallelogram models (four students), (3) translating the staircase in the rectangle models (three students) and (4) translating the staircase in the parallelogram models (six students). As a result of class presentations, students gained access to classmates' solutions and were able to solve the *Oil tank task* using parallelogram models or rectangle models of the oil tank.

Case of Australia
The Australian experimental class consisted of two 60 minute lessons (see Lamb et al., 2014). The class included 23 Year 6 students (aged 11 or 12) from an elementary school.

Showing the Oil tank task
At the beginning of the lessons, the teacher showed photographs of two oil tanks and framed the problem within the context of a fireman needing to climb to the top of one of the tanks as quickly as possible to extinguish a fire. The teacher then asked the students if the length of spiral stair was equal or not. The teacher showed 3D models of the oil tanks displayed in Figure 2 and asked the students to produce 2D drawings of the 3D models.

No student was able to draw the mathematically correct models of the oil tanks from the 3D models of the oil tanks. Eleven students (48%) drew the rectangular representation of the oil tank. However, in each case the students drew the staircase as a curved line on their 2D model. The remaining students (52%) were unable to draw a 2D model, tending instead to copy the 3D model provided for them.

Teacher's intentional switching (1):
Guiding to the Toilet paper tube task
In order to switch from the first cycle of the *Oil tank task* to the second cycle of the *Toilet paper tube task*, the teacher showed the students a toilet paper tube and asked them to predict what the toilet paper tube would look like when cut along the slit. No student was able to draw a mathematically correct 2D model. Six students (26%) drew a shape close to a parallelogram in which the spiral stair was curved. Other students pro-

duced shapes similar to a roll. To assist the students in finding the relationship between the *Oil tank task* and the *Toilet paper tube task*, the teacher asked them to cut the toilet tube vertically and confirm that the shapes created were parallelograms and rectangles.

As most students in the class were not able to first visualize and then draw 2D models from the 3D models of the oil tank or the toilet paper tube, at the beginning of the second lesson, the teacher used a concrete aid to demonstrate how the 2D models related to the 3D model. A rectangular piece of cardboard, rolled into a cylinder and marked with a red line, was cut at an angle and unrolled to illustrate the relationship between the 3D model and the 2D parallelogram model. Furthermore, the teacher cut a similar cylinder vertically and unrolled it to show the 2D rectangular model.

Teacher's intentional switching (2): Returning to the Oil tank task

In order to switch from the second cycle of the *Toilet paper tube task* back to the first cycle of the *Oil tank task*, the teacher again asked the students whether the spiral stair was the same or different for each oil tank. The students tried to solve the *Oil tank task* collaboratively. One group made another 3D model of the oil tank by using concrete 3D models. They opened the model and measured the length of spiral stair in the 2D rectangle model and the 2D parallelogram model. A student in the group explained, "I think they are all the same because the parallelogram and rectangle are almost the same size, so I expect they are the same".

During the last lesson the students were able to explain that both staircases were the same length for both the rectangle model and the parallelogram model through cutting and placing the pieces of their concrete 2D models on the whiteboard. The teacher demonstrated both models represented the same 3D model (Figures 8 & 9).

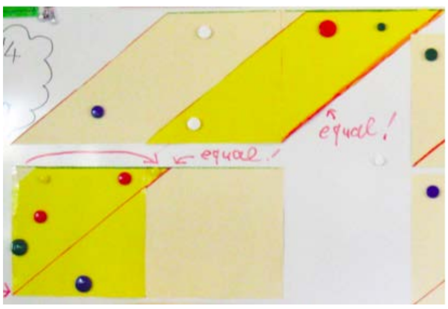

Figure 8: Solutions by both models

DISCUSSION

Using the *dual mathematical modelling cycle framework* (DMCF) to examine the same problem in both Japanese and Australian classes allows for comparisons to be made. The results from this study indicate that the teachers needed to change the method used to switch between modelling cycles intentionally to account for different levels of student ability. The Japanese elementary students in this study had more sophisticated visualisation skills and were able to move between 2D and 3D models of an ordinary helix on the side face of a cylinder as well as visualise the shape of the staircase in a 2D model. This allowed them to calculate the length of the spiral stairs and to compare the rectangle and parallelogram models, facilitating their understanding of the problem. As the Australian students had more difficulty with the problem, the teacher changed two of the switching methods. The teacher asked students to cut up the toilet tubes to confirm that parallelogram and rectangle models were equivalent, and demonstrated how concrete 3D models were related to 2D parallelogram and rectangle models. The changed method for the modelling lesson still depended on the students' understanding and promoted class discussion. It also remained grounded in the context, with a focus on the need to find the fastest route to the top of the oil tanks.

Use of the DMCF and its emphasis on switching between modelling cycles benefited both Japanese and Australian students by deepening their understanding as they moved between 2D and 3D models and the two cycles. The approach encouraged all students to participate at their ability level and to gain access to more sophisticated modelling approaches during whole class discussions.

Our future work will be to compare Japanese and Australian students' international switching by analysing the students' protocols, activities, and worksheets.

Solving a problem by students with different mathematical abilities: A comparative study using eye-tracking

Miroslawa Sajka and Roman Rosiek

Pedagogical University of Cracow, Faculty of Mathematics, Physics and Technical Science, Cracow, Poland, msajka@up.krakow.pl, rosiek@up.krakow.pl

The main purpose of this study is to compare the problem solving processes of mathematically gifted and underperforming students by utilizing eye-tracking methodologies. We have found the following differentiators between the groups: (a) time of the analysis of the problem's wording, (b) the number and placement of fixations, (c) the number of fixations while analysing the text of the problem. We also prove that total amount of time of solving a problem is not an important differentiating parameter; speed is not a characteristic of mathematically gifted students.

Keywords: Mathematics education, problem solving, eye-tracking, gifted students, comparative study.

INTRODUCTION

The use of eye-tracking technology for the analysis of the learning process has become more and more widespread in recent years. Examining visual attention provides information not only on where the gaze is directed and how, but also constitutes a basis for further analysis and reflections on the ways of solving problems, reasoning, attention, and mental images (Just & Carpenter, 1976; Zelinsky & Sheinberg, 1995; Ball, Lucas, Miles, & Gale, 2003; Yoon & Narayanan, 2004).

Lai and colleagues (2013) reviewed 81 papers dedicated to the use of eye-tracking technology in research related to the analysis of the learning process, describing 113 studies carried out in the period of 2000–2012. The authors distinguished the following themes of studying eye movements and learning: patterns of information processing, effects of instructional design, reexamination of existing theories, individual differences, effects of learning strategies, patterns of decision making, and conceptual development. This research refers to the mainstream of examining patterns of information processing, and strategies, and individual differences during the process of solving mathematical problems.

In the field of didactics of mathematics, studies are still being undertaken (e.g., Andra et al., 2009; Chesney, McNeil, Brockmole, & Kelley, 2013; Merkley & Ansari, 2010; Schneider, Maruyama, Dehaene, & Sigman, 2012; Susac, Bubic, Kaponja, Planinic, & Palmovic, 2014).

Some research results indicate that the measurement of eye movements provides insights into otherwise unavailable cognitive processes and may be used for exploring problem difficulty, student expertise, and metacognitive processes (e.g., Susac et al., 2014). The authors have found that the number of fixations of the eyes represents a reliable and sensitive measure that can give valuable insights into the participants' flow of attention during equation solving. The authors claim that the more efficient participants developed adequate strategies, i.e., "knew where to look." They found a correlation between the number of fixations and the participants' efficiency in equation solving. What is more, they observed that the measures derived from eye movement data were more objective and reliable in comparison to the participants' reports.

Examining the differences between the performance of novices and experts during the process of mathematical problem solving is also the interest of other researchers who use eye-tracking as a research method. They have found quantitative and qualitative differences in the way of looking at a geometry problem (Epelboim & Suppes, 2001) and reading mathematical representations (Andra et al., 2009) by novices and experts in terms of eye movements.

An in-depth knowledge on effective strategies of reading mathematical problems has important didactic consequences. Students need to learn how to read mathematical problems, but this knowledge should be recognised by researchers and teachers beforehand. What is more, it can be useful for the authors of tasks, textbooks, and other didactical materials.

RESEARCH METHODOLOGY AND DESIGN

The aim of the research

The main purpose of this study is to find the differences and similarities in the process of solving the same problem by mathematically gifted students and non-gifted students, by utilizing eye-tracking methodologies.

The objectives of this study refer to the following comparisons in the two test groups of students:

> Aim 1 (A1). Comparison of the total time of solving the problem,
>
> Aim 2 (A2). Comparison of the time of analyzing the wording of the problem,
>
> Aim 3 (A3). Comparison of the number of *fixations* (the stopping of the eyeball at a certain point on the screen) while working on the problem,
>
> Aim 4 (A4). Comparison of the number of *fixations* while analyzing the wording of the problem.

Equipment used

The participants' eye movements of the left eyeball were recorded by the eye tracker SMI Hi-Speed 1250 as well as iViewX™ software. The sampling rate was set to 500 Hz, monocular. The data obtained in the experiment were processed by SMI BeGaze software.

All students attended the experiment in the same physical conditions, in the same air-conditioned room with the same intensity of lighting.

All of the study participants passed the calibrations with an accepted angular accuracy of less than 0.5° and were included in the eye-tracking experiment of solving the science problem. All respondents sat at a distance of 50 cm from a screen the size of 30 cm × 47,5 cm.

The participants' eye movement data, question responses and mouse clicking were recorded by *SMI Experiment Center 3.4* software. In addition to providing answers by using mouse clicks, all respondents were also asked to verbally confirm the selected choices. There was no time limit in regard to the duration of the experiment.

Study participants

The research was carried out in June 2014. The experiment included 52 fifteen-year-old students attending the last grade of junior high school (gymnasium) in Poland, all of which had already taken the final external exam after finishing junior high school.

The sampling of experiment participants was diversified in terms of abilities and mathematical skills, where 18 students were finalists in a regional science competition and therefore recognized as gifted in the field of science. The remaining 34 students attended various lower high schools in Cracow, having mixed abilities and mathematical skills.

Each participant of the experiment was interviewed twice with the use of a questionnaire, both before and after the experiment.

Problem

The problem was provided in the Polish language, as shown in the subsequent figures using the data generated by the *BeGaze* software. Figure 1shows an English translation of the screen.

This problem can be solved by children at the age of 12, but it is more appropriate for lower high school students (13–15 years old). The problem is nonstandard in comparison to typical school tasks. The main difference and difficulty in solving it lies in the application of a methodological approach based on analytical thinking, using reduction. If a student considers how many days pass until half of the pond is overgrown with duckweed, the answer to the problem appears evident.

What is more, the formulation of the problem activates "System 1" according to the psychological *dual*

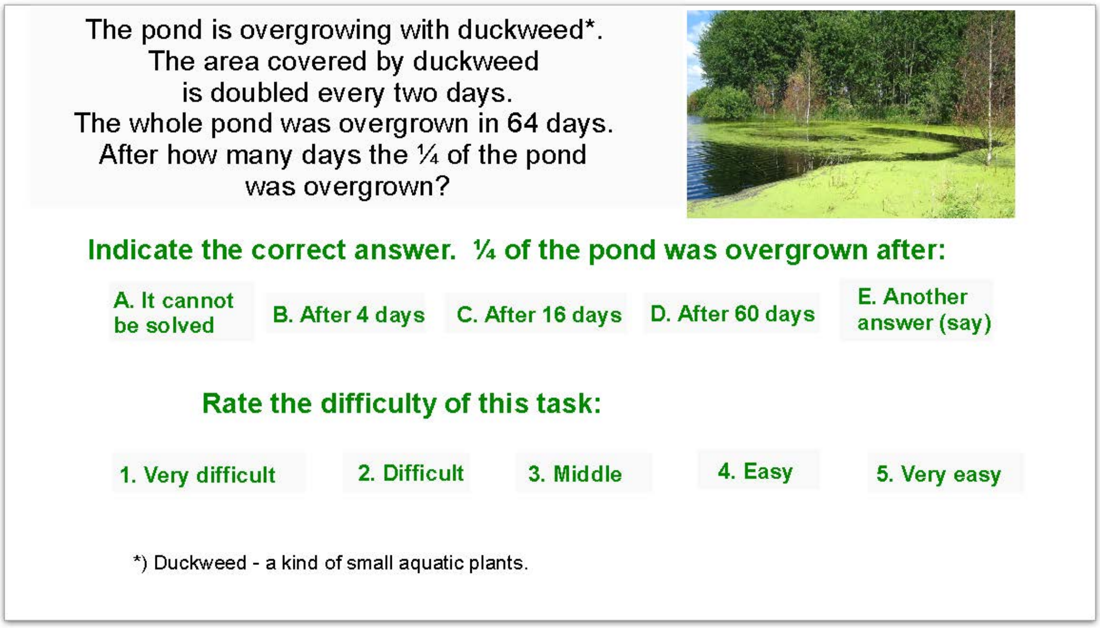

Figure 1: English translation of the Problem (slide 1)

process theory (Kahneman, 2011; Stanovich & West, 2000), and students have to overcome it. Answer C, "after 16 days," is a System 1 trap which forces quick, intuitive judgements with low mental effort which are frequently wrong. The Problem is analogous to the "lily problem" described by Kahneman.

The slide showed as Figure 1 was followed by two more slides with additional questions, the first of which suggested a method of reduction and provided graphical representations of the pond, as well as some hints and questions. The aim of slide 2 was to verify the answer provided to slide 1 and to suggest the proper method. After familiarizing themselves with this slide, all students were asked to check and correct their previous answer and rerate the difficulty of the problem.

The final slide was provided to the students in order to check their understanding of the method required to solve the problem. The students were asked to determine how many days it would take for the pond to be overgrown to 1/8 of the pond. They were also asked to assess six different methods of problem resolution, shown on the slide.

In this article we are focused only on the analysis of the answers to the initial Problem (slide 1).

Methodology

The analysis of all the answers to the questions presented in the three slides allowed us to select the students who correctly understood the whole problem and solved it perfectly. A ranking of the 52 participants was generated, taking into consideration the following criteria:

1. The correctness of answers to the whole problem (all questions on the three slides),
2. The mathematics score achieved on the final external exam after finishing junior high school.

The selection criteria for the comparative study was made by choosing a group of the best and worst performing participants from the ranking. However, we analysed the results of the groups in the context of general results.

Data for the analysis

The following sixteen "Areas of Interest" (AOIs) for obtaining the participants' data were defined within the slide area:

> Text of the problem, Picture – lake, Indicate the answer, Cannot be resolved, After 4 days, After 16 days, After 60 days, Another answer, Assign the difficulty, Very difficult, Difficult, Middle, Easy, Very easy, Explanation, White space.

Our analysis is based on numerical data, including graphical representations, such as: *focus maps*, *scan paths*, *AOI charts*, *key performance indicators*.

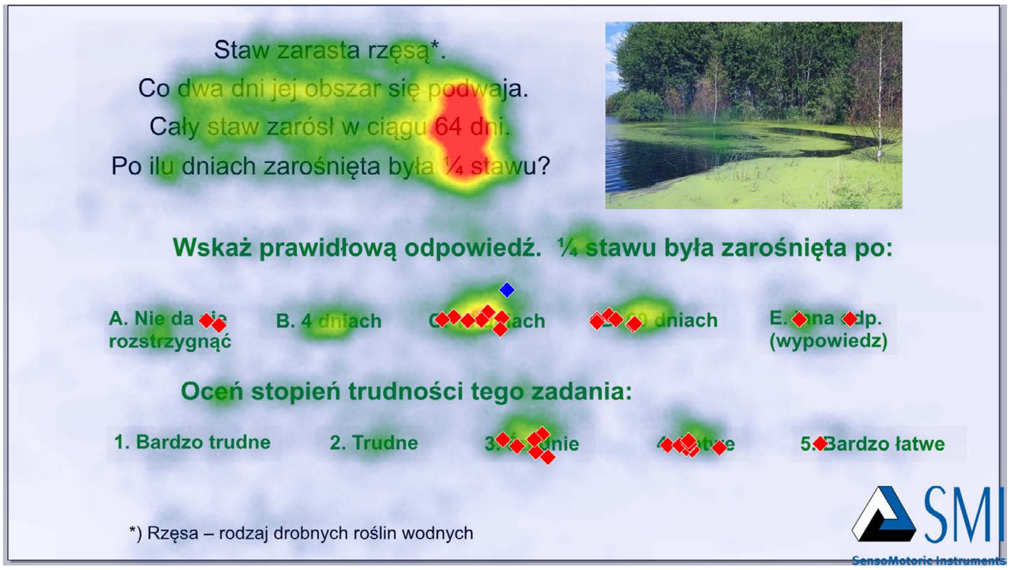

Figure 2: Heat map for all participants

RESEARCH RESULTS AND DISCUSSION

Overview of the general results

Only 5 students correctly solved the whole problem contained on the three slides. The correct answer, D, was provided only by 17 out of 52 students. The incorrect answer, C, "after 16 days," was selected by over half of the participants, i.e. 27 students. Despite the unsatisfactory general results, many participants rated the difficulty of the problem as "middle" (27) and "easy" (19).

The heat map for all participants is shown in Figure 2. Depending on the length of fixation time, the screen shows different colours – from blue (lack of fixations) through green, yellow, orange to red – representing the longest time of fixation.

The highest visual attention while reading the text of the problem was devoted to the most important phrases: "is doubled" („podwaja" at the end of the sentence); "64 days" and "¼ of the pond". The selected options are also visible as red symbols: ♦.

Two groups for comparison: „High Five" and „Low Six"

Only 5 students answered all of the questions from the three slides correctly. We call this group the "High Five". All of them were finalists of regional science competitions and they were recognized as gifted and interested in mathematics.

The second group in this comparative study was made by choosing a group of five the lowest performing participants from the ranking. This group consisted of 6 students and is called the „Low Six" group, as two of the students achieved the same mathematics score at the final external exam after finishing junior high school. The students from this group were the only respondents who did not pass the exam, achieving a result of below 30% of the available points.

A1. Total time of the analysis of the problem

The average total time for solving the problem by all participants of the study was 72 480 ms, the maximum time was 106 084 ms, and the minimum time was 32 890 ms.

The average total time for the "High Five" group was 72 150 ms, whereas the maximum time was 105 307 ms, and the minimum time was only 32 959 ms. Relevant individual differences can be observed (see Figure 3).

For the "Low Six" group, the corresponding values are the following: 57 275 ms; 69 981 ms, and 40 918 ms. The duration of solving the problem by the "Low Six" participants was more homogeneous (see Figure 3) and shorter than the average time of all participants.

A2. Time of the analysis of the problem's wording

In the two compared groups, we observe a crucial difference in the strategy of the analysis of the problem. The proportions between the visual attention devoted to analyzing the wording of the problem and the remaining text on the slide are significantly different.

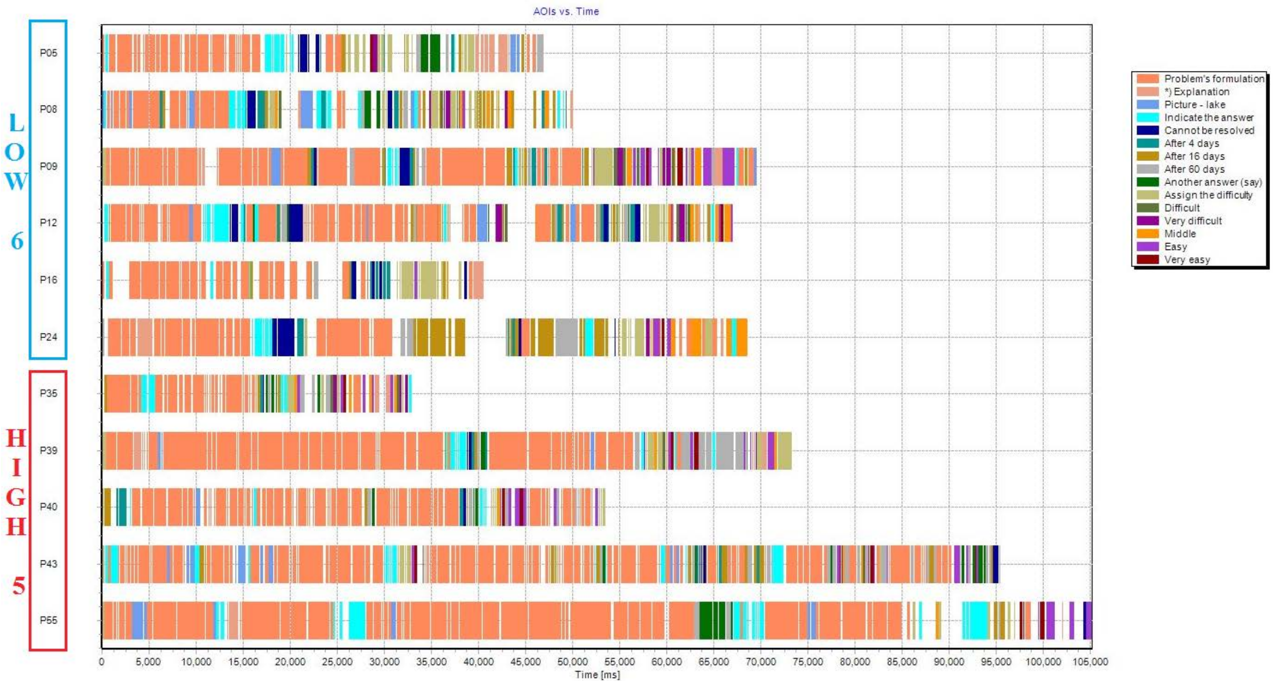

Figure 3: Sequence chart for "High Five" and "Low Six" groups

The average time percentage of the analysis of the wording of the problem in the "High Five" group is 65.9%. On the contrary, for the "Low Six" group it is only 36.5%. The proportions between visual attention devoted to the text of the problem and to the other parts of the screen are reversed for the two groups.

Figure 3 shows time (in milliseconds) spent by the participants' eyes at the defined AOIs respectively in the "High Five" and "Low Six" groups. The colors of the chart segments correspond to the sixteen respective AOIs described above. For example, the text of the problem is visible on the chart in orange. The sequence charts for both groups show an important difference in the way of looking at the screen.

A3. Number and placement of fixations while solving the whole problem

The respondents' visual attention is significantly different for the two compared groups. The heat maps (see Figure 4) show that students from the "High Five" group were concentrated on the wording of the problem and they achieved the maximum number of fixations on the area containing crucial information: "64 days", which had to be the starting point of discovering the correct answer.

On the other hand, the attention of the students from the "Low Six" group was more dispersed. They looked at the middle part of the screen as well – C and 3 an-

HIGH FIVE LOW SIX

Figure 4: Heat maps for "High Five" and "Low Six" groups

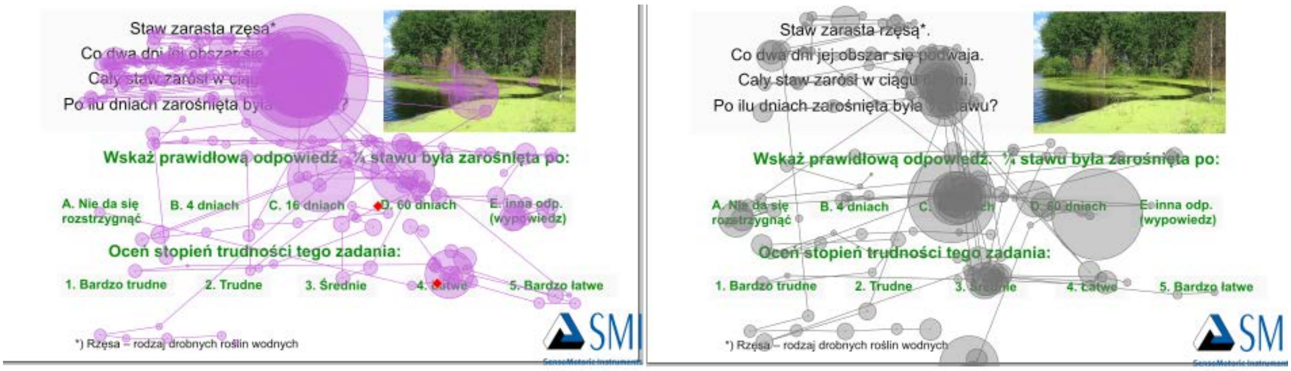

Figure 5: Scan paths of the representative participants from the "High Five" and "Low Six" groups

swers. This is a typical subconscious and intuitive way of looking.

The effect of dispersion can be observed individually, analyzing the students' looking paths, called *scan paths*. BeGaze™ software presents a clear graphic interpretation of data, showing the successive *fixations* (using circles) and *saccades*, i.e. paths of displacement between two consecutive *fixations* (using segments). In Figure 5, we present the *scan paths* of chosen two representative members from both groups.

A4. Number of fixations while analyzing the wording of the problem

The number of fixations while analyzing the text of the problem is the following for the "Low Six" and "High Five" groups respectively: Average number of fixations: 75,17 and 152,2; Maximum number of fixations: 110 and 225; Minimum number of fixations: 42 and 50.

SUMMARY

The following conclusions on the basis of the results of our research can be posed:

A1.

a) The average total time of solving the problem by the gifted students was the same as the average total time of all participants in our study. This parameter did not turn out to be a differentiator between gifted students and non-gifted students in the context of our research.

b) The total time of solving a problem by gifted students was very diversified. In this group we observed fast solvers (32 959 ms), average solvers, as well as slow ones (105 307 ms). Speed was not a parameter of mathematically gifted students.

A2.

The time of the analysis of the problem's wording was a differentiator between the group of gifted students and underperforming students in our research. Gifted students dedicated on average 65.9% of the total time of solving the problem to the analysis of the wording of the problem while the underperforming students devoted only 36.5% of their time for this purpose.

A3.

Analyzing the respondents' visual attention by observing the numbers and placement of fixations we observed significant differences between the two groups. The gifted students were concentrated on the text of the problem and they achieved maximum number of fixation at the area of the crucial information, which had to be a starting point to discover the correct answer. They did know where to look.

On the contrary underperforming students looked at various places of the screen, in a seemingly chaotic way. They also looked for longer periods in the middle of the screen, which is a natural way of looking. Their fixations were more often observed occurring at the areas on the slide without the wording of the problem.

A4.

The number of fixations while analyzing the text of the problem was also a differentiator between the groups of gifted students and non-gifted students. Both the average and the maximum number of fixations of the gifted students double those of the underperforming students.

On the basis of our research results, fixations were the visual symptoms of mental effort and motivation to solve the problem. It can be argued that the underperforming students were not sufficiently motivated to solve the problem or to make mental efforts.

The eye-tracking method allowed us to distinguish important differences in the strategy of reading a mathematical problem between gifted and underperforming students. It is be worth examining this topic further if the conclusions seem too broad, verifying them using different problems and a wider sample of students.

A comparative analysis of mathematics textbooks from Kosovo and Albania based on the topic of fractions

Eda Vula, Jeta Kingji–Kastrati and Fitore Podvorica

University of Prishtina, Faculty of Education, Prishtina, Kosovo, eda.vula@uni-pr.edu

This study analyses the presentation of fractions in Kosovar and Albanian mathematics textbooks designed for students of one to fifth-grade. Physical characteristics of the selected textbooks, the presentation of fractions and the nature of the problems were analysed as well. Findings showed that Albanian mathematics textbooks covered more lessons on fractions than Kosovar textbooks. Textbooks from both countries focus mostly on part whole and operator construction. Also, the majority of problems focused on pure mathematics and single procedures. Few problems in Kosovar textbooks required problem explanation, while problem solving as a cognitive requirement was used more in Albanian textbooks. A common deficiency in all texts was the lacks of problems requiring special requirement.

Keywords: Textbooks, fraction representation, subconstruct, problems.

INTRODUCTION

Numerous studies have shown that there are enough similarities but also differences in curricula and textbooks of countries with different history, culture, language, economy and geographical stretch (Delaney, Charalambous, Hsu, & Mesa, 2007; Charalambous, Delaney, Hsu, & Mesa, 2010; Alajmi, 2012; Erbaş, Alacaci, & Bulut, 2012; Cheng & Wang, 2012; Özer & Sezer, 2014). It is shown also that in addition to the culture of a country, language and structure of the school, students' performance in certain countries is affected particularly by the educational background of teachers and textbooks (Cheng & Wang, 2012).

Kosovo and Albania have been carrying out innovative reforms to increase the quality of the system of education. Unfortunately, studies that show the degrees of student achievement as a result of these reforms are very limited. While, the data for improved student achievement on internationally comparable standardized tests in Albania (PISA, 2012) are welcome, for Kosovo, participation in international assessment programs still remains a challenge. Thus, both countries are making the efforts to reform school curricula and textbooks to achieve the educational objectives of European Union (EU) and Organization for Economic Co-operation and Development (OECD). Since majority of the population in Kosovo and Albania speak the same language, have the same culture and tradition, regarding the improvements on education there are efforts to unify Curriculum for Pre-University Education System, with the assumption that this unification will have impact on improving quality in schools and students' learning. By considering the textbooks as an important part of classroom life, as very important tools for quality assurance (Pehkonen, 2004; Nicol & Crespo, 2006) and as an important indicator that enable students to reflect on school curricula (Erbaş, Alacaci, & Bulut, 2012), it seems important for us to explore how fractions as one of the key concepts presented in elementary mathematics textbooks are used in Kosovo and Albania.

BACKGROUND AND RESEARCH QUESTIONS

Many researchers identified several factors which contribute to students' learning fractions. Teachers can improve students' fraction learning by placing more emphasis on examining and improving the design of their instruction (Brown & Quinn, 2007; Pitsolantis & Osana, 2013). Keijzer and Terwel analysed how low-achieving students learn fractions in the context of Realistic Mathematics Education (2004) and Reimer and Moyer found that the virtual manipulative helped students in the class to learn more about fractions (2005). However, the textbooks are the major written source which play an important role in guiding teachers in lesson planning and present them to their classes (Li, 2000; Alajmi, 2012). Textbooks, as an important resource in support of teaching and learning have received increased attention from the international education community over the last decades (Nicol & Crespo, 2006; Fan & Zhu, 2007; Charalambous, Delaney, Hsu, & Mesa, 2010; Alajmi, 2012; Erbaş, Alacaci, & Bulut, 2012). The TIMSS survey found that in almost all countries, the majority of teachers use textbooks as the main written source in deciding how to present a given topic in their classrooms (Beaton, et al., 1996). Textbooks influence what teachers teach, how they teach it, and how they measure the learning opportunities (Alajmi, 2012; Özer & Sezer, 2014). We could consider that textbooks help teachers with their workloads because the books provide ready and sensible structures for lessons and enough exercises for pupils (Pehkonen, 2004). They are an instrument for learning as well as an object of learning, and textbooks address both students and teachers (Erbaş, Alacaci, & Bulut, 2012). Because of their importance, many researchers focused on reviewing mathematical textbooks regarding the presentation of a particular mathematical concept or they focused on the cognitive demands of the material in the texts (Kieren, 1976; Behr & Harel, 1990; Alajmi, 2012). Fractions are among the most complex mathematical concepts that children learn in primary school. It was documented that teaching and learning of fractions has traditionally been one of the most problematic areas and one of the most serious obstacles in primary school mathematics (Behr, Post, Harel, & Lesh, 1993; Charalambous & Pitta-Pantazi, 2007). The misconceptions that students have about fractions, both in terms of fractions as numbers and how to operate with fractions relates particularly to the way in which fractions are represented and how they are taught (Barmby, Harries, Higgins, & Suggate, 2009). Various theoretical models have been proposed for understanding fractions in the elementary school (Behr et al, 1993; Charalambous & Pitta-Pantazi, 2007; Nicolaou & Pitta-Pantazi, 2011). Early subconstruct theories postulated that integrating the qualities of multiple perspectives were crucial to the understanding of fractions (Moseley, 2005). According to Behr and colleagues (1993), rational numbers can be interpreted as a part-whole comparison, an indicated division or quotient, a ratio, as an operator and as a measure. The part-whole construct refers to a continuous quantity or a set of discrete objects partitioned into parts of equal size. This perspective emphasizes situations which are related to the comparison of parts with the total amount. On the other hand the quotient construct considers a fraction as a result of a division of two whole numbers. The ratio perspective is based on comparing separate quantities and usually presented as *a:b* or *a/b*. Whereas the ratio is a relation between two sets, an operator is a relation between two states of a set. The operator construct reflects a function that transforms line segments, figures, or numbers. And lastly the measure construct identifies fractions as numbers or associating fractions with the measure assigned to some interval (Kieren, 1976; Behr & Harel, 1990).

Using multiple representations makes the fraction concept more concrete and understandable. But, it was shown that even in cases where students seem to understand the conceptual meaning (Hiebert & Carpenter, 1992) of the different perspectives of fraction representations they still struggle to connect fraction ideas to real world problems (Moseley, 2005; Alajmi, 2012). Textbooks should focus not only on problems that have low-level cognitive requirements, such as recall and reproduction (Li, 2000). Also, they should not present only the pure mathematics contexts but they should emphasize real-world problems dealing with fractions in all lessons (Alajmi, 2012).

This study reviews the similarities and differences of the presentation of fractions and problems of fractions in textbooks in Kosovo and Albania. Specifically, the study addressed the following questions:

1) What are the physical characteristics of first-to fifth-grade mathematics textbooks in the selected series in Kosovo and Albania?

2) What similarities and differences can be observed in the representation of fractions in the mathematics textbooks in Kosovo and Albania?

3) How are problems involving fractions introduced in these textbooks?

METHODS

Textbook sampling

Two elementary mathematics textbook series from Kosovo and Albania were chosen for this study.

Kosovo has a national curriculum. In this system only one textbook series is available, and it is published and distributed at no cost to students by the Ministry of Education, Science and Technology - MEST. Thus, all public primary schools use the same mathematics textbook series. Albania also has a national curriculum but any of fifteen commercial series of textbooks may be used in Albanian schools. Teachers together with the parents' council analyse each of these series of books and choose which textbooks will be used throughout the school year. For this study we selected the series of EduAlba publishing house, because these textbooks are used as secondary textbooks by some schools in Kosovo. Focusing on the fraction content, this study examined textbooks from both countries in detail, with respect to two aspects: presentation of fractions and the mathematics problems provided for students' practice. In this study we have taken into account only the basic textbooks and not the student workbooks or other materials.

Data Analyses and Procedures

In this study a framework and the coding system was developed in two stages. First we analysed the textbooks' physical characteristics, such as page size, number of pages and number of pages containing fractions while using a horizontal approach which gives readers an initial introduction of the textbooks. Secondly, for the vertical-analyses (Charalambous et al., 2010) we read each lesson relevant to fractions from each textbook carefully in order to analyse the meaning of tasks (Cheng & Wang, 2012). The meaning of tasks here indicated a meaning of a specific task, a definition, a picture, a question, an example, practical exercise or a problem that serves as a particular purpose in the lessons. Based on the meaning of tasks we developed the coding system which includes the following two dimensions: conceptual and contextual. Under first dimension we analysed the fraction meaning and presentation based on Kieren (1976) model of the five subconstructs: the part-whole, the ratio, the operator, the quotient and the measure construct. For the second dimension, Li's (2000) framework was used to analyse textbook problems provided to students. The problems selected from each textbook were those exercises or questions that did not have solutions or answers. Each problem was coded based on the three dimensions below:

1) Mathematical features: Single procedure (S) and Multiple Procedure (M);
2) Contextual features: Purely mathematical context in numerical or word form (PM) and illustrative context or story (IC);
3) Performance requirements:

    3.1 Response type: no explanation or solution process required (numerical answer or numerical expression only) (NES) and explanation or solution process required (ES)

    3.2 Cognitive requirement: conceptual understanding (CU); Procedurals practice (PP); Problem solving (PS) and Special requirements (SR).

Cognitive requirement mean 'the kind and level of thinking required from students in order to successfully engage with and solve the task (Stein, Smith, Henningsen, & Silver, 2000, p. 11), while special requirement (SR) refers to the problems that contain special or mixed cognitive requirements. For example, the problem asks students to write up a problem based on given information (Li, 1990).

After we selected the pages with fractions' content from each textbook and we coded them independently, the tasks that were coded differently were discussed and recoded again for compatibility. The researcher's agreement was 97 %.

RESULTS

Physical characteristics

Textbooks in Kosovo differ from Albanian textbooks. Textbooks in Kosovo are larger in size (28.5 x 20.5 x 0.8 cm) in each grade level. Albania textbooks have smaller sizes (27 x 20.5 x 1 cm). For the first time fractions are introduced in the second grade texts both in Kosovo and Albania. The number of pages devoted to fractions increased by grade to grade level in all two textbook series. In Kosovar textbooks, the percentage of pages grew from 2.34% on the second grade to 10.73% on the fifth grade, while in Albanian texts the percentage of pages grew from 3.15% to 24.89 %. Based on these facts the number of tasks per page related on fractions is bigger in Kosovar texts (5–6 tasks per page) than in Albanian textbooks (2–3 tasks per page). Also, the number of lessons on fractions increased each year from three lessons in the second grade to fourteen lessons in the fifth grade in Kosovar textbooks while in Albanian text books it increased from one lesson in the second grade to eleven lessons in the fifth grade. Addition and subtraction of fractions with same denominator for the first time are presented in third grade in the Albanian textbooks, though in Kosovar textbooks they are presented for the first time on the fifth grade. Also, in the Kosovar textbooks decimal numbers are not covered in the textbooks, whereas in the Albanian textbooks they are introduced in the fifth grade. The greatest difference in these textbooks is related to the quantity of real world problems included. It was found that the Albanian textbooks emphasize real world problems more than their Kosovo counterparts. Only two real world problems were found in the Kosovo fifth grade textbook, while in Albanian textbooks there are two real world problems in the second grade, twelve in the third grade, twenty-six in the fourth grade level and thirteen real world problems in the fifth grade level.

Fraction meaning and presentation

Based on the model of the multiple representations of fractions, the fraction constructs were identified in all textbooks (Table 1). Table 1 shows that the part-whole construct is used from the 2nd grade, when fractions appear for the first time, up to 5th grade in both series of textbooks. It was identified that the part-whole construct was used in a higher percentage in 2nd grades and 3rd grades, while in 4th and 5th grades the percentage of tasks presented by this construct is reduced. It seems that the ratio and quotient constructs were used only in a few tasks. In Kosovar textbooks there are only two tasks presented with the ratio construct, while in Albania textbooks, the ratio construct appears in 3rd grade and 4th grade, with a total of six tasks. It was found that only 5 tasks in the 5th grade Albanian textbook used the quotient construct. In Kosovar textbooks there were no tasks presented with the quotient construct. The dominant construct among tasks identified in 4th and 5th grade textbooks in both series of textbooks was the operator construct. Most of the tasks in 4th and 5th grade of both series of textbooks used the operator construct (about 70% in 4th and 87% in 5th grade Kosovar textbooks, whereas in Albanian textbooks, about 91% and 94% of all tasks). The measure construct was identified in three Kosovar textbooks (grade 3, 4 and 5) while in Albania only one task in the textbook of the 3rd grade was identified.

Classification of problems with fractions

Table 2 shows the percentages of problems classified in terms of problems' requirements (Li, 2000). It was found that there is a significant difference between the types of problems presented in the textbook series of the two countries.

From the third to fifth grade in Kosovar series of textbooks we have a higher percentage of problems or practice exercises which requires a single procedure (SP) in the solution process, while in Albania in third grade texts 76% of the tasks require multiple procedures (MP). Also we founded that 50% of problems require single procedures and 50% multiple procedures in the Albanian textbook of the 4th grade. In contrast, the Albanian textbooks of the 5th grade contained about 85% of the problems that required a single procedure for the solution. In Kosovar 3rd grade textbook, the majority of problems are presented through illustrative contexts (76.47%). In contrast, Albanian third grade textbooks have more pure mathematics problems (52.78%) than illustrative context exercises (47.22%). In the 4th and 5th grade textbooks we have approximately the same percentage of tasks with PM and IC. What is also important to mention (see Table 2) is the number of tasks that require only the numerical result (NES) of the assignment and no explanation on how the solution was reached (ES). Only in the Kosovo

Country	Kosova									Albania

Table 2: Problems Classified According Li's Framework (Li, 2000)

5th grade textbook about 10.4% have problems that required the explanation. Regarding cognitive requirements, it was identified that in textbooks from Kosovo as well as in Albanian textbooks, the largest number of problems requires conceptual understanding (CU) and procedural practice (PP). There are very limited requirements for problems which ask for problem solving in Kosovar textbooks. There was only one problem in each of the 4th and 5thgrade Kosovar textbooks, while in the Albanian textbooks it was a greater percentage of problem solving (about 38% and 19% of problems in the 4th and 5th grade respectively).

A common deficiency in all analysed texts is the lack of problems requiring special requirements (SR). Textbooks do not provide assignments in which students have the opportunity to practice more complex cognitive requirement or require contextualising fractions in everyday life.,,

DISCUSSION

This study has analysed the physical characteristics of the textbooks, fraction presentation and nature of problems used in Kosovar and Albanian textbooks. In both series of textbooks, fractions are presented for the first time from the 2nd grade. The number of pages covered by fractions is larger in the Albanian textbooks than in the Kosovar textbooks. But, it was observed that there is a difference in terms of the number of tasks, associated figures, tables or diagrams per pages. While in the books from Kosovo there are five or six tasks per page, in Albanian books every page has at most 3 tasks. Also, there are differences in terms of content. An introduction to fractions as decimal numbers is presented only in the Albanian textbooks. It seems that Kosovar textbooks covered less content and less representations for fractions. Thus, low fraction content coverage can have a negative effect on the student's abilities to use fractions in the future. According to Brown & Quinn (2007), students should spend the majority of their time learning fractions before the 6thgrade if we want to devote the time to the developing of their conceptual understanding of fraction relationships. Both series of textbooks used mostly two constructs for fraction presentation (part-whole and operator) and were focused more on rules and procedures, even though using multiple representations would assist students in developing more interconnected and viable representations knowledge for fractions (Behr et al., 1993; Charalambous & Pitta-Pantazi, 2007; Moseley, 2005).

It was found that the majority of problems in both series of textbooks are presented in purely mathematical contexts and that almost in all problems single-procedures are required. Also, it was found that the largest number of tasks requires contextual cognitive requirement with illustrative context. But, as Hiebert and Carpenter (1992) argue, there is a need to have a conceptual understanding, as well as the necessary skills for procedural practice, in order to be successful in mathematics .Only few problems were found in Kosovar textbooks that demanded problem explanation and problem solving. Based on Li's point of view, focusing only in the problems that have low-level cognitive requirements, such as recall and reproduction (Li, 2000) doesn't help students to be good problem solvers. On the other hand, Albanian textbooks pay more attention to the idea of including more practice examples that require problem solving compared to Kosovo. However, it is important to mention a common deficiency in all analysed textbooks, which is the lack of practice exercises that require special requirements. In this case connecting fractions to students' lives and with real word problems is an important issue. Students should be provided with opportunities to see fractions in their real lives and use these meanings in the learning process. Therefore, the texts should assist teaching and learning in order to enable the development of the meaning of fractions, understanding them (Moseley, 2005; Alajmi, 2012) and solving problems from everyday life contexts.

The study has highlighted some differences that textbooks from different countries have, and aims to encourage authors of textbooks to cooperate at the international level in order to improve the quality of mathematics textbooks. A comparative study of mathematic textbooks from Kosovo, Albania and other countries will help to share the best practices for fraction introduction in elementary textbooks. The recommendation of this study is to increase both the number and the variety of problems in all textbooks, especially those with a high level of cognitive demand. Finally, taking in consideration that the elementary mathematics textbooks are the main instructional resource and learning tool, the teachers' and students' views on textbooks are crucial for their improvement.

The history of mathematics in the lower secondary textbook of Cyprus and Greece: Developing a common analytical framework

Constantinos Xenofontos and Christos E. Papadopoulos

University of Nicosia, Nicosia, Cyprus, xenofontos.c@unic.ac.cy

In this paper, we examine the ways the history of mathematics is integrated in the national textbooks of Cyprus and Greece. Our data-driven analyses suggest that the references identified can be clustered in four categories: (a) biographical references about mathematicians or historical references regarding the origins of a mathematical concept, (b) references to the history of a mathematical method or formula containing a solution or proof, (c) mathematical tasks of purely cognitive elements that require a solution, explanation or proof and (d) tasks that encourage discussion or the production of a project that would connect the history of mathematics with life outside mathematics.

Keywords: History of mathematics, textbooks, Cyprus, Greece.

INTRODUCTION

A number of recent studies highlight the importance of introducing elements from the History of Mathematics (HoM) in lessons as an alternative and supplementary means to establish more efficient teaching and learning of the subject (see, for example, Fauvel & van Maanen, 2000; Siu & Tzanakis, 2004). While recognizing the various pedagogical benefits of such an incorporation –as, for example, the development of more positive attitudes towards the subject (Farmaki et al., 2004), better conceptual understanding of mathematical ideas (Fasanelli et al., 2002), the elimination of racial discriminations (Michalowicz et al., 2002; Strutchens, 1995) and so on – this paper describes and discusses the developed framework that facilitates our analyses for the textbooks of the two countries under scrutiny, Cyprus and Greece, as well as some of our findings.

COMPARING MATHEMATICS TEXTBOOKS ACROSS COUNTRIES

Textbooks constitute the main teaching resource for most countries around the world (Mullis et al., 2012), especially for highly centralised educational systems, as are those of Cyprus and Greece. Textbooks play a significant role in the ways mathematics lessons are designed and delivered; their influence over the content of the lessons; the instructional approaches; the quality of activities assigned for pupils, in classrooms and for homework; and, the learning outcomes and achievement (Alajmi, 2012; Törnroos, 2005; Weiss et al., 2003; Robitaille & Travers, 1992). Drawn from the well-known trichotomic distinction of the curriculum in the *intended* (vision and intentions as specified in official curriculum documents and/or materials), the *implemented* (teachers' interpretation and enactment of the curriculum according to their perceptions and knowledge) and the *attained* (learning experience as perceived by learners and their resulting learning outcomes), mathematics textbooks could be seen as a mediator between the first two types (or what Schmidt, et al. call the *potentially implemented curriculum*). From this perspective, Mesa (2004, pp. 255–256) talks about "a hypothetical enterprise: What *would* students learn if their mathematics classes were to cover all the textbook sections in the order given? What *would* students learn if they had to solve all the exercises in the textbook?" Rezat and Straesser (2014) take this argument a step further and distinguish between three perspectives on textbooks analyses. The first perceives textbooks as *curriculum materials* that offer supplementary ideas for teaching. From another perspective, textbooks are approached as *artifacts* that are employed for the preservation and transition of acquired skills. Analyses from this perspective focus only on opportunities to teach and to learn. Lastly, textbooks can be seen as *instruments*. Such analyses take into consideration the actual use of textbooks in lessons.

Many studies make use of various frameworks for analysing mathematics textbooks, which include, among other things, their physical characteristics (i.e. size, number of pages, volumes, and so on), the structure of the lessons, the topics covered, the presentation of particular mathematical concepts, and the level of the cognitive demands of tasks (Bayazit, 2013; Alajmi, 2012). As far as cross-national comparisons of textbooks are concerned, a specific interest is shared between scholars, which shows how the cultural expectations and goals of different educational systems are manifested in the instructional materials produced (Haggarty & Pepin, 2002). Cross-national textbook analyses typically fall under three broad categories; namely, *horizontal*, *vertical*, and *contextual* (Charalambous et al., 2010). Horizontal analysis focuses on textbooks' general characteristics (i.e. content, structure, etc.), while the textbook is examined as a whole. Such examples include Stevenson's and Bartsch's (1992) analyses of Japanese and American textbooks, and the work of Campbell and Kyriakides (2000), who have investigated Cypriot and English elementary textbooks as part of the national curriculum of the two countries. In vertical analysis, the interest is on how the textbooks under examination treat certain mathematical concepts. From this perspective, Ding and Li (2010) discuss the ways the distributive property is presented in US and Chinese elementary textbooks, while Alajmi (2012) examines how elementary textbooks in the US, Japan, and Kuwait address fractions. Finally, contextual analysis is concerned with the role of the textbooks in classroom activities, either by the teacher or the pupils (see Remillard, 2005). Only few comparative studies employ more than one of the types of analysis above, as, for example, Haggarty's and Pepin's (2002) work with English, French and German textbooks, and their function in classrooms, and Charalambous and colleagues' (2010) framework developed for analysing learning opportunities provided by Cypriot, Irish, and Taiwanese textbooks.

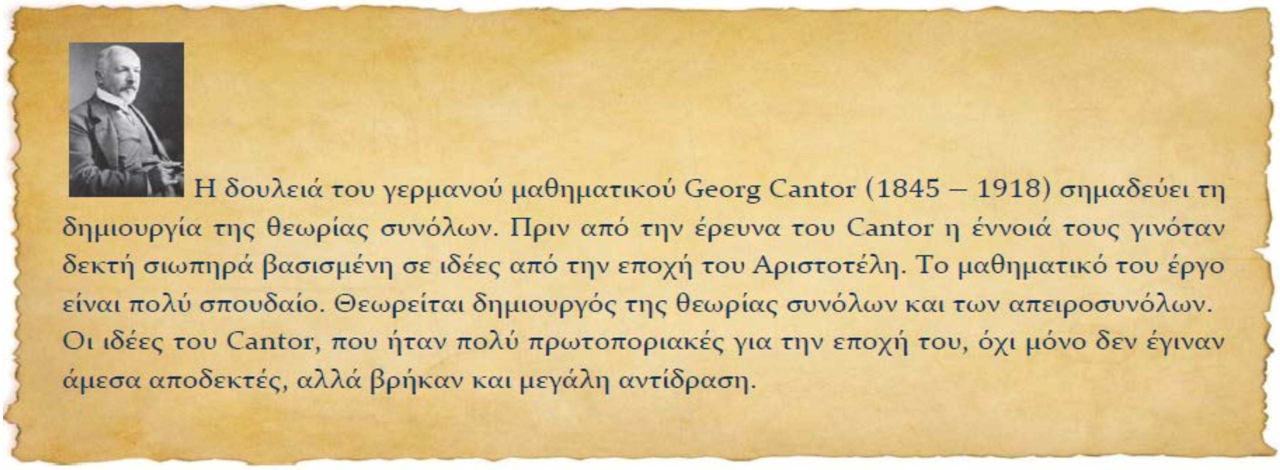
THIS STUDY

In this paper, we analyse references included in the lower secondary textbooks of Cyprus and Greece in regards to the HoM. Both countries have highly centralised educational systems (Charalambous et al., 2010; Saiti & Eliophoto-Menon, 2009) in which schools are considered segments of the domain of government, and not of the community. The national curricula and continued textbooks are prepared by each country's respective Ministry of Education, more specifically, by the Pedagogical Institute, a department of the Ministry of Education. In both the Cypriot (MoEC, 2010) and the Greek intended curriculum (MoERA, 2002), explicit references are made to the importance of the HoM. Nevertheless, the purpose of this paper is to examine how the general curricular references to the HoM are actually transformed into learning opportunities in the Cypriot and Greek textbooks for both teachers and pupils.

In our study, textbooks are treated as artifacts (Rezat & Straesser, 2014) since we examine their content in relation to the HoM, and not in relation to other teaching material, or the ways by which they are utilized in classrooms. Furthermore, our approach could be regarded as a comparative vertical analysis (Charalambous et al., 2010), which focuses on how the two sets of textbooks, Cypriot and Greek, treat a particular concept, namely the HoM.

For the purposes of this project, we analysed the national textbooks of Cyprus and Greece for lower secondary education (grades 7, 8, and 9). The educational system of Cyprus is currently reforming its curriculum for all subjects and grades; consequently, only the textbooks for lower secondary education were available to us once our study began, therefore, we chose to focus our analyses on the three lower secondary grades. The Cypriot textbooks were launched between 2012 and 2013 by the Pedagogical Institute of Cyprus, and the Greek ones were introduced in 2007 by the Pedagogical Institute of Greece.

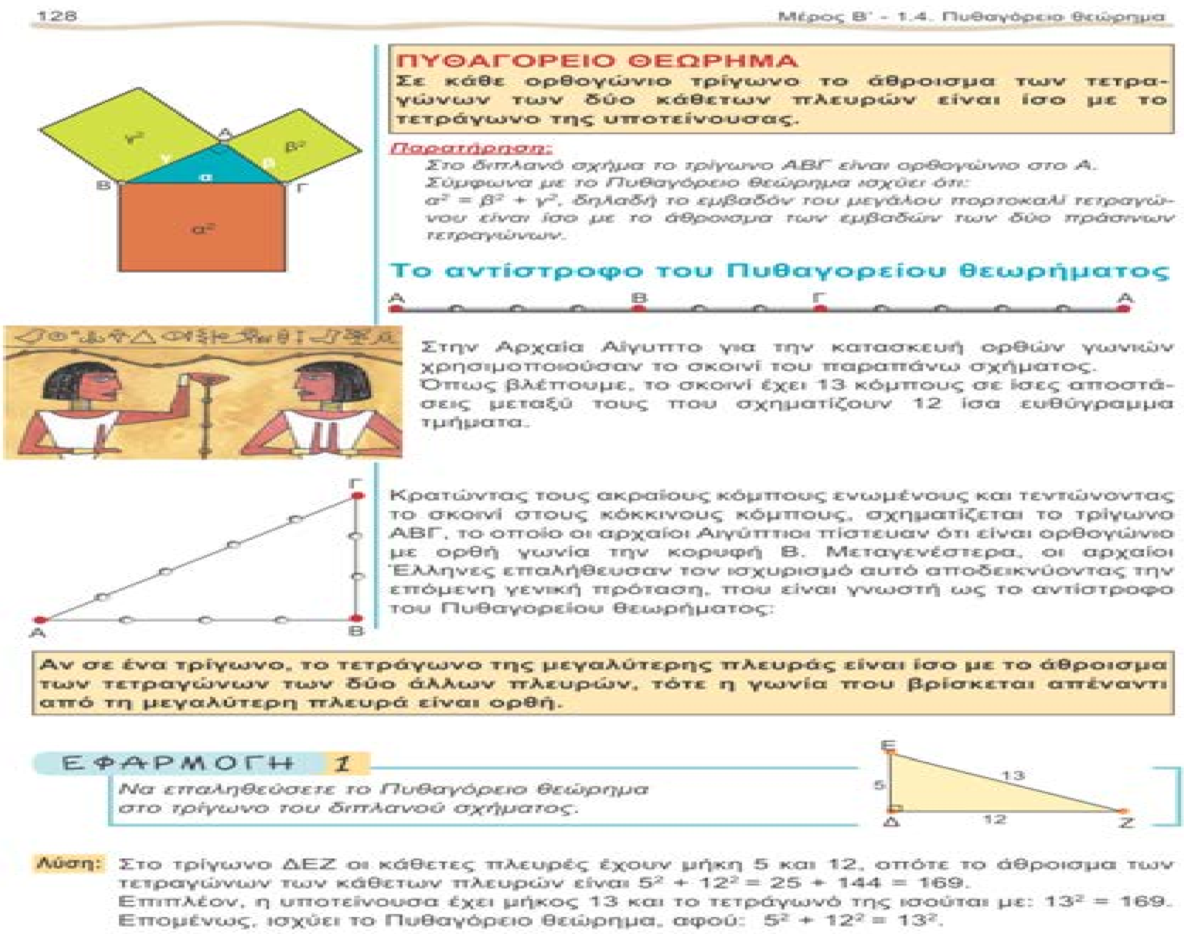
At the first stage of data collection, all references to the HoM in both textbook series were identified. We were interested in both encyclopedic pieces of information and mathematical tasks inviting pupils to interact with them and provide solutions or answers. We worked independently with the two data sets (Cypriot and Greek), trying to find ways of clustering the references identified. Due to the long distance, in person meetings were not possible; however, after individual progress we had online meetings to discuss our ideas, which were, interestingly, similarly handled. After combining our working ideas, we applied



Η δουλειά του γερμανού μαθηματικού Georg Cantor (1845 – 1918) σημαδεύει τη δημιουργία της θεωρίας συνόλων. Πριν από την έρευνα του Cantor η έννοιά τους γινόταν δεκτή σιωπηρά βασισμένη σε ιδέες από την εποχή του Αριστοτέλη. Το μαθηματικό του έργο είναι πολύ σπουδαίο. Θεωρείται δημιουργός της θεωρίας συνόλων και των απειροσυνόλων. Οι ιδέες του Cantor, που ήταν πολύ πρωτοποριακές για την εποχή του, όχι μόνο δεν έγιναν άμεσα αποδεκτές, αλλά βρήκαν και μεγάλη αντίδραση.

Figure 1: An example of a biographical reference

a data driven analysis (Kvale & Brinkmann, 2009) as well as the constant comparison process outlined by Strauss and Corbin (1998), which led to clustering the references in two broad categories. Further analyses resulted in the division of the two categories into two subcategories each. The first category was concerned with references that did not pose questions to pupils; they'd rather provide historical pieces of information. In this category, we could find (a) simple biographical references about mathematicians or historical references concerning the origins of a mathematical concept and (b) references to the history of a mathematical method or formula including a solution path or proof. Figure 1 shows an example of the first subcategory and provides biographical information about



128 Μέρος Β' - 1.4. Πυθαγόρειο θεώρημα

ΠΥΘΑΓΟΡΕΙΟ ΘΕΩΡΗΜΑ

Σε κάθε ορθογώνιο τρίγωνο το άθροισμα των τετραγώνων των δύο κάθετων πλευρών είναι ίσο με το τετράγωνο της υποτείνουσας.

Παρατήρηση:

Στο διπλανό σχήμα το τρίγωνο ΑΒΓ είναι ορθογώνιο στο Α. Σύμφωνα με το Πυθαγόρειο θεώρημα ισχύει ότι: $\alpha^2 = \beta^2 + \gamma^2$, δηλαδή το εμβαδόν του μεγάλου πορτοκαλί τετραγώνου είναι ίσο με το άθροισμα των εμβαδών των δύο πράσινων τετραγώνων.

Το αντίστροφο του Πυθαγορείου θεωρήματος

Στην Αρχαία Αίγυπτο για την κατασκευή ορθών γωνιών χρησιμοποιούσαν το σκοινί του παραπάνω σχήματος. Όπως βλέπουμε, το σκοινί έχει 13 κόμπους σε ίσες αποστάσεις μεταξύ τους που σχηματίζουν 12 ίσα ευθύγραμμα τμήματα.

Κρατώντας τους ακραίους κόμπους ενωμένους και τεντώνοντας το σκοινί στους κόκκινους κόμπους, σχηματίζεται το τρίγωνο ΑΒΓ, το οποίο οι αρχαίοι Αιγύπτιοι πίστευαν ότι είναι ορθογώνιο με ορθή γωνία την κορυφή Β. Μεταγενέστερα, οι αρχαίοι Έλληνες επαλήθευσαν τον ισχυρισμό αυτό αποδεικνύοντας την επόμενη γενική πρόταση, που είναι γνωστή ως το αντίστροφο του Πυθαγορείου θεωρήματος:

Αν σε ένα τρίγωνο, το τετράγωνο της μεγαλύτερης πλευράς είναι ίσο με το άθροισμα των τετραγώνων των δύο άλλων πλευρών, τότε η γωνία που βρίσκεται απέναντι από τη μεγαλύτερη πλευρά είναι ορθή.

ΕΦΑΡΜΟΓΗ 1

Να επαληθεύσετε το Πυθαγόρειο θεώρημα στο τρίγωνο του διπλανού σχήματος.

Λύση: Στο τρίγωνο ΔΕΖ οι κάθετες πλευρές έχουν μήκη 5 και 12, οπότε το άθροισμα των τετραγώνων των κάθετων πλευρών είναι $5^2 + 12^2 = 25 + 144 = 169$.
Επιπλέον, η υποτείνουσα έχει μήκος 13 και το τετράγωνό της ισούται με: $13^2 = 169$.
Επομένως, ισχύει το Πυθαγόρειο θεώρημα, αφού: $5^2 + 12^2 = 13^2$.

Figure 2: An example of a historical reference to a method and its solution process

	No question(s) for pupils		Asks pupils to interact with it	
	Simple historical/biographical references	*Show solution/proof of a method/formula*	*Mathematical tasks*	*Encourage discussion/ project*
Cyprus	27	2	28	2
Greece	41	4	26	7

Table 1: Distribution of the historical references in the two textbook series

the life and work of the German mathematician Georg Cantor (Cypriot textbooks, grade 7, part A, p. 27).

Figure 2 shows an example of a historical reference to a method and its solution process. In particular, it explains how Ancient Egyptians used a piece of rope with 13 knots and 12 equal line segments to create right angles, a method called in the book, "the reverse of the Pythagorean theorem" (Greek textbooks, grade 8, p. 128).

The second category comprised tasks that invited pupils to interact with them and provide some sort of answer. This included (a) mathematical tasks of purely cognitive elements that require a numerical solution, explanation or proof and (b) tasks that encourage discussion or the production of a project that would connect the history of mathematics with life outside mathematics. Examples of these subcategories are illustrated in Figures 3 and 4 respectively. Figure 3 shows the method applied by the ancient Greek mathematician, Thales, for the calculation of the distance between a ship and the coastline. Furthermore, pupils are asked to prove Thales' method and explain how he could be sure that the distance was right (Greek textbooks, grade 9, p. 197).

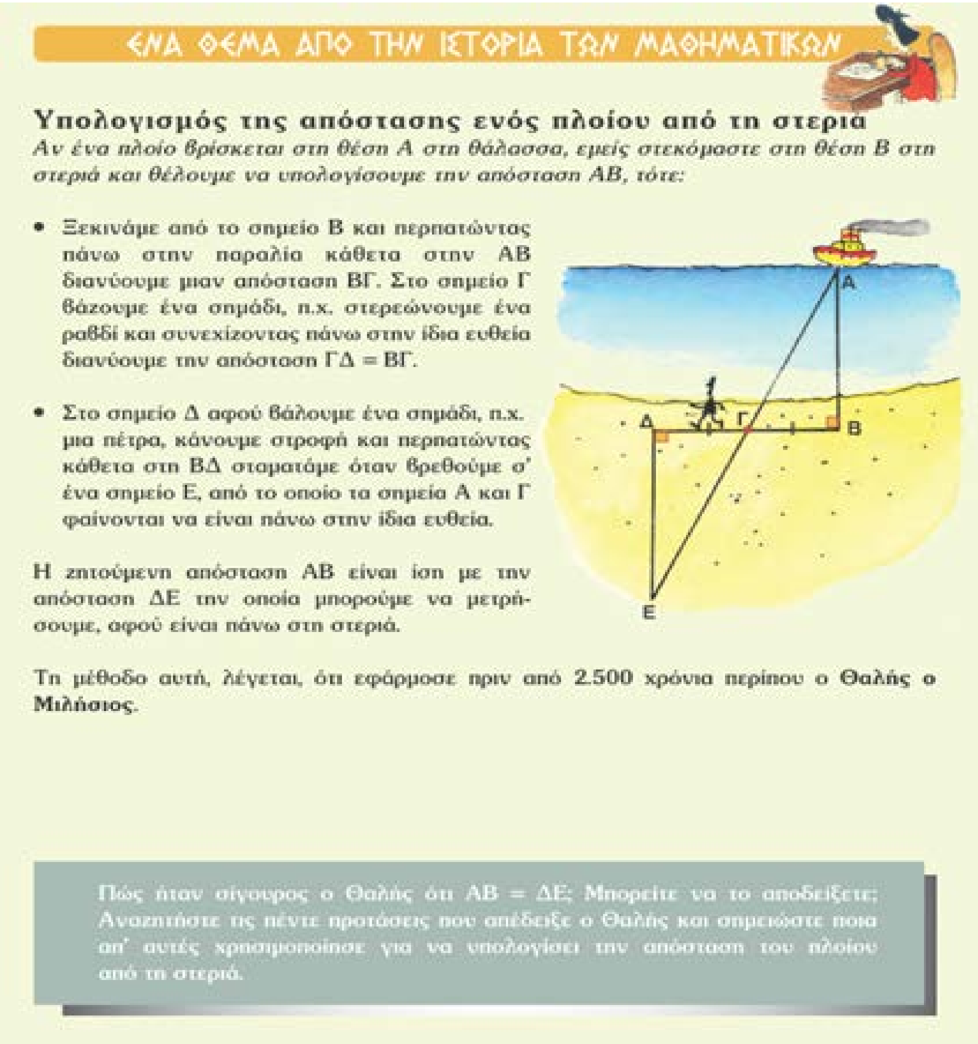
Figure 4 provides an example of a task that requires pupils to carry out a small project comparing and contrasting the number systems of Mayans and of Babylonians-Sumerians, as well as discussing the difficulties of these two systems, which eventually led to a need to establish the positional decimal system (Cypriot textbooks, grade 6, part A, p. 85). It is worth stating that there are no previous references to the two ancient number systems in the textbooks. Pupils are asked to conduct their own research and find information about them, since the textbook implies that there is no further instruction about these systems.

Table 1 shows the distribution of the HoM's references per country. No significant differences could be observed as regards the two broad categories and the references of the HoM from each country, χ^2 (1, N = 137) = 0.986, p = 0.32.

DISCUSSION AND CONCLUSIONS

Clearly, both countries value the HoM, a fact not only expressed in their curricula, but also reflected in their national textbooks. This could be attributed to a common cultural-historic heritage and the profound role of ancient Greek mathematics in the development of contemporary mathematical thinking. Nevertheless, the two countries' educational traditions share much in common, historically speaking (Koutselini-Ioannidou, 1997). In the case of their mathematics textbooks, Cypriot textbooks, launched a few years after the Greek ones, include several slightly modified examples. For instance, in the Greek textbook of grade 8 (page 10) we find a mathematical riddle from the tombstone of the ancient Greek mathematician Diophantus, inviting passers to solve it and calculate the age of his death. In the textbook, an equation showing the solution to the riddle follows. In the Cypriot textbooks (grade 7, part A, p. 173) although the same riddle is included, no solution is presented and pupils are asked to calculate Diophantus' age.

About half of the HoM's references in the Cypriot series and more than half in the Greek one constitute biographical and historical information that do not ask pupils to interact with them in any way. From our experiences as former pupils in the two educational systems, such information typically remains unexploited in classrooms, in a similar way to those arguing that the mathematics curriculum so overloaded with topics that teachers do not have much time to dedicate to the HoM. Also, despite comments of authors like Lawrence (2008) and Jahnke and colleagues (2002), who see advantages of the HoM in lessons as an



ΕΝΑ ΘΕΜΑ ΑΠΟ ΤΗΝ ΙΣΤΟΡΙΑ ΤΩΝ ΜΑΘΗΜΑΤΙΚΩΝ

Υπολογισμός της απόστασης ενός πλοίου από τη στεριά

Αν ένα πλοίο βρίσκεται στη θέση Α στη θάλασσα, εμείς στεκόμαστε στη θέση Β στη στεριά και θέλουμε να υπολογίσουμε την απόσταση ΑΒ, τότε:

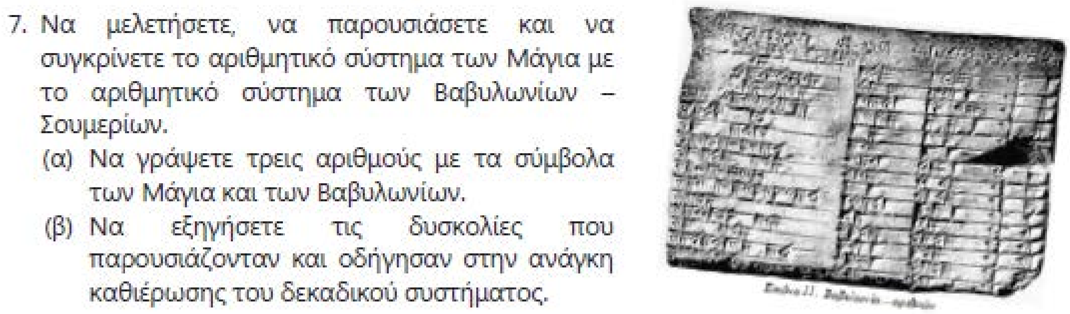
- Ξεκινάμε από το σημείο Β και περπατώντας πάνω στην παραλία κάθετα στην ΑΒ διανύουμε μιαν απόσταση ΒΓ. Στο σημείο Γ βάζουμε ένα σημάδι, π.χ. στερεώνουμε ένα ραβδί και συνεχίζοντας πάνω στην ίδια ευθεία διανύουμε την απόσταση ΓΔ = ΒΓ.
- Στο σημείο Δ αφού βάλουμε ένα σημάδι, π.χ. μια πέτρα, κάνουμε στροφή και περπατώντας κάθετα στη ΒΔ σταματάμε όταν βρεθούμε σ' ένα σημείο Ε, από το οποίο τα σημεία Α και Γ φαίνονται να είναι πάνω στην ίδια ευθεία.

Η ζητούμενη απόσταση ΑΒ είναι ίση με την απόσταση ΔΕ την οποία μπορούμε να μετρήσουμε, αφού είναι πάνω στη στεριά.

Τη μέθοδο αυτή, λέγεται, ότι εφάρμοσε πριν από 2.500 χρόνια περίπου ο Θαλής ο Μιλήσιος.

Πώς ήταν σίγουρος ο Θαλής ότι ΑΒ = ΔΕ; Μπορείτε να το αποδείξετε; Αναζητήστε τις πέντε προτάσεις που απέδειξε ο Θαλής και σημειώστε ποια απ' αυτές χρησιμοποίησε για να υπολογίσει την απόσταση του πλοίου από τη στεριά.

Figure 3: An example of a mathematical task



7. Να μελετήσετε, να παρουσιάσετε και να συγκρίνετε το αριθμητικό σύστημα των Μάγια με το αριθμητικό σύστημα των Βαβυλωνίων – Σουμερίων.
   (α) Να γράψετε τρεις αριθμούς με τα σύμβολα των Μάγια και των Βαβυλωνίων.
   (β) Να εξηγήσετε τις δυσκολίες που παρουσιάζονταν και οδήγησαν στην ανάγκη καθιέρωσης του δεκαδικού συστήματος.

Figure 4: An example of a project-based assignment

opportunity for pupils to realise how mathematical knowledge of the past has influenced our modern everyday life, both series include very few project-based tasks. Once again, from our experiences, Cypriot and Greek secondary mathematics teachers perceive such tasks as not "mathematical" and often ignore them, as a result. It is worth mentioning that both series are not restricted to ancient Greek mathematics; they include references from many civilizations, and this is an opportunity considered important for the elimination of racial discriminations (Michalowicz et al., 2002; Strutchens, 1995).

In closing, we cannot but emphasize the significance of collaboration between researchers from different countries in respect to comparative enquiries. Scholars must be aware that things with the same name might have a different meaning and function across nations, and they ought, therefore, to avoid assuming that colleagues elsewhere share the same understanding. Furthermore, we would like to invite colleagues from other countries to draw on our emerged framework of analysis about the types of historical references in mathematics textbooks, and to examine the ways in which HoM is included in other curricula, textbook series, and classrooms around the world.

7 Portuguese Association of Mathematics Teachers, Portugal, anavieiralopes@gmail.com

We are briefly describing the proposal of an international project for enhancing mathematical literacy in different European countries (Italy, Germany, Portugal, Spain and UK), through the cooperation of teacher societies of mathematics and university researchers.

Keywords: Teacher education, comparative curriculum, international assessment.

INTRODUCTION

Our goal is to announce the proposal of the Teachers and Researchers Understanding Mathematics in PISA (TRUMP) project, submitted to Eramus + EU programme in 2014 (Key Action 2: Cooperation for innovation and the exchange of good practices).

The TRUMP project seeks to enhance adolescent's mathematical literacy at a European level. PISA 2012 (as others international projects) suggests that European mathematics education is often less successful in developing mathematical literacy than other OECD members (PISA, 2012).

Mathematical literacy is essential, in modern society, for effective citizenship. In this way, the TRUMP project aims to create a network of European teachers and researchers in partner countries that, informed by the PISA framework and its assessment, helps teachers' professional development.

Although the proposal presented in 2014 to Erasmus+ was declined, the potential of the project has been recognised and the current team is searching for new European members to collaborate with and to further develop the original proposal.

CURRENT TEAM MEMBERS

The current working team is led by the Spanish Federation of Mathematics Teachers' Societies (FESPM). This 25-year-old non-profit organisation comprises 21 Spanish mathematics teachers' societies, with about 6000 members who are mainly secondary education teachers. The group team includes also universities from England, Germany, Italy, Spain and Portugal, as well as professional associations of teachers of mathematics from Portugal and England.

The project is unique in the sense that it involves both universities and professional associations of mathematics teachers. We believe that universities will provide research and development expertise and teachers' associations will ensure wide participation and dissemination to practicing teachers, and long-term sustainability. Digital technologies will be used to support collaboration among different partners.

MAIN PROJECT ACTIVITIES TO BE UNDERTAKEN

The participant members will work within the PISA theoretical framework to devise and evaluate strategies for teacher professional development, drawing on existing materials and resources. Some examples are provided below:

1) Teachers and researchers from all the member groups will undertake bilateral visits to learn from teaching practices in the different countries.

2) Researchers from the member groups will develop an evaluative framework to assess materials, classrooms teaching practices and learner outcomes.

3) A network of teachers will be created and guided to trial and evaluate the programmes and educational resources emerging from the project.

4) Teachers in each participant country will adopt and adapt shared resources to their cultural and educational context.

5) Transnational meetings of group leaders will be held to share resources, review progress to date, and to agree on priorities for the subsequent stages of the project.

EXPECTED RESULTS

Within the results expected are the following:

1) Establishing a community of researchers to design the training programmes materials and evaluative framework for teachers' professional development and enhanced mathematical learning.

2) Establishing a community of teachers and researchers working together internationally and locally to enhance professional competences.

3) Enhancing and developing student mathematical literacy.

4) As a resulting outcome, the TRUMP project intends to contribute to reducing the number of low-skilled adults.

A comparison between paper and pencil and computer based assessment

Alice Lemmo

University of Palermo, Palermo, Italy, alice.lemmo@unipa.it; alice.lemmo@gmail.com

In this study, we describe two tools designed for comparing paper and computer assessment modalities: a "comparison table" to control migratory process from paper to computer modality and vice versa and a "grid for observation of students" to codify students' behaviours in solving process.

Keywords: Paper and pencil based assessment, computer based assessment, comparability, students' behaviours comparison.

INTRODUCTION

A large number of Institutions for Assessment (OECD-PISA, PIAAC, NAEP, …) introduced a computer-based section. Ripley (2009) analyses the main approaches to the use of technology to support assessment. In particular, he defines the *migratory approach* to indicate paper based tests migrating to screen based environment. Research on migrated tests, involving comparative analysis on outcomes, finds no statistical evidence to suggest that the administration modality changes the coherence and consistency of the test (Kim & Huynh, 2007).

Quantitative studies give information on students' performances in scoring without dealing with cognitive aspects affected by this changing of environment. Threlfall and colleagues (2007) explore the effect on assessment of paper and pencil test items migrating into their computer corresponding ones. They show that, even if in most cases changing to the different environment seems to make little difference, for some items computer deeply affects how the question is attempted and what is being assessed. Furthermore, researches start from the assumption that it is possible to consider these assessment modalities as equivalent. The aims of this study is to develop a scheme to control, in terms of equivalence, migrating processes from paper to computer and vice versa and to analyse cognitive aspects influenced by these migrated tests.

FRAMEWORK AND METHODOLOGY

Comparing students involved in tests in different environments requires considering comparable questions. In migration process corresponding features of the questions probably change, such as syntax, vocabulary, editing, layout, and others. For this reason, it is necessary to define a monitoring tool in order to control any possible changes that might affect the comparability of questions. We define a *comparison table* to control the migration from paper to computer based question and vice versa.

We administer to couples of students two parallel tests of migrating items, one in computer and the other in paper environment. Every couple involves in only one of these tests; protocols are video taped with the purpose to focus on behaviours and heuristics processes.

Protocol analysis is performed through a *grid for observation of students' behavior*, inspired by the definition of problem solving episodes proposed by Schoenfeld (1985), which allows to identify differences focussing on strategies, planning and results, in qualitative terms.

CONCLUSION

Qualitative analysis on migrated questions shows that migration from one administration modality to another is necessarily influenced by the environment in which these questions migrate. It reveals the inconsistency in the definition of equivalence between questions in computer and paper environment.

In general, protocols analysis highlights that students achieve the same outcomes in both administration modalities. However, a deeper study on cognitive processes shows case studies in which administration environment greatly influences students' strategic choices in resolution process. In other cases, despite comparable heuristic choices, the organization of the problem-solving process is less linear in computer than paper modality.

TWG12

History in mathematics education

Introduction to the papers of TWG12: History in mathematics education

Uffe Thomas Jankvist[1], Snezana Lawrence[2], Kathleen Clark[3] and Renaud Chorlay[4]

1 Aarhus University, Aarhus, Denmark, utj@edu.au.dk

2 Bath Spa University, Bath, UK

3 Florida State University, Tallahassee, USA

4 Université Paris-Diderot, Paris, France

CERME9 was the fourth time of the TWG on "History in Mathematics Education". For CERME9 the group had fourteen papers and two posters, and around twenty participants in the sessions. TWG12 covers a range of topics related to history in mathematics education, but on an overall scale, submissions to the group may be distinguished by either concerning "History in Mathematics Education" (HiMEd) or "History of Mathematics Education" (HoMEd). This time round, the group had five papers addressing topics of HoMEd, while the remaining nine papers and two posters were concerned with issues of HiMEd at various educational levels, which also included teacher education.

BULLETS IN THE TWG12 CALL FOR PAPERS

For CERME9, TWG12 in particular welcomed empirical and theoretical research papers and posters, but to some degree also methodological and developmental papers related to one or more of the following issues (bullets below) – although any paper/poster of relevance to the overall focus of the group was taken into consideration:

- Ways of integrating original sources in classrooms, and their educational effects, preferably with conclusions based on classroom experiments;
- Surveys on the existing uses of history or epistemology in curricula, textbooks, and/or classrooms in primary, secondary, and tertiary levels;
- Design and/or assessment of teaching/learning materials on the history of mathematics;
- The role of history or epistemology of mathematics at the primary, secondary, and tertiary level, and in pre- and in-service teacher education, from cognitive, pedagogical, and/or affective points of view;
- Investigations or descriptions of the historical instances of research cultures and cultures of teaching and learning in mathematics;
- Relationships between (frameworks for and empirical studies on) history in mathematics education and theories and frameworks in other parts of mathematics education;
- Possible parallelism between the historical development and the cognitive development of mathematical ideas;
- Theoretical, conceptual and/or methodological frameworks for including history in mathematics education;
- The potential role of history of mathematics/mathematical practices in relation to more general problems and issues in mathematics education and mathematics education research.

FOUR AREAS OF QUESTIONS FOR REFLECTIONS DURING SESSIONS

The work following the presentations of participants' papers and posters was orchestrated by four overarching themes cutting across the topics of papers:

Meta-level or methodological reflections on HiMEd and HoMEd

- What (if any) is (could be) the role assigned to epistemological/historical reflection in some major mathematics education theoretical frameworks: e.g. TDS; ATD; APOS; MKT; etc.?

- With regard to the local/global tension: Can large-scale surveys (e.g., history of algebra, historical development of geometry, notion of proof from Euclid to Hilbert, evolution of the concept of function, etc.) go beyond the "bird's eye view"? Can we elicit necessary conditions for such large-scale surveys to make any sense? Is the "epistemological narrative" the only way to organize historical material on a large scale?

HiMEd – the student perspective

- Which theoretical perspectives provide fruitful orientation for empirical studies designed to measure students' engagement/learning/etc. of mathematics (when history of mathematics is "used")? What measures are valued in such studies? What methods of analysis can be (should be) employed?

- What is the role of students' mathematical ability (or mathematical interest or prior mathematical experience) in successfully including (elements of) history of mathematics in the teaching of mathematics?

HiMEd – the teacher perspective

- What minimal/satisfactory level of command of history of mathematics can we reasonably attempt to achieve in teacher training?

- Sub-issue: *The able reader*: knowledge of available sources, distinction between primary and secondary sources (more generally, the ability to identify the nature of a source), ability to assess a document with a critical mind, deontological aspects (basically, citing one's sources, indicating alterations when altering a text).

- Sub-issue: *The epistemological toolbox*: what descriptive/analytical concepts do we wish to make available to teachers? Concepts such as: proof-generated concept, zero-definition, conceptual differentiation, analysis/synthesis, epistemic object/tool, etc. Beyond the toolbox, are there "facts" about the "nature of mathematics" that we find we ought to teach (cf. the wealth of literature in physics education on the "nature of science")?

- To what extent should we expose (future) teachers to elements of history of mathematics that have no direct connections with classroom contents (in particular to enrich their "image" of the parts of higher mathematics, which they studied but will not teach)?

HoMEd – the mathematical education landscape

- Lessons from history that can be learned from the construction of the curriculum: Who is the curriculum mainly for? What "big" problems or issues does it aim to resolve? Who benefits most in the short and long run? What are the preferences of areas and topics from mathematics that are being promoted – and why? Who become the developers (and carriers) of the curriculum and how?

- How are mathematical institutions built and are they linked with the new curricula or aims of the society?

- How are cultural values created, narrated, and developed within the new mathematics education landscapes?

- What are the elements by which the tradition in mathematics education, practice, and research is perpetuated?

- What are the outputs of the new curricula/institutions/new mathematical education landscape (the material, the ephemeral, i.e. new values)?

In the following, we give examples of some of the specific questions addressed for each of these four topics. We conclude the report with some selected reflections related to the areas of questions.

SELECTED CONCLUSIONS

TWG12 participants – within both the small group and whole group discussions – had much to offer regarding the several subquestions related to the role of large-scale and small-scale surveys of history of mathematics. Several participants shared the view that using a general survey of history (i.e., "global view") helps to create a cultural landscape, which includes and accommodates multiple tools, concepts, and ideas – and which establishes a meaningful lens to use from the outset. Group discussions during CERME9 consistently returned to the notion that accessing and reading general surveys of history of mathematics provides a good starting point from which to approach resources. However, it was also important to access different types of resources so that practitioners would be equipped to address different views that emerge from history of mathematics in mathematics education. Participants also offered several examples of general survey textbooks and sourcebooks that would serve practitioners.

Given the current educational landscape in several countries, particularly regarding curriculum reform, the participants of TWG12 spent a great deal of time discussing lessons that can be learned from the construction of curriculum over time. When considering the question, *For whom is the curriculum constructed?* participants believed that a country's mathematics curriculum is for the ministers of education. However, this also raised further questions in the group's discussion, such as, *What does 'curriculum' mean?* That is, there are several meanings and contexts that apply and what might be considered 'curriculum' by one may not hold for another. Our group also discussed history in a different way when considering the questions of the fourth topic area. For example, we thought of historical heritage, and questioned whether mathematics curriculum had caught up with what is needed. And, of particular interest to many of the TWG12 participants, we raised the question of: *How can history inform the decisions that are made with regard to mathematics curriculum?*

We look forward to exploring this issue in particular at the next CERME.

TWG12

Research papers

'Mebahis-i İlmiye' as the first periodical on mathematical sciences in the Ottoman Turkey

Mustafa Alpaslan[1], Gert Schubring[2] and Feza Günergun[3]

2 Bielefeld University, Institute for Didactics of Mathematics, Bielefeld, Germany

3 Istanbul University, Department of the History of Science, Istanbul, Turkey

Mebahis-i İlmiye (1867–1869) was the first periodical on mathematical sciences published in 19th century Ottoman Turkey. The authors primarily attempted to introduce the mathematics required for the financial, societal, educational and military development of the country. This paper analyzes the periodical in order to understand (i) the fundamental reasons for its publication, and (ii) transmission of contemporary mathematics from Europe to Ottoman Turkey. Findings unveiled that the periodical had various reasons for mathematics education in the Ottoman society of the time. Moreover, it served the transmission issue to a certain extent.

Keywords: Mebahis-i İlmiye, Ottoman Turkey, history of mathematics education, reasons for mathematics education, transmission of mathematical knowledge.

INTRODUCTION

During the 18th and 19th centuries, the Ottomans transmitted mathematical knowledge from Europe on the grounds that it was the leading region of the time in terms of mathematical sciences. The mathematical knowledge was chiefly conveyed by translating European textbooks. Periodicals were salient in this process too, because editors could compile various kinds of sources, such as excerpts from journal articles, in accordance with the needs of the society. According to Günergun (2007), the earliest Turkish periodical introducing mathematical sciences was *Mebahis-i İlmiye* (Scientific Themes), issued between 1867 and 1869 in Istanbul, capital of Ottoman Turkey. It was published in Ottoman Turkish, which included Arabic and Persian words and was written in Arabic alphabet. The authors aimed to contribute to the teaching of pure and applied mathematics (other disciplines such as astronomy and physics). *Mebahis-i İlmiye* was a monthly publication of *Cemiyet-i Tedrisiye-i İslamiye* (Educational Society for Muslims) which was founded in 1865 by enlightened Ottoman state officials Yusuf Ziya Bey (1826–1882), 'Vidinli' Hüseyin Tevfik Bey (1832–1901) and Ahmet Muhtar Bey (1839–1919) with the goal of enlightening Muslim society by promoting mathematics and science education.

The idea of publishing the periodical belonged to Yusuf Ziya Bey, who was teaching basic arithmetic to apprentices in Grand Bazaar as an accountant in *Daire-i Askeriye* (Military Office) (Zeki, 1924). However, Hüseyin Tevfik Bey, a graduate of Mühendishane (School of Engineering) (Schubring, 2007), committed himself to the publication from the very beginning (Günergun, 2007). He was a remarkable mathematician and had a deep background in education: military attaché and vice-principal in *Mekteb-i Osmani* (Ottoman School) in Paris. During the time of *Mebahis-i İlmiye*, he gave courses on mathematics and mechanics in *Mekteb-i Harbiye* (Military Academy), and he taught mathematics to apprentices as a member of *Cemiyet-i Tedrisiye-i İslamiye*. He was well-known for his book originally titled "Linear Algebra" (first edition in 1882), in which he introduced the general notion of linear algebra independent of the terms 'associative' or 'non-associative' (Schubring, 2007). Given Tevfik Bey's education in the context of traditional Islamic mathematics and his later formation in European mathematics, he was the appropriate person for transmitting European mathematics into the Ottoman context of mathematics. Lastly, Ahmet Muhtar Bey, who was a graduate of *Mekteb-i Harbiye*, was teaching science in the time of *Mebahis-i İlmiye* in this school.

In her historical research, Günergun (2007) asserted that the periodical served the purpose of teaching mathematical sciences for different groups of individuals in the Ottoman society, which was considered as indispensable for the growth of national prosperity. Yet, there may be further reasons for publishing this periodical, which can be unfolded through mathematics education literature. In accordance with Niss' (1996) reasons for mathematics education in a society, this study intends to analyze *Mebahis-i İlmiye* with respect to the motives leading to its publication. Moreover, it aims to clarify the mathematical traditions that the authors relied on in the publication, which will also reveal the transmission of mathematical knowledge from European powers as the 'metropolis' to the Ottoman Turkey as the 'periphery' (Schubring, 2000). Hence, the following research questions are asked:

1) For what reasons did *Mebahis-i İlmiye* provide the 19th century Ottoman Turkey society with mathematics education? How were the reasons addressed in its content?

2) On which mathematical traditions did the authors of *Mebahis-i İlmiye* rely?

According to Niss (1996), the reason why a society is educated in mathematics is "a driving force, typically of a general nature, which in actual fact has motivated and given rise to the existence (i.e. the origination or the continuation) of mathematics teaching within that segment, as determined by the bodies which make the decisions (including non-decisions) in the system at issue" (p. 12). Niss makes a distinction between the reasons addressing *formative ends* serving the individuals' development, and those referring to *practical ends* resulting in practical outputs for the society.

Niss (1996) sets three categories of fundamental reasons for mathematics education: (i) *technological and socio-economic development of society*, (ii) *political, ideological and cultural maintenance and development of society*, and (iii) *providing individuals with prerequisites which may help them to cope with life*. The reasons may be driven by the desire for the societies' own welfare or their effort for competing against the other groups of societies of the time. Related to *technological and socio-economic development of society*, mathematics education aims to train individuals who would serve their country as labor force of high quality. Such an education attempts to develop individuals with high abilities, knowledge and dispositions for performing their role in the society. In other words, it requires individuals to have "knowledge, skills, flexibility, and attitudes so as to allow them to obtain, manage, and develop jobs in the present and in the future" (Niss, 1996, p. 25). This requirement connotes the indispensable relationship between science and commerce, manufacture and industry. Individuals should possess certain general qualifications (i.e., some applicable side of mathematics and geometry such as mensuration) as well as those specifically related to their vocation. The reasons of this first category are expected to produce practical ends. The global mathematics education in the 19th century substantially served this kind of reasons.

The initial needs for a mathematics education have virtually sprung from the reasons under *society's political, ideological and cultural maintenance and development*, for example, to meet the administrative requirements of the society. More precisely, this type of reasons indicate that mathematics education can assist individuals to become nationalist, collaborative, hardworking and dedicated to work for their society. Moreover, it enriches the individuals' mental capability and skills, especially those related to reasoning.

Providing individuals with prerequisites which may help them to cope with life refers to making individuals to acquire the required knowledge and skills for different aspects of their daily lives such as business life, education, personal development and so on. This kind of reasons are valid for addressing practical ends, to exemplify, an individual may confront with a task in his work which requires the application of basic mathematics.

Schubring (2000) defines the notion of 'transmission' of mathematical knowledge as the dissemination process of mathematical ideas from scientifically established 'metropolis' countries of the time to not yet scientifically productive countries in the 'periphery'. In this process, contrary to a received view where by 'transmission', it is understood to hand over concepts remaining identical, traditional and new mathematical knowledge becomes transformed according to the particular national, cultural and societal context of the peripheral country through an active role played by innovative individuals. Thus, in this conception, reception transforms the received. Herein, the reasons behind such transmission are important as well. In order to examine such a transmission process, selecting a country, which was not colonized in the imperialism period, is a good choice because this situation could enable the country to be independent in receiving the new mathematical knowledge.

THE 18TH AND 19TH CENTURY CONTEXT OF THE OTTOMAN TURKEY

Decay strongly felt in the economic, educational, social and military fields was the main cause of the decrease in the political authority that existed in the 18th and 19th century Ottoman Empire. There were wars with neighboring countries and nationalistic upheavals in various communities under the Ottoman rule (Günergun, 2008). The Ottomans fought mostly against European and Russian armies, and most of the wars were lost. The defeats drew the Ottoman administrators' attention to the superiority of the opposing military forces which developed new military organizations (Günergun, 2006). The losses were also linked to complete regression including the abuses in the administrational and financial areas (Somel, 2001).

As a result of the decay, Ottoman Muslim administrators led a variety of necessary reforms in the above-mentioned fields to preserve the borders and to increase the prosperity of the Empire. In this sense, teaching of mathematics was initially modernized through the foundation of modern engineering and military schools in the late-18th and 19th century (İhsanoğlu, Şeşen, & İzgi, 1999). Günergun (2008) states that learning and application of the European scientific, mathematical and technical knowledge behind the military reforms were studied in these military schools which were systematized and tutored by both Ottoman and European (e.g., French, English and German) professors, technicians and experts. The schools focused on reaching contemporary European mathematics and science (Günergun, 2008). Correspondingly, there was a need for new books in which western methods were utilized (İhsanoğlu et al., 1999). The Ottoman administrators and military officers translated and edited European mathematical texts (mostly French) including applied mathematics, geodesy, mechanics, ballistics, and so on (Günergun, 2008). Mathematical studies according to the traditional eastern methods had seriously decreased after 1850. It was clear that these attempts by Ottoman scholars contributed greatly to the formation of the Ottoman mathematical and scientific nomenclature which was formed of words in Turkish, Arabic, Persian and European languages in the 18th and 19th centuries (Günergun, 2006). Therefore, the Ottoman Turkey became a meeting point for the Eastern and the Western cultures of science (Günergun, 2008).

Mathematics education in the modern trend was initiated in 1775 with *Hendesehane* (School of Geometry) (Günergun, 2006). Technical training was first given here for military officers of artillery, fortification and navy. Various branches of mathematics were taught by French and Ottoman experts in the leadership of the French military expert François Baron de Tott. Some mathematical tools were imitated in parallel with the west. The sources for mathematics education were mostly European texts at the beginning. The school was named as *Mühendishane* after 1781. Günergun (2008) states that teachers of this school in the 19th century translated and composed some European mathematics textbooks for teaching, for example, Ibrahim Edhem Pasha's (1818–1893) translation of the geometry book by Adrien-Marie Legendre (1752–1833). Indeed, this was the time for replacing the medieval Islamic sources of mathematics by the modern European ones. *Mühendishane-i Bahri-i Hümayun* (Imperial School of Naval Engineering) was established in 1784. Çınari İsmail Efendi (died, probably 1790) and Gelenbevi İsmail (died 1790), who were teachers in this school, wrote translations and compilations regarding algebra and logarithms considering the European sources in addition to the traditional books on algebra. For instance, Çinari İsmail Efendi translated Cassini and Clairaut's tables (Günergun, 2006). In order to train cadets in military officership and engineering that was necessary for the modern army *Nizam-ı Cedid* (New Order), *Mühendishane-i Berri-i Humayun* (Imperial School of Military Engineering) was founded in 1795. Hüseyin Rıfkı Tamani (died 1818) was a prominent teacher in this school through his translated and edited geometry and engineering textbooks from French and English. For instance, he and Selim Efendi translated John Bonnycastle's (1750–1821) "Euclid's Elements" from English as *Usul-i Hendese* (1797). Another teacher of *Mühendishane-i Berri-i Humayun* was Hoca İshak Efendi (died 1836) who wrote books on arithmetic, algebra, geometry and mechanical drawings based on the recent European mathematics. To illustrate, he used French Etienne Bézout's (1730–1783) works in the first volume of his *Mecmua-i Ulum-i Riyaziye* (Compendium of Mathematical Sciences) (İhsanoğlu et al., 1999). In 1834, *Mekteb-i Harbiye* was founded to train the cadets for the new army. This time a number of Ottoman administrators and teachers were trained in Europe (Günergun, 2006). To illustrate, Hüseyin Rıfkı Tamani's son was Emin Pasha (died 1851), who graduated from University of Cambridge with his doctoral thesis "Calcul de Variation", was assigned as director of *Mekteb-i Harbiye* in 1841.

The modernization process addressed above was not easy to accomplish. There were uproars mainly from *Yeniçeriler* (Janissaries) and *Ulema* (the learned of Islam). The janissaries were opposed to any military reforms because they probably regarded new developments in the military as a threat for their existence. They had further become extremely influential in politics with their conservative character. They created telling crises of modernization, for instance, destroying the institutions of *Nizam-ı Cedid* (e.g., printing house and schools) after the military defeats in Balkans and Arabian geography, and deposing Sultan Selim III in 1807 (Abdeljouad, 2012). In 1826, the reformist Sultan Mahmud II (1808–1839) abolished the *Yeniçeri Ocağı* (Corps of Janissaries) on the grounds that the janissaries had become inefficient as warriors. He established a modern army titled *Asakir-i Mansure-i Muhammediye* (Muhammed's Victorious Army) which completely replaced the rebellious Janissaries in 1826.

FINDINGS

Mebahis-i İlmiye had two volumes formed of issues corresponding to 1867 and 1868. During the publication period, there were main topics serializing a mathematical subject or mathematics problems for the public. In Table 1, main topics in the periodical are illustrated with corresponding author(s) and brief contents.

Table 1 indicates that the topics in *Mebahis-i İlmiye* consisted of collections from both pure and applied mathematics. No primary research existed, hence *Mebahis-i İlmiye* can be characterized as a periodical rather than a journal. The authors apparently reflect-

Main Topics	Author(s)	Contents
Hesab-ı Müsenna (Dual Arithmetic)	Hüseyin Tevfik Bey	Oliver Byrne's dual arithmetic with explanations
Fenn-i Basite (Science of Sundial)	Ahmet Muhtar Bey	Construction and usage of Islamic sundials
Fenn-i Makine (Mechanical Sciences)	Hüseyin Tevfik Bey	The concepts of mechanical operation of machines
Mahsusat ve Gayrimahsusat (Perceptible and Imperceptible Matters)	Hüseyin Tevfik Bey	Physics: motion, movements of the earth, Newton's law of gravitation... Metaphysics: logic, philosophy of knowledge...
Arsa Taksimi (Partition of Lands)	Hüseyin Tevfik Bey	Division of lands with various geometrical shapes
Emsile (Examples)	Anonymous	17 problems asked to the reader and their solutions sent to the periodical
From Public to the Reader*	Anonymous	Problems sent by newspapers and their solutions by the periodical
Vocational Mathematics*	Hüseyin Tevfik Bey & Yusuf Ziya Bey	Mathematical knowledge and skills needed for industry or craft segments to increase effectiveness
Topics from European Science*	Hüseyin Tevfik Bey	Contemporary topics from European mathematics journals
Islamic Contributions to Science*	Hüseyin Tevfik Bey & Yusuf Ziya Bey	Topics from Islamic mathematicians' textbooks (e.g., al-Karaji's proof for $1^3+2^3+3^3+...+n^3 = [1+2+3+...+n]^2$)
Topics from Greek Mathematics*	Hüseyin Tevfik Bey	Diophantus's problem on five equations with five unknowns
Main topics with a '*' mark are categorized by the authors of this study considering the aim and content of shorter papers.		

Table 1: Main topics in *Mebahis-i İlmiye* by the authors and contents

ed their educational background and their lectures in *Mekteb-i Harbiye* when selecting and ordering the main topics such as *Fenn-i Basite* (Günergun, 2007). The periodical included recent European mathematics, ancient Greek mathematics and medieval Islamic mathematics.

Technological and socio-economic development of the society

Some of the articles under Vocational Mathematics* seem to stress the relationship between industry and science. It was stated in Hüseyin Tevfik Bey's *Sanayiinin Muhtac Olduğu Ulum* (Knowledge Needed by Industry) that blacksmiths should master mechanics, drawing, geometry and the relevant computation underlying metal working. Goldsmiths had to know basic chemistry, drawing and geometry. It was also noted that theoretical knowledge provided by science was a must for improving crafts and industrial professions. It is not solely dependent upon practical knowledge. In another article by Hüseyin Tevfik Bey, *Bakırcılık ve Demirciliğe Mütealik Bir Mesele* (An Issue in Copperworking and Ironworking), the optimum ratio between the radius (of the base) and height of a container was given to produce the container with the smallest possible surface area and the least raw material. *Kavaid-i İlm-i Hisab* (Rules of Arithmetic) was the serial of an arithmetic book written by Yusuf Ziya Bey for educating the students of the *Cemiyet-i Tedrisiye-i İslamiye*'s school. The content mainly consisted of numbers (integers, rational numbers, prime numbers, irrational numbers), the arithmetical operations, checking the results of the operations, extraction, ratio and proportion, and equations. This could be for training "'human calculators' for business and commerce" (Niss, 1996, p. 25).

Another relevant main topic was *Fenn-i Makine* (Mechanical Sciences). Based on his lecture notes in *Mekteb-i Harbiye*, Hüseyin Tevfik Bey explained the basic concepts such as velocity, time, rotation, power, resistance, motion, work and efficiency needed for geometrical and mechanical study of machines. He intended to teach the characteristics and working principles of machines and how to construct them.

Arsa Taksimi (Partition of Lands) included common problems for dividing lands of various geometrical shapes and their solutions according to the recent scientific methods of the time. Partition of triangular areas into two or three equal parts and curvilinear areas through integral calculus such as the trapezoidal rule, Thomas Simpson's (1710–1761) rule and Jean-Victor Poncelet's (1788–1867) rule. Exploiting such new European sources in the periodical illustrates the notion of transmitting mathematical knowledge. Moreover, some widely consulted measurement information about surfaces and solid matters was provided for workers.

In *Emsile* (Examples), there were questions which would familiarize the audience with the working principles of some technological tools of the time such as pendulum (#14), lenses (#15) and barometers (#17). These questions were selected for those asked to students of a French lycée, and they indicate an attempt to knowledge transformation.

Political, ideological and cultural maintenance and development of the society

From political and ideological perspectives, the authors emphasize Islamic Contributions to Science* through several articles. For example, *Hasan bin Ali bin Ömer el-Marakeşi'nin "Cami el-mebadi ve'l gayat fi amel el felekiyat" Nam Kitabından Tercüme Olunmuş Bir Meseledir* (A Problem Translated from Hasan ibn Ali ibn Omar al-Marrakechi's Book Titled "Cami el-mebadi ve'l gayat fi amel el felekiyat") by Yusuf Ziya Bey was the translation of a problem on latitude and declination from a book by al-Marrakechi, a Moroccan astronomer of the 13th century. The geometrical method in this problem based on length of shadow and geometrical path did not require observational tools or logarithmic scales. *Bir Zaman Ulema-yı Arabın Malumları Olan Havas-Adaddan Bir Mesele* (A Problem Known by Arab Scholars in Former Times) gave place to geometric justification of the sum of the cubes problem, $1^3+2^3+3^3+...+n^3=(1+2+3+...+n)^2$, which referred to al-Karajī's (953–1023) famous book titled al-Fakhri fi'l-jabr wa'l-muqabala (The Glorious Book of Algebra).

The periodical presented cultural perspectives by means of displaying the interdisciplinary characteristics of mathematics and multi-cultural face of mathematics. To illustrate, mathematics was linked to other disciplines such as astronomy and physics. Real life problems like al-Marrakechi's calculation of latitude and declination can be shown as an example of the link between mathematics and astronomy. As for mathematics and physics, *Fenn-i Muvazene-i Miyah Usulü ile Bir Dairenin Mesaha-yı Sathiyesini Tayin* (Finding the Area of a Circle with Fluid Mechanics Method) under Topics from Greek Mathematics* discussed a law by Archimedes and the related proof. It was about finding the area of a circle which served as a basis for a cylinder whose height was equal to the diameter of the circle. In order to find the area of this circle, the cylinder was filled with water. Then the water was transferred into a cube that had a length of the diameter of the circle. The area of the circle was equal to the product of the length of the cube and the height of the water in the cube. Mathematics in physics could also be distinguished in *Emsile* through some problems regarding the concepts of heat and temperature (#3), mass and density (#5), velocity (#4), and so on.

Mahsusat ve Gayrimahsusat (Perceptible and Imperceptible Matters) contained issues of physics and philosophy. Newton's law of gravitation, which could be considered as relatively new mathematics-related knowledge, was utilized to distinguish between perceptible and imperceptible matters which were explained as that could be observed (e.g., free fall of objects) and could not be directly observed (e.g., gravitational force). Herein, the necessity of asking the possible reasons behind the perceptible matters in daily life was stressed as well, for instance, why balloons fly rather than fall to the ground. Force, absolute and relative motion, the Earth's daily and yearly rotation were also explained in the same manner.

Mebahis-i İlmiye also took up interesting contemporary topics in order to develop curiosity for mathematics revealing the mystery of the universe. Hüseyin Tevfik Bey's *Arıların Peteklerinin Müseddes El-Şekl Olmasının Sebep ve Hikmetine Dairdir* explained why bees made hexagonal wax cells in their nests together with the related mathematical proof. This subject and all the others under Topics from European Science* seemed to contribute to the transmissions from the 'metropolis'.

In order to make the society more intellectual, *Mebahis-i İlmiye* allowed exchange of ideas (Günergun, 2007). The periodical published the answer of *Emsile #3* by Saadet Efendi, a teacher in *Mekteb-i Harbiye*; and the answer of *Emsile #7* by Zeki Efendi as a second grader in the same academy. In the latter, it was notable that Hüseyin Tevfik Bey stated that there might be alternative solutions. The authors of the periodical also published the answer to an interest payment problem by *İstanbul Gazetesi* (Istanbul Newspaper) in From Public to the Reader*. In *Mahsusat ve Gayrimahsusat*, Hüseyin Tevfik Bey criticized Resul Mesti Efendi's essay in a newspaper claiming that the earth does not move. This was in line with the periodical's modern view of science.

Providing individuals with prerequisites of life

Mebahis-i İlmiye included some basic mathematics required for individuals' day to day working life. Under Vocational Mathematics*, *Mesele: Acaba Ayakları Ne Vecihe Vaz Etmekte Ziyade Faide Vardır* (Issue: What is the Effective Position of Legs to Firmly Stand Up) by Hüseyin Tevfik Bey accounted for the ideal geometrical standing position for a soldier when on guard. In *Fenn-i Basite* (Science of Sundial), how to design, construct and use the Islamic sundial was displayed in order to help local timekeepers determine the five prayer times in a day and also the Mecca direction for prayers. Another topic here was *Fenn-i Makineden Dülgerliğe Dair Bazı Mebahis* (Some Issues about Woodworking, A Branch of Mechanical Sciences) in which matters of physics such as force (e.g., direction, magnitude) and resultant force for the construction of poles underlying the construction of wooden buildings were explained. The content of *Mebahis-i İlmiye* was also composed of mathematics serving the individuals' educational life and personal development. *Emsile #14*, *#15*, *#16* and *#17* were mathematical problems taken from French periodicals for lycée students published a decade earlier. Lastly, mathematical problems that would be encountered in everyday private lives were presented, for example, the interest problem in *İstanbul Gazetesine Cevap* (Answer to Istanbul Newspaper).

CONCLUDING REMARKS

Findings indicate that *Mebahis-i İlmiye* addressed all the three kinds of reasons for mathematics education (Niss, 1996) to a certain degree. The authors utilized transformation of the recent knowledge of both pure and applied mathematics from Europe, mainly from France, as the 'metropolis' of the time (Schubring, 2000). Reception occurred in the difficult social setting of conflicts between modernizers and traditionalists, and within the already existing culture of Islamic mathematics. An important aspect of this transmission was the development of a terminology for the modern mathematics in Ottoman Turkish language, since the traditional mathematics did not provide terms for the new developments in the field.

The development of an own terminology is essential for an eventual take-off.

Future research will, on the one hand, focus on identifying the public reading of this periodical and its reception in the 19th century Ottoman Turkey and, on the other hand, introducing an international comparative dimension on the transmission of mathematical knowledge to the other 19th century non-colonized countries (e.g., China) which have original mathematical cultures (e.g., the development of 19th century publications in mathematics). The further comparative studies may assess results of the project, begun in France in 2013, on *Circulations des mathématiques dans et par les journaux: histoire, territoires et publics*. The transmissions of mathematical knowledge from Europe to the Ottomans by *Mebahis-i İlmiye*, which is investigated in this paper, can shed light on a broad systematic investigation of the above-mentioned future research. Moreover, *Mebahis-i İlmiye*'s promotion of mathematics education can enable such a further study to reveal national, cultural and societal motives behind the transmission in a clear way.

Was Euclid in Iceland when he was supposed to go?

Kristín Bjarnadóttir

University of Iceland, School of Education, Reykjavík, Iceland, krisbj@hi.is

In a seminar on new thinking in school mathematics, held in Royaumont, France, in 1959, one of the main speakers, Jean Dieudonné, summarized the new school-mathematics programme he had in mind in the sentence: Down with Euclid. The purpose of the article is to analyse the context in which this quote was expressed and connect it to geometry teaching in Iceland where Euclidean geometry instruction seldom had a firm ground. Euclidean geometry in an amended version gained new interest in Iceland by the introduction of the New Math in the 1960s.

Keywords: Royaumont seminar, Dieudonné, Euclidean geometry, New Math.

INTRODUCTION

One of the most renowned phrases connected with the Royaumont seminar in November 1959, where the reform movement, entitled New Math, was launched world-wide, was 'À bas Euclide' (Down with Euclid), attributed to Jean Dieudonné, who belonged to the Bourbaki-group. This seminar led to substantial alterations in mathematics teaching and geometry teaching in particular. In the following, some consequences of this reform movement will be considered with special respect to geometry teaching in Icelandic schools. The research questions are:

> In what context was the above quote expressed?
>
> What context did the New-Math geometry meet in Iceland?

The research method is historical: i.e., a careful analysis of a range of documents. The history is traced by referring to scholars' published work, legislation, regulations, reports, articles and mathematics textbooks, and the remembrance of the author of this article. Textbooks were analysed, their forewords as well as their mathematical content, and information about their lifetime was sought in official reports.

The importance of this study is contained in an analysis of some important seeds for development of school mathematics, sowed at Royaumont more than half century ago, but also in an analysis of an example of a dissemination process of mathematical ideas from scientifically established 'metropolis' of the time to a not yet scientifically productive one in the 'periphery' (Alpaslan, Schubring, & Günergun, 2015).

BACKGROUND

The New Math movement and the Royaumont seminar

In the aftermath of WWII, reforms of mathematics and science teaching were considered in many countries. A notable arena was the Commission Internationale pour l'Étude et l'Amélioration de l'Enseignement des Mathématiques, CIEAEM, the International Commission for the Study and Improvement of Mathematics Teaching, founded in 1950. Among its members were the Swiss psychologist Jean Piaget, mathematicians Jean Dieudonné and Gustave Choquet from France, and some outstanding secondary school teachers. The main concern of the CIEAEM was a growing attention to the student and the process of teaching, the relevance of psychology in mathematics education, the key role of concrete materials and active pedagogy, and Piaget's research of the relation between mental and mathematical structures as introduced by the French Bourbaki group of mathematicians, including Dieudonné, called *Mathématique Moderne*, Modern Mathematics (Furinghetti, Menghini, Arzarello, & Giacardi, 2008).

The actions of the CIEAEM, containing important germs of didactic research, were paralleled by the

New Math movement in the United States. World War II had focused national attention on the growing need for trained personnel to serve an emerging technological society (Osborne & Crosswhite, 1970), and several important school mathematics projects were launched. The actions by CIEAEM and the New Math movement had roots in common with the Bourbaki School: set theory, functions, relations and logic were to be placed in the new curricula, supported by the methodology of discovery. The reform movements gathered at a seminar on school mathematics reform in November 1959, held by OEEC, the Organisation for European Economic Co-operation, at Royaumont, France. The member countries were invited to send three delegates each, and the seminar was attended by representatives from all the invited countries except Portugal, Spain and Iceland. A questionnaire was sent out before the seminar and replies were reported from most countries, also from Iceland (OEEC, 1961, pp. 7, 135–140, 213–219).

Down with Euclid!

Among the guest speakers at the Royaumont seminar was Jean Dieudonné from the CIEAEM. In his speech, reproduced in full in the seminar's report (OEEC, 1961, pp. 31–46), he described the diverse curriculum that first year students at university should master: on one hand to be familiar with a certain number of elementary techniques in which it takes a long time to achieve proficiency, and on the other hand be already fairly well trained in the use of logical deduction and have some idea of the axiomatic method (p. 32). In the universities, new developments in analysis had been incorporated in the curriculum. Under the new overcrowded curriculum, most students emerged with the haziest notions about it.

Easing this squeeze could only be done in one way: The curriculum of the secondary schools had to be reorganized to eliminate any undue waste of time. Some elements of calculus, vector algebra and a little analytic geometry had recently been introduced for the last two or three years of secondary school, while such topics had been relegated to a subordinate position, the centre of interest remained as before pure geometry taught more or less according to Euclid with a little algebra and number theory (pp. 33–34). In Dieudonné's opinion, the day of such patchwork was over. Much deeper reform was required, and if he were to summarize the whole programme he had in mind in one slogan, it would be: *Down with Euclid*!

Recently, it had become possible to reorganize the Euclidean corpus placing it on simple and sound foundation – separating what is fundamental from a chaotic heap of results with no significance except as scattered relics of clumsy methods or an obsolete approach. The whole course could actually be taught in three hours: one of them occupied with the description of the axiomatic system, one by its useful consequences and possibly a third one by a few mildly interesting exercises (p. 35).

Actually, the whole system could easily be replaced by an axiomatic system producing two-dimensional linear algebra. The present process of teaching geometry was fantastically laborious, no complete system of axioms was ever stated and it was completely impossible to check the correctness of any proof. Dieudonné suggested the following list to take the place of Euclidean geometry (pp. 37–38):

a) Matrices and determinants of order 2 and 3.

b) Elementary calculus (functions of *one* variable).

c) Construction of the graph of a function and of a curve given in parametric form (using derivatives).

d) Elementary properties of complex numbers.

e) Polar coordinates.

Dieudonné's guiding principles were two: Firstly, that a mathematical theory could only be developed axiomatically in a fruitful way when a student has already acquired familiarity with the corresponding material, i.e. with constant appeal to intuition. The other principle was that when logical inference is introduced in some mathematical question, it should always be presented with absolute honesty without trying to hide gaps or flaws in the argument (p. 39).

In his outline of a modern curriculum, Dieudonné recommended to limit the teaching of mathematics up to the age of 14 to experimental work with algebra and plane geometry and to make no attempt at axiomatization. He referred to recent research and experimentation in educational circles, especially in Belgium, concerning the methods by which this teaching of geometry as a part of physics could be conducted. This development should be highly encouraged, provided it did *not* put the emphasis on such artificial playthings as triangles, but on basic notions such as symmetries, translations, compositions of transformations etc. (pp. 40–41).

The language and notations universally in use, such as $\in$ and $\Rightarrow$, should be introduced in these experimental mathematics as soon as possible, and objects should be called by their proper name like 'group' and 'equivalence relation' whenever such an object was naturally observed in some algebraic or geometric setting. This did not at all imply to develop in advance the abstract theory of those objects. The laws of arithmetic could also be developed, starting from the 'Peano axioms' (p. 41).

Dieudonné proposed detailed programme for age 14 with the idea of a graph of functions; age 15 when a statement of axioms of two-dimensional linear algebra should be given with both algebraic and geometric interpretation, by emphasis on the various linear transformations and the groups they form; age 16 with deeper study of the groups of plane geometry, and in particular the use of angles and of trigonometric functions; and age 17 with three dimensional geometry by use of matrices and determinants. The programme should lead up to and connect directly with the then present programme of the first years in the university (pp. 42–45).

GEOMETRY IN ICELAND

Earlier times

Iceland was a tributary of Denmark since the 14th century. Its population was 40.000–50.000 until the 19th century. There was no army and therefore no military academy and no need to teach geometry for that purpose. The sole Learned School adhered to Danish regulations of the Royal Directorate of the University and the Learned Schools. A certain number of graduates from the school had priority for grants at the University of Copenhagen, (Þorláksson, 2003, p. 382) until Iceland's sovereignty in 1918.

In 1822, Björn Gunnlaugsson (1788–1876), who had studied mathematics at the University of Copenhagen, came to work at the school, to stay there until 1862. In his inauguration speech, Gunnlaugsson emphasized the utility aspect of mathematics education. During summers of 1831–1843, he travelled around the country to make geodetic surveys as a basis for a scientifically drawn map which served as a basis for maps of Iceland into the 1900s. Gunnlaugsson taught the prescribed syllabus of arithmetic, algebra and geometry by textbooks that were stipulated for the learned schools by the Royal Directorate, but remarked in his reports of 1823 that he gave exercises in land-surveying in order to enhance the students' interest. Gunnlaugsson wrote his own textbook in geometry in Icelandic. The yearly cohort of learned-school graduates was 10–12 students which was not enough for such a publication. Danish legislation of 1871 prescribed streaming at the learned schools. The Icelandic school could only offer one stream, language and history stream, and mathematics teaching became severely reduced. Students who wanted to study mathematical subjects at tertiary level, such as engineering, had thereafter to spend an extra year in Denmark. That situation remained until 1919 (Bjarnadóttir, 2007, pp. 87–90, 108, 110–170).

The Jul. Petersen's secondary school geometry textbook

The Danish geometry textbook, *Lærebog i elementær Plangeometri* [*A Textbook in Elementary Plane Geometry*] (Petersen, 1870) was adopted in 1877 in the Icelandic Learned School for the lowest grade where the average age of students was 14 years but could be in the range 13–16 yrs. It remained on the reading list into the 1970s – in translation from 1943 – with breaks in the 1920s while a textbook by Daníelsson (1920) was in use in the late 1930 and in the 1960s during the influence of the New Math reform movement (*School reports for the Reykjavík School*, 1846–1976).

The content of Jul. Petersen's plane geometry textbook is probably typical of European textbooks in Euclidean geometry. In chapter one, several fundamental concepts are listed and the postulate that one and only one line may be drawn through two points. The structure: *Fundamental concepts and their postulates – Definitions – Theorems with proofs*, is explained. In next two chapters, enough definitions and the parallel postulate are presented in order to be able to present theorems and their proofs. Chapter four is devoted to triangles and chapters five to seven to constructions using circles and triangles. Chapters eight to twelve concern angles and arcs, trapezes and parallelograms, the loci of points, similar triangles, and measuring area, with appropriate definitions, theorems, proofs and constructions. One might interpret Dieudonné's speech so that the first three chapters sufficed as geometry teaching. Against that, one could say that objects for exercising proofs on were then lacking, such as the triangles, Dieudonné's 'artificial playthings'.

Even if this textbook managed to survive in the Reykjavík School for a century, it had notable criticism. In Denmark, the textbook was intended for the so-called *Mellemskole* [middle school] for age 11–14 (Hansen, 2002, p. 40). A reviewer said about Petersen's 1905 edition:

> … one reads between the lines the author's disgust against modern efforts, which … deals with making children's first acquaintance to the mathematics as little abstract as possible by letting figures and measurements of figures pave their way to understanding of the geometry's content … Working with figures … aids the beginner in understanding the content of the theorems, which too often has been completely lost during the effort on 'training the mind'. If the author knew from a daily teaching practice, how often pupils' proofs have not been a chain of reasoning but a sequence of words, he would not have formed his introduction this way … for the middle school it [the textbook] is not suitable.[1] (Trier, 1905)

In Petersen's obituary in 1910 it said:

> … People began to realize that the advantages of these textbooks were more obvious for the teachers than for the pupils … the great conciseness and left-out steps in thinking did not quite suit children. These books were excellent when the whole syllabus was to be recalled shortly before examination, but if the students were to acquire new material one had to demand a wider form for presentation. (Hansen, 2002, p. 51)

A student at the University of Copenhagen, Finnur Jónsson, later philology professor, wrote in 1883, criticizing Reykjavík Learned School and its regulations:

> … the new regulations have [prescribed] … that the [geometry] study is to commence in the first grade; in order to grasp it, more understanding, more independent thought is needed than first-graders master … [I] tutored two [first grade] boys in geometry … and for both of them it was very difficult to understand even the simplest items; but the reason was that they did neither have the education nor the maturity of thought needed to study such things, which is very natural. (Jónsson, 1883, p. 116; underlining KB)

The pupils of the Learned School were sons of farmers, priests and other officials who also made their living from farming, so the majority of the pupils came from farming communities where there were no primary schools. The novices were prepared for school at home and by priests in Latin, Danish and basic arithmetic, and had seldom met geometric concepts. Land was e.g. not measured in square units. Dieudonné's first guiding principle was that a mathematical theory could only be developed axiomatically in a fruitful way when a student had already acquired familiarity with the corresponding material, i.e. with constant appeal to intuition. This is in accordance to Jónsson's remark that the pupils did not possess "the maturity of thought" needed to study deductive geometry as presented in Jul. Petersen's textbook. The young pupils had not acquired familiarity with the corresponding material with the appeal to intuition that Dieudonné recommended.

Daníelsson's high school geometry textbook

The textbook *Um flatarmyndir* [*On plane geometry*] by Ó. Daníelsson (1920), intended for novices at the six-year Reykjavík High School, around age 14, may be interpreted as strictly adhering to the Euclidean tradition. It began by a section on limits to prepare proving the existence of irrational numbers. Next section was a list of definitions. The author admitted in his foreword that his experience was that students were relieved when that section was completed. The third section was on parallel lines, followed by exercises whereof there were five on computing angles, one of them in the hexadecimal system, and all exercises after that through chapter six out of fifteen, were on proving on the basis of the definitions and theorems introduced. Following exercises were alternatively on constructions and proving, and computations by recently proved formulas, such as Heron's formula on area. Eventually, *On plane geometry* was transferred up to the upper level. Geometry was again required for novices in 1937. From that time, Danish textbooks were translated, among them Peterson's *Geometry* in 1943 (*School reports*, 1846–1976).

1 Translations of quotes were made by the author of this paper.

The first two grades were dropped from the high school level in 1946 and after that there was no Euclidean geometry below the age of 16. There was shortage of trained mathematics teachers who had to seek their training abroad, traditionally in Denmark with which all connection was broken during World War II. Only five high school teachers in the whole country had graduate degree in mathematics in 1959. Training of engineers at University of Iceland began in 1940 due to the broken connection to Denmark. Mathematics had not been taught before at the university. Mathematics teachers might be trained in engineering or natural sciences. In the 1960s, the high schools had to cope with up to ten times as many students as at Daníelsson's time, beginning their mathematical training at the age of 16 by studying Petersen's (1943) *Plane Geometry* (Bjarnadóttir, 2007; *School reports*). The experience of the author of this article in 1959–1960 was that the main emphasis laid by a geologist teacher was on construction, the scattered relics of clumsy methods, according to Dieudonné, and the axiomatic structure of the content was scarcely visible.

Other school levels

The first primary school legislation in 1907 contained requirements on knowledge in computations of area and volume of common objects. These requirements were repeated in national curriculum documents issued in 1929 (*Námsskrá fyrir barnaskóla*, 1944) and 1960 (Menntamálaráðuneytið, 1960). By the introduction of the New Math, a draft national curriculum was made, but when it came to geometry, the authors claimed that experience was lacking to build geometry on (*Drög að námsskrá*, 1970). So, indeed, the only geometry taught at compulsory school level before the introduction of the New Math was mensuration, computing area and volume.

The studies at the University of Iceland were tailored after the Technical University in Copenhagen. The mathematical subjects were mathematical analysis and linear algebra and no Euclidean geometry, but they surely built on the high school training.

The New Math in Iceland

For the Nordic countries the Royaumont Seminar was a catalysing event. The Nordic participants agreed upon organising Nordic cooperation on reform of mathematics teaching. A committee, *Nordiska kommittén for modernisering af matematikundervisningen* (The Nordic Committee for Modernizing Mathematics Teaching), abbreviated as NKMM, was established. The committee produced model textbooks which were then translated into the various Nordic languages. Iceland did not have a member in that committee but learned about its activities through personal contacts of high-school and university mathematics teachers G. Arnlaugsson and B. Bjarnason with Svend Bundgaard who was guest speaker at Royaumont. Arnlaugsson and Bjarnason were the leaders of the introduction of New Math in Iceland (Bjarnadóttir, 2015). Their choices of textbooks for mathematics-teacher training witness that they were aware of Dieudonné's recommendations.

Bjarnason chose a Danish textbook: *Matematik 65* (Christiansen and Lichtenberg, 1965), for a special course to train high school mathematics teacher students, the first time a course of its kind was run in the academic year 1966–67 for only three students. Other courses were part of a programme for engineering students. Section V of *Matematik 65* concerned questions from geometry. The authors remarked that around the last turn of the century, David Hilbert had succeeded in composing such a system of axioms that could follow Euclid's thought and solve all Euclid's unsolved problems at the same time (pp. 309–311). They also mentioned Gustave Choquet's system of a so-called transformation geometry with few but strong axioms: 5 undefined concepts (plane, point, line, distance function and order relation) in a set-theoretical presentation; and 4 axioms (10 in total with sub-axioms): axioms of incidence, axioms of order, axioms for affine structure, and a folding (symmetry) axiom (Christiansen and Lichtenberg, 1965, pp. 312–320; Choquet, 1969, pp. 17–75). Choquet was also member of CIEAEM and guest speaker at Royaumont. Dieudonné may have referred to his work in that recently it had become possible to reorganize the Euclidean corpus, putting it on simple and sound foundation.

For the training of teachers at primary level, one of the three teacher students was entrusted to give a course in the New Math style in 1967. Bjarnason and Arnlaugsson chose a Danish textbook on geometry (Anderson Bo, Nielsen and Damgaard Sørensen, 1963) which was built on basic notions such as symmetries, translations, compositions of transformations, etc., as Dieudonné suggested. For the more advance students, an American textbook by Schaaf (1965) was chosen. These three books for training mathematics teachers at different stages were not in use for a long time, however. Not many educators were ready to interpret them, and the educational system was in flux. The training of compulsory school teachers was transferred to tertiary level and reorganized, as was the training of high school teachers. Arnlaugsson and Bjarnason became principals for new modern high schools and did not work further on promoting the New Math (Bjarnadóttir, 2015).

Some products of the NKMM for the primary and lower secondary school levels were translated into Icelandic. Primary level mathematics textbooks, written by Agnete Bundgaard, Svend Bundgaard's sister, and E. Kyttä, were translated year by year, beginning in experimental edition in 1966 (Bundgaard and Kyttä, 1967–1972). It had not reached the geometry in volume 5 when a draft national curriculum (*Drög að námsskrá*, 1970) was published, and people therefore did not know how to present New-Math geometry for primary level. For the lower secondary level the NKMM *Rúmfræði* [*Geometry*] by Bergendal, Hemer and Sander (1970) was translated with foreword by Arnlaugsson. It was based on set theory with e.g. lines defined as sets of points, but no axiomatization. Both products provided teachers with new ideas about geometry for compulsory level while both were in use for less than a decade.

During a six-year period, 1967–1973 various texts with new topics were tried in Iceland in order to replace Petersen's Geometry in high schools, such as NKMM-texts with emphasis on vectors, functions and their derivatives, and *Book T4* in the British SMP series (School Mathematics Project, 1966), which aimed at linking algebra and geometry by vectors and matrices to present transformations and their combinations, with a final chapter on algebraic structure of matrices and examples of groups of transformations. These texts included trigonometry. Influences from Royaumont were thus channelled to Iceland through various routes: from the Nordic countries, the United States and from Britain.

SUMMARY AND CONCLUSIONS

We may understand from Hansen (2002) and Dieudonné's presentation at Royaumont that it was customary in Europe to teach axiomatic Euclidean geometry to young children, even 11–13 year old. Dieudonné's reaction, such as to limit the teaching of mathematics up to the age of 14 to experimental work with algebra and plane geometry, and to make no attempt at axiomatization, must be considered in that context. This was less the case in Iceland. It may though be spotted in Jónsson's (1883) criticism on the teaching of geometry in the Reykjavík School. However, from *School reports for the Reykjavík School* (1846–1976) one may gather that Eucliean geometry was most of the time transferred from the beginners' stage at age 14 up to age 15 or 16. While the Reykjavík School was small, only enrolling 25 students a year, and Daníelsson was the head teacher in 1919–1941, Euclidean training may have been considerable, but less so later when the number of students increased out of proportions to trained mathematics teachers. The axiomatic structure of geometry was thus not much visible in the peripheral Iceland before the New Math reform as only few teachers were capable to interpret Petersen's century old textbook successfully with respect to an axiomatic system in the 1960s.

Within a six years period, 1967–1973, geometry, modernized in the spirit conveyed by Dieudonné and Choquet, had been implemented in the teacher training and at all school levels. Euclid might thus be interpreted to have arrived in Iceland in Choquet's modified versions, at least in the teacher training, at the time of the claim 'Down with Euclid'. The conclusion is therefore that Euclidean geometry was revived in Iceland by the New Math movement.

Why is it difficult to learn from history?

Renaud Chorlay

Université Paris Diderot, ESPE de Paris – IREM & LDAR, Paris, France, Renaud.chorlay@espe-paris.fr

This paper is of a methodological nature. First, it aims at spelling out several structural differences which may stand in the way when researchers in mathematics education endeavor to derive didactically relevant information from the history of mathematics as written by today's historians. Second, the core of the paper aims at illustrating what historians actually do, with a methodological focus on the notions of "agency" and "puzzle-solving".

Keywords: History, epistemology, methodology, Euclid, Descartes.

In a paper of 1990 entitled *Epistémologie et didactique* (Artigue, 1990), Michèle Artigue reflected on 10 years of practice within the French mathematics education community, while stressing the *need* of epistemology for the working researcher. First, she underlined the need for epistemological awareness as an *experience* for the researcher, enabling him to distance himself from his personal mathematical culture; second, she pointed out that some *knowledge* of the history of mathematics was of a key component of didactical research, either to understand the historical development of some mathematical concept, or to understand the shaping of mathematics as a ruled cultural activity.

This paper will, to a large extent, directly echo this Artigue paper, and is hence somewhat dependent on the French context [1]. For these reasons, we will here use the adjective "epistemological" to denote the *endeavor* to derive from knowledge/awareness of the history of mathematics some insight that is relevant from a mathematics education research perspective. As Artigue did, we will focus on issues of method, although with a shift of emphasis. Instead of focusing directly on didactical concepts, we will mainly discuss research practices at the intersection of two autonomous fields of knowledge: math education research on the one hand and history of mathematics on the other hand; in this context, "history of mathematics" will denote the outcome of the work of historians of mathematics.

After spelling out some basic structural differences (and some similarities) between the two fields of inquiry, we wish to present several examples in order to illustrate what historians actually do. These examples will enable us to highlight two methodological aspects: the focus on agency (how actors engage with mathematics), and the riddle-solving (or puzzle-solving) aspect of historical research (which we would like to contrast against the "erudite description" view some may have of historical research). We wish to provide a basis for further methodological discussion, and for ever more fruitful interactions.

STRUCTURAL DIFFERENCES BETWEEN TWO FIELDS OF RESEARCH

RME (Research/researchers in mathematics education) and HM (history/historians of mathematics) are two different and autonomous disciplines: each one has its own empirical field of investigation, its own set of legitimate questions, its own way of validating claims, its own reference works etc. That fact may be self-evident; however, we feel this fact should be taken into account seriously in order to pave the way for fruitful collaborations. It is also a fact that RME and HM have often been speaking at cross purposes: when HM read what RME say about the history of mathematics, the typical reaction goes: "this is not history, but a sketchy reconstruction of history framed within a-historical categories; what really happened is really much more complicated than that, you know …"; which RME are usually fully willing to acknowledge while wondering why historians would deny them the right to make *heuristic* use of HM in a preliminary phase to their main investigation. For them, learning *about* history (which one of the things historians do) is a means to learn something *from* history (which is not what historians do). Reciprocally, RME are sometimes surprised by the lack of theoretical frameworks in the work of historians, since such frameworks provide the main tools to describe and analyze specific issues; and enable researchers to integrate their particular study to a growing and soundly-structured body of knowledge about the learning of mathematics in current educational contexts. Historians do not usually rely on explicit theoretical frameworks.

The purpose of this paper is not to claim that these usual misunderstandings are only the result of the relative isolation of the two communities, and that they would soon fade away if everyone decided to work together with an open mind. Quite the contrary, we think these misunderstandings point to differences which are *structural*, and our purpose is to sketch ways of living with this fact.

Since the intended audience of this paper is that of RME, we would like to point to some elements which show what historians actually do. Of course, our approach is descriptive and not normative.

REM and HM have at least this in common: contrary to what research mathematicians do, the object of their investigation is not *mathematics*, and this object is not studied primarily *mathematically*. Rather, they study how agents *engage* with mathematics, in a context which can be described; mathematics is necessary to make sense of this engagement and this context, but cannot possibly be the only background tool

Beyond this common agent-based approach, dissimilarities become striking: MER study learners, HM tend to focus on experts (of course, both parts of this statement call for qualification). MER has direct access to the living agents it studies, which means empirical data can be gathered, hypotheses can be put to the test in finely-tuned conditions, and cognitive processes can be investigated; HM have indirect access to the agents they study, and it is part of the trade to attempt to assess what biases it entails (critique of sources, careful methodological reflection on corpus delineation etc.). HM have to deal with events which happened once, but can be understood, compared and, to some extent, fit into narratives; MER has an experimental side to it, and can aim for invariants and reproducibility.

The fact that historians depend heavily on the availability of sources and do not explicitly rely on theoretical frameworks does not imply that their work is purely descriptive and erudite. To use Kuhn's phrase, a historians *solve puzzles*, just as any researcher does, whatever the field. We would like to illustrate this *agent-based*, *puzzle-solving* approach from three different angles.

A SHARED INTEREST IN MATHEMATICAL AGENCY

First, let us mention the kind of questions that historians aim at tackling. A very general and context-free list of questions can be found, for instance, in Catherine Goldstein's methodological paper (Goldstein, 1999, p. 187, trans. RC):

> At a given period in time, what were the networks, the social groups, the institutions, the organizations where people practiced mathematics or engaged with mathematics? Who were mathematicians? In what conditions did they live; in what conditions did they carry out mathematical work? How were they educated and trained? What did they learn?
>
> Why did they work in mathematics, in what preferred domain? What did this domain mean to them? (...) Where did mathematicians find problems to be solved? What were the form and origins of these problems? Why was some result considered as very important, or of lesser importance? According to which criteria? What was considered to be a solution to a problem? What had to be proven, and what did not require a proof (tacitly or explicitly)? Who decided so? When was a proof accepted or rejected? When was an explicit construction deemed indispensable, optional or altogether irrelevant?
>
> When, where and how mathematics were written? Who wrote, and for whom? For instance, were new results taught, were they printed, were they applied? What got transmitted? To whom was it transmitted, in which material and intellectual conditions?
>
> What changed and what remained fixed (and according to what scale, to which criteria)?

The variety of structural differences between history and didactics does not imply that no questions may be shared, in particular when one focuses on agency.

For instance, Goldstein's list strikingly echoes the list of questions which Guy Brousseau considered to be meaningful for RME when attempting to derive didactically-relevant insight from a study of mathematics from the past. Discussing Georges Glaeser's paper on the epistemological obstacles relative to negative numbers (Glaeser, 1981), he critically summed up Glaeser's "obstacle" approach, and then pointed to what he would consider to be the more relevant questions (as cited in Artigue, 1990, p. 252, trans. RC):

> This formulation shows what failed Diophantus or Stevin, seen from our time and our current system. We thus spot some knowledge or possibility which failed 16th century authors and prevented them from giving the "right" solution or the proper formulation. But this formulation hides the necessity to understand by what means peopled tackled the problems which would have required the handling of isolated negative quantities. Were such problems investigated? How were they solved? (...) What we now see as a difficulty, how was it considered at the time? Why did this "state of knowledge" seem adequate; relative to what set of questions was it reasonably efficient? What were the advantages of this "refusal" to handle isolated negative quantities, or what drawbacks did it help avoid? Was this state stable? Why were the attempts at changing it doomed to fail, at that time? Maybe until some new conditions emerge and, some "side" work be done, but which one? These questions are necessary for an in-depth understanding of the construction of knowledge [*pour entrer dans l'intimité de la construction de la connaissance*] (...).

In both list, we can see that a focus on agency does not mean that the object of study is a freely creative cognitive agent. Quite the contrary. Agents are born in a world which pre-exists, and constrains their actions. When it comes to mathematical activity, constraints come from a great variety of sources, ranging from the material environment (a Chinese abacus is not an electronic calculator) to epistemic values (rigor, generality, simplicity, accuracy, applicability, etc.) and epistemic categories (definition, justification, proof, example, algorithm, analysis/synthesis, principle, etc.). The historical contingency of these constraints does not imply that they have no a-historical components, be they mathematical properties (a rule such as "minus times minus equals minus" is not compatible with distributivity of × over +) or semiotic properties (an algebraic shorthand with no parentheses – such as Cardano's – has different properties from Bombelli's). Making historical sense of how actors engage with mathematics involves understanding how they act *within* a given set of constraint, what *meaning* they give to their actions, and in what respect these actions *alter* the system of constraints.

FOCUSING ON AGENCY: USES OF A DIAGRAM

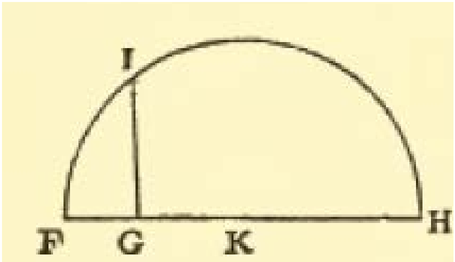

Figure 1

Let us now flesh out this notion of agent-based approach – this focus on mathematical agency – from another angle. We will use the example of this diagram to illustrate several methodological points.

The very same diagram (Figure 1) appears in two of the most influential works in the history of mathematics: Euclid's *Elements* and Descartes' *La Géométrie*. One could argue that not only the diagram is the same, but the mathematical content is the same; however, the parts these diagrams play in both works are strikingly different.

In Euclid's *Elements* (Heath, 1908), this diagram comes with proposition 14 of book II; a proposition which solves the following construction problem: to construct a square equal (in area) to a given rectangle. If the sides of the rectangle are equal (in length) to FG and GH, then the perpendicular IG is the side of the sought-for square, which Euclid proves using proposition 47 of book I (which we call Pythagoras' theorem). At the end of book I, a series of proposition established that, for any given polygon, a rectangle with the same area could be constructed (with ruler and compass only), hence prop. 14 provides the final positive solution to the problem of quadrature of polygons (i.e. to transform any polygonal area into a square). In turn, this fact implies that – at least for polygons – area is a well behaved magnitude: areas can be compared (since square areas can), and added (since the Pythagorean construction provides a means to add square areas). On this basis, a modern reader would conclude that a theory of measure in possible for polygonal areas; the modern reader also knows that this requires the set of real numbers. Euclid was very well aware of the fact that the theory of well-behaved geometrical magnitude (even line-segments, for which comparison and addition are straightforward) requires more than natural numbers and their ratios. The solution he presented in book V is a number-free solution, based on the notion of ratio of magnitudes and not of measure. The positive result of II.14 also points to open questions in the theory of magnitudes, in particular the extension of the theory beyond the case of polygons (the case of the circle being of prime importance).

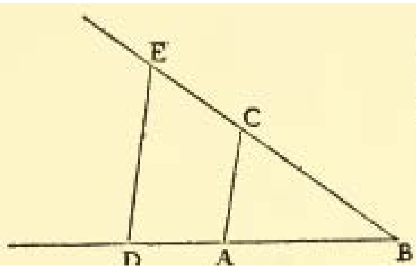

Figure 2

The same diagram (Figure 1) appears on the second page of Descartes' *La Geométrie* (1637). Along with another diagram (Figure 2), he aims at defining operations on segments; operations for which he would use the same names as for arithmetical operations. In Figure 2, if AB denotes a unit segment, then BE will be called the "product" of segments BC and BD. In Figure 1, if FG is the unit segment, then IG will be called the "square root" of GH. Descartes then adds that he would not only use the same names as those of arithmetical operations, but that he would also resort to the same signs as in algebra: letters for segments (known or unknown), symbols such as $\times$ and $\sqrt{}$ for the above mentioned constructions. The project is to use the means of algebra (rewriting rules, elimination in simultaneous equations, identification in polynomial equalities, method of indeterminate coefficients) to capture and analyze geometrical relations between segments; among such relations, those expressed by one equation in two unknowns capture plane curves.

This specific Cartesian project is quite different both from Euclid's, and from what we call either algebra or coordinate geometry. In the *Elements*, prop. II.14 solved an *area* problem; in terms of magnitudes, considering two line-segments could lead either to a new segment (by concatenation, which can be seen as a form of addition), or to an area (that of a rectangle, which can be seen as a form of multiplication), or to a ratio (which is not a geometrical entity, but not a number either). On the contrary, Descartes uses elementary construction (with an *ad hoc* unit segment) to define operations such as "time", "divide" or "root" as internal operations within the domain of segments; this enables him to make free use of algebraic symbolism while warranting geometrical interpretability. This system, however, involves no global coordinate system; it does not even involve coordinates, since no numbers play any explicit part in the system.

The fact that Descartes' system is an algebra of segments has other far-reaching consequences. Let us mention one of general epistemological importance. At first, when we read in *La Géometrie* that the solution of equation $z^2 = az + b^2$ (z being unknown, a and b known) can be expressed by formula:

$$z = \frac{1}{2}\mathrm{a} + \sqrt{\frac{1}{4}aa + bb},$$

we feel we are on pretty familiar ground. However, we need to recall that this formula is not a symbolic summary for a list of arithmetical operation on numbers, but is a symbolic summary for a geometrical construction program; a ruler-and-compass construction program which involves two concatenations, two multiplications (Figure 2), the construction of a "square-root" segment (Figure 1), and three midpoints. This, in turn, means that the algebraic manipulation of formulae and equations deals with the transformation and comparison of geometric construction programs. Here, the comparison with Al-Khwarizmi (ca 820 CE) is striking:

> Roots plus numbers equal squares; for instance, when you say: three roots and four in numbers equal one square.
>
> Procedure: halve the number of roots, you get one and one half; multiply it by itself, you get two and one quarter; add four, you get six and one quarter; take its root, which is two and one half, add it to half the number of roots, that is one and one half, you get four, which is the root of the square, and the square is sixteen. (Rashed, 2007, p. 106. Trans. RC)

With its purely rhetorical algebra and its use of generic examples, this excerpt from Al-Khwarizmi's *Algebra* may look less familiar than Descartes' formula. However, it presents a *bona fide* list of operations which enables one to solve an equation, in a numerical context. In the rhetorical context, algorithms are easy to express, but not so easy to compare, transform and calculate upon. One of the properties of Descartes' system is that its symbolic algebra allows for calculation to operate on algorithms; the fact that the basic steps of the algorithms involved are ruler and compass constructions and not numerical operations is irrelevant, and testifies to the meta-level function of symbolic algebra.

This interplay between the familiar and the not-so-familiar (yet understandable) may feel disorienting at first, but this disorienting effect is a positive effect, as Artigue stressed. It has a *critical* function, helping the researcher to distance himself from his own mathematical culture ; and a *heuristic* function, suggesting new viewpoints on seemingly familiar notions, for instance on the role of symbolism in algebra, or the role of real numbers in geometry (as measures and as coordinates). At least two other functions can be mentioned. First, it helps identify *problems* to which there are no straightforward answers. For instance, what should we consider to be the geometrical analogue of multiplication, at least for one-dimensional objects? In particular, should the analogue of the product be one-dimensional or two-dimensional? A long series of different – yet mathematically sound – constructions provide different answers to this question, including dimension changing solutions (going down with the dot product, or up with the exterior product). Secondly, it helps question the notion of *identity*. It could be argued that, from a purely mathematical point of view, Euclid and Descartes rely on the same content associated to Figure 1; this probably makes sense, but it is probably not very helpful, either to the historian of to the RME. Indeed, researchers in both fields aim at analyzing how content depends on – for instance – semiotic resources, or intended use.

To finish with this Euclid-Descartes example, we would like to make plain what it took to come up with such an example. On the one-hand it is relatively small scale: we did not need to include it in any large-scale narrative on the "stages" in the history of geometry for this sketchy comparison to serve the four above listed functions of epistemological inquiry; on an even smaller scale, the comparison with a short passage of Al-Khwarizmi could play a relevant part even with no background "big picture" on the history of algebra, or even on the *Kitāb al-Jabr*. On the other hand, to compare the uses of the same diagram required that its role in the whole structure of the works (the *Elements*, and *La Géométrie*) be analyzed. It requires some knowledge of history to make sense of highly sophisticated but largely forgotten theoretical constructs such as the classical theory of ratios, or the 17th century research program of construction of equations. This knowledge cannot derive from a quick look at short extracts from the original sources, and probably not even from a long look at the whole books; here we depend on professional historians such as (Netz, 1999) for Euclid, and (Bos, 2001) for Descartes.

SOLVING PUZZLES, DESIGNING RESEARCH-QUESTIONS

Finally, we would like to illustrate the fact that erudite analysis is not all there is to historical research. Finding answers and grounding answers through erudite analysis of documents come only in a second phase; in a first phase, historians strive to identify challenges, and craft non-trivial (and possibly innovative) questions. Let us give five pretty different examples.

In (Proust, 2012), Christine Proust studies the algorithm displayed in paleo-Babylonian tablets when working out the reciprocals of large numbers in the sexagesimal system. The clay-tablets display instances of calculations, but no general descriptions of the method (much less any justifications), which is why historians endeavor to come up with reconstructions of the algorithm. Pioneer in the history of Babylonian mathematics Otto Neugebauer (1899–1990) reconstructed an algorithm on the basis few tablets; an algorithm which required that additions be used along the way. However, in the *floating point* sexagesimal number system, and in the purely numerical context of these tablets, addition is not possible (whereas products and reciprocals make perfect sense)! On the basis of a much larger sample of tablets, Proust reconstructed a different algorithm; one which is fully compatible with a floating point arithmetic.

In his now classic *The Shaping of Deduction in Greek Mathematics* (Netz, 1999), Reviel Netz attempted to re-historicize the endeavor of the Greek mathematicians of the classical and Hellenistic periods, and help us question many things we implicitly take for granted. This difficult for two at least reasons: first, some of the basic elements of practice displayed in these texts – in particular, the practice of discussing lettered diagrams using only explicit axioms and formerly established results – is so familiar to us that we cannot imagine how a few men strove took to establish this specific cultural form on the background of other cultural activities. Second, because we feel we know that mathematics was a central intellectual activity in these periods, as many texts of Plato and Aristotle seem to indicate. Netz established that it was *not* the case, and discussed why Plato and Aristotle distorted our perception of historical realities. In a stimulating review of this erudite book, Bruno Latour emphasized the extent to which it echoed central methodological trends in the social history of science (Latour, 2008).

The question of the circulation of mathematics between different cultural areas – and not only different periods – is also a central field of investigation. In (Chemla, 1996), Karine Chemla discussed the introduction of "western" mathematics in 17th century China by Jesuit missionaries. It was usually thought that, in this period, the indigenous Chinese tradition of mathematics was to a large extent forgotten in China, and that western mathematics had been adopted passively. Actually, studying the Chinese sources leads to a more nuanced picture. In particular, when Jesuit Matteo Ricci and Chinese scholar Li Zhizao collaborated to write a treatise of arithmetic based on Clavius, they ended up with much more than a translation: Li added many elements from the indigenous tradition, in particular the *fangcheng* algorithm to solve simultaneous linear equations (similar to Gaussian elimination). This work of synthesis did not stir interest in the West; in China however, the introduction of western mathematics revived scholarly interest in classical Chinese mathematics, and triggered comparative studies of both traditions.

It is well-known that for the founders of the calculus the prime goal was the study of curves defined by ordinary differential equations, in a geometrical of physical context. Pen and paper, and formulaic solutions were not all there was to it, as is demonstrated by the deep and original work of Dominique Tournès. In (Tournès, 2003), he studied the intense work on graphical methods and graphing devices carried out from the very beginning (Leibniz, Newton, Jean Bernoulli, Euler), up until the advent of digital instruments in the second half of the 20th century. This work brings to light a great wealth of largely forgotten mathematical ideas and techniques; shows the continuity between the algebraic research program on the "construction of equations" (as in Descartes) and the late-17th and 18th century researches on ODEs; and documents the deep connections between the most theoretical considerations on the one hand, and the demand for effective approximation methods in the engineering communities on the other hand.

The distinction between "local" and "global" is now standard in the scholarly mathematical world, but it was not always the case. Studying the emergence of an explicit local-global articulation is tricky for a number of reasons: it concerns more or less all mathematics; the *meta* level terms "local" and "global" have definitions which differ in every specific mathematical context; actually they can be used with no definitions at all. Moreover, the question of the *explicit* is crucial. When, at the turn of the 20th century, some mathematicians began to explicitly express a such distinction, was the general context one in which it was actually clear to everyone that this mattered (though it went without saying), or one in which no clear distinction was made between local and global statements, resulting in a wealth of faulty proofs and ambiguously-worded theorems? These questions were addressed in (Chorlay, 2011), who provided answers based on a combination of quantitative and qualitative methods.

CONCLUSION

This short list of examples illustrates how historians endeavor to design non-trivial questions; what means they use to answer these questions; and what kind of answers they tend to consider relevant and innovative. Although we feel historians provide a great wealth of material of prime interest for mathematics education research, it is a fact that they do not usually provide this material in a form which directly meets the needs or wishes of the mathematics education research community.

To further this paper, we can identify at least three avenues for research: (1) to analyze papers in mathematics education research which depend heavily on historical analysis, such as (Sierpinska, 1985), (Katz, 2007) or (Dorier, 2000); (2) to discuss the relevance of standard conceptual tools such as "epistemological obstacle", "(mis)-conceptions", "historical genesis"; (3) to review the main theoretical frameworks in mathematics education research in order to identify which (if any) role they assign to epistemological or historical investigation.

The contribution of history of mathematics on students' mathematical thinking competency

Kathleen Clark

Florida State University, School of Teacher Education, Tallahassee, USA, kclark@fsu.edu

This paper presents a small subset of results from a pilot study conducted at a small private university in 2012. The study sought to identify changes in students' mathematical thinking competency. In this paper, I present summaries of pre-instruction and post-instruction think-aloud interviews for one of 18 items on the think-aloud instrument, for two of the participants. I propose that history and philosophy of mathematics courses do have the potential to impact students' mathematical thinking competency and further studies such as the one presented here must be undertaken to expand what we know and how we can use the knowledge to enhance the teaching and learning of mathematics.

Keywords: History and philosophy of mathematics course, think-aloud protocol, mathematical thinking competency.

INTRODUCTION

In the past, much of the available research on history of mathematics courses has been primarily focused on how to teach such courses (e.g., Miller, 2002). Recently, however, scholars have attempted to "describe ways in which a history of mathematics course can help prospective teachers of mathematics develop knowledge they will need for teaching" (Huntley & Flores, 2010, p. 603). Although investigations into the development of mathematical knowledge for teaching constitute important contributions, there exists a need to examine the potential impact of a history of mathematics course on the more general undergraduate mathematics major population. I propose that what is missing from the research literature regarding the alleged influence of the history of mathematics is inquiry on the actual impact on learning, or as considered here, on students' mathematical thinking competency as a result of studying mathematical ideas from the perspective of the historical and philosophical development of those ideas.

The field of mathematics education boasts fewer empirical examples about how the study of the history and philosophy of mathematics contributes to student thinking about and understanding of essential mathematics concepts than it does theoretical studies on the same. The outcomes of the study discussed here hold promise for increasing awareness of what the history of mathematics contributes to learning and thinking about mathematics (if anything) and for contributing something further to the empirical base of previously well-known theoretical studies.

Based upon research that I have conducted with prospective mathematics teachers (Clark, 2012), I conjectured that the think-aloud task interview results would in fact reveal changes in the undergraduate students' mathematical thinking competency, using the definition provided in Danish KOM-report (Niss & Højgaard, 2011, pp. 52–53). In particular, I am interested in identifying evidence for which participants engaged in different aspects of this competency, such as:

> ...being able to *recognise, understand* and *deal with the scope of given mathematical concepts* (as well as their limitations) and their roots in different domains; *extend the scope* of a concept by *abstracting* some of its properties; *understand* the implications of *generalising* results; and be able to *generalise* such results to larger classes of objects. (emphasis in original; Niss & Højgaard, 2011, p. 53)

That is, the primary goal for the research was to link students' experiences from a history and philosophy of mathematics course to changes in their competency for thinking about mathematics with regard to important fundamental mathematical concepts. Thus, this qualitative, exploratory study set out to document and analyse changes in the students' mathematical thinking competency on three topics of interest (infinity, the complex number system, and the axiomatic structure in mathematics).

The results of the present research may enable instructors of history and philosophy of mathematics (HPhM) courses to consider the power of the course on improving mathematical understanding and could find it beneficial to revise courses to capitalize on this implication. Additionally, researchers interested in the "value-added" impact of a course on the history (and philosophy) of mathematics for prospective mathematics teachers may be able to make a stronger case for the inclusion of a history of mathematics course in teacher preparation programs that do not currently require it.

METHODOLOGY

The importance of such an empirical study—even an exploratory one—on changes in how students articulate their mathematical thinking as a result of an HPhM course is timely. The study is exploratory along two dimensions. The first dimension entails piloting the mathematical task think-aloud protocol, created to allow students to articulate their thinking about the mathematical ideas of infinity, the complex number system, and the axiomatic structure of mathematics. The second dimension, which is the focus of this paper, is the description of students' mathematical thinking pre- and post-instruction in the HaPM course and an attempt to qualify changes that occurred in their mathematical thinking competency with respect to these fundamental ideas in mathematics.

I heavily draw on Corbin's and Strauss' (2008) definition of qualitative analysis as "a process of examining and interpreting data in order to elicit meaning, gain understanding, and develop empirical knowledge" (p. 1). The nature of data analysis required me to search for changes between a student's thinking during the think-aloud interview post-instruction when compared to their pre-instruction thinking, and to qualify those changes using most of the aspects of the mathematical thinking competency (Niss & Højgaard, 2011): recognise, understand, and deal with the scope of the given concept; extend scope by abstracting; understand implications of generalising results; and generalising results to large classes of objects. For this reason, each student's pair of interviews was coded individually, according to their own phrasing, references (e.g., to the HPhM course material), and examples.

Participants

The particular context for the study was selected for two reasons, First, I was already familiar with faculty members at the university (one in mathematics education, one in mathematics), which would facilitate my multi-day visits to collect data, get to know the students in the course, and to conduct the think-aloud interviews. Second, students from a variety of majors took the history and philosophy of mathematics (HPhM) course at Private Christian University (PCU; a pseudonym). Thus, a course with a diverse student population as the one at PCU (e.g., first-year through fourth-year undergraduate students; mathematics and non-mathematics majors) was a valuable convenience sample to use.

Students were recruited from the HPhM course at the beginning of Fall 2012. The course instructor introduced the opportunity to participate in the research study during the first class session. Then, at the end of the second class session, I introduced myself and explained that the primary goal of the research was to investigate changes in students' mathematical think-

Participant	Year in school	Major	Highest level mathematics course taken in high school; college mathematics courses taken
Jenny	Senior	Elementary Education	Precalculus (high school); Intro to Mathematical Thinking (PCU)
Tabitha	Senior	History (Secondary History Education)	Intro to Mathematical Thinking (PCU)
Darren	Sophomore	Mathematics or Music (undecided in Fall 2012)	Advanced Placement Calclulus (high school); currently enrolled in two math courses (PCU)
Michael	Junior	Mathematics (recently changed major to Mathematics Education)	Mathematical Analysis II (high school); Intro to Mathematical Thinking (PCU)

Table 1: Student participants (Private Christian University, Fall 2012)

ing about mathematics concepts (e.g., the concept of infinity) that occur as a result of studying the history and philosophy of that concept. Finally, I explained the nature of the think-aloud interviews and answered students' questions about the research, interview process, and their potential participation. Of the 19 students enrolled in the course, four students volunteered to participate in the pre- and post-instruction "think aloud" interviews. Brief descriptions of the four participants are given in Table 1. The names that appear in bold indicate the participants on whom I focus for the results discussed in this paper.

Data collection

Mathematical task interviews were conducted using a think-aloud approach, in which student participants were asked to articulate their methods, interpretations, and thought processes while working on mathematical tasks. During the think-aloud process, the researcher intervenes as little as possible, with the exception of limited prompts such as "talk about what you're thinking" or simply "keep talking" (Young, 2005). The think-aloud interviews were conducted before and after classroom instruction and subsequent study of the three concepts of interest. Smartpen technology was used during each interview. The Smartpen was used by students during the interviews and enabled me to capture audio as well as written documentation of the students' responses to each of the tasks. Interview transcripts, once transcribed, were analysed for qualitative differences in students' mathematical thinking competency, as a result of studying historical details and philosophical perspectives of fundamental mathematics topics. In addition to the audio and written documentation, the course instructor's instructional plans and documentation related to the three selected topics comprised the third data source (e.g., lecture notes, assigned reading, homework assignments, class session activities).

Think-aloud interview instrument

A three-part interview instrument was constructed for this research, which was composed of 18 items. The instrument included items about the concept of infinity (five items), the complex number system (six items), and axiomatic structure in mathematics (seven items). However, due to space limitations, I discuss only one of the items in this paper: Item 1 (complex number system) asked students to *draw a Venn diagram to show the relationships among the different types of numbers that comprise the number system.*

In the following discussion, I present a summary of the pre- and post-instruction responses for both Tabitha and Michael. Additionally, I identify which aspects of the mathematical thinking competency were found in their responses. Finally, I provide a profile for Tabitha and Michael (based upon their pre- and post-responses) in an attempt to identify changes in their mathematical thinking competency resulting from their experience with a history and philosophy of mathematics course.

SELECTED RESULTS

The four students who participated in this study generated a surprising amount of rich data in their responses to the 18 items during the think-aloud interviews. In an effort to make sense of the various ways to describe the changes in students' mathematical thinking competency, this paper presents responses for only one item of the think-aloud instrument from two of the four participants.

The important results of this study are found in the qualitative analysis of the participants' pre- and post-instruction think-aloud responses. Tabitha's and Michael's responses to one item are presented to display the potential for HPhM course work to impact students' mathematical thinking competency. For this paper I selected an item in which the HPhM course might impact students' competency differently, given the range of student abilities and experiences represented.

To illustrate the scope of changes in the mathematical thinking competency for Michael and Tabitha, I present a summary of the key content of their responses, along with identification of aspects of the competency exhibited in their response. When necessary, I also provide a continuum rating to quantify the extent to which the aspect was evidence (e.g., "naïve or beginning understanding", "stronger example").

The case of Tabitha

To begin, I provide the summary of Tabitha's pre-responses to Item 1 (complex number system), with elements of the mathematical thinking competency (Niss & Højgaard, 2011) given in bold as well as an image from Tabitha's think-aloud interview (Figure 1):

(a) She expressed types of numbers as dyads: positive and negative; real and fake, or "unreal" numbers; ra-

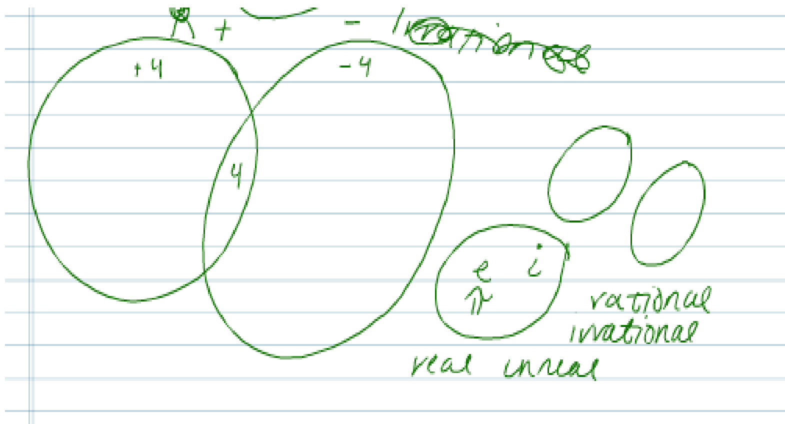

Figure 1: Tabitha's pre-response Venn diagram

tional and irrational, which belong to real numbers (though her Venn diagram did not reflect this) *[recognise a given math concept]*;

(b) Numbers that are not numbers: *e, i, π*; she later changed her mind: *π* is a number—but not *[recognise a given math concept (naïve or beginning understanding)]*;

(c) She first stated that *i* means "infinity" and then changed her mind and stated that *i* stands for "irrational" *[(attempt to) recognise a given math concept]*;

(d) +4 and – 4 mean the same thing, since they each just reduce to 4 *[(attempt to) recognise a given math concept]*; and

(e) She tried to seek connections throughout her discussion *[extend concept by abstracting properties]*.

Next, I summarised Tabitha's post-responses to Item 1:

(a) She identified whole numbers and fractions and those numbers that cannot be written as fractions: "so irrational" *[recognize and understand a given math concept]*; she also asked: "can prime numbers be irrational?" *[awareness of types of questions]*;

(b) In her Venn diagram she needed two non-intersecting circles one for rational, one for irrational *[recognise and understand a given math concept]*;

(c) She again listed dyads of numbers: rational/irrational; prime/composite; imaginary/complex *[recognise and understand a given math concept]*;

(d) Her post-response included imaginary versus real numbers (Figure 2) *[recognise and understand a given math concept; extend concept by abstracting properties]*;

(e) She also added infinity and zero to her diagram, noting that these particular numbers represented divine connections for her *[extend concept by abstracting properties; deal with scope of given mathematical concept in different domains]*.

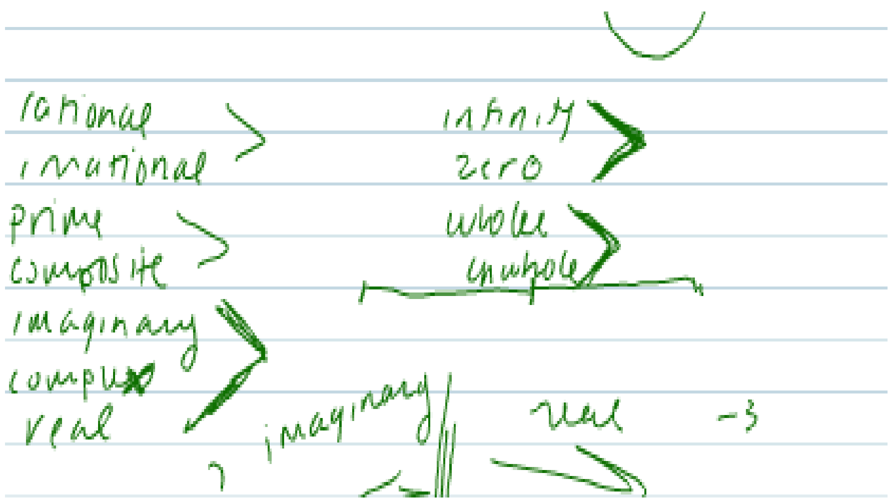

Figure 2: Tabitha's list if types of numbers needed for her Venn diagram (post-response)

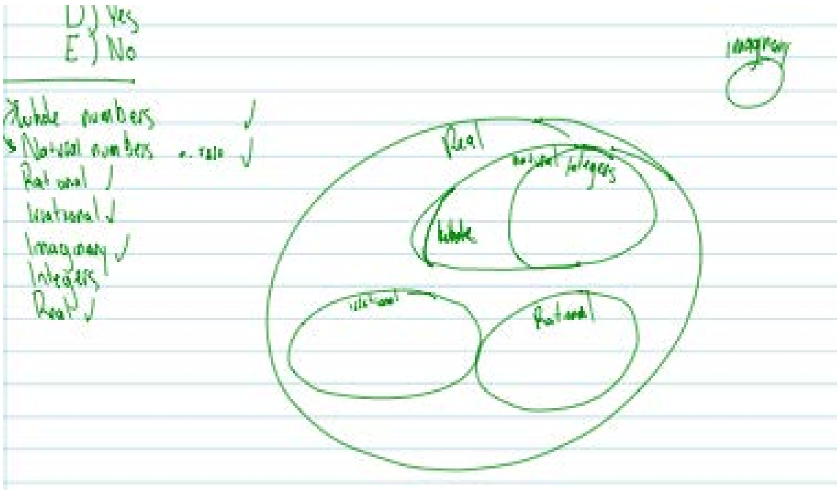

Figure 3: Michael's pre-response Venn diagram

Finally, I constructed a mathematical thinking competency profile for Tabitha (Item 1, complex number system), based upon the elements from the mathematical thinking competency (in bold in the summary). This profile shows growth from pre- to post-instruction, in that the variety of aspects from the mathematical thinking competency developed from several instances of only two aspects to multiple instances of four aspects of mathematical thinking.

Tabitha: Item 1 (complex number) pre-response

— Recognise a given math concept (four instances, including two at a beginning or naïve level of understanding)

— Extend concept by abstracting properties

Tabitha: Item 1 (complex number) post-response

— Recognise and understand a given math concept (four instances at varying levels)

— Extend concept by abstracting properties (two instances)

— Deal with scope of given mathematical concept in different domains

— Awareness of types of questions

The case of Michael

Michael, a mathematics major who recently changed his program of study (major) to mathematics education, possessed stronger mathematics content knowledge than Tabitha. However, the history and philosophy of mathematics course experience did appear to impact his mathematical thinking competency. Michael's pre-response summary and the identification of the relevant competency aspects for Item 1 (complex number system) included:

(a) He first listed kinds of numbers, including whole, natural, rational, irrational, imaginary, and integers (of the last category Michael asked: "where do these belong?") *[recognise and understand a given math concept (transitional understanding, not completely sophisticated)]*;

(b) He asked: Are you going to be paying attention to how big my circles are?...because there is this whole debate on if there are more rational or irrational numbers" *[extend concept by abstracting properties]*

(c) He was careful to make sure that the circles representing the sets of rational and irrational numbers did not overlap in the Venn diagram, but he did want the two circles to touch (see Figure 3) *[recognise and understand a given math concept (transitional understanding)]*.

In his post-response to Item 1:

(a) Michael began the discussion of his Venn diagram by beginning with the top of the hierarchy for the number system as he understood it: "...[we have] real numbers, then we have imaginary, then you'd have... complex numbers, which is a little of both" *[recognise, understand, and deal with the scope of a given math concept]*;

Figure 4: Michael's post-response Venn diagram

(b) He listed sets of numbers as he did before: whole, natural, integers; and real, irrational, algebraic, transcendental, and transfinite *[recognise, understand, and deal with the scope of a given math concept]*; and

(c) He felt there was more that he could do with classifying types of numbers: "I feel like I could do this forever; just drawing circles and breaking them up… because even with all of these you could define them into primes and which primes are seen more often, and…" *[extend concept by abstracting properties]*.

Using the summary above, I constructed Michael's mathematical thinking competency profile for this item:

Michael: Item 1 (complex number) pre-response

— Recognise and understand a given math concept (two instances; though not completely correct on each instance (e.g., "transitional understanding"))

— Extend concept by abstracting properties (one instance)

Michael: Item 1 (complex number) post-response

— Recognise, understand, and deal with scope of a given math concept (two instances)

— Extend concept by abstracting properties (stronger example than in pre-response)

Michael's understanding of the complex number system before participating in the HPhM course was fairly strong. Yet even with his understanding of the complex number system, his mathematical thinking competency was strengthened by the end of the course.

DISCUSSION

The pre- and post-response summaries, identification of mathematical thinking competency aspects, and construction of a competency profile for Tabitha's and Michael's work on Item 1 (complex number system) attempt to show that the HPhM course had some influence on students' mathematical thinking competency—at least from the perspective that the students themselves noted this while cognitively addressing the content before them. For example, Michael's ability to discuss and organise the different numbers of the complex number system (although "complex" was purposely not given to participants in the item or during the think-aloud interview) was already strong before the HPhM course. However, after the course, Michael revealed a more complete or nuanced understanding of the complex number system, which he stated was due to his reading of a required course text, *Zero: The Biography of a Dangerous Idea* (Seife, 2000). Classroom observations also revealed that Seife's book was used during classroom discussions and assignments.

Tabitha's post-instruction responses do reflect a better understanding of the types of numbers comprising the complex number system. However, except for a brief reference to learning about Venn in a class lecture, it is difficult to explicitly link the change in her thinking about the complex number system to the HPhM course. That said, I believe the course did influence her knowledge because as a Secondary History Education major, it is unclear from where she would have gained such knowledge during the semester of study. Instead, an attempt to identify changes in Tabitha's mathematical thinking competency shows promise for characterising the impact of HPhM courses on tertiary students' mathematical experience.

CONCLUSION

This paper reports only a very small subset of results from a pilot study conducted in 2012 and its purpose is to highlight the potential for history and philosophy of mathematics courses to enhance students' mathematical learning. In the current attempt, I tried to qualify the profile of two students' mathematical thinking competency, using student responses to identify aspects of the competency (Niss & Højgaard, 2011), for a single item from the interview instrument developed for this project. In the next step I will analyse responses to several additional items from the interview instrument. Then, in a future publication, all four student cases (Darren, Jenny, Michael, and Tabitha) will be presented, along with supporting data from classroom observations and instructor documentation, in order to reveal a more extensive landscape of changes in students' mathematical thinking competency resulting from their experience in a history and philosophy of mathematics course. In the interim, it is my hope that this initial report will promote discussion about similar empirical studies.

Using calculus in economics: Learning from history in teacher education

Peter Collignon

University of Erfurt, Erfurt, Germany, peter.collignon@uni-erfurt.de

Historical awareness has an impact on teaching and learning mathematics. It includes knowing the historical development, the questions under investigation and the answers given to these problems. In this paper, the focus lies on calculus and its applications in economics. It shows how far the knowledge of a changing scientific understanding can be beneficial in teacher education. The paper covers this issue from an epistemological, historical and educational perspective and suggests a constructivist view for educational purposes.

Keywords: Calculus, constructivism, economics, epistemology, teacher education.

INTRODUCTION

Within teacher education, an expansion of scientific understanding can be achieved, which promotes an adequate epistemological view and modifies naive-realistic ideas. For this purpose, covering mathematical economics using methods of calculus is an unusual but promising approach. According to Fischer & Malle (1985, p. 107), the absence of a law-of-nature-character is necessary to allow learners the free use of mathematics describing "reality". In this way the modelling perspective demonstrates a human distance to reality. Jablonka (1996, p. 34f) states, that this view assumes an understanding of the underlying mathematical concepts separate from the context. In the following text, this consideration will be modified by discussing the usage of a certain mathematical concept (calculus) for modelling (economic) circumstances, which originally did not contribute to its genesis. However, this approach should go along with an adequate historical awareness of the evolution of the mathematics involved.

In most cases first-year students have not experienced the formal treatment of scientific issues in the classroom as a modelling process. Even more there is little or no experience with a systematic processing of economics applications. Dealing with economics in terms of mathematical modelling offers general education and provides insights into epistemological concepts and helps to foster an enlightened understanding of science. In view of the above and considering also the potential of a constructivist understanding of science due to Ernest (2007) and Lyotard (1979) it is promising to use a mathematical tool in connection with a subject that it is originally not meant for. This approach aims at prospective teachers primarily, but it applies to their educators as well.

APPLIED MATHEMATICS IN TEACHER EDUCATION

Mathematical modelling is listed as one of the six important competencies in Germany's "Bildungsstandards Mathematik". This is a consequence of the postulate of integrating more reality-based problems in lessons and lectures on mathematics. The focus is not the application of a given algorithm, but the mathematization of facts and problems whose relation to mathematics may be not initially obvious. Circumstances of the so-called "real world" are to represent formally by abstraction so that the representatives enable a quantitative analysis. The solution found for the model may be interpreted as a proposal for the solution of the real problem.

In many cases, such an approach is presented as a multiple passage of a modelling cycle that shows the interaction between "reality" and model as an idealized scheme. Critical validations should successively lead to a revised design of the model as an interpretation of reality.

Beginning their studies, prospective teachers have years of experiences in applying mathematical methods. For example, elementary calculus, stochastic and analytical geometry are known in principle. Introductory lectures at university address those issues again and there is the chance to add new aspects corresponding to the didactic spiral principle. This includes applications in general and should cover topics from mathematical modelling in particular.

MATHEMATICAL MODELLING IN ECONOMICS

In current mathematics education discussion the modelling cycle of Blum and Leiss (2005, p. 19) is widely accepted as a "model of modelling", but also different approaches are considered, e.g. an interpretation of the modelling process in the sense of taking the spiral principle or descriptions including a coexistence of cyclic and progressive courses into account. Meyer and Vogt (2010, pp. 142ff.) argue for an increased emphasis on the processual character and the inclusion of an appropriate terminology. Möller (2014) analyses the concept of the "rest of the world" and exposes the problems of the disjoint separation of mathematics and reality.

Facets of the reliance on mathematics

The field of economics shows a multitude of aspects that differ from those of the natural sciences. There are much less "canonical" formalizations than in physics, e.g.

Human action is involved, which refers to needs and wants. The scarcity of goods and services forces people to economize. Economic actions go along with conflicts and competition; they require decisions under uncertainty. Therefore, they are fraught with risks. Economic activities are goal- or benefit-oriented, often for-profit.

Economic issues, due to their reliance on mathematics, must take all aspects of the modelling process into account. Using mathematics within the "exact" and natural sciences often appears canonically, and in school they are rarely taught as a result of a modelling process. An in-depth understanding of their non-canonical nature, which manifests itself in the different models of the physics of classical mechanics, Maxwell's electrodynamics, the theory of relativity, quantum mechanics to recent developments in cosmology remains a domain of advanced students and experts.

Nevertheless, mathematical modelling is often demonstrated in the context of physical-technical issues. The decision for a certain model is closely related to the finding and definition of suitable parameters and their functional relationship. Frequently the number of parameters involved and their skillful assignments are looked upon as a quality criterion.

While early graders get involved in proportionalities relating to quantities, on the secondary levels the notion of function comes to the fore. It requires good education to impart the features of modelling in such a framework. This applies to teacher training, too.

At this point the comprehension of economic topics carries a valuable educational potential. The fundamentals of the conditions and circumstances – with respect to the subject of the application as well as the mathematical methods used – gives insight into the processes of gaining knowledge.

The values of goods and services are defined by their position on a common one-dimensional discrete scale; a price is assigned. So already the introduction of the quantity "money" is an early normative modelling item (cf. Möller, 2007, pp. 3ff.). It allows a comparison and measuring with monetary units, which implies the definition of an order relation for all the goods and services. Here a descriptive aspect becomes apparent: Aspects of economic objects can be characterized (via prices). Once the concept of functions is available, rates may be expressed by functional dependencies and forecasted under appropriate model assumptions. In accordance with and in extension to Henn (2000) the descriptive aspect can be interpreted as a summary of description, declaration and prognosis.

The role of calculus

Even if modelling using functional relationships is regarded as reasonable, there is initially no need to apply methods of calculus. Under what conditions and for what motives does this happen, at all? In order to answer this question one must distinguish between

- a use of a calculus not reflected upon (cf. Doorman & van Maanen, 2009, p. 4), which offers the possibility of using methods taught in school to discover certain properties of functions (local extrema, inflexion points, monotony etc.);

- a deliberately chosen approach, which allows an analysis of the model with methods of infinitesimal calculus in the first place with the aim of gaining knowledge.

The latter begins with the substitution of discrete quantities, such as money or lot sizes, with continuous ones. In this way, the real numbers (as well as real intervals) are involved. Functional dependencies described by tables or in terms of numerical sequences must now be expressed by functions defined on (connected) subsets of the real numbers. Often the mapping rules are chosen in a way, that allows an analysis according to infinitesimal calculus, i.e., they are continuous, differentiable etc. Providing this, it is possible

- to use methods from calculus on the mathematical model level;
- to interpret the available mathematical concepts relative to the real situation, i.e., an economic interpretation.

Corresponding to the second point, we often observe an interaction between the mathematical practice and the subject to be mathematized: Several economic concepts were generated or at least clarified by the use of a certain kind of mathematics. Marginal costs, defined by the first derivative of the cost function, are an example. The history of physics and its partial co-evolution with calculus offers a variety of relevant analogies.

STUDENTS' PREVIOUS KNOWLEDGE ABOUT THE CO-EVOLUTION OF CALCULUS AND PHYSICS

Modern calculus textbooks are characterized by an axiomatic representation and by offering physical applications. The representations are supplemented by graphics or pictures to support their understanding. The main concepts include the real numbers, the notion of a function and a limit. They are proposed by a formalised representation following a trias that is definition, theorem and proof, supplemented by a few examples illustrating the propositions. In this way the representation of calculus made its way during the first half of the last century (see also Jost, 1998). This outcome is still regarded as "modern" and results from a long historical non-linear development with discontinuations. Thus it may be an ambitious task for first-year students to look into history of calculus self-contained. In the case of master's students an independent research is more appropriate. The following sections outline the knowledge students should have to participate in a discussion about further applications in social sciences, especially in economics.

The discovery of the Archimedean palimpsest (cf. Netz & Noel, 2007) revealed his geometric view consisting of several singular perceptions of areas bordered by parabolas. His way can be characterized as singular efforts but he did not deduce a method which could have led to a general view. He took first steps onto the way to Riemannian integration, but however, he did not develop a general method like Riemann did.

New steps towards a theoretical approach of analysis were taken more than a thousand years later within occidental mathematics. Further efforts were made within the influence of natural sciences in particular the planetary movements as well as the ballistic investigations. These considerations corresponded to the notion of dynamics, e.g. the velocity, and both concepts involve the dependency between a geometric position and the time. Here Johannes Kepler (1571–1630) used the lists made available by Tycho Brahe (1546–1601) (lists that put the loci of the planets in dependency of the time) and deduced his laws of planetary orbits.

Newton (1643–1726) further developed and refined the theory of planetary movements by using an infinitesimal calculus that emphasized dependencies of time. However he did not yet apply yet our modern concept of a function. Around the same time Leibniz (1646–1716) generated an infinitesimal calculus by introducing infinitesimal quantities, not using consequently a functional approach either. However, both of them and some other contemporary scientists provided a basis for their followers in the 18th century, see also Sonar (2011).

Euler (1707–1783) picked up these conceptions and was the first to introduce the functional concept in a way in which we use it still nowadays. This means the infinitesimal calculus reached the next level and is since called modern. During the following decades the focus was on computational aspects but there was still a lack of theoretical foundations. The real numbers had no theoretical foundation and the concept of a limit was still missing.

Karl Weierstrass (1815–1897) bridged both gaps (real numbers and limits) using the epsilon-delta-statement for the definition of a limit and contributed a theoretical approach to the real numbers. The latter was refined later on by Dedekind and Cantor who defined the real numbers by Dedekind-cuts. Cantor contributed the concept of Cauchy sequences (equivalence classes of Cauchy sequences) and the continuum hypothesis (cf. Hairer & Wanner, 1996, pp. 172ff.). Their contributions established a completion of the rational numbers to the real numbers so they obtained a complete field of numbers.

Teacher students should be also aware of the following: In the classroom, but also in contemporary university lectures, especially in teacher education, one can observe some kind of (anti-) didactical inversion (cf. Freudenthal, 1983, pp. 305ff.), interpreted in terms of history. There is an introduction to the real numbers on secondary I level, which mainly consists of some examples of irrational numbers. As a matter of fact this is part of the recent history of calculus and it is, strictly speaking, mathematics from the 19th century. Regarding the concept of functions, the situation is similar: It is introduced before a discussion about infinitesimal concepts takes place on secondary II level. The figure below presents a very rough scheme that reflects teacher students' often observed reception of the history of calculus and the (experienced) order of teaching.

EDUCATIONAL POTENTIAL

There is no controversy about the necessity of gaining insight into economics and economics applications using mathematical concepts. However, this is defined differently or non-specifically. According to May (2001, p. 3),

> ... economic literacy can be paraphrased as the qualification (knowledge, competencies, skills, attitudes etc.) to manage living conditions determined by economics.

At the same time we find the statement:

> The intention of teaching economics is ... the (economically) responsible citizen.

Engartner (2010, p. 15) emphasizes the social meaning of economic literacy:

> Only an appropriately qualified citizen, educated in matters of responsibility, is in a position to follow the rapid process of social change at least rudimentarily.

Orientation towards the "basic experiences"

Sociological and economic issues affect the reality of young adults' lives to a larger degree than topics from physics do. From the mathematics educational point of view they are matters of the "basic experiences" of Winter (1996): Mathematics education is providing general education by

- realizing phenomena of nature, society and culture;
- knowing (and appreciating) mathematical issues, represented by language, symbols, images an formulas;
- acquiring heuristic competencies.

Mathematics education has a general and life preparatory function (Heymann, 2013, pp. 131ff.). Mathematical modelling offers the opportunity to realize this in two ways: firstly, on the basis of concrete facts to be modelled, then again by modelling itself on a meta-level. This provides access to epistemological issues.

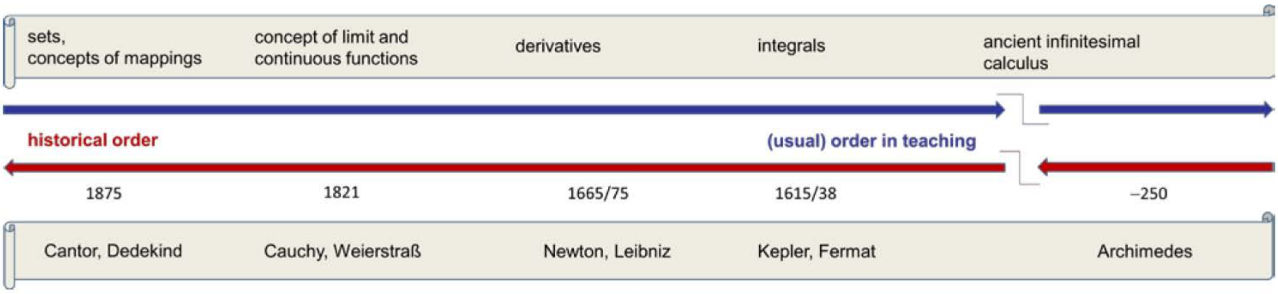

Figure 1: Didactical inversion – in terms of history

Epistemological aspects

Theory of science is not science philosophy, and the latter is not the same as epistemology. Especially the German language is differentiated here, although not uniformly (Poser, 2012, pp. 15ff.). It is not the role of an introductory mathematical lecture to explicate this in detail. But particularly with regard to teacher education one should not ignore the observation, that students, but also teachers, often show a naively realistic understanding of science. Zeyer (2005) confirms their socialization through their academic training in terms of an unconsidered positivistic attitude. In this context a proposal from Duit (1995, p. 905) deserves consideration.

> Knowledge acquisition is regarded as an active construction on the basis of existing ideas. The active, self-directed and self-reflective learner is in the center and the idiosyncratic processes of construction are always embedded in a particular social context.

In case of the natural sciences and pure mathematics there are justified objections to a strong emphasis of relativism, even from a didactic point of view. Regarding economics, the situation is quite different. It is obvious, that the economic denominations listed above are closely connected to human action. The implications and theories deduced do not have the significance of "laws of nature". This makes it easier for students who did not have any contact with epistemological questions until this point to identify the reference objects of many scientific discourses as models.

The history of economic sciences shows various paradigm shifts – even within the radical meaning of Kuhn (1992) –, and even the contemporary ones are more accessible to laymen than the development of physics in the twentieth century. This supports an open-minded modelling activity in economic contexts in which the distinction between "wrong" and "correct" solutions becomes less important and is put into perspective. The main idea of the paradigm and the paradigm shift relates to the facts to be modelled and the mathematics used at the same time. For example, the economic marginal analysis uses infinitesimal methods originally physically and geometrically motivated. In economics, however, quantities of discrete nature are often modelled as continuous ones with intent to apply methods of differential calculus, which emerged from completely different requests. Lectures and seminars on calculus offer the opportunity to point to the transfer of methods from natural to economic sciences and discuss how far this is an historic attempt to make economy "accurate".

Considering everyday experiences, and apart from the necessity of laboratory conditions, Newtonian mechanics may be a "canonical" modelling. Anyway, the use of infinitesimal methods in economics is based on model assumptions which are replaceable in a more obvious way, e.g. by the application of methods from discrete mathematics.

Brodbeck (1998, pp. 22ff.) refers to these observations as "social physics" and continues:

> The mechanical approach in economics shall primarily allow the application of mathematical and experimental methods in analogy to physics (...).

Prospects

Jablonka (1996, p. 187) concludes her meta-analysis of approaches to mathematical modelling and applications by declaring:

> The lack of examples from which we can learn where to ask more questions and to try different ways and to illuminate the problem from different perspectives and to weigh the outcome and evaluate critically clearly shows that a reflection beyond the scope of an analysis of purposes and efforts has little place in mathematics lessons, which target the comprehension of mathematical procedures and theories.
>
> As a resource to change the viewing angle self-consistent, and as an instrument to recognize and evaluate alternatives, to search for reasons and in the exchange of arguments, reflection is not knowledge, but an attitude in the assessment of mathematical methods to be aimed at an intentional creation of situational activity, which results in the insight, that recipients or persons concerned are authorized and applying operators are obligated, to adopt a critical attitude.

Teaching experience meets the high expectations linked to the potential of economic modelling against the background of the history of calculus outlined here. Qualitative investigations planned in this context will provide further indications.

2 Universidade do Minho, Centro de Investigação em Educação, Instituto de Educação, Guimaraes, Portugal, mhm@ie.uminho.pt

This paper aims at discussing how a context of argumentation can be created in the classroom through the development of tasks based on the history of mathematics. These were proposed to a class of 8th grade. Through this experience, we found that students use different types of arguments that show different degrees of formality and kinds of reasoning; express and justify their ideas; and interpret and understand the opinions that are presented to them. The history of mathematics proved to be an enabling tool for mathematics learning, particularly for building a community of mathematical discourse, in which mathematical argumentation is reflected.

Keywords: History of mathematics, argumentation, Pythagorean theorem.

INTRODUCTION

The integration of the history of mathematics in mathematics classes has, over time, attracted the interest of researchers, mathematicians and mathematics teachers (Fasanelli, 2000). In fact, in recent years, such an integration has been prominently featured in literature and in educational curricula of different countries. In parallel, there are several studies that highlight the value of argumentation in mathematics (Pedemonte, 2002; Knipping, 2008) as well as a number of specific references in the curriculum guidelines that advocate the development of students' ability to communicate the way they reason. Taking as starting point these principles, we intend to show how the integration of tasks based on the history of mathematics in the context of the classroom can foster the development of mathematical reasoning, influencing students' ability to reason.

HISTORY AS A PROVIDER OF MATHEMATICAL ARGUMENTATION

A number of arguments justify the benefits of integration of the history of mathematics in teaching and learning mathematics. Tzanakis and Arcavi (2000) point out five fields in which such an integration may be particularly relevant to support, enrich and improve the teaching and learning process: the learning of mathematics; the nature of mathematics and mathematical activity; the didactical background of teachers; the affective predisposition towards mathematics; the appreciation of mathematics as a cultural endeavor. On the other hand, Jankvist (2009) proposes two sets of categories in which to place the arguments for using history (the "hows") – history as tool or history as a goal – and the different approaches to doing this (the "whys") – illumination, the modules and the history-based approaches.

Discussing and developing mathematical arguments implies creating conditions for students to learn how to reason mathematically, since a classroom culture that promotes the argument stimulates the participation of students in their own learning (Krummheuer, 1998). In this sense, the history of mathematics can play a useful role in creating a community of mathematical discourse, namely fostering contexts for argumentation. The different points of view that arose from different historical contexts provide an opportunity for students to argue and to develop the art of arguing, to justify their own opinions and to present their thoughts to their peers (Fasanelli, 2000). Thus, students develop not only deeper mathematical skills but also other sorts of skills such as the ability to discuss, analyze and "talk about" mathematics (Tzanakis & Arcavi, 2000). In fact, according to Siu (2007), using the history of mathematics in the classroom does not necessarily make students obtain higher scores in a particular subject, but it can make learning mathematics a more meaningful and lively experience, thus helping to learn more and more easily. It contributes to establish a context of teaching and learning that provides both teachers and students with different ways of using and acquiring knowledge about what is taught in its diversity. These different forms may arise, for example, by proposing and solving certain problems, since they allow not only the observation of the historical evolution of the concepts, but also promote reasoning and comparison of resolution strategies. Such a process promotes the exchange of ideas and reasoning schemes (Lakoma, 2000), which allows not only the development of argumentation situations, but also the establishment of connections with previously acquired knowledge or other areas knowledge, fostering, in particular, the students familiarity and personal involvement in mathematics (Tzanakis & Arcavi, 2000). Therefore, the history of mathematics appears as a way promoting communication development and, in particular, mathematical reasoning in the context of the classroom.

ARGUMENTATION IN MATHEMATICS CLASS

Argumentation refers to techniques or methods for establishing a speech statement, i.e. processes that produces a (not necessarily deductive) logical assertion on a given subject. The value of arguments in mathematics classes, arises not only associated to the idea of explanation and justification – to convince the other – but also to the discussion and evaluation of different ideas expressed in the classroom, for example while addressing a given task.

The model proposed by Toulmin makes possible a local analysis of the arguments. This model aims at capturing the "logical form" of a speech (Pedemonte, 2002). Toulmin (2008) describes the basic structure of rational arguments as a pair *data/conclusion*. The passage from data to conclusion can be put in question, and often is justified by a *warrant*. Although, sometimes the distinction between data and warrants is unclear, their functions are different: data transmit a set of information; warrants authorize the step of inference. This distinction allows Toulmin to provide the skeletal elements of a pattern that we call *simple argumentation form*. However, this elementary scheme may not be sufficient to analyze certain argumentative discourses. Toulmin, thus, adds three auxiliary elements of discourse analysis: *modal qualifiers*, *conditions of rebuttal* and *foundation*. In particular, in mathematical argumentation these auxiliary elements arise, respectively, as indicators of the strength of the argument, as exception conditions and warants to support the inference. We designate this by *complex argumentation*.

A classification of the different arguments produced is given by Reid and Knipping (2010), who establish four categories of arguments: empirical, generic, formal and symbolic. Moreover, they state that within these four categories several subcategories can be identified. Other cases may lie at the borderlines between them.

METHODOLOGY AND CONTEXT

This experience, as part of a broader research study, followed a qualitative methodology, involving students in a class of 8th grade and the respective teacher. It aimed at examining how the integration of history-related tasks in the context of the classroom may influence the students' ability for reasoning and argumentation.

The study had several phases: organization of the task; implementation (along two-class periods of ninety minutes each) and data collection; analysis of the arguments produced by students, local and global analysis of different discursive interactions, identification of difficulties experienced by students and their own assessment.

The task – *two towers, two birds and a fountain* – was structured in different parts. Thus, for Part I, students were asked, in small groups, to solve the following problem: Two towers, measuring 30 meters and 40 meters of height, respectively, are placed at a distance of 50 meters. Between the two towers there is a fountain to where two birds, flying down from the towers at the same speed, arrive at the same time. What is the distance between the fountain and each of the two towers? The problem is found on Fibonacci's *Liber Abaci*. In Part II, students were asked to read and review strategies of resolution of this problem by Fibonacci himself and Gaspar Nicolas (a Portuguese mathematician of the 16^{th} century).

Data collection was carried out through observation field notes, as well as audio and video records. A documental analysis was also carried on using documents produced by the students: resolutions of the tasks performed and their critical reflection upon them. The teacher put a strong emphasis on group work and discussion with the whole class, interacting with students whenever considered necessary.

The analysis of the arguments produced by students was done using local analysis as proposed by Toulmin and the classification of arguments proposed by Reid and Knipping (2010) model arguments. The evaluation made by the students was based on the five domains mentioned by Tzanakis and Arcavi (2000).

PRESENTATION OF RESULTS

We present in the sequel some examples of the work done by the students during the resolution of task's Part I as well as a brief reference to how students reacted when reading and discussing the different arguments documented in the historical primary sources (Part II).

Type of arguments (in solving the problem)

In Part I all groups tried to solve the problem and different types of argument were observed. Using unrepresentative examples, the arguments produced by students were not restricted to a simple enumeration. In some cases they can even be framed in the subcategory *crucial experience*. Taking into account that at a certain moment the two birds are flying down from the two towers at the same speed and arriving at the center of the fountain at the same time, and that both birds start from the top of two towers, 30 and 40m high, respectively, the students observed that "the [tower] 40 is higher than 30, so it must be closer to the fountain so that the birds arrive at the same time and with the same speed." (Nelson, group G2). Moreover, given the difference between the heights of the two towers, 10 meters, the students felt that this value would influence the distance from the fountain to each of the towers. The fact that students take into account the data of the problem, noting what should be the position of the fountain (closer to the highest tower), suggests that they are addressing the problem in general. In fact, the initial argument of this group lies between the empirical and the generic, as it is the result of a refutation.

Nuno: We depicted the towers [pointing to the towers drawn on paper] and the space between them is 50. If we put the fountain in middle, which is 25, gives this [pointing to the bird that is in the 30m tower] going down faster than this one [pointing to the bird that was in the 40m tower], because the building is taller.

Argumentation: local analysis (in solving the problem)

Yet in Part I, through the various types of arguments used, it was possible to carry out a functional reconstruction of various statements made in the different groups. Observe an excerpt of the dialogue between the teacher and the G4 group:

1 Teacher: What have you done?
2 Diana: We have depicted two towers with two birds each. A 40m high and another with 30m and the distance between them was 50m. Afterwards we put the fountain here. 20m from this [pointing to the tower with 40m] and 30m from that [pointing to the tower with 30m, Figure 1], because the difference between them [the two towers] was 10m. So the fountain has to be closer 10 meters to one of them than to the other.
3 Teacher: That is...
4 Diana: It is closer to this one [pointing to the tower 40m]. This one [pointing to the tower 40m] is 10m higher than that [pointing to the tower with 30m], therefore the fountain must be 10m farther to walk the same distance. And here [pointing to the tower 30m] has as least 10m, then [the bird] will walk less, then the fountain must be farther.
5 Filipa: That is, the fountain has to be closer to this [pointing to the 40m tower].

The excerpt shows that this group considers the following solution for the problem: the fountain must be located 20m from the highest tower and 30m from the lower (§2) one. The determination of these values was based on two preliminary conclusions, (§4) and (§5), which acted as new data in the argumentative discourse, to obtain the final conclusion. In this reasoning chain it is still possible to identify a warrant (§2) "because the difference between them [the two towers] was 10m. So the fountain has to be closer 10

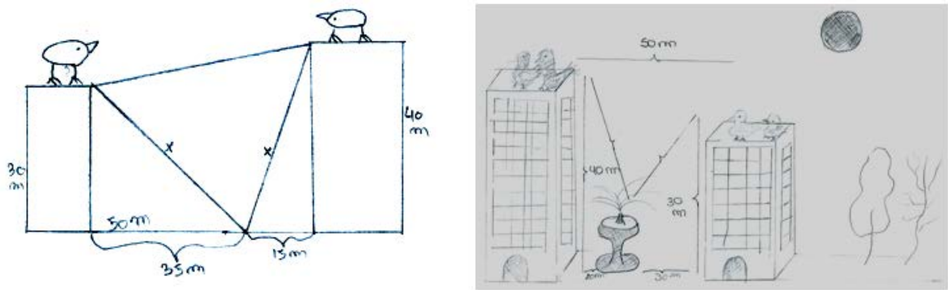

Figure 1: Illustration of the problem made, respectively, by groups G1 and G4

meters to one of them than to the other", whose role for this group of students was to legitimize the final conclusion. For the Toulmin model, the argumentative discourse corresponds to a simple form of argumentation.

Almost all groups obtained the wrong values mentioned above. Group G1, however, initially proposed a set of different values. Their initial solution took the form of a conclusion obtained after a refutation, although later they also refute the conclusion.

Nuno: We depicted the towers [pointing to the towers, Figure 1] and the space between them is 50. If we put the fountain in the middle, which is 25, results in this [pointing to the bird in the lowest tower] coming down faster than this one [pointing to the bird in the other tower], because the building is taller. As this is higher, we added 10m ahead [for 40m along the tower], so that they come down at the same speed [and arrive at the same time], we get 35 [25 + 10] with this [pointing to the tower 30m] and x [pointing to the way the bird would go] and use the Pythagorean theorem.

Through this passage, we can conclude that the first solution figured out by the students was 25m, i.e. the fountain would distance 25m of each of the towers. However, students refute this possibility, because the bird on top of lowest tower would reach quicker the center of the fountain, since the other tower was "a higher building". Although, at this moment, they do not mention the problem data given, they certainly consider it: the birds fly at the same speed and arrive at the same time to the center of the fountain. Therefore, considering the negation of the claim refuted as a new data, they claim that the fountain should "move forward"' 10m, i.e. come 10 meters closer to the highest tower. Accordingly, they add 10m to 25 (which was given as half of the distance between the two towers). Thus, for those students, the fountain should be located 35m away from the lowest tower and 15m from the highest one. It should be noted that, although not explicitly mentioned, the choice of 10m is related to such being the difference in height between the towers. According to the Toulmin model, this argumentative discourse is a complex form of argument.

In the final phase of the excerpt shown, students insist they still need to apply the Pythagorean theorem. Later this group will come to refute the consensual conclusion: that fountain is located 35m ahead from the lowest tower and 15m from the highest one. Note that this group using the same method, will refute the conclusions of the others. Thus, at the end of Part I no group had come up with the correct solution.

Reading and interpreting the reasoning argument present in primary sources

Although students have not found the correct solution, in Part II they were faced with three new resolutions coming from historical primary sources. They read, reviewed and discussed each of these resolutions, and arrived to the actual solution. They compared the resolutions, not only among themselves, but also with their own attempts. From what students wrote we are able to undertake a local analysis of the arguments, but also to identify the difficulties shown and the assessment they made of their work, namely, the confrontation of different resolutions.

From the claim accompanying the arithmetic resolution by Fibonacci, which reads "(...) in geometry it is clearly demonstrated that the height of either tower multiplied by itself added to the distance from the tower to the center of the fountain multiplied by itself is the same as the straight line form the center of the fountain to the top of the tower multiplied by itself; this therefore known (...)", the students were able to solve the problem algebraically. Observe the following:

1 Emanuel: 900, here 1600 (writing next to the respective towers, Figure 2).
2 Teacher: Then what does he say? He adds what?
3 Emanuel: The distance from the tower to the center of the fountain multiplied by itself.
4 Teacher: You have already the square of the distance from the lower tower to the center. How much it is?
5 Emanuel: 900.
6 Teacher: And what does he do? He add 900 to…
7 Emanuel: The square of the distance from the lowest tower to the center of the fountain.
8 Teacher: You know how much is this distance?
9 Emanuel: It is x!
10 Teacher: It is x?
11 Emanuel: Can be x, because I don't know the length (marks on the drawing x)
12 Emanuel: It'll be this (pointing to 900) plus x squared (writing next to the figure $900 + x^2$). Then there is also this 1600.
13 Teacher: And you agree with what is there?
14 Emanuel: (After a silence) Yes, it is the Pythagorean theorem.
15 Teacher: Let's continue. Could you do the same for the other triangle?
16 Daniel: Yes.
17 Emanuel: This is not x! (pointing the distance from the fountain to the highest tower).
18 Teacher: So here is…
19 Emanuel: $50 - x$. [The distance from the center of the fountain to the highest tower]

(Next, they write the expression $1600 + (50 - x)^2$ to denote the square of the distance from the highest tower to the center of the fountain).

20 Teacher: Yes, and what can you do with these two expressions?
21 Emanuel: We have to match! (they reply very promptly).
22 Teacher: And why did you match?
23 Emanuel: Must be the same distance, because the flights were of equal lengths. (Writing $900 + x^2 = 1600 + (50 - x)^2$). And now we solve.

Through this passage, we can conclude that the students translate, in current notation, the information given. Although the purpose of this task was to analyse the process of resolution presented by Fibonacci, this group, from reading the first part of the resolution of Fibonacci, chose to translate it algebraically, obtaining an equation. Thus, for this group, it was enough to solve the equation and thus get the solution.

After solving algebraically the equation, group G2 continued to read and analyse the Fibonacci resolution. They noted that the method used by Fibonacci was the false position, a method often used by the Egyptians to solve problems. Students refer this fact, because the procedure used by Fibonacci corresponds to choose a measure for the distance from the center of the fountain to the highest tower, which is not the problem solution. Then this is revised in order to obtain the correct solution. Students observe that Fibonacci appointed for 10 the distance from the fountain to the highest tower, introducing new data in the problem; naturally the distance from the lowest tower to the fountain is 40, since "the distance between the towers is 50 steps". Students justify Fibonacci's choice of this value (10) as being related to the difference between the heights of the towers. Next, students report that Fibonacci squared these values (heights of the towers and the distance from each tower to the fountain), as he "knew that what was shown in the figure was the Pythagorean theorem". Students continue their interpretation, noting that actually the result has to be the same. Therefore, they report that Fibonacci put the fountain 5 steps more ahead of the lowest tower. Implicitly, they account for the fact that the birds fly at the same speed and arrive at the same time to the center of the fountain, which shows that the birds travel the same distance. By the same procedure, which corresponds to the application of the Pythagorean theorem, students say that Fibonacci got a new value for the difference between the distance

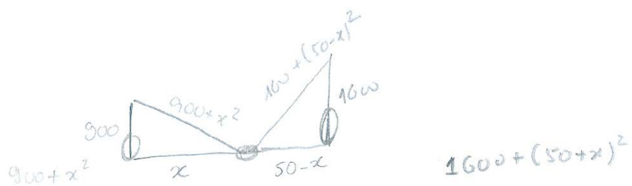

Figure 2: Illustration of the problem made by group G2

travelled by birds. Again the values obtained are not equal, and thus conclude "the fountain was not well positioned". They state that Fibonacci noted that when he "moves" the fountain 5 steps ahead the difference between the distance travelled by each bird was 300, i.e. the difference decreased in 500 steps. Since the birds travel the same distance, students report he used "the rule of three to see how many steps they had to walk so that the difference stays equal to 0". However, in Fibonacci's resolution there is no reference to this rule, but rather a numerical recipe – "multiply 5 by 300, and divide by 500".

In the local analysis of the arguments produced, it is observed that those are presented sequentially, which did not happen when students attempted to solve, initially, the problem. It was also noted a common concern with effective warrants and even with the corresponding foundations, which could legitimate the inference steps.

The second strategy to solve the problem is based on the similarity of triangles, Figure 3, *efz* and *gem* where *m* is the intersection point of *ef* and the parallel to *df* which contains *g*. Fibonacci started solving the problem by showing geometrically that the point *z* is the center of the fountain. Then he proceeded numerically. In this first phase, the students were challenged to read the beginning of Fibonacci's resolution and to find a justification for point *z* be the center of the fountain.

After some discussion students observed that *e* is, by construction, the midpoint of the segment *ga*, and *ez*, and also by construction, a segment perpendicular to the segment *ga*, and thus the triangles *aez* and *gez* are geometrically identical, since both sides are identical

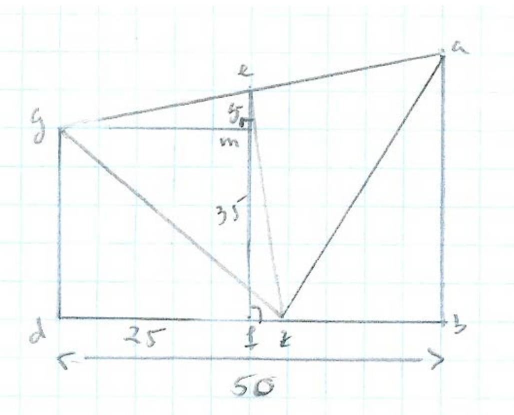

Figure 3: Illustration of the problem made by group G2 to the second strategy

and form an angle (90°). With respect to the arithmetic resolution, although the students were able to identify its main elements, they did not understand how Fibonacci arrived, in current notation, to the expression $[35x(35 - 30)] / 25$.

Daniel: Subtract this 35 by 30 will give 5; drawing this parallel line will get this 5 [pointing to the Figure 3]. Then multiplying 35 by 5 gives 175. Then dividing by 25 will [pointing to the segment]. But to divide by 25 will give the result of this [pointing to *fz*]. I'm not understanding why it gives the result of fz here [pointing to *fz*], if it is to change this [pointing to 5 and 35] for this [pointing to 25].

This excerpt reflects the difficulty expressed by students. Although the figure can identify the values reported by Fibonacci, it cannot justify the solution. Involving the whole class in the discussion the teacher points to the relationship between the triangles *efz* and *gem*.

1 Teacher: And these two triangles are equal?
2 Andrea: Which ones? This [pointing to the triangle *egm*] and this [pointing to *efz*]?
3 Teacher: Yes.
4 Daniel: No!
5 Emanuel: They do not have the same measures.
6 Teacher: Are they similar?
7 Teacher: [after a silence] What is required for two triangles to be similar?
8 Daniel: They must have two equal angles...
9 Nelson: Or the sides proportional....
10 Teacher: Or two proportional sides and the angle formed by them equal.
11 Daniel: They have a right angle [pointing to *egm*]... and also this [pointing to *efz*].

This extract, shows that students observed that triangles, *gem* and *efz*, are not geometrically identical (§4), since they have different sides (§5). Questioned whether they were similar (§6), students pointed out two cases of similar triangles, (§8) and (§9), and the teacher a third one (§10). Students observed the existence of the two right angle triangles (§11). For them to be similar triangles it would be necessary to find another pair of geometrically equal angles. Later, the students find that angles *gem* and *fze* are geometrically identical and therefore the triangles are similar.

The resolution proposed by Gaspar Nicolas, is written in the form of a recipe without any algebraic symbol. Although he considered the towers with 80 and 90 fathoms and the distance between both to be 100 fathoms, the students understood easily the calculations but question the procedure: "why to subtract 6400 to 8100", "why to add this difference to the square of the distance between the two towers" and "why to divide that result by 200". The teacher suggested a possible correspondence with the algebraic process used previously. With two unknowns, students were able to establish a correspondence between Nicolas's and their own algebraic process.

CONCLUSION

The experiment shows that different sorts of arguments were produced by different groups of students. Many of them were not developed sequentially, i.e. in a deductive way. The need for sharing ideas and exchange opinions was responsible for the emergence of not only parallel arguments, but also of new data which was suitably inserted into the argumentative chain. In simple forms of argumentation, we also observed the existence of inference steps for which the corresponding warrants or foundations were not explicitly presented. On the other hand, when analyzing the resolution strategies of Fibonacci and Gaspar Nicolas, students exhibit a strong concern for seeking warrants or some sort of formal explanations (eventually not explicit in the resolution shown) to legitimize certain inference steps. The analysis of the forms of argument used shows that students were not only able to express their ideas, but also to interpret and understand the ideas presented to them, as well as to participate constructively in the discussion. In assessing the experience, students highlighted the importance of solving the same problem through different processes and of becoming able to compare different resolution strategies. They also stressed the exercise influenced the predisposition to this discipline, while providing a broader view of its nature: "the geometrical resolution was the most difficult, but we learned that it was possible to solve the same problem geometrically"; "for me the most interesting was the resolution of Gaspar Nicolas, because I liked to try understand his thought and to solve an equation in words".

Experience has shown the potential of integrating the history of mathematics in the context of the classroom. This entails the need for a broader consideration of this problematic and its importance. Similarly, it seems necessary to outline a number of guidelines that promote this integration and scales up its potential namely, in what concerns the development of mathematical reasoning. This experience confirms that the development of reasoning in the mathematics class is a complex process: it requires a careful selection of the tasks, and entails the need for promoting a suitable environment for them, focused on the students' mathematical maturation.

The paper describes a course the purpose of which is to introduce future mathematics teacher educators to the topic of using history in mathematics education. Excerpts from students' hand-in mini-projects are displayed and discussed in terms of the Danish mathematics competency framework.

Keywords: History in mathematics education; teacher education.

INTRODUCTION

The paper addresses the question: *how to introduce future mathematics teacher educators to the discussion of history in mathematics education, and how to prepare them theoretically for a potential use of history of mathematics in their own future practice*. The "answer" presented to this question is one by example, since the paper reports on a concrete design and implementation of a course. The theoretical framework adhered to in the paper is that of the Danish KOM-report (Niss & Højgaard, 2011), which lists eight mathematical competencies that all students of mathematics should come to possess, and an additional six didactic and pedagogical competencies that mathematics teachers should also develop (to be described later). Illustrative examples of students' reports from the course will be displayed and discussed. First, however, a bit of the background of the course participants and the educational setting is provided.

EDUCATIONAL BACKGROUND AND SETTING

To become a mathematics teacher educator of primary and lower secondary teachers in Denmark, it is often favoured by the teacher training colleges that the educators hold a master's degree in mathematics education (in Denmark a Ph.D. is not required), which the Department of Education at Aarhus University is the only provider of in the country. More precisely, to enter the master's program the student must already have a university bachelor's degree, e.g. in mathematics, or a vocational bachelor degree, e.g. as a primary and lower secondary mathematics teacher. The two-year master's program consists of courses in mathematics, courses in general didactics, a course in didactics of mathematics, several of these involving student projects, and finally a master's thesis. The course of our interest here is that in "didactics of mathematics". In this course, the mathematics educators of the department, of which we are presently four, are given the opportunity to teach in a mathematics education topic of their own choice. One of the ideas behind this is that students in this way also are confronted with recent research, in which the mathematics educators themselves are involved. The course counts 10 ECTS, and each topic takes up six lessons of two to three hours teaching and supervision plus student group work, etc. For each of the topics, groups of students hand in a mini-project. Based on a random draw, at the end of the course the student groups are examined in one of the four mini-projects. In the following, I present the design of the six sessions related to the topic of "history in mathematics education" – but first, a brief description of the theoretical framework of the paper.

KOM: THE DANISH COMPETENCY FRAMEWORK

In KOM – a Danish abbreviation for competencies and mathematics learning – a mathematical competency is defined as: "a well-informed readiness to act appropriately in situations involving a certain type of mathematical challenge" (Niss & Højgaard, 2011, p. 49). More precisely, KOM deals with eight mathematical competencies: *mathematical thinking competency*, i.e., to carry out and have a critical attitude towards mathematical thinking; *problem tackling competency*, i.e., to formulate and solve both pure and applied mathematical problems and have a critical attitude towards such activities; *modelling competency*, i.e., to carry out and have a critical attitude towards all parts of a mathematical modelling process; *reasoning competency*, i.e., to carry out and have a critical attitude towards mathematical reasoning, comprising mathematical proofs; *representation competency*, i.e., to use and have a critical attitude towards different representations of mathematical objects, phenomena, problems or situations; *symbols and formalism competency*, i.e., to use and have a critical attitude towards mathematical symbols and formal systems: *communication competency*, i.e., to communicate about mathematical matters and have a critical attitude towards such activities; *aids and tools competency*, i.e., to use relevant aids and tools as part of mathematical activities and have a critical attitude towards the possibilities and limitations of such.

In addition to the above mathematical competencies, KOM also provides a competency-based description of the profession of mathematics teachers, describing a set of six didactic and pedagogical competencies: *curriculum competency*, i.e., to evaluate and draw up curricula; *teaching competency*, i.e., to think out, plan and carry out teaching; *competency of revealing learning*, i.e., to reveal and interpret students' learning; *assessment competency*, i.e., to reveal, evaluate and characterise the students' mathematical yield and competencies; *cooperation competency*, i.e., to cooperate with colleagues and others regarding teaching and its boundary conditions; and finally *professional development competency*, i.e., to develop one's competency as a mathematics teacher.

DESIGN OF THE SIX LESSONS

In the following, I describe the content and purpose of the six lessons. For each lesson the students read a collection of texts, mainly research papers, which the students then worked with during the lesson. Also, supplementary texts were given for each lesson.

In *lesson 1*, students were to familiarize themselves with different arguments for and against the use of history (and epistemology) in mathematics education, potential dilemmas, and of course different approaches to involving history. The texts read included Fried (2001), Jankvist (2009) and Niss & Højgaard (2011). The purpose of this was to enable the students to more competently discuss concrete uses of history at different educational levels including teacher training. *Lesson 2* focussed on the role and use of theoretical frameworks in empirical studies related to a use of history in mathematics education. The students were presented with two studies (Jankvist, 2011; Kjeldsen & Blomhøj, 2012) which served as cases, and they then were to discuss the use of Sfard's (2008) framework of commognition in these (the students were already somewhat familiar with this framework). As supplemental literature for this lesson, students were also encouraged to look at Jankvist and Kjeldsen (2011) and the use of the Danish competency framework (Niss & Højgaard, 2011) in this. *Lesson 3* addressed the use of original sources in the teaching and learning of mathematics as well as different approaches to involving such sources (e.g. Barnett, Lodder & Pengelley, 2014; Jankvist, 2013). Also here, one purpose was to qualify the students to argue for and against a potential use of original sources in a particular educational setting. Supplementary texts for this lesson included Glaubitz (2011) and Jankvist (2014). The topic of *lesson 4* was that of history in mathematics teacher education and not least the teachers' potential benefits of being introduced to elements of the history of mathematics. Drawing on the topics of the previous lessons, the students were to compare an older empirical study (Arcavi, Bruckheimer, & Ben-Zvi, 1982) with a newer one (Clark, 2012), and discuss the outcomes of these in the light of interpreting results by means of the framework of *Mathematical Knowledge for Teaching*, MKT (e.g., Ball, Thames, & Phelps, 2008, students were already somewhat familiar with this), drawing also on a reading of Mosvold, Jakobsen and Jankvist (2014). *Lesson 5* was a workshop in which the students were to further relate the read texts to each other as well as to a concrete case of their own choice. This work eventually resulted in a hand-in mini-project report (approximately 12 pages plus appendices) for each student group. These reports were presented and discussed during *lesson 6*, where each student group would also have read the report of another group in order to provide constructive feedback and receive feedback themselves.

ILLUSTRATIVE EXAMPLES OF STUDENTS' MINI-PROJECTS

In this section, I provide three examples of students' hand-in mini-projects: one centred around an activity to compare different historical proofs of the Pythagorean Theorem; one dealing with the changing notions of the concept of function through the 18th and

19th century; and finally, one that applies the presented theoretical constructs of the course literature in an analysis of the inclusion of history of mathematics in a secondary school mathematics textbook.

Example 1: The Pythagorean Theorem

The idea of *Group 1* was to design an activity centred around four different proofs for The Pythagorean Theorem, more precisely that from Euclid, those of Liu Hui and Zhao Shuang, respectively, and finally, one from a modern day textbook. The focus of the group was mainly one of history as a goal, following a modules approach (Jankvist, 2009). The group explained:

> The case may illustrate to the pupils that mathematics develops differently depending on the culture in which the development is embedded. The difference may be seen from the many different proofs for The Pythagorean Theorem. The Chinese proofs are characterized by wanting to picture the approach and in this way convince the receiver. Euclid's proof is characterized by a more stringent way of proof and an axiomatic composition. The modern proof is also stringent, but makes use of modern notation which is easier for the pupils to follow. This amounts to an argument of history as a goal, since the different approaches to proving The Pythagorean Theorem may contribute to pupils' understanding of mathematics not being absolute, a point also made by Fried (2001). (Group 1, 2014)

Group 1 argued that their historical case in principle may be backed by all three of Fried's (2001) reasons for resorting to history:

> [i] By including the history of the proofs from different cultures and presenting the originators, the mathematical content may be 'humanized'. [ii] The history and the context may be more 'interesting' for some pupils that for others and the proofs may appeal to different pupils as well, so that more pupils may experience the mathematics as understandable, and hence may obtain an insight into the theorem and the associated concepts. [iii] Finally, examples and tasks from the history of mathematics may be used to provide pupils with insights into the use of the theorem in 'problem solving'. Such tasks might for example be the nine tasks, which Liu Hui described and solved, now named the *Sea Island Mathematical Manual*. These include tasks where one has to find the height of an island, or a tree, or the width of a river using The Pythagorean Theorem [...]. (Group 1, 2014)

Following Sfard (2008) and Kjeldsen and Blomhøj (2012), the group discussed how their historical case may introduce meta-discursive rules:

> Since the proofs are different, it becomes possible to ask the question: *What is a good mathematical proof?* That is to say, it becomes possible to make the pupils conscious about this meta-discursive rule by including history of mathematics in the teaching. By working with the historical sources, the pupils can become aware of the discourse they are themselves part of, and develop an understanding of that working with and developing mathematics is part of the discourse in force in the time of question. (Group 1, 2014)

Group 1 ended their project by discussing the potential anchoring (Jankvist, 2011) of meta-issues of their historical case in the in-issues of the four proofs.

Example 2: Concept of function

The case of *Group 2* was four different definitions of the concept of function; more precisely Euler's definitions from 1748 and 1755, respectively, Dirichlet's from 1837, and a modern definition relying on the notion of sets (e.g., see Kjeldsen & Petersen, 2014). The group aimed for a small module to be implemented in 9th grade of secondary school, since they found that the concept of function is one that is troublesome for pupils at this grade and the beginning of upper secondary school. Hence, an assumption of the group was that such a module might assist in easing the transition phase between the two educational levels (Jankvist, 2014). Unlike the previous group, this one used history as a tool:

> We intend a half-half relationship between mathematics and history, and we use the history of mathematics as a means to teach the pupils the concept of function, i.e. our 'why' is history as a tool. We use it [history] as a motivating and cognitive tool by offering different ways to introducing the concept. (Group 2, 2014)

In terms of approach, Group 2 intended a four-session module relying on the hermeneutic approach (Glaubitz, 2011):

> We find that the hermeneutic approach fits our case, because it is the contrasts between past and present that are to be examined consciously, and because it is the embracing of these tensions that provides the deeper understanding of both the mathematics itself and the history of mathematics (Barnett et al., 2014). Since we choose the hermeneutic approach we first present the pupils with the modern definition of the concept of function and afterwards the original sources. (Group 2, 2014)

The idea, the group explained, is that the pupils must relate the early definitions to the modern one. In relation to Dirichlet's definition, they said that the point of it and the modern one is actually the same, but the associated concepts have changed over time, e.g. set theory was not available at the time of Dirichlet. And by relating the modern definition and Dirichlet's to those of Euler, the pupils must obtain an idea of why Euler's concept of function is insufficient for us. Following this explanation, the group addressed the potential benefits of relying on original sources:

> One of the advantages of original sources is that they promote the reader's abilities to think like the author, and another is an understanding of the different context in which the sources are written (Barnett et al., 2014). If the pupils become aware of the historical context and try to understand what the author did, there is a chance that they also try to understand the mathematics. [...] Other advantages are, among others, to bring the pupils closer to experiencing the creation of mathematics and see the road of mathematical development, flow, errors, and success (Barnett et al., 2014). (Group 2, 2014)

Finally, Group 2 touched on the discussion of having a Whig approach to history, and even though they admitted that their purpose of using history as a tool may have such consequences, the important issue is that they did so in an informed and conscious manner:

> In our case we have chosen not to use all of the original sources, because even in the Danish translations they appear to be too difficult. Hence, we have chosen to use only the definitions, which are what the pupils get as 'original sources'. [...] We have found ourselves in the dilemma that either the original sources were too difficult, or we had to face that it was not possible to avoid being a 'little' Whiggist in our approach. Hence, we are aware of the fact that our approach is a little Whiggist, but we have found this difficult to avoid when the target group is secondary school. (Group 2, 2014)

Example 3: A textbook analysis

The case of *Group 3* was a Danish textbook system called *Sigma*, and in particular they looked at the books for 8th grade, which consist of one textbook for the pupils and one for the teacher. For their initial analysis of the books' use of history, the group relies on the constructs of Fried (2001) and Jankvist (2009). Firstly, the group discuss the textbook authors' purpose of using history and the degree to which they find this realized:

> In the teachers' textbook [...] we find the following statement in the chapter on Numbers and Algebra: *"We believe it to be important that the pupils learn about the development of mathematics and in particular that of numbers. Although such knowledge may not have a direct yield, it assists in providing the background for a part of the world, which we live in today. Without this knowledge, mathematics [...] appears as if it has always existed in the form we are introduced to today"* [*Sigma 8*, teachers' textbook, p. 6]. Here, knowledge of the history of mathematics is viewed as relevant in itself. Hence, generally speaking, we have to do with a goal argument [of using history]. The interesting thing then is how this is reflected in the pupils' textbook [...]. Through the entire chapter, we see a large focus on the history of mathematics. 10 out of 24 pages are dedicated entirely to history of mathematics, where the pupils are informed about the historical development of the numbers from hieroglyphs over Roman numerals to negative numbers and the number 0. Occasionally, the historical account is replaced by traditional mathematics exercises. However, there is almost no connection between the historical information and the exercises, since these can be solved without having read the historical account. Hence, the intention from the teachers'

book is not clearly implemented in the pupils' book. (Group 3, 2014)

Group 3 also provided another example, one on the Pythagorean Theorem, where the teachers' textbook provides an extensive account of Pythagoras, his school, and the presumed Babylonian origin of the theorem. Again, the implementation of this piece of history in the pupils' textbook is reduced to a cartoon drawing, a picture of a marble bust of Pythagoras, and several examples accompanied by modern-day notation. As pointed out by the group, the book misses an opportunity of applying excerpts from original sources here. Original sources, however, are part of the teachers' book, but the book authors' intention with this remains unclear:

> ... in the teachers' book [...] six excerpts from original sources on the proof of The Pythagorean Theorem are shown [...], but no suggestions as to how the pupils may be brought to work with these sources are provided – actually, there is no mentioning of the sources themselves, so it is unclear why they are included in the first place. (Group 3, 2014)

In further relation to the discussion of purpose of using history versus approaches to using it, the group pointed out that despite it being difficult to realize 'history as a goal' through mere 'illumination approaches' (Jankvist, 2009), this appears to be what is happening in the *Sigma* system. They continued:

> The teachers' textbook [...] contains quite a number of test exercises, but history of mathematics is not a part of any of these. In the teachers' book it is clear that history is used as a 'spice' and seen as a tool, not as a goal. In the notion of Fried (2001), what we are dealing with is a 'strategy of addition'. (Group 3, 2014)

With continued reference to Fried (2001), Group 3 went on to argue that the book system has a somewhat Whig approach to using history, in particular in the pupils' textbook. Following this, the group discussed the missed opportunities of the book system in relation to fostering Sfard's commognitive conflicts, with reference to Kjeldsen and Blomhøj (2012):

> In the teachers' textbook [...] it is stated that the pupils should become acquainted with the Roman numerals, although not to a very large extent: *"The positional number system should – once more – be examined carefully with the pupils, while the Roman numerals should not be examined as much – they merely serve to illustrate the advantages of the numeral system we apply today"* [*Sigma* 8, teachers' textbook, p. 7]. The authors' intention here is that of having one numeral system meet another in order to illustrate clearly the good idea of one of them. It is exactly in this meeting between two different discourses that the opportunity for learning arises, since the difference between the two discourses is made clear by the advantage of one of them. The intention here is for students to discover the ineffectiveness of addition in the Roman numerals as compared to our current positional system. Unfortunately, as seen before, this idea is not pursued in the pupils' textbook, which only contains little information about the Roman numerals, and not a single exercise where pupils are to work with these. (Group 3, 2014)

Finally, Group 3 attempted a small analysis of the (potential) role of history of mathematics in the Danish mathematics teacher educational program. Using their own knowledge of KOM, the group was able to deduce that from a curricular and rhetorical stance, history ought to play some role in Danish mathematics teacher education, but unsurprisingly it does not. As a potential explanation, the group pointed to the non-trivial relationship between mathematics, history of mathematics, and didactics of mathematics, and that teacher educators will need to possess knowledge and competencies not only in each of these, but also in their cross-sections.

CONCLUDING DISCUSSION

In the following, I discuss the students' yield in terms of 'history *in* mathematics education' as part of their future practice as teacher educators by relating this to KOM's didactic and pedagogical competencies (Niss & Højgaard, 2011). A basic assumption in KOM is that to be able to develop pupils' mathematical competencies, teachers must themselves possess the eight mathematical competencies. A similar assumption is that for future teacher educators to be able to develop teachers' didactic and pedagogical competencies, they must themselves also possess these. In the mini-projects, some of these competencies of course reveal themselves more clearly than others and some not at

	Curriculum Competency	Teaching Competency	Revealing Learning Competency	Assessment Competency	Cooperation Competency	Professional Development Competency
Group 1	✔	✔			✔	✔
Group 2	✔	✔			✔	✔
Group 3		✔			✔	✔

Table 1

all. The competencies of revealing students' actual learning and of assessment cannot be analyzed meaningfully based on the mini-projects. For that reason these are not discussed here, and they are marked out of the given summarizing table (see Table 1).

As for the curriculum competency, both Group 1 and Group 2 were well aware that the contents of their modules fit into the curriculum, and that their teaching sequences focus on a variety of the mathematical competencies as well. Group 1's module on proofs for the Pythagorean Theorem required pupils to develop both their reasoning and their thinking competency. Group 2's module also built on these two competencies, but draw in the representation competency to a large extent as well in the pupils' comparison of concrete functions as a means for evaluating the definitions of function. All three groups reveal aspects of teaching competency: group 1 and 2 in the active part of the competency, since they themselves plan and organize a teaching activity; and group 3 in the passive part of the competency, since they analyze already designed activities in textbooks. Group 2, in particular, also takes into account the pupils' "characteristics and needs" (ibid, p. 86) in designing their activity, e.g. by evaluating the difficulty of the original sources and by arguing for looking at the concept of function in relation to the transition problem between educational levels.

Having to do these mini-projects, the students, i.e. the future teacher educators, depend on, train, and develop their cooperation competency. In particular the KOM-framework mentions "the ability to bring the above-mentioned [...] competencies into play in mathematical, pedagogical and didactic cooperative projects" (ibid. p. 88), which is most certainly what is taking place when the students have to design these teaching activities in their groups and write up the mini-project reports, while drawing on the course literature and putting this into play in design considerations, etc. This matter of being able to apply the various theoretical constructs from the course literature is of course closely connected to the professional development competency, i.e. being able to develop one's competency as a mathematics teacher. The competency involves "being able to enter into and relate to activities which can serve the development of one's mathematical, didactic and pedagogical competency" (ibid, p. 88), which of course is a basis for the course design to begin with, but in relation to using history it is exactly the theoretical constructs from the literature which to a large extent assist the students in this. Also, this competency is "about keeping oneself up-to-date with the latest trends, new material and new literature in one's field, about benefiting from relevant research and development contributions" (ibid, p. 88), which certainly also took place since much of the literature had only recently been published.

The professional development competency is to some degree a 'meta-competency', as can be seen from its drawing on the other didactic and pedagogical competencies. Perhaps for this reason, in particular, it is essential for teacher educators. KOM's six teacher competencies are of course directed towards the teaching of mathematics, and teacher educators will have to teach mathematics as part of their future profession. So, in this sense, it is quite meaningful for the students to reflect upon the potential role of history and how it may best be used in various situations and contexts, i.e. not only in primary, lower and upper secondary school, but also in pre-service and in-service teacher education. Nevertheless, the teacher educators are also going to teach courses on the didactics of mathematics to pre-service teachers. And in this respect, the professional development competency appears relevant as well. The way the students are able to articulate their considerations and choices regarding a potential use of history using theoretical frameworks and constructs to make their arguments, is likely to be reflected in their own teaching of future teachers, and hence also in the pre-service teachers' professional development.

Algebra in Dutch education, 1600–2000

Jenneke Krüger

University of Utrecht, Freudenthal Institute, Utrecht, Netherlands, jenneke.kruger@gmail.com

Algebra became part of mathematics education in the Netherlands in course of the seventeenth century. At first in the form of cossic algebra, but by the end of the century, the influence of the notation of Descartes was noticeable. In the eighteenth century, algebra was part of the basic curriculum of the Foundation of Renswoude. In the second half of the nineteenth century, algebra was seen as useful for a technical career. The number of topics in school algebra grew, but eventually algebra became mainly a subject in which complicated calculations were performed, which did not seem to serve a purpose outside the subject. At the end of the twentieth century, school algebra in lower secondary became a fairly informal way of solving 'practical' problems.

Keywords: Algebra education, Leiden Engineering School, Foundation Renswoude, HBS.

INTRODUCTION

When we consider examples of mathematics curricula in Dutch education it is obvious that the content of geometry didn't change very much for a long time. Some problems on geometry in the lecture notes from the Leiden Engineering School, dating from 1620 (Krüger & Van Maanen, 2014), were recognisable for a student in secondary education around 1960. With algebra it is a very different matter.

In 1600 Simon Stevin wrote the *Instruction* for the Duytsche Mathematique, as the Leiden Engineering School was called. In the *Instruction* Stevin specified the content of the course. He mentioned arithmetic, specifying calculations with decimal numbers, geometry, surveying techniques and fortification, but no algebra (Krüger & Van Maanen, 2014).

In the second half of the 18th century the Foundation of Renswoude provided talented orphans with an education for technical professions. A large part of the curriculum consisted of mathematical subjects: arithmetic, algebra, geometry (*Euclid*) and trigonometry (Krüger, 2014a). Algebra included operations with algebraic forms, formulating and solving linear and quadratic equations and also geometric, arithmetic and harmonic series.

About a hundred years later, in 1863, national legislation for secondary education was introduced by mr. J. Thorbecke, the liberal prime minister. The 'Hogere Burger School' (higher secondary school for citizens) or HBS as it was called, provided general education, with science and mathematics as important subjects and prepared students for admission to the Polytechnic School in Delft. The HBS was meant for sons of the middle class. Mr. Thorbecke advised on the content of mathematics for the HBS, the only subject on which he gave such an advice. He advised that algebra should contain quadratic equations, arithmetic and geometric series and the binomial theorem, not very different from the algebra in the Foundation of Renswoude. The HBS attracted many students. Towards the end of the 19th century the number of topics in school algebra had expanded considerably (Krüger, 2014b).

By the end of the 20th century the word 'algebra' had disappeared from textbooks, though algebra itself was very much part of the curriculum and caused a lot of debate in mathematics education (Drijvers, Goddijn, & Kindt, 2006).

Which role did algebra have in mathematics education from 1600 until 2000?

METHOD

Information on algebra in curricula from the seventeenth, eighteenth and nineteenth century was collected in the course of research on factors and actors which influenced the content of mathematics curricula in the past, from 1600 to the present (Krüger & Van Maanen, 2014). Archives, manuscripts and textbooks were an important source of data. For the twentieth century there are many sources: textbooks, articles in teachers' periodicals, the archives of the Ministry of Education, research journals, other publications on education research and curriculum development and the authors' own archives provide abundant data. For this paper only changes in the algebra curriculum are taken into account.

ALGEBRA IN THE CURRICULUM: 1600–2000

Seventeenth century: Leiden Engineering School, 1600–1681

Towards the end of the sixteenth century the Republic of the Seven United Netherlands had become rather successful in its war with Spain. The war was mainly fought around fortified towns, with help of new military techniques, which required mathematically well trained engineers. The expanding population in Holland and the strong economy also caused demand for military and civil engineers, surveyors and building masters. Prince Maurice of Nassau (1567–1625), one of the two commanders of the army and former student of Leiden university, arranged with the curators of Leiden university that an Engineering School would be attached to the university. Simon Stevin (1549–1620) wrote the formal curriculum, the *Instruction,* in which he stated the aim, the teaching language, the content, learning activities etc. (Krüger, 2010). The formal aim was to train military engineers as quickly as possible, the teaching language would be Dutch, hence the name 'Duytsche Mathematique' and the curriculum consisted of mathematical theory and practical exercises in surveying and in the basics of fortification. However, in a copy which the curators had made of the *Instruction* to have it printed, they slightly modified the aims into 'training in engineering or other mathematical professions'. The Duytsche Mathematique was going to be a course for engineers and also other mathematical practitioners.

Stevin did not mention algebra in the *Instruction*; evidently algebra was not yet useful for an ordinary engineer. But he mentioned the possibility of further study for those who had mastered the basic course in Duytsche Mathematique. Further study may have included cossic algebra, with different symbols for the unknown, its square, its cube, etc. and numerical values for known quantities (Figure 1), as used by Stifel in his *Arithmetica integra* (1544). The introduction by Viète, in 1591, of vowels for unknowns and consonants for known quantities, was an improvement, but the close link with geometry remained. Descartes used a more advanced notation in his *Géométrie* (1637) and allowed powers higher than third degree, which made algebra more useful (Figure 2).

The first teachers at the Engineering School were Ludolf van Ceulen, a respected mathematics teacher and advisor and Simon Fransz. van Merwen, a Leiden surveyor; not much is known about their interpretation of the curriculum. They both died in 1610 and were succeeded by Frans van Schooten Sr. (1581/2–1645), who was a student of Van Ceulen and Van Merwen and who had assisted Ludolf van Ceulen. His lecture notes in the library of Leiden university, *Mathematische Wercken* (BPL 1013) date from ca. 1620 (Van Maanen, 1987). They show the interpretation by Van Schooten of the *Instruction* and were also used by his successor, Frans van Schooten Jr. (1615–1660).

These lecture notes do not contain algebra, but the library of the university in Groningen possesses a manuscript by Van Schooten Sr., also a teaching text, on cossic algebra (Hs 443), which probably dates from ca. 1623 (Figure 1). The problems which are discussed in this manuscript were also used by Frans Jr. (Dopper, 2014). It is likely that Frans van Schooten Sr. taught cossic algebra in private lessons or to advanced students of the Engineering School. Frans van Schooten Jr. gave public lectures on algebra, using the cossic notation, though he knew the work of Viète and of Descartes very well. He produced a Latin translation

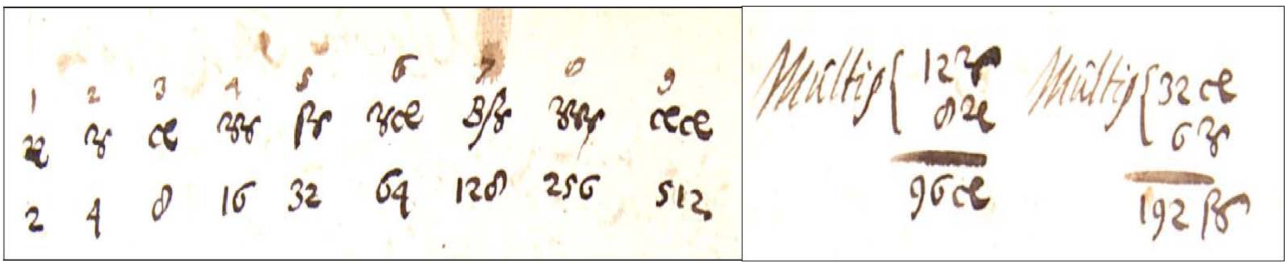

Figure 1: Hs 443, cossic symbols and examples of multiplication, by Frans van Schooten Sr.

of *Géométrie*, which made the work available to a much larger public.

Frans van Schooten Sr. was a mathematical practitioner, who worked as a teacher, surveyor and cartographer, also for the army. He had a good knowledge of mathematics and of the practice of surveying, mapping and fortification. Frans van Schooten Jr. was a very respected and well-known mathematician, but not so much a mathematical practitioner. He attracted a circle of talented private students, with whom he discussed Descartes' work. Dopper (2014) suggests that in his public lectures Van Schooten Jr. used cossic symbols instead of Descartes' notation for didactical reasons.

So there was some cossic algebra taught at the Engineering School, probably by Frans van Schooten Sr., certainly by Frans van Schooten Jr. At the start of the 17th century geometrical solutions for problems were common; gradually geometrical problems were more often translated into equations, algebra gained importance (Van Maanen, 1987, p.174–175). Van Schooten Jr. made occasional use of Cartesian notation in his *Mathematische Oeffeningen* (*Mathematical Exercises*, 1659), published shortly before he passed away. In 1672 Abraham de Graaf (1635–ca. 1717), a teacher of mathematics, astronomy and navigation in Amsterdam, published *De beginselen van algebra volgens de manier van Renatus des Cartes* (*The principles of algebra according to Renatus des Cartes*). In this book he treated the rules for operations, linear and quadratic equations and he gave many geometrical applications, but also other examples of use of algebra, using Cartesian notation (Figure 2).

So gradually algebra, with Cartesian notation, became more common.

However, surveyors, an important group of potential students for the Engineering School, were not particularly interested in new mathematical techniques, they did not feel a need to use algebra (Muller & Zandvliet, 1987; Morgenster, 1707; Van Nispen, 1662).

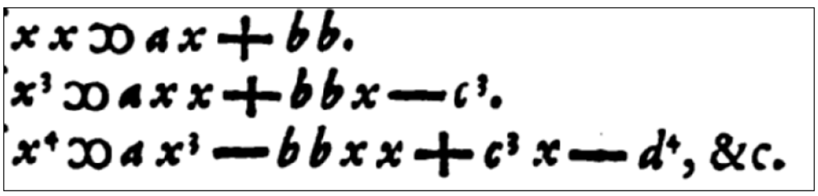

Figure 2: Cartesian notation in Algebra, by A. de Graaf (1672)

Eighteenth century

Several mathematicians contributed to the development of algebra during the seventeenth and eighteenth century (Grattan-Guinness, 2000; Struik, 1995). Examples are Wallis (1616–1703), who published his *Algebra* in 1685, Newton (1642–1727), Euler (1707–1783) and Lagrange (1736–1813). When in 1761 teaching started in the Foundation of Renswoude in Utrecht, algebra naturally was part of the curriculum. The Foundation was the outcome of the legacy of a Dutch millionaire, Maria Duyst van Voorhout, baroness of Renswoude. She bequeathed her capital to three orphanages, in Delft, The Hague and Utrecht, on condition that the money should be used to educate talented orphan boys, to prepare them for a technical profession (Krüger, 2014a). In her own words (translation by author):

> … select some of the most talented and suitable boys, at least 15 years old, to set them apart from the orphanage in order to teach them Mathematics, Drawing or Painting Art, Sculpture or Stone Cutting, practices in building dykes to protect our Country against floods or similar Liberal Arts…." (Utrecht Municipal Archive: *HUA* 771, inv. 1).

The Foundation thus aimed to educate selected boys for a wide range of technical professions. This meant that a large part of the teaching was on mathematical topics, with drawing as the second most important subject. In Utrecht the governors of the Foundation left the decisions on what mathematics to teach to the mathematics teacher. However, they took care to find an excellent teacher, with a good reputation for knowledge content and for teaching. Laurens Praalder (1711–1793) had no academic background; he had been teaching mathematics, surveying, navigation and other subjects, in the North of Holland and as mathematician and examiner at the Naval School in Rotterdam. In 1761 he accepted the position of mathematics teacher of the Foundation in Utrecht. Praalder indeed was an excellent teacher, who integrated mathematical theory with practical work and did physical demonstrations with his students. Through his extensive network he managed to find useful apprenticeships for many of his students. He also attracted private students.

The curriculum was divided into three phases, the first phase lasted ca. 2 years and was the same for every student; algebra was one of the topics in this phase. Praalder used his own teaching notes for lessons, but the students were also provided with books on all topics taught. During the first years of teaching in the Foundation, the governors bought mathematics books for the first and second phase, after consulting with Praalder. For geometry the choice was fairly simple; an edition of *Euclid* by Warius and a standard work on geometry and surveying by Morgenster, this book also contained chapters on trigonometry and logarithms. For algebra the choice was more difficult, as is clear from the different publications which were purchased during the first three years, for 11 students. Eight copies of a Dutch translation of *Elemens d'Algèbre* by Clairaux, eight copies of *Elements of algebra* by Hammond and six copies of *Algebra* by Venema, a Dutch author. After some years Venema became the standard book for most students, it offered a small amount of theory and many exercises. As Praalder taught the theory from his own notes, the students could use the book by Venema to make the exercises. Theory treated the principles of algebra, linear and quadratic equations and series.

A similar program for algebra was taught in 1776 by professor Hennert at the university of Utrecht, though ten years later he had diminished the amount of algebra taught (Bos, 1984). In 1789 the first three military academies were established in the Netherlands, their mathematics curriculum was similar to that of the Foundation. One of the students of the Foundation was appointed as a tutor to the military academy in Breda in 1789 (Krüger, 2014a).

Evidently algebra was considered useful as a tool for solving problems; geometrical and other problems. Formulating and solving linear and quadratic equations formed a major part of the content in teaching. Negative solutions of quadratic equations were sometimes ignored, so were complex roots. For most students this would be sufficient knowledge for their future career.

After Praalder retired, his colleague at the preschool of the Foundation, Dirk de West, was asked to take over the mathematics teaching in the Foundation. De West used copies of Praalders teaching notes, including the four bands on algebra, for his lessons. In later years four copies of Euler's *Elements of algebra* were bought, probably for the more advanced students, who could not be taught further by De West.

Nineteenth century

Characteristics of mathematics in the nineteenth century were: an increasing specialisation, more emphasis on the distinction between pure and applied mathematics and a striving for mathematical exactness (Grattan Guinness, 2000; Struik, 1995). The algebraic properties of numbers, the fundamental theorem of algebra, roots of equations, complex numbers and quaternions were some of the topics in which much development took place. The mathematics curricula of secondary schools were somewhat influenced by these developments.

In the Netherlands secondary education remained a matter of private initiative until 1863 (Krüger, 2014b). Industry and commerce required an educational system of good quality, which would offer subjects such as mathematics and science, modern languages and economics. Also the Royal Academy for Civil Engineers in Delft and the Royal Military Academy in Breda had problems with the relatively large number of students who entered with insufficient knowledge of mathematics and science. In 1863 the HBS, with a curriculum of five years, was Thorbecke's answer to these problems. The programme for algebra should enable the pupils to do well in the physics lessons. Also after the first three years of HBS the pupils should be able to pass the entrance exams of the Royal Military Academy and after passing the final exams a student should be ready for the Polytechnic School, the successor of the Royal Academy for Civil Engineers. The mathematics teachers at the HBS had to have a university degree or an equivalent teaching degree.

Mathematics was one of the 18 subjects taught in the HBS and one of the 16 subjects in the final exams. Mathematics was subdivided into several topics: arithmetic, algebra, plane and solid geometry, trigonometry and descriptive geometry. The final exams on mathematics consisted of four exams: arithmetic/algebra, geometry, trigonometry, descriptive geometry. Mathematical and science subjects took ca. 33% of teaching time, the same amount as the four languages and literature. Mathematics received ca. 18% of the teaching hours, more than any other subject (Steyn Parvé, 1868).

Until about 1890 most students at the HBS did not take the final exams. Many students left school after the first three years, to sit for entrance exams for a range of professional institutions or to enter the workforce. The content of mathematics in the first three years consisted of arithmetic, algebra and geometry, usually 2 hours each in every year. During the first three years of algebra the pupils were taught the main operations, also with fractions; roots, powers, negative and fractional exponents; linear and quadratic equations and sometimes also equations of degree higher than two, exponential equations and indeterminate equations. In year four and five there was more difference between schools in the choice of topics. Newton's theorem (an extension of the binomial theorem), factorizing, combinations and permutations, infinite series, convergent series, continued fractions, limits, theory of irrational numbers and complex numbers were topics which were taught, but not in all schools. The exam syllabus, introduced in 1870, mentioned arithmetic and geometric series, Newton's theorem, indeterminate and exponential equations. Teachers and textbook authors included topics outside the prescribed exam syllabus for various reasons, i.e. the topic occurred in entrance exams of some institutions or the topic was of educational or didactical value. There were many different textbooks available, most of them written by teachers of HBS or gymnasium (the former Latin school).

By 1899 the authors of a popular textbook on algebra explained that they had not included the theory of irrational numbers, as there was no time to treat the topic with the necessary exactness (Derksen & De Laive, 1899). Gradually, the topics which were not in the final exams would be treated in fewer schools.

In the Polytechnic School algebra would be used in analytic geometry and in analysis. There were occasional complaints about lack of skills of first year students, but overall the results of the first year students in these topics were satisfactory (*Onderwijsverslagen*, 1866–1876 [Education reports to Parliament, 1866–1876]).

Twentieth century

Groen (2000) presents a concise overview of changes in the mathematics curriculum of the HBS between 1900 and 2000. In 1937 a new mathematics curriculum for the HBS was introduced, after many fruitless attempts to modernize the curriculum. Differentiation and integration, number theory, functions and graphs were some of the new topics. However, the exam syllabus did not change and so the topics in the final examinations remained the same. As the final exams had gained considerable importance since the start of the HBS, this meant that the new curriculum did not have much influence on the lessons. In 1958 a new curriculum was introduced, this time including a new exam syllabus. Analytic geometry, differentiation and integration were part of the new curriculum; descriptive geometry was at long last abolished. There was less emphasis on extensive calculations in algebra.

In 1963 new legislation introduced a new structure for secondary education; the HBS was replaced by new types of school. The pupils should receive general education and preparation for entrance into higher education (Van Kemenade, 1981). The new curriculum started in 1968; it was influenced by the ideas of 'New Math', as happened in many countries. For a short time algebra was fairly abstract, with emphasis on formal language and sets. Algebra was mainly taught in the first three years of secondary schools; pupils in higher years were supposed to make use of algebraic techniques in differentiation, integration and analysis. In the 1970's, new teaching methods for lower secondary schools were introduced, exercises in algebra were based on realistic situations (contexts); the use of tables, graphs and simple formula's was emphasized (Kindt, 2000). In 1998 new exam syllabi for upper secondary schools were introduced, these contained topics such as graphs, functions, combinatorial analysis, matrices, analysis and differentiation and integration. It was a very full curriculum, but as at the same time the graphic calculator was introduced into the schools, the curriculum designers assumed that the use of a graphic calculator would save much time. This curriculum was supposed to improve transition to higher education and also to provide general education. One of the many reasons it didn't work as expected was the lack of algebraic skills with which students entered upper secondary school. Another reason was the lack of training of teachers in the use of graphic calculators in teaching (Krüger, 2014b).

CONCLUSION

From the mid-seventeenth century algebra was recognized as a valuable topic in mathematics education. The content expanded from mainly arithmetic with letters and modelling problems in linear and quadratic equations to a variety of topics at the end of the nineteenth century. Algebra in the curriculum of the HBS was considered useful for physics; it also was part of the preparation for technical studies. In the twentieth century the emphasis shifted, at first from elaborate calculations to a more formal approach of structures, following that with an emphasis on global understanding and modelling of 'realistic problems'. At the end of the twentieth century there were many complaints about (lack of) algebraic skills, made by teachers from universities and colleges, by high school teachers and gradually also by other people who felt the need to make their point. It is interesting to note that this type of complaint was also made in the nineteenth and the first part of the twentieth century. It is evident however that the introduction on a large scale of new learning materials, graphic calculators and software for algebra, is bound to have a large impact on the learning of algebra (Drijvers & Van Reeuwijk, 2006; Goos, Galbraith, Renshaw, & Geiger, 2003). These developments should have a large impact on teacher training and teaching methods as well. These aspects received insufficient attention from nearly all those who were involved.

E-Dynamic.Space: A 21ST century tool to stage-manage and build experience in the field of the history of mathematics and its teaching

Caroline H. Kuhn

Bath Spa University, Bath, UK, c.kuhn@bathspa.ac.uk

This study aims to answer the question of how can the history of mathematics resort to a digital tool – E-Dynamic.Space – designed by teacher-students and intended to serve as a workbench not only to create supportive knowledge from historical material, which has proved to support the understanding of mathematics but, also to orchestrate both, their actual learning of the tangent line problem and their future mathematics teaching experience. It therefore explores aspects for the design of the teaching activities, and it analyses the 'whys' and 'hows' of including the historical dimension into the teaching experience. It is part of a bigger research project that looks at how can teacher-students favour from a historical informed pedagogy of mathematics that uses a personalised learning environment as a means to learn.

Keywords: Digital tool, PLE, orchestration, tangent line problem, teacher education.

INTRODUCTION

Digital technologies are the landmarks of the 21st century, ubiquitous and bearers of social identity for the majority, especially young people (Boyd, 2014). In what way can digital technologies support 'history in mathematics education', which is understood here as the learning of mathematics supported by the integration of elements from the history of mathematics. Researchers of mathematics education call for more research of digital technology (e.g., Hoyles et al., 2010; Trouche & Drijvers, 2014), and this paper extends their call to the integration of supportive knowledge created by teachers (Kuhn, submitted at the 7th ESU in History and Epistemology of Mathematics) using web-based tools, which have their own possibilities and difficulties. In this paper, digital technologies are understood in a broader sense, not only as mathematical software but also as web-based tools and social media, which brought together by the end user in a flexible digital environment will constitute what I will call from now on personalised learning environment (PLE) (Buchem, 2010; Kuhn, 2014a[1]).

Teachers have to keep up to date with young students' mind-set and expectations, and the advancement of digital technologies. On the other hand teacher-students need support in being prepared in a sensible manner for their job in the near future and to move confidently in this new ecology of digital resources (Luckin et al., 2012). There is evidence that shows how designing and developing a PLE will improve the digital skills of the end-user (Wild et al., 2008), teacher-students in this particular case.

How can teachers explore the affordances[2] of digital tools, take advantage and build experience in the digital world and in the field of history and mathematics, integrating them for the learning of mathematics and further teaching? Looking for possible answers I propose a PLE, E-Dynamic.Space (Kuhn, 2014a) as a 21st century self-management tool, designed and populated with new content created by teacher-students to support them in the design and organisation of the learning experience.

My proposal aims to address not only how to stage-manage the learning of mathematics but also to explore how teacher-students can create supportive material from historical sources, which has proved to support the understanding of mathematics (Kuhn, submitted op. cit.), using the E-Dynamic.Space as a tentative tool for constructing meaning or in words of Noss & Hoyles (1996), webbing[3] in the process of grasping and understanding the tangent line. The tangent line has been chosen as a starting point that will set the ground of a number of concepts to develop (as a mid term goal of the project) in order to craft a more unified and connected way of teaching the background concepts of calculus for GCSE and A-levels in the UK.

In a first stage of the project I will focus on the design of some of the teaching activities I propose for teacher-students and in a second stage, not addressed in this paper, I will look at how they can transfer these skills to their classroom practice and improve the learning experience of their pupils. Empirical evidence indicates that following the work of teacher-students during "a time long enough to be able to catch real changes (a) during a program, (b) immediately after the program, and (c) one or more years later, can assist in providing valid feedback mechanisms for professional development programs" (Trouche et al., 2013).

SOME THEORETICAL ASPECTS FOR THE DESIGN

Troublesome Knowledge

The introduction of analytic geometry revived the tangent line problem in early 17th century. Descartes in his 1637 work La Géométrie described the problem of finding a tangent line to a given curve at a specific point as:

> (...) the most useful and general problem in geometry that I know, but even that I have ever desired to know. (Smith & Latham, 1925, p. 95)

Reading this sentence in combination with my interest in the calculus as a rich topic, both historically and conceptually, made me wonder why would an intellectual of the calibre of Descartes find this problem so useful and worth knowing. Although I was motivated and thrilled to know more I encountered difficulties while finding my way into Descartes' ideas. I found myself confronted with some trouble, or maybe with troublesome knowledge? But what exactly is troublesome knowledge and what it has to do with the history of mathematics in mathematics education? The notion derives from a research project in the UK looking to identify key factors leading to high quality learning environments in higher education, very much in line with the aim of my own research. The idea is associated with threshold concepts, conceptual gateways that have the potential to open up new conceptual spaces transforming the way learners understand the subject matter (Meyer & Land, 2005). Threshold concepts, although usually attached to particular concepts, sometimes they are not necessary concepts in any rigorous sense but different ways of thinking and practicing with a threshold-like nature, all of them providing entrance in one sense or another to a new or different conceptual landscape (Meyer & Land, op. cit.). Transformative ideas, and it is in this sense that I am using the term.

These ways of thinking and practicing, often lead to what Perkins (2006) describes as *troublesome knowledge*, knowledge that is conceptually complex, alien or counter intuitive, thus challenging students' beliefs and intuitive knowledge but at the same time, developmental productive. This is in line with Barbin's idea within mathematics education, of *depaysement* or reorientation, challenging student's perceptions, making the familiar seems unfamiliar. History shows also how mathematics is a human understanding, a history of human beings disabling or extending established ideas, allowing the learner to see mathematics as much more than disconnected algorithms or discrete chapters, integrating the subject in a sociocultural context.

Why and how to use this historical knowledge in mathematics education?

The previous section introduced, in a general way, some of the reasons for using history of mathematics in teacher education. Adding to this Jankvist (2009) answers this question in a more focused and didactical oriented way connecting it with content knowledge, suggesting that history can be used as a goal or as a tool. In particular he refers to a cognitive tool for the learner (teacher-student in this particular case). In this latter sense he implies the idea of epistemological obstacles (Jankvist, 2013). Brousseau (1997) highlights in this regard that knowledge exists and it makes sense only because it represents an optimal solution in a system of constraints. For him, history can be illuminating in finding those systems of constraints. Sierpinska (1994) suggests: "epistemological obstacles are not obstacles to right or correct understanding: they are obstacles to some change in the frame of mind." (p. 121)

Dimensions of knowledge in teacher training that can profit from the history of mathematics

One of the aims of our community for the history and pedagogy of mathematics is to find ways in which teacher-students can profit from the history of mathematics for their learning/teaching experience. In each profession there are core skills and knowledge to be mastered. In mathematics education, Ball and colleagues (2008) have developed a theoretical framework, Mathematics Knowledge for Teaching (MKT), proposing the kind of knowledge demanded by the teaching profession. This framework has been explored recently by Clark (in press), cited by Jankvist and colleagues (2012). She contextualised it in the history of mathematics exploring how the history can add to teachers' MKT. In this work I will use three of the six dimensions of the model: knowledge of content and curricula (KCC); knowledge of content and students (KCS), and horizon content knowledge (HCK), in order to see how teacher-students' knowledge can potentially profit from and be enhanced by the history of mathematics. This choice responds in part to a call that Jankvist (op. cit.) has made to address the absence of clearer links to general mathematics education research frameworks. This theoretical construct –the MKT- seems to have productive implications for teacher education (Jankvist, op. cit.).

Epistemological obstacles and conceptual development, and its association with the Mathematics Knowledge for Teachers

Tracing the historical development of a particular concept, following Brousseau (op. cit.) is a way to understand the constraints of each time, hence to understand some of the epistemological obstacles involved in the development of an idea. Connecting epistemological obstacles with the didactical situation of teacher-students is possible through the idea of conceptual development, which has been researched for didactical purposes by different authors (e.g., Vosniadou, 1994). The general consent is that for conceptual change to happen there must be, in the student, a cognitive conflict or a 'stuck place' in words of Meyer & Land (2005), a difficult stage in the conceptual development as it confronts them with different epistemological obstacles (Brousseau, 1997) blocking any transformation in the cognitive realm. Teachers are responsible to identify the sources of those obstacles and free them up making the change possible. In this regards, teachers ought to develop knowledge of content and students (KCS) (Ball et al., 2008).

This 'stuck place' is similar to what happens to the collective culture of mathematicians throughout the development of an idea. Teachers can look closely at these epistemological obstacles in order to find inspiration and knowledge to identify possible sources of obstacles in their students. This kind of understanding can also improve teachers' knowledge of content and curriculum (KCC) allowing them to make a historical informed decision in relation to the breadth and depth they should teach in the different key stages. All of the above seems to add to a wider kind of knowledge, one that goes beyond the basic knowledge teachers need to deploy in class. Following Ball & Bass (2009), it is called horizon content knowledge (HCK), and they describe it as " (...) an awareness – more as an experienced and appreciative tourist than as a tour guide – of the large mathematical landscape in which the present experience and instruction is situated" (p. 6). This kind of knowledge "confers a comprehensible sense of the larger significance of what may be only partially revealed in the mathematics of the moment." (p. 6). There is evidence (Mota, 2008; van Maanen, 2009) that this knowledge will profit from the history giving teacher-students a wider breath of the mathematical cultural context of a particular idea to be taught.

Having explored the whys of using history in teacher education and looking at how the mathematics knowledge for teaching can be enhanced by the use of historical material, let us look at how can this material be integrated in the teaching experience. Taking into account the varied background of Bath Spa University PGCE students (PGCE responds to Post Graduate Certificate in Education and it is a one year program for students with different backgrounds that want to become teachers), I decided to follow Tzanakis and Arcavi's (2000) idea of *historical packages* in which a mathematical topic (in my case the tangent line problem) from the curriculum is taught by means of historical materials in a relatively short period of time; similar to Jankvist's approach with historical modules.

How can a teacher-student get involved with the history of mathematics in order to gain a deeper understanding of the epistemological development of the concept and also take advantage of the affordances of the PLE and its available tools? One way to do this is through the activities proposed below for which the didactical intention is underpinned by the idea of webbing described previously. There is also a wider mathematical aim and it is to explore in depth the development of the tangent line problem in order to gain a deeper understanding and a wider vision, in epistemological terms about the historical process of the definition of the derivative in terms of the limit; for that the tangent line is key. In words of Whiteside (1961): "It will be illuminating therefore, to discuss the particular methods invented to resolve the tangent-problem, and this will yield a truer perspective on the *elegant general treatments which were later abstracted from the particularised methods of the mid-century* [emphasis added, p. 348]." History shows that the starting point of that definition was neither limits nor the differentials or fluxions. It has been a process of successive abstraction (Lehmann, cited in Swetz et al., 1995), which is what we aim to trace with this module.

THE HISTORICAL TOUR: FROM EUCLID TO FERMAT

In this section I will describe briefly what teacher-students will explore during the sessions. The online sheets and the web-based tools are allocated in the PLE, which they will further populate with their own creations. The didactical intention is that the learner generates new supportive knowledge as a product of webbing while exploring the historical material, making sense of new chapters of the tangent line's history. Teacher-students will course from Euclid to Fermat and reflect around the systems of constraints of each period identifying the epistemological obstacles and the change in the collective frame of mind. In doing so they will become the appreciative tourist of the larger mathematical landscape as they advance in their epistemological tour.

We need to bear in mind that there is this unavoidable risk – clearly explained by Fried (2001) – of doing 'Whig history'. In order to address this issue (though not sure to completely avoid it) an initial reading of his paper (2001) is assigned to the group.

Time and allocation of session is to be determined

As an integrative and final activity for webbing the learning of the topic and also intended to develop the epistemological understanding of the concept, students will create an interactive timeline with at least two of the resources created by them through out the module. They need to add the group reflections where pertinent and illustrative, as well as the relevant comments posted in Padlet. Highlighting new frames of mind is important in this task. The interested reader is invited to follow the link[9] to explore the PLE with man examples of sheets and resources, as well as a time line crafted by the author to explore the affordances of the tool.

DATA COLLECTION AND THE PROCESS OF WEBBING THE UNDERSTANDING OF THE TANGENT LINE PROBLEM

As suggested by Barbin and colleagues cited in Fauvel & van Maanen (2000), we can evaluate the effectiveness of introducing a historical dimension into teacher education through an examination of each of the processes involved in the development of understanding, namely, the change in how teachers perceive and understand mathematics which generally is reflected in the way they subsequently will teach, and finally in the understanding and perception of their pupils about mathematics. None of those processes can be captured in a quantitative approach, instead a qualitative and holistic method is much more desirable for understanding more in depth how to best integrate historical material into the teacher experience. Therefore qualitative data will be gathered (with the proper software, e.g., Camtasia) in their online public and private spaces. There is also a reflective logbook with didactical prompts (still under development) for each student to document their learning; the process of webbing the tangent line problem making sense of the different frame of mind and the historical development of the concept studied. The prompts will trigger in the student the cognitive processes that will help them to describe their main struggle when trying to elaborate the resources. In particular the timeline is considered a rich intellectual artefact with the potential to uncover partial understandings of the student in relation to the epistemological advancement of the concept. What resources they choose, what they consider to be an illustrating example and how they justify it will reflect students' process of constructing meaning throughout the task. An important aspect of the learning experience will be the idea of extending the web of ideas and intellectual resources (at the beginning of the journey) and re-structuring it as a result of the connections made for the learner to be able to find and construct meaning through the sequence of activities he/she is doing including discussion and reflection.

Author	Resources	Task + Question + Reflection
Euclid	Book III, def. 2 and prop. XVI Online version of Oliver Byrne[4]	Go through the definition and work out the proposition in your group, post your work in padlet[5] for a common discussion. Have a look at other posts and comment on at least one+reflect
Apollonius	a. Module of the MAA: 'Tangent line then and now'	Read the extract about Apollonius method. Interact and explore the GeoGebra example and discuss with your peers your thoughts, difficulties and any 'aha' moment.
	b. Treatise of conic section. Heath translation 1896. Online[6]	Go through proposition I.33 and discuss, try to make sense of it with your peers. Find the analogue elements with the MAA method and document the process in your logbook. Pay special attention to any difficulty in understanding any of the parts, documenting it for further thinking in the group discussion.
	c. Working with online sheets in GeoGebra[7]	Work in pairs and interact with the sheets for finding the tangent line to a parabola. Produce your own example in GeoGebra, record the steps in the sheet and post it to GeoGebra Tube. Do one of the sheets posted by your peers, comment your experiences in Padlet (difficulties + ahas + findings + remarks). Reflect on the system of constraints you think could be present in that period and what implications do they have in the method you just did. Read and comment on one post in the wall
Descartes	a. Look at the video[8] by Jeremy Gray about the history of the calculus. b. The History of mathematics (Fauvel, J & Gray, J.) Section 11.A10	Watch with particular care the section where the method of Descartes to find the tangent line is explained. Read section 11.A9 to complement. Make notes for a discussion session with the group about the steps of the procedure. Try it your self with a simple curve ($y=x^2$) and document the process. Work in a small group for a richer and more reflective discussion.
	Online GeoGebra sheets in the PLE	Go to GeoGebra and do the sheet with Descartes' method. Take notes about things that were important for you to accomplish the task, key ideas. Think about your own difficulties along the exercise and write them down for a common discussion. Try to write about the new mathematical features introduced in his method and compare it to Apollonius' one. Reflect about the system of constraints in Descartes' time and think about the new frame of mind introduced then. Think about the implications and epistemological difficulties of a more general method comparing it to the Greeks (section 11.A10)
Fermat	The history of mathematics (Fauvel, J & Gray, J). A copy of the relevant text of module 9 of the Open University course: Topics in the history of mathematics	Read section 11.C – 11.C1b. Tinker with the method. Try to create your own example working with a curve that you feel comfortable with (use pencil and paper). Make notes about your process and document any difficulties. Think about the *adequate* method he used, trace the history of the term and give meaning to it in that context. What was the problem then? Can you see why Fermat could work with a wider range of curves? Go to GeoGebra, work through the sheet. Once you have understood the method create your own sheet with its animation and uploaded it to GeoGebra Tube. Try out one of the sheets of your peers and comment on his/her work. Reflect on the steps taken by your peer.

Table 1: Sources and questions in relation to the tangent line problem

A session will be dedicated to reflective writing and how to do it in a way it can enhance their own learning process. The three dimensions, specified above, of the MKT framework will be explained in detail and their reflections will be stated in terms that make reference to these dimensions so consistent evidence can be collected (still an idea under development). The prompts given in the activities are focused in the mathematical features that have been shifting from time to time and are intended to bring students to reflect on how those changes have transformed the tangent line problem into what we know today giving them a wider background knowledge or in words of Ball & Bass (op. cit.) enhancing their HCK. Important ideas to grasp along the learning experience are the optimal solutions in a system of constraints stated above by Brousseau and the change in the mind frame argued by Sierpinska.

The module has not been tried out yet therefore a real and fruitful discussion will be part of a next piece of research, where the data will be collected and analysed, and hopefully the analysis will shed some light to the rich discussion in relation to the benefits of the integration of history for the mathematics education community.

The history of the fourth dimension: A way of engaging pupils in secondary classrooms

Snezana Lawrence

Bath Spa University, Faculty of Education, Bath, UK, s.lawrence2@bathspa.ac.uk

The National Curriculum in England has, over the past decade, been revised a multitude of times. Disengagement of pupils was one of the reasons for revisions. In September of 2014, a new curriculum in mathematics was introduced, aiming to give greater freedom to teachers and schools to construct a curriculum and teaching episodes that are engaging and appropriate for their students. This paper investigates how such episodes can be constructed through the investigations based on historical development of mathematical concepts and how they could easily link to the new curriculum, offering at the same time greater opportunities for pupils' engagement. The history of the fourth dimension is one such possible topic, and the paper suggests a way of using it in a secondary classroom.

Keywords: Fourth dimension, engagement, Schläfli, Stringham, Flatland.

INTRODUCTION

In the decade between 2004 and 2014, mathematics curriculum changed twice, about fifty reports on mathematics education in the country have been published, and seven different Secretaries of State for Education passed through the British Parliament. Each of the changes and reports suggested that the state of mathematics education in Britain is troublesome; the causes were identified, the evidence was given (in either a narrative or analytical format), and of course the suggestions to improve the situation were recommended.[1] The most troublesome of all troubles listed was the perceived irrelevance of mathematics and the lack of desire to engage with it.[2]

When exploring the issue of disengagement, teachers reported that it was the curriculum that narrows down the topics and the lack of choice to engage with different topics from the curriculum that was at the basis of the problem.[3] The organizations such as National Strategies (discontinued 2010) previously tried to help teachers devise teaching episodes and gave suggestions on pedagogy. The new curriculum instead offers an element of autonomy, meaning that schools and teachers are given freedom to choose and design the topics and teaching episodes appropriate to their environments. Likewise, the curriculum itself lists the skills and knowledge to develop in pupils, but gives no (or minimal) guidance as to the choice of topics.

The choice of topic described in this paper – the history of the fourth dimension – arose from two experiences: of working with gifted and talented pupils some years ago on the representations of the fourth dimension in mathematics (Lawrence, 2012) and the engagement reported in alternative curricula, such as, for example, Steiner system, which introduces projective geometry and the study of the fourth dimension in the final years of secondary school (Woods et al., 2013).

The paper thus first gives a historical overview of the topic, and then investigates the possible pedagogical approaches to develop material based on certain principles listed. It concludes by showing how an unorthodox topic such as this, can nevertheless be easily linked to the new curriculum and the skills and knowledge it aims to develop in pupils. The engagement is expected but not yet empirically proven; this is proposed as a possible future study, and some initial experiments from schools in which the teaching pedagogy is trialed are described.

HISTORY OF THE FOURTH DIMENSION

Whilst the concept of the fourth dimension was developed in the nineteenth century, the origins of it could be traced as far back as the antiquity in the most possibly wide sense of conceptual development. Aristotle for example, discussed it in *De Caelo*,[4] and Ptolemy denied and disproved it but nevertheless mentioned and contemplated upon it (Cajori, 1926, p. 397; Heiberg, 1893, p. 7a, 33). John Wallis, although writing this whilst considering geometric interpretations of quantities he was developing in the context of algebra, wrote (Wallis 1685, p. 126):

> A Line drawn into a Line shall make a Plane or Surface; this drawn into a Line, shall make a Solid: But if this Solid be drawn into a Line, or this Plane into a Plane, what shall it make? A Plano-Plane? That is a Monster in Nature, and less possible than a Chimaera or Centaure. For Length, Breadth and Thickness, take up the whole of Space. Nor can our Fansie imagine how there should be a Fourth Local Dimension beyond these Three.

With the French Revolution, some revolutionary mathematical thinking happened, and Lagrange in particular, spoke of three coordinates to describe the space of three dimensions, introducing time as the fourth, and denoting it *t* (Lagrange, 1797, p. 223).

The reader is reminded that this can by no means be an exhaustive study, but is a sketch of the history of the fourth dimension and the narrative given is but a thread that will later be examined in possible educational setting and application to teaching.

Let us then trace further historical development. The first such opportunity was the example of Möbius and Zöllner. Möbius (1827) first spoke about an object getting out of a dimension it belonged to in order to perform a spatial operation. If one had a crystal, structured like a left-handed staircase, how would one get its three-dimensional reflection? Zöllner (Johann

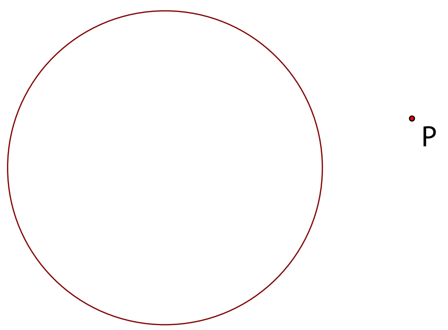

Figure 1: Zöllner illustrates that in order to perform certain operations in space, objects must exit their current dimension (Zöllner, 1878)

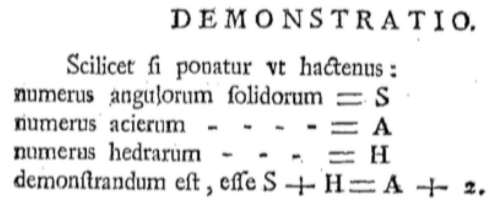
Friedrich, 1834–1882) further simplified this. If one has a circle and a point outside of it, how can one get the point into the circle without cutting or crossing over the circumference?

In 1852, Ludwig Schläfli (1814–1895), a Swiss mathematician published a book *Theorie der vielfachen Kontinuität, (Theory of Continuous Manifolds)*, in which he wrote about the four dimensions. Schläfli looked at *Elementa doctrinae solidorum* published in 1758, in which Euler described for the first time what was to become known as *Euler's characteristic*, the expression which conveys the information that in all convex solid bodies the sum of the solid angles and the number of faces is equal to the number of edges add 2.



DEMONSTRATIO.

Scilicet ſi ponatur vt hactenus:
numerus angulorum ſolidorum = S
numerus acierum - - - - = A
numerus hedrarum - - - = H
demonſtrandum eſt, eſſe S + H = A + 2.

Figure 2: Euler's characteristic first described in *Elementa doctrinae solidorum*, 119

We now usually denote Euler's characteristic by Greek letter chi and describe it for convex polyhedra $\chi = V - E + F = 2$, where V is the number of vertices, E is the number of edges, and F is the number of faces in a polyhedron. If we further analyze the formula we notice that we begin from the first variable which counts points (point we earlier took to represent 0^{th} dimension); the second variable which numbers the edges in a solid, (representing line, 1^{st} dimension) and the third variable, numbering the faces of a solid, (polygon is bound part of a plane, representing the 2^{nd} dimension).

Schläfli (1852) showed that this formula is also valid in four dimensions or indeed any higher dimension. We will get there – but let us first look at how he first defined a system which would describe any regular polytope in any dimension.

There is only one polytope in 1^{st} dimension, a line segment, and the Schläfli symbol denoting this is {}. Regular polygons in two dimensions are, for example, triangle {3}, square {4}, pentagon {5}, etc. Remembering that he only used these symbols to denote regular polytopes, we continue. In three dimensions the five regular polyhedra, Platonic solids, can be described as {3, 3} – tetrahedron has three-sided polygons that meet three at each vertex; {4, 3} – cube has four-sided polygons three of which meet at each vertex; {3, 4} – octahedron has three-sided polygons four of which meet at each vertex; {3, 5} – icosahedron has three-sided polygons five of which meet at each vertex; {5, 3} – dodecahedron has five-sided polygons, three of which meet at each vertex (Schläfli, 1852).

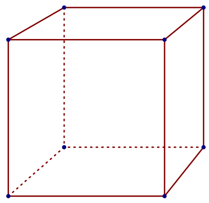


Figure 3

Schläfli realized and showed that Euler's characteristic can be represented in a slightly different form: he stated that $V - E + F - C = 1$, in effect stating that the number of vertices, minus the number of edges, plus the number of faces, minus the number of cells, equals 1. Cell in three dimensions is a solid (convex); so for a cube this formula would be:

8 (vertices) – 12 (edges) + 6 (faces) – 1 (cell) = 1

He then showed that the minus plus pattern continues with even dimensions (0th, 2nd, etc.) having positive value and odd (1st, 3rd, etc.) negative. This was a big breakthrough: by extending the validity of Euler's characteristic to the fourth and any other higher dimension, Schläfli showed that it was possible to calculate various characteristics of four-dimensional polytopes if we had certain other information. This also meant that the four-dimensional solids could be now identified, classified, and studied.

The mathematical description of generating the fourth (and higher dimensions) was first given in an elegant way by William Stringham (Stringham, 1880, p. 1):

> A pencil of lines, diverging from a common vertex in n-dimensional space, forms the edges of an n-fold (short for n-dimensional) angle. There must be at least n of them, for otherwise they would lie in a space of less than n dimensions. If there be just n of them, combined two and two they form 2-fold face boundaries; three and three, they form 3-fold trihedral boundaries, and so on. So that the simplest n-fold angle is bounded by n edges, $\frac{n(n-1)}{2}$ faces, $\frac{n(n-1)(n-2)}{2}$ 3-folds, in fact, by $\frac{n!}{k(n-k)!}$ k-folds. Let such an angle be called elementary.

Stringham tried to illustrate this in his paper in the following manner (Figure 4).

The study of the dimensions became something of a vogue in the 19th century and many a famous mathematician, from Graßman (1844), Riemann (1854), Clifford (1873) and Cayley (1885) to name but a few, wrote on it. But how to translate this into a classroom experience for teenagers? A novel from 1884 may give us some guidance on that.

NARRATIVE ABOUT LIFE IN DIFFERENT DIMENSIONS

The introduction to 'dimensionality' could be given and illustrated finely through the metaphor about *Flatland*, the 19th century English mathematical novel written by Edwin Abbott Abbott (1838–1926), a London schoolmaster and Shakespearean scholar. Flatland is a land that is flat. It is (Abbott, 1884, p. 2):

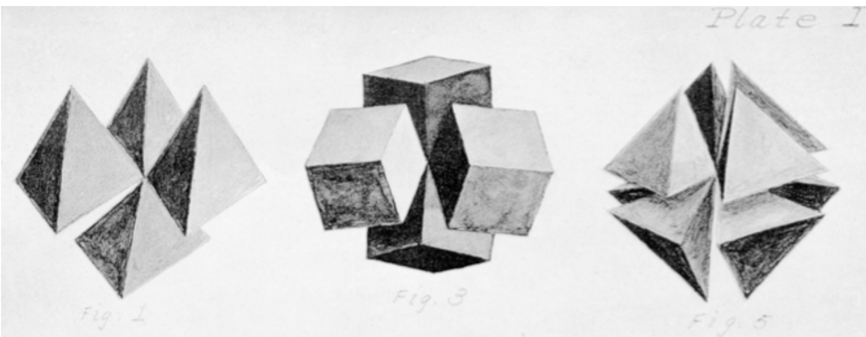

Figure 4: These represent 'respectively summits, one in each figures of the 4-fold pentahedroid, oktahedroid, and hexadekahedroid, with the 3-fold boundaries of the summit spread out symmetrically in three dimensional space' (Stringham, 1880, p. 6)

> like a vast sheet of paper on which straight Lines, Triangles, Squares, Pentagons, Hexagons, and other figures, instead of remaining fixed in their places, move freely about, on or in the surface, but without the power of rising above or sinking below it, very much like shadows – only hard and with luminous edges – and you will then have a pretty correct notion of my country and countrymen…

Flatland, whilst it gives opportunities for many discussions to be brought into the mathematics classroom, also offer a good introduction to the bigger questions that are not easily dealt with in mathematics education. Abbott for example raises the question of ethics and the place of women in the world as he knew it. The two dimensional beings who are stuck in the two dimensional reality are also stuck in the belief that women should be treated in a different way to men. One of illustrations from this strange world shows that very clearly.

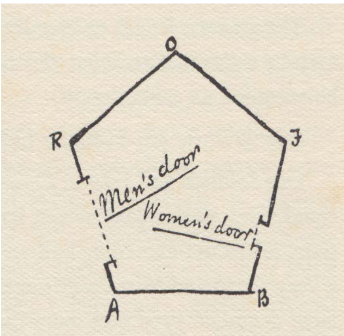

Figure 5: The most common construction for a house in Flatland, with separate doors for men and women

Apart from the social dimension, Flatland further offers ample opportunities to introduce some higher order thinking about 'big' questions in mathematics – what is the nature of space for example and how many (real) dimensions does it consist of? The question of dimensionality is in the book introduced with an almost mystical experience that the main protagonist, Square, has when he meets Sphere. First the Square saw Sphere through Sphere's intersection with the Flatland, but eventually Sphere spoke the Square. And the 'mystical' wasn't that after all as Sphere explains (Abbott, 1884, p. 77):

> Surely you must now see that my explanation, and no other, suits the phenomena. What you call Solid things are really superficial; what you call Space is really nothing but a great Plane. I am in Space, and look down upon the insides of the things of which you only see the outsides. You could leave this Plane yourself, if you could but summon up the necessary volition. A slight upward or downward motion would enable you to see all that I can see.

Of course Sphere is, similarly to Square, stuck in his own world of limited dimensions and when, towards the end of the novel, Square regurgitates the analogy between dimensions and speaks of projections of fourth dimensional bodies in three dimensions, the Sphere explains a simple "Nonsense!" – of course there are no higher dimension than that which he could experience.

What Flatland offers is an introduction to the discussion about dimensions in mathematics that can lead to asking pupils to imagine a life in dimensions different to the ones they are used to. What if they lived in two dimensions? How would they see the friend sitting next to them? Equally what if they lived in four dimensions? What would they and their friends look like?

SOME SERIOUS MATHEMATICS, BUT HOW TO DO IT IN THE CLASSROOM?

We will now turn to examining points we have so far mentioned on our way from Aristotle to Flatland and suggest a way of constructing a narrative and teach-

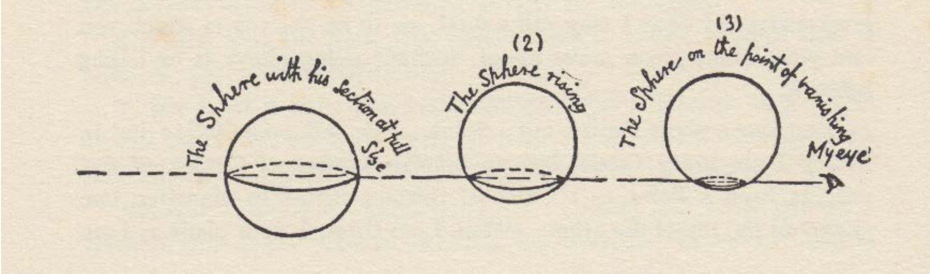

Figure 6: The diminishing sphere leaving projections in Flatland, its cross sections being circles, p. 72

ing episodes that could be used to engage teenagers in a classroom setting.

A Firstly, the trace we plotted of discussions about dimensionality stretch different times, cultures, and geographies. By analogy there could be some new mathematics born just right here and now, from their own thoughts and ideas. We mention philosophers and mathematicians that span twenty three centuries. The development of mathematical ideas can be employed in the classroom in various ways: from construction of timelines to open-ended discussions about the nature of mathematical inventions, and the contributions that are possible in this field.

B We begin with defining of the fourth dimension by musing about our ability to describe it mathematically. Both Wallis' and Lagrange's descriptions could be used in the classroom to give possible interpretations from different context and offer an insight into how new mathematics begins. In this way the way to model behaviors and attitudes may begin to emerge, and pupils may feel emboldened to pose new questions, mathematical exploration is thus brought closer to the classroom practice. A teacher can illustrate this by examples and geometric diagrams from original works some of which are mentioned above and listed in bibliography, and some interpretations illustrate also this paper.

C We meet with the study of Platonic solids. This is a rich field in the history of development of mathematical concepts that also spans centuries, and can be investigated in the classroom in a number of ways. For example, construction of Platonic solids, their representations in art (Emmer, 1982), and the study of Platonic solids by Euler are some instances that could be used as starting points for activities. Students can derive formula for Euler's characteristic and further investigate it in the light of Schläfli's extension of it.

D We come across various mathematical descriptions and symbols – the development of notation and formulae gives pupils opportunities to engage with the process and attempt to do the same/similar themselves in their own contexts. Teachers can work with pupils on Euler's, Schläfli's, and Stringham's algebraic formulations and discuss their different approaches: Schläfli symbols are also an interesting way of presenting geometrical entities.

E Finally the depiction of how life would exist in different dimensions and the consequences for our world are well narrated with the help of Flatland. We come to the practical construction of that narrative – suggestion is to mimic a dialogue by examining existing dialogues in the book and one such example may be that between Square and Sphere, appearing throughout the novel.

CURRICULUM LINKS

At this point it would be good to see whether we can, after all, establish some connections between the history of the fourth dimension and the new National Curriculum (DoE, 2014). We propose to state the NC

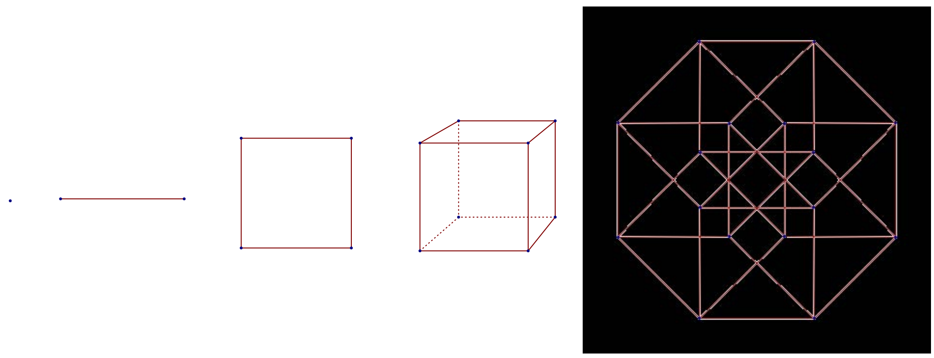

Figure 7: Here is an opportunity to use dynamic geometry software in illustrating different dimensions: starting from the 0th dimension, represented by point, we generate one-dimensional object – the line segment. Further by moving the line segment perpendicularly to itself we generate a square, a two-dimensional object. By moving the square perpendicularly to itself, we generate four-dimensional object, a tesseract (image by the author).

description and 'answers' from the 4th dimension as follows.

NC *(National Curriculum description): Mathematics is a creative and highly inter-connected discipline that has been developed over centuries, providing the solution to some of history's most intriguing problems.*

4dh *(4th dimension history lesson for the classroom):* Whilst mathematics is often described as a method and a way of exploring and solving the big questions of life and existence, the pupils in the classroom report a different experience (Smith, 2004). The history of the fourth dimension can give a concrete and a very tangible view of mathematical development that occurred in the pursuit of the question of existence of higher dimensions as we have shown on above examples.

NC: *Mathematics is an interconnected subject in which pupils need to be able to move fluently between representations of mathematical ideas.*

4dh: An example of dimensionality which can be described both visually and algebraically is the way Stringham described the n^{th} dimension. Stringham says that, the simplest n-fold angle is bounded by n number of edges, and so on. Stringham's formulations are related to number theory and figurate numbers. An investigation can be conducted on the similarities and certainly representations of the two corresponding strings of formulae. We can here return to Wallis' studies in context of algebra.

NC: *Move freely between different numerical, algebraic, graphical and diagrammatic representations, including of linear, quadratic, reciprocal functions.*

4dh: The descriptions of the fourth dimension include all of the above as we have seen in this short paper.

CONCLUSION AND FURTHER DEVELOPMENTS

From the listed history of the fourth dimension, the materials are being developed for the use in the classroom by the author and current cohort of trainee teachers studying with me, in the context of three very different educational settings.

Institution A is the first school where we have started working with the pupils. It is a mainstream boys' school, has a high achievement record in mathematics, and is comparable to specialized and grammar schools (i.e. the study of history, classics, and high achievement in mathematics are the norm). The school A poses the challenges in terms of producing the material that would engage and stretch pupils' abilities so the material developed aims to link geometry and algebra as seen from our mention of Wallis, Euler, and Stringham. It appears that pupils in this setting are very keen to engage with mathematics, and the study of the 4th dimension is seen as a way of stretching the pupils to study beyond the curriculum.

Institution B is a national institution promoting the study of mathematics for the gifted and talented pupils. Whilst many pupils in this setting have some idea about the dimensionality, exercises offering them possibility to represent them in different ways as described above given pupils not only the sense of achievement, engagement, and enjoyment, but their further interest and individual research is also noted.

Institution C is a special school for disabled pupils whose abilities in functional mathematics are low and hence the mathematical curriculum is narrowed down to teaching basic skills such as financial functioning. The challenge in this school was to provide a curriculum that engages and instigates an aesthetic appreciation and enjoyment of mathematical ideas lest mathematics is perceived by both pupils and teachers as a discipline which is only functional or arithmetic bound.

By working within these three very different institutions, we trialed the three aspects of mathematics that we have identified as possible principles of developing teaching programmes for the new curriculum. These are:

a) extending the most able pupils by modeling mathematical practices from the past

b) engaging pupils by learning mathematical skills and understanding via 'big' questions of mathematics

c) teaching mathematical appreciation via aesthetic experience rooted in mathematical concepts.

The preliminary conclusions are that researching a historical development of mathematical concept can give opportunities for multiple settings, differentiation in terms of possible levels of achievement in mathematics, and cover different aspects of modeling mathematical practice with different types of pupils.

Finally, after identifying the links with the curriculum so easily, an idea is forming that the new programme for secondary school mathematics can indeed be entirely based on historical development of mathematics, offering for the first time an educational programme that would be truly meaningful and engaging and give pupils a glimpse of the big questions of mathematics about the nature of space and time that many past mathematicians had been enthused by.

4. Aristotle says (2012, 268a, pp. 10–15): "A magnitude if divisible one way is a line, if two ways a surface, and if three a body. Beyond these there is no other magnitude, because the three dimensions are all that there are, and that which is divisible in three directions is divisible in all." He however rejected the possibility of an extension of this thinking: "All magnitudes, then, which are divisible are also continuous. Whether we can also say that whatever is continuous is divisible does not yet, on our present grounds, appear. One thing, however, is clear. We cannot pass beyond body to a further kind, as we passed from length to surface, and from surface to body." (Aristotle, 2012, 268a, pp. 25–30)

Teaching the concept of velocity in mathematics classes

Regina Dorothea Möller

University of Erfurt, Erfurt, Germany, regina.moeller@uni-erfurt.de

The genesis of the concept of velocity refers to a centuries-old search within the context of motion. This led to Newton's definition which is still taught in school. The historical development has shown that both mathematics and physics classes have their respective characteristic manner using this term. However, the mathematical potential for teaching this concept is by far not exhausted.

Keywords: Concept of velocity, historical development, teacher education.

INTRODUCTION

The causes to investigate the historical development of the concept of velocity are mathematical problems which lately can be found in German fourth grade classes.

Several pictures are given which show people or machines such as cars or trains each with information about the respective velocity: the train covers 150 km in an hour. The assigned task is to fill out tables in which the students write the distances for different time spans: 1h, 2h, and so forth. Above the assigned tasks one can read the title velocities. One can observe at once that like in other cases in which an introduction into the field is in the focus of interest – here a start with a series of different observable motions and a leading to the question how they can be quantified – there is an emphasis on the computational aspect under which the ideas that have led to the possible to computations, have disappeared (Doorman & van Maanen, 2009). Instead of an approach pinpointing the quantities in question there is a given table to be filled out by the students.

This kind of problem can be considered as an anticipation. There are at least three other kinds of anticipation tasks on the elementary level: one refers to the ratios such as a half, one quarter and three quarters and the second refers to the decimals within the context of magnitudes. The third is the appearance of tables in application problems. In these problems prices of products are given – like 1 kg of apples cost 75c – and the question is how much is to pay for 2 kg / 3kg / 5kg. These three kinds of anticipations occur in math classes because of the application principle. Students see these kinds of numbers and these kinds of questions in their daily life and math classes respond to this phenomenon by introducing these numbers and these tables without giving a rigid mathematical reasoning.

What kind of anticipation is done when students solve this kind of velocity problem? Since the students are to fill out tables, which are methodically a representation of functions one could argue that functions have arrived in elementary math classes since the inspection of Felix Klein (1905) to make functions a subject matter in math classes. It also could be understood as an example of an (anti-) didactical inversion (Freudenthal, 1983, pp. 305ff.). In any case it is obvious that this is not following the historical development and it is not showing an elementary approach which is possible at this stage of mathematics classes.

Since this kind velocity problem is not really an application task, since only tables need to be filled out, one could argue that they give a mathematical way to compute velocities which the students can observe in their daily lives because our modern world presents this phenomenon. Since the formula is given later at secondary I level one chooses tables to compute.

Having in mind the way magnitudes are introduced in math classes on the elementary level (finding representatives, studies of comparisons with chosen measurement objects and afterwards with agreed upon measurements objects, leaning the standardized measurement unity and at last solving of application problems), the velocity problems in focus do not show any such procedure although velocity is the first composed magnitude that the pupils encounter.

Since this is a mathematical concept one would expect a series of steps that lead to a definition. A possible approach would be the didactical triangle of Bruner (1960) in which he argues for an approach that encompasses the enactive, iconic and symbolic level. Another didactical theory of leaning concepts is given by Vollrath (1984) who outlines in general what kind of different steps lead to an understanding of mathematical concepts.

Another concern is the fact that the concept of velocity can be looked upon as a real mathematical modelling procedure (e.g., Blum & Leiß, 2005). Observable movements can be measured in two dimensions: length and time span. It could be arranged as a project for students in which the definition of velocity is the end product of their investigative endeavour.

This point also leads to the question why a fundamental phenomenon like the concept of velocity lacks any historical approach in textbooks. The students could measure for example the free fall of objects getting an idea of how scientists in the middle ages approached problems of velocity.

The paper focuses on the historical development of the concept of velocity with the idea that Newton might not have thought primarily of it as a function since he was still following Galilei's proportional theory. The development starts with some inherent philosophical aspects since in times of Newton the subject matter still belonged to the so-called natural philosophy.

PHILOSOPHICAL AND HISTORICAL ASPECTS

The concept of velocity is one with a long tradition, similarly like the history of calculus (e.g., Doorman & van Maanen, 2009). Embedded in the concept of motion already Greek mathematicians, especially Aristotle (384–322 BC), had ideas about velocity which he combined with his observations of the spheres and of the free fall of objects. Before the next step was done by Galilei (1564–1642), Nicole of Oresme (1360) used graphic representation of changing qualities. Later Galilei used experiments to argue for the statement that there is a quadratic dependency between the distance travelled and the falling time. Even later Newton (1642–1727) defined velocity using the concept of force that initiates motion. Leibniz (1646–1716) developed the differential and integral calculus also considering the idea of (planetary) movements.

In the following sections, two aspects are discussed: Firstly, the formal definition of the concept of velocity was preceded by a struggle for a clarification of the concept of motion. Secondly, the concept of velocity embodies a circular reasoning.

Although a lot of the work of Archimedes (287–212 BC) concerning mechanics is transmitted and gives an idea of his far-reaching mathematical understanding, we have no clear idea what he understood by velocity. Assured work is passed on us of Aristotle (384–322 BC), who investigated the phenomenon of motion qualitatively and verbally (Aristotle, Physics, 1829). He distinguished three types of motion: motion in undisturbed order, such as the celestial spheres, the "earthy" motion such as the concept of the rise and fall, and the violent motion of bodies that needs an impulse (cf. Hund, 1996, p. 29). Although his remarks touched the phenomenon of velocity, his conceptions proved wrong later on: "Aristotle came close to the concept of velocity when in the sixth book, the words 'faster' (longer distance in the same time, same route in shorter time) and the 'same speed' are explained." (Hund, 1996, p. 30)

Galilei (1564–1642) succeeded in a better understanding of the concept of velocity, as he did not rely on his direct perception: "The means of scientific evidence was invented by Galilei and used for the first time. It is one of the most significant achievements, which boasts our intellectual history [...]. Galilei showed that one cannot always refer to intuitive conclusions based on immediate observation because they sometimes lead to the wrong track" (Einstein, 1950, p. 17).

As Weisheipl (1985) points out, Galilei struggled with the Aristotelian concept of nature (pp. 8ff.). Aristotle considered nature as an active principle. "Nature is a source not only of activity but also of rest" (p. 22) which has an impact on the understanding of motion (p. 49ff.) He also still pondered over the idea of Parmenides "all change is illusion" and the one of Heraclitus "everything is flux". Galilei can be understood as being at the brink of Aristotelian sight of nature and the one later proposed in Newton's Principia and Descartes' Principia. Newton formulated the principle of inertia like this: "Everybody preserves in its state of rest or of uniform motion in a straight line, unless it is compelled to change that state by forces impressed upon it (Weisheipl, 1985, p. 69).

Another author, Palmerino (2004), argues for a new sight of the reception of Galilei's theory since like any other theory it was not at once in the way accepted in which textbooks nowadays present for example the free fall and projectile motion (Palmerino, 2004, p. 140). During the last decades it became apparent that the ideas that Galilei, Descartes and Newton presented at their times were different from each other. Also the European continent was not aware of Galilei's and Newton's theories and later Leibniz focused very much on his functional approach using variables. That is, the way the theory of motion and velocity is presented nowadays is much more formed by Leibniz than by Galilei and Newton although it was very much their ideas that came through eventually.

Only Newton (1643–1726) introduced the concepts of absolute time and absolute space and opened up the exact relationship between force and motion: The power does not get the motion upright (Aristotle), but it causes its change (acceleration). While Aristotle argued by inspection, Newton made an abstraction, as he looked upon length and time as not necessarily bounded materially.

In today's linguistic usage, we understand motion as a change in position in the (Euclidean) space over a certain period of time. Lengths and time periods are conditions for the quantification of such motions. On this basis, the (average) velocity is defined as the quotient of the distance travelled over the time required.

A circular argument is obvious on closer inspection: time depends on a movement and vice versa, because time is measured using motion (Mauthner, 1997, Vol. 3, p. 438). In the hourglass sand runs through, in an analogous clock the pointer moves, and for the period of a year, we follow the cycle of the earth around the sun.

Likewise, the idea of space is connected to motion, for only through movement we perceive the space. Mauthner said: "His [The people, note of the author] language makes it impossible for him to understand the metaphorical tautology of the preposition 'in'. Only rigorous reflection will enable him, to at least understanding the metaphorical of the preposition (in time). In space means something like 'in the space of the room', for the time as much as 'in the space of time' (ibid, p. 443)".

Even Piaget refers to this circular argument: "Speed is defined as a relationship between space and time – but time can be measured solely on the basis of a constant velocity" (Piaget, 1996, p. 69). For him the concepts of space, time and speed are mutually dependent.

MATHEMATICAL ASPECTS OF THE VELOCITY CONCEPT

Towards a functional terminology of velocity Oresme (ca. 1320–1382) sought the help of experiments to assign a rate of change to certain intensities and concluded: "All things are measurable with the exception of numbers .... (Pfeiffer, Dahan-Dalmedico, 1994, p. 228ff.)". The difficulties mathematicians had at that time are well summarized there.

The reasoning of Aristotle and Galilei were based on their observations of linear motions. However, both had also planetary motions in mind. For motions on a curved path you need two different aspects: the direction and the magnitude of a velocity vector. It is this distinction which led, in modern terms, to a vectorial description and thus to a further clarification of the concept of velocity, which is thus a generalization of the concept of velocity on a straight line. Bodies on a straight line have the same speed, in the same direction and the same quantity. Since then, the following statement is true: the change in force and velocity are vectors with the same direction (Einstein, 1950, p. 38). We observe an idea of permanence, because all statements that apply to velocities along curved paths must also apply to linear trajectories.

The cause of this observation is given by an idealized thought experiment, which confirmed the theory (cf. Einstein, pp. 25ff.); this is yet another idea that came to an effect only at the time of Galilei. Since then, the mathematical language has been used in physics to reason for not only qualitative but also quantitative conclusions.

As soon as you engage in quantitative calculations, one deals with quantities ("Größen"). With respect to the concept of velocity you have the dimension (the quotient of distance and time) and the measured value (an element of real numbers), which is a composite physical quantity.

Griesel analysed the subject matter of quantities on the primary level (length, weight, time periods) (1973, vol. 2, pp. 55ff.) as a technical background for the didactics of quantities. This presentation does not fit the quantity of velocity (and is not mentioned there) because it requires a description as an element of a vector space, which can be higher than one-dimensional.

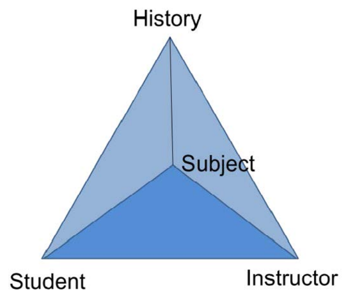

Figure 2: Extended didactical triangle

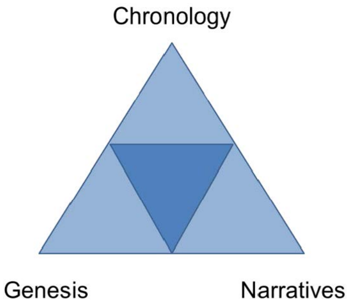

Figure 3: Aspects of history

However, Freudenthal (1977, vol. 1, p. 188) argues that one can interpret measure indications as function symbols; an idea that was not previously addressed in class. Another functional aspect occurs in two ways with the concept of velocity: The distance-time function leads with considering of the difference quotients to the average speed and the transition to differential quotient to instantaneous velocities that are themselves again functions, namely, the velocity-time functions.

It has taken over 2000 years for the concept of velocity to be defined consistently out of the concept of motion – in today's usage an act of mathematical modelling. It is therefore a prime example of a mathematical and interdisciplinary concept development – with both mathematical and physical – mechanical – representations throughout history. The intuitive conclusions drawn by Aristotle led to difficulties and proved much later untenable. Only an idealized thought experiment led eventually to a verifiable physical theory. The concept of velocity is an example of a mathematical modelling of a qualitative knowledge with more potentials as there are quantitative statements and other insights. The knowledge of such phenomena, the resulting misconceptions and the trodden paths of knowledge are essential components of mathematical education and exemplify scientific processes.

The genesis also shows a potential for didactical perspectives of mathematics education. Despite the scarce representation of this topic in mathematics class (in many curricula of the German provinces the concept of velocity is only mentioned only one time on the secondary level), there are a diversity of ideas which can be reflected.

DIDACTIC CONSEQUENCES

This example shows again, that the mathematical subject matter is not always the 'first philosophy' in mathematics education (e.g., Ernest, p. 213). Although of great importance for the development of mathematical and physical theory, it plays only the role of a physical application in mathematics classrooms. Hidden under algorithmic manipulations, the ideas that lead to the definition of concept of velocity do not appear to pupils in class. Since this topic also disappears during teacher training, there is an extra afford needed to pull the history into the light.

In the light of the use of language in math classes, Vygotsky (1964) elaborated on the relationship between everyday experiences and logical reasoning. Everyday experiences may interfere with scientific reasoning which in the case of the concept of velocity occurred historically for quite some time because of the lack to understand the invisible forces. It is therefore necessary for teacher students to learn to discriminate between the appearance or motions and its scientific reasoning.

This afford can be done in three ways: there is a chronology of historic development which can be shown on a line. There is the genesis which makes apparent who under which presumptions found a concept or an algorithm.

The genesis of the concept of velocity is influenced by interdisciplinarity for centuries. Therefore, it is wrong to neglect it in mathematics education by pointing to the physics education or to avoid it in the classroom at all. In mathematics teaching, it owns several important functions:

Basic everyday experiences relate to the phenomena of velocity and can be used on several grade levels by taking up Vollrath's idea and take seriously measurement processes as a basis of experience (Vollrath, 1980). This can be addressed in propaedeutic form at the primary level and in a quantitative manner at secondary levels.

Under the current relations of applications of mathematics education, the concept of velocity is a prime example of mathematical modelling of everyday phenomena of motions which can be quantified normatively, allowing measurements and calculations. According to the current understanding these are necessarily factual and methodological skills.

As a first composite quantity the concept of velocity can be addressed in lower secondary education at many occasions. Before getting to the usual algorithmization (Doorman & Van Maanen, 2009) teaching this concept allows for teaching the fundamental idea of measuring. This is a valuable and vital contribution to the implementation of the rules in the educational standards and curricula and guiding principles would be met. The implementation of the items listed would be an important part in promoting mathematics education.

To arrive at an overall conception of the concept of velocity in mathematics education, a strategy is needed which leads from an intuitive to a structured taxonomy (Vollrath, 1984, p. 14). Vollrath has given a general theory to teach mathematical concepts. The following steps outline the procedure scheme for the specific concept of velocity which teachers could have in mind before teaching the respective classes (Vollrath, 1984, pp. 202ff). It would mean to get a clear view on the subject matter and teach perhaps more than what is given by the textbooks:

1) The concept as a phenomenon (intuitive understanding of the concept)

They recognize that

— the feature of the motion is the continuous change of position of subjects and the objects.

— for describing motion two quantities, length and time intervals, are required.

— with a constant distance the one object is faster that needs less time. Conversely, at constant time, the object is faster that has travelled a longer distance.

2) The second term and his wealth aspect (constructive understanding of the term)

They recognize that

— rest and motion of a body are always give relative to a reference system.

— with a rectilinear and uniform motion in equal intervals of time, equal distances are covered.

— for a linear and non-uniform motion the same time intervals can be covered in different journeys.

— for a linear and uniform motion, velocity can be described as the ratio $v = s / t$.

3) The concept is a carrier of properties (substantive understanding of the term)

They recognize that

— for mathematical calculations of the body and the mass, they are idealized to a point.

— the ratio $\Delta s / \Delta t$ possess a constant (average) value relative to the total distance and total time.

— at constant velocity Δs to Δt proportional.

— the quantity velocity possesses the dimension "distance per time" with the units m/s or km/h.

4) The concept as a tool for problem solving (problem-oriented understanding of the term)

They can

- bring the definition v = s / t into relation to everyday life contexts.
- calculate uniform velocity.
- appreciate that the concept of velocity is a fundamental physical phenomenon that can be described quantitatively by mathematical means.

The discussion of the velocity concept in the context of the stage scheme shows the potential that this concept already has in mathematics education. From this more elaborated standpoint the potential for the interdisciplinary character can be developed further and more in detail.

The four steps in the concept development to enlighten teacher students in their knowledge of this topic also gives a good background to approach the topic in an ethical manner. It is essential for their teaching to have a grip on solid knowledge and cultural heritage in the subject matter they are to teach.

Proportionality problems in some mathematical texts prior to fourteenth century

Antonio M. Oller-Marcén[1] and José María Gairín[2]

1 Centro Universitario de la Defensa de Zaragoza, Zaragoza, Spain, oller@unizar.es

2 Universidad de Zaragoza, Departamento de Matemáticas, Zaragoza, Spain

Proportional reasoning seems to be one of the oldest mathematical problem solving tools. Problems involving proportionality have consistently appeared in mathematics texts over time. Moreover, proportionality is still today one of the main topics in school arithmetic and several studies point out difficulties shown by the students in this context. In this paper, we perform an analysis of historical proportionality problems in order to describe the main situations where proportionality naturally appeared. Knowledge of these situations might be of interest in order to design and develop well-contextualized teaching and learning activities.

Keywords: Proportionality, arithmetic, problems, history.

INTRODUCTION

Rhind papyrus is the oldest known work that can be considered, in some sense, a Mathematics textbook. It is dated by the copyist Ahmose to the sixteenth century BC, although he acknowledges to be copying older material from around nineteenth century BC. In this papyrus, we already find problems like the following one (Chace, 1979, p. 102):

> "If 10 *hekat* of fat is given out for a year, what is the amount used in a day?"

This daily problem clearly points out the important applications that proportional reasoning had in several situations involving productive aspects, commerce or administration. This fact, together with the difficulties that many students show when they face concepts related to proportionality (Modestou, Elia, Gagatsis, & Spanoudis, 2008; Van Dooren, De Bock, Janssens, & Verschaffel, 2008) justify that proportionality and its applications are still important topics in Primary and Secondary school curricula in many countries.

THEORETICAL FRAMEWORK

Mathematics, just like any other human activity, takes place in a particular historic, social and cultural context that is, of course, changeable (Wussing, 1998). Consequently, the study of mathematical concepts and problems from a historical perspective must be an essential part of research in Mathematics Education. In this sense, the contributions of History of Mathematics to Mathematics Education are diverse and admit many different approaches (Fauvel & Van Maanen, 2000; Katz & Tzanakis, 2011).

Phenomenology can also be approached from a historical perspective. Freudenthal (1983) presents historical phenomenology as one of the four types of phenomenology which have interest from a didactical point of view. The idea is to pay attention to those phenomena lying in the origin of the concept that we want to study.

Since Mathematics can be conceived from a problem-solving point of view (Ernest, 1989), it seems interesting to focus a historical-phenomenological study on those problems arising in the origin of a particular concept. This interest is even clearer if we note that "problems have occupied a central place in the school mathematics curriculum since antiquity" (Stanic & Kilpatrik, 1989, p. 1). Moreover, Tzanakis and Arcavi (2000, p. 224) point out that historical problems that motivated and/or anticipated the development of a mathematical domain are interesting from a didactic perspective.

Many authors (De Lange, 1996; Van Reeuwijk, 1997) point out that contextualization is an important issue regarding mathematical work in the classroom. Obviously, the case of proportionality is not an exception. Thus, the knowledge of those situations in which proportionality has historically appeared can be useful in order to design and develop well-contextualized teaching and learning activities that might help the students to overcome their difficulties.

OBJECTIVE AND METHOD

In this paper, we perform an analysis of historical proportionality problems. In particular we are interested in studying the contexts in which these problems appeared. Our main goal will be to give a survey of the most important situations in which proportional reasoning arises in a natural way.

In order to do so, we will focus on the study of ancient texts following the steps of content analysis (Krippendorff, 1990).

It is difficult to make a selection of texts. First of all we must determine a temporal frame. We decide that the most recent work in our study would be the *Liber abaci*, edited twice during the thirteenth century, because it presents proportionality in a relatively closed form. Later medieval and renaissance texts on Arithmetic will not include any essentially new problems regarding proportionality [1].

On the other hand, since proportionality admits different conceptual approaches (Oller & Gairín, 2013), it is necessary to gather works coming from different traditions. Moreover, to ensure the representativeness of the sample, it seems interesting to search for texts that were *encyclopedic* in the sense that they tried to summarize the mathematical knowledge at the moment and place where they were written.

As a consequence of the previous considerations the following main sources were selected:

1) *Rhind papyrus*, ca. 1650 BC, from Egypt (Chace, 1979).

2) *Jiu zhang suan shu*, an ancient Chinese text commented in 263 by Liu Hui but containing older material (Kangshen, Crossley, & Lun, 1999).

3) *Lilavati*, written in 1150 by the Indian mathematician Bhāskara II (Patwardan, Naimpally, & Singh, 2001).

4) *Liber abaci*, written in 1202 by Leonardo of Pisa, *Fibonacci* (Sigler, 2002).

Quite often, ancient texts only present the statement of the problems or, even if they provide a solution, it is only of numerical nature. In these cases we do not have a clue about the actual solving method. Thus, if we want to avoid the mistakes [2] pointed out by Grattan-Guinness (2004) we cannot classify the problems according to their (modern) method of resolution. Instead, we decide to classify the problems according to the particular context and situation where they appear. This criterion is coherent both with the practical nature of proportional reasoning and with the didactical usefulness of the study.

CONTEXTS WHERE PROPORTIONALITY PROBLEMS ARISE

The practical and pedagogical importance of proportionality is made clear by the great amount of related problems that appear in the consulted texts. In the *Jiu zhang suan shu*, for instance, three out of the nine chapters are solely devoted to this topic. Also, in Fibonacci's text we find a chapter exclusively devoted to companies presenting thirteen problems with their detailed solutions.

This huge number of problems also represent a variety of problems ranging from distribution of food to purely mathematical and abstract situations. Hence, it is difficult to give an exhaustive and detailed classification of proportionality problems according to their contexts. Nevertheless, we have identified four categories that include most of the problems:

1) Exchange problems.
    a) Exchange of merchandise (barter).
    b) Buying and selling.
    c) Exchange of currency.
2) Distribution problems.
3) Loan problems.
4) Mixing problems.

EXCHANGE PROBLEMS

It is quite possible that the exchange and distribution of merchandise were the situations where proportional reasoning firstly appeared. In fact, texts like the *Jiu zhang suan shu* or the *Liber Abaci* use barter situations as an introduction to this topic. In cultures where currency existed buying and selling made sense but these situations can be seen as an Exchange of merchandise for Money. Finally, when different cultures, towns or countries interacted, the need to compare and interchange their respective currencies arose. We also consider these cases as exchange problems.

Exchange of merchandise

In order to perform an interchange, some criterion is needed to guarantee its fairness. Throughout our study we have found different criteria that we now exemplify.

1) Sometimes a table or some additional information giving exchange rates for different merchandise is given. That is the case, for instance, in the *Jiu zhang suan shu*, where a table indicating the exchange rates for different cereals is presented and used to solve problems such as the next one (Kangshen et al., 1999, p. 146):

   "Now 5 *dou* 2/3 *sheng* of millet is required as sesame seed. Tell: How much is obtained?"

2) In other cases, the monetary value of both merchandises is known and this information is used to deduce the fair way to interchange them. These kind of situations appear, for instance, in the *Liber abaci*, where we find problems like the following (Sigler, 2002, p. 181):

   "A hundredpound of pepper is worth 13 pounds, and a hundredweight of cinnamon is worth 3 pounds; it is sought how many rolls of cinnamon are had for 342 pounds of pepper."

3) Finally, we can find a unit that measures, in some sense, the quality of a certain good. This happens remarkably in the *Rhind papyrus*, where a unit called *pefsu* (Robbins & Shute, 1987, p. 51) measures the lack of quality. This gives rise to problems like this (Chace, 1986, p. 108):

   Example of exchanging loaves for other loaves. Suppose it is said to thee, 100 loaves of *pefsu* 10 are to be exchanged for a number of loaves of *pefsu* 45. How many of these will there be?

Buying and selling

Buying and selling processes can give rise to several different problematic situations, but the two main possibilities that we have found are:

1) The price of a certain quantity of merchandise is known and the price of some other quantity is sought. For instance (Sigler, 2002, p. 134):

   "Also a hundredweight of some merchandise is worth 14 pounds and 7 soldi; how much are 37 rolls of the same merchandise worth?"

2) The *inverse* situation; i.e., the price of a certain quantity of merchandise is known and the quantity of merchandise that can be bought with other quantity of money is sought. For instance (Patwardan et al., 2001, p. 78):

   "If 3/2 *pala* of saffron costs 3/7 *niskas* O you expert bussinessman, tell me quickly what quantity of saffron can be bought for 9 *niskas*."

Exchange of currency

The exchange of currency is a relatively recent commercial phenomenon. Among the revised texts, only the *Liber abaci* presents these problems. This is not surprising considering the historical and geographical context in which it was written. In fact, these problems will be popular in renaissance arithmetics due to the active commerce around the Mediterranean Sea.

Just like in the case of barter, there can be different pieces of information available at the moment of the exchange. The main possibilities are:

1) In the simplest case, the amount of one currency that is obtained in exchange of a certain quantity of the other is known (Sigler, 2002, p. 157):

   "Also a Genoese soldo is sold for 21½ Pisan denari, and it is sought how much 7 Genoese soldi and 5 denari are worth."

2) In some cases a third currency is involved that acts as a measure for the value of the two exchanged currencies (Sigler, 2002, p. 186):

"Also it is proposed that one Imperial soldo is worth 31 Pisan denari, and one Genoese soldo is worth 22 Pisan denari, and it is sought how many genoese denari 7 Imperial denari are worth."

3) The previous situation can be generalized so more than one currency acts as mediator (Sigler, 2002, p. 195):

"Twelve Imperial denari are worth 31 Pisan denari, and one Genoese soldo is worth 23 Pisan denari; and one Turin soldo is worth 13 Genoese denari, and one Barcelona soldo is worth 11 Turin denari; it is soought how many Barcelona denari are 15 Imperial denari worth."

4) Finally, the exchanged can be performed according to the actual value of the silver (for instance) contained in each coin (Sigler, 2002, p. 199):

"Again one indeed has 26/3 pounds of some common coin that has 2¼ ounces of silver, an one pound of silver is worth 149/20 Pisan pounds, and it is sought how many Pisan pounds will be had for the 26/3 pound of the coin."

DISTRIBUTION PROBLEMS

As we already pointed put, distribution situations are among the oldest situations where proportional reasoning arises. *Rhind papyrus* already presents this type of problems.

The "fair" way to perform the distribution is often implicitly assumed and the context determines if the distribution must be direct or inverse. We now give some examples.

1) Sometimes there is a benefit to distribute, coming from either work or investment. In these cases the distribution is made directly proportional to the individual contributions (Chace, 1979, p. 104):

"Suppose a scribe says to thee, four overseers have drawn 100 great quadruple *hekat* of grain, their gangs consisting, respectively, of 12, 8, 6 and 4 men. How much does each overseer receive?"

2) In other cases, there is a loss to be distributed (like a tax payment, for instance) and the distribution is inversely proportional to the "rank" of the payers (Kangshen et al., 1999, p. 166):

"Now given five officials of different ranks: *Dafu*, *Bugeng*, *Zanniao*, *Shangzao* and *Gongshi*. They should pay a total of 100 coins. If the payment is to be shared in accordance with ranks, the higher pays the less, and the lower pays the more. Tell: how much should each pay?"

3) Finally, there can be several factors involved in the distribution which will be made directly proportional to some of them and inversely proportional to the others (Kangshen et al., 1999, p. 315):

"Now given a problem of fair distribution of tax millet. The tax bureau is at County A, which has 20520 households and where millet costs 20 coins a *hu*. County B, 200 *li* away from the bureau, has 12313 households and millet costs 10 coins a *hu* there. [...] County E, 150 *li* away, has 5130 households, and millet costs 13 coins a *hu*. The total tax millet for the five counties is 10000 *hu*. A cart carries 25 *hu*; the transport cost is 1 coin a *li*. Assume the payment by each household is equal in cash and labour. Tell: how much millet shoud each county pay?"

These distribution problems will continue to appear consistently over time, leading to the so-called problems of companies that received much attention from thirteenth century on (Lamassé, 2001).

Other interesting and important situation where distribution problems can be found is that of inheritance [2]. This is particularly the case in Muslim tradition because of the strict and somewhat complicated rules determined by the Islam. In fact, the whole third chapter of al-Khwarizmi's *Algebra* (Rosen, 1986) is devoted to inheritance problems. A typical example is given by the following problem coming from the twelfth century Andalousian mathematician al-Hufi (Laabid, 2001, p. 321):

"Une femme a laissé après sa mort, son mari, sa mère, sa sœur germain, sa sœur consanguine, sa sœur utérine. Et une succession constituée d'un esclave et de 15 dinars. La sœur germaine a pris pour sa quote-part l'esclave et a remboursé pour

> les autres héritiers 5 dinars. (Il s'agit de calculer le montant global de la succession et la valeur de l'esclave, la quote-part de chaque héritier.)"

This type of problems do not appear in the sources used for this work and, strictly speaking, they could be considered as an example of benefit distribution problems. Nevertheless, their context is specific enough to study them separately.

LOAN PROBLEMS

In spite of the bad reputation that the loan of money at a certain interest had in several cultures, it seems that this was a quite ancient and common practice. Moreover, simple interest is still a topic in textbooks; although this is more due to tradition than to its practical use (compound interest is far more common).

The problems that we have found in this context are very similar, if not identical, to problems that appear nowadays. For example (Patwardan et al., 2001, p. 84):

> "If the interest on 100 for 4/3 months is 26/5, what will be the interest on 125/2 for 16/5 months?"

In most ancient problems the reader is asked to find the interest obtained by a certain amount of money after a certain time. In some cases the unknown quantity corresponds to other magnitude. The following example from the *Liber abaci* shows such a situation, although it is not strictly a proportionality problem since it involves an affine function (Sigler, 2002, p. 384):

> "A certain man placed 100 pounds at a certain house for IIII denari per pound per month of interest, and he took back in each year a payment of 30 pounds; one must compute in each year the 30 pounds reduction of capital and the profit on the said 100 pounds. It is sought how many years, months, days and hours he will hold money in the house."

MIXING PROBLEMS

The idea of mixing products of different qualities and prices naturally arises when working with raw materials. In this way one can obtain a product of a predetermined price or improve or worsen its quality. A very particular case is that of alloys. These problems were important in Europe during the thirteenth century (Williams, 1995). In fact, chapter 11 from the *Liber abaci* is entirely devoted to this topic (Sigler, 2002, pp. 227–257).

Again, a huge variety of different situations arise in this context. Nevertheless there are essentially two types of problems.

1) Knowing the weight and quality of the ingredients, the weight and quality of the resulting mixture is sought (Patwardan et al., 2001, p. 98):

> "O golden mathematician, four types of gold 10 *masas* of 13 carats, 4 *masas* of 12 carats, 2 *masas* of 11 carats and 4 *masas* of 10 carats are melted together to form a new one. Find its fineness. Is this is purified and 16 *masas* gold is obtained, what is its fineness? If the mixed gold when purified has 16 carats fineness, what is its weight?"

2) Inversely, knowing the weight and quality of the mixture some information about the ingredient is required (Sigler, 2002, p. 255):

> "A certain man wishes to make a bell with five metals, of which a hundredweight of one metal is worth 16 pounds, another truly 18 pounds, an another 20 pounds, another truly 27 pounds, and another indeed 31 pounds; he therefore makes a bell from them that weights 775 rolls and costs 651/4 pounds; it is sought how much he puts in of each metal."

SOME DIDACTIC IMPLICATIONS

As we already pointed out, the previous study might be useful in order to design teaching and learning activities involving proportionality and, in particular, to decide which situations can promote that students significantly construct the main concepts regarding proportionality.

From this point of view, we think that the situations that are more adequate to introduce the basic techniques of proportionality in the classroom are exchange problems. This choice is not only motivated by the historical importance of those situations but also by the fact that students are very familiar to them.

Exchange problems are particularly suitable to introduce outer ratios and what Cramer and Post (1993) call unit rate strategies to solve missing-value problems. In addition, these situations can be used to present the idea of co-variation that may lead to a functional view of proportionality (Bosch, 1994).

Distribution problems are as old as exchange problems and they can also lead to meaningful activities that help to present important aspects of proportionality.

For example, distribution situations are suitable to work at the same time with inner and outer ratios and discuss their relations and different meanings. Moreover, the idea of fair distribution can help to clarify the concept of proportional magnitudes and a distribution situation is a natural context in which inverse proportionality appears.

We find loan and mixing problems less useful, mainly because students are less familiar to them. Nevertheless, they are also interesting and can also be used under certain circumstances. For instance, mixture problems can be a nice context in which progressively start the difficult transition (Wagner & Kieran, 1989) between arithmetic and algebra.

ENDNOTES

1. We must point out that we focus on arithmetic proportionality. Of course, we find proportionality in several geometric problems of practical nature and the theoretical frame can be traced back to Euclid and before. Nevertheless, we think that arithmetic situations are more useful in order to introduce proportionality in the classroom.

2. Namely, the confusion of history and heritage. History describes what happened (and did not happen) in the past and tries to explain it, while heritage focus on the question "how did we get here?" In our case, it would be a mistake to classify problems as 'direct proportion problems', 'inverse proportion problems', etc. since these are modern categories.

The history of the concept of a function and its teaching in Russia

Ildar Safuanov

Moscow City Pedagogical University, Moscow, Russia, safuanov@yahoo.com

The history of teaching the concept of function in Russian school and university mathematical education is described. For this reason, in the first section the brief survey of the history of the function concept is given. Finally, we conclude that the opinion about the introduction of a modern rigorous and precise definition of a mapping has not been reached not only in school-based education, but also at the undergraduate level of mathematics education.

Keywords: Textbooks, history of mathematical education, function.

BRIEF SURVEY OF THE HISTORY OF THE FUNCTION CONCEPT

The function concept is one of most complicated concepts not only of school mathematics but also at undergraduate level. The students' difficulties with this notion have been reported for several decades (see, e.g., Tall, 1990; Sierpinska, 1992; Bardini et al., 2014). Therefore, a need to elaborate upon effective approaches to the teaching of this notion still exists.

This survey is a first step to the research project aimed at elaborating new ways of teaching the concept of function using the genetic approach. The application of genetic approach to the undergraduate mathematics teaching is described, e.g., by Safuanov (2005). The genetic approach could be combined with methods based on the APOS theory (Dubinsky, 1991).

In order to understand the problems of teaching the notion of function, first of all we will trace the history of its teaching, at least in Russia. The changes in the teaching the concept of function have been largely determined by the history of the concept itself. Thus, in order to trace the history of teaching the concept of function, we should first make a short survey of the history of the concept itself. The other reason for surveying the history of the concept is our belief in the necessity of knowing the historical development of the concept for elaborating its teaching by genetic method.

We will briefly trace the history of the development of the concept of function following the fundamental monograph edited by Yushkevich (1970, pp. 139–148, and 1972, pp. 250–255), and also books by Klein (1977, pp. 286–292), Gleizer (1983, pp. 20–25) and the "Mathematical encyclopaedic dictionary" (1988, p. 617). We also trace the history of the development and teaching of the concept of function in Russia on the basis of the analysis of mathematical, didactical, educational and reference books and articles.

In the monograph edited by Yushkevich (1970) it is noted that "shoots of this concept though not yet realized or made explicit, were present in the Greek mathematics and natural sciences" (Yushkevich, 1970, p. 139).

The concept of function for the first time emerged in medieval Europe in connection with the renewal of attempts of mathematical studying of various natural phenomena...

For the subsequent development of the theory of functions crucial importance belongs to trigonometry and logarithms, on the one hand, and to the birth of symbolic algebra, on the other hand.

At the beginning of 17th century functions were still quite often defined verbally, graphically, kinetically or through tables, but already in the second half of the century their analytical expressions being to play a leading role.

The term 'function' for the first time appeared in Leibniz's manuscripts of 1673, in particular in the manuscript entitled 'The inverse method of tangents, or on functions' (Methodus tangentium inversa, seu de functionibus)... The terms 'variable' and 'constant' were introduced by Leibniz" (Yushkevich, 1970, p. 146).

The definition of function as analytical expression, for the first time was distinctly formulated by I. Bernoulli in the article published in "Memoires de l'Academie des Sciences de Paris" in 1718: "Definition. A function of a variable is a quantity composed in any way from this variable and constants". The notation $f(x)$ for a function was introduced by Leonhard Euler in 1734.

The further development of the concept of function is connected first of all with Euler's name. Yushkevich (1972) noted that "in the foreword to the 'Introduction to the calculus of infinitesimals' he (Euler. – I.S.) for the first time has distinctly expressed the idea that the analysis is the general science about functions, that the analysis of infinitesimals rotates around variable quantities and their functions" (Yushkevich, 1972, p. 250).

In the first chapter of the first volume L. Euler, correcting the definition of his teacher I. Bernoulli, "... has emphasized that functions are defined by formulas: 'A function of a variable quantity is the analytical expression composed somehow by its variable and numbers or constant quantities'. Thus the important step forward was done; the independent variable is considered as the set of all real and imaginary numbers so that functions of a complex variable were introduced on the equal rights with functions of a real variable" (Yushkevich, 1972, p. 250).

To compose analytical expressions one could use four elementary operations, computation of a root, exponential and logarithmic operations and, furthermore, "uncountable others, provided by integral calculus", meaning thus also the integration of differential equations.

Euler's definition of a function given in the first volume of the "Introduction to the analysis of infinitesimals", appeared to be too narrow for the calculus as a whole. Euler formulated the new definition of a function in his foreword to the "Differential calculus" (Euler, 1755): "When quantities depend on others in such a way that at the change of the last they are also changed the first are called functions of the second ones. This term has extremely wide character; it covers all the ways by which one quantity can be determined by means of others". In the quoted definition nothing is spoken about the way of calculation of values of a function.

Close to the modern definition of a function is Lobachevsky's definition: "...the general concept of function demands, that one should name a function of x a number that is given for every x and that gradually changes together with x. A value of a function can be given either by analytical expression or by a condition which gives means to test all numbers and to choose one of them, or, at last, dependence may be unknown" (Mathematical encyclopaedic dictionary, p. 617).

Thus, "... the classical definitions of a function given by Lobachevsky in 1834 and by Dirichlet in 1837 the second of which has passed to the latest textbooks ("If in some interval to each separate value x a unique value of the variable y corresponds then the variable y is called a function of x"), are hereditarily connected with a definition belonging to Euler" (Yushkevich, 1972, p. 254).

Felix Klein (1977, p. 291) on the other hand noted that, beginning with the development of Cantor's set theory "also functions defined for values of x from any set (not necessarily numerical) are considered..." In van der Waerden's classical textbook, we already see the quite modern definition of a mapping: "If to each element from some set M by any rule a unique (generally speaking, new) object ?(x) is put in a correspondence then this correspondence ? is called a function. If all objects ?(x) belong to some set N, the correspondence x??(x) is called also a mapping from M into N" (van der Waerden, 1930).

In the post-war decades (1945–1960), in connection with fast development of topology and abstract algebra, the most formal definition of a function (=mapping) was introduced into the world of mathematics: a function is a correspondence from one set into another (i.e., a subset of their direct product) where for any element x from the first set there is a unique element y from the second set such that the pair (x, y) belongs to this correspondence.

Klein (1977, p. 292) complained that "...the school mostly ignores all the development of a science which took place after Euler" and offered: "... we wish that the general concept of a function … has entered as the enzyme into all the teaching of mathematics at school; but it should be introduced not in the form of abstract definition but rather on concrete examples … in order to make this concept a living property of a pupil". He noted that "it would be desirable that among numerous teachers there was at least a small number of independently working people who would be familiar also with newest concepts of the set theory".

Despite Klein's appeal, formulated by him (and attributed by him to Euler) and more precisely by van der Waerden definitions of a function did not soon find the way to the educational practice and literature not only in secondary school but also in undergraduate mathematical education in our country. Up to the beginning of 21th century only the first part of Klein's appeal has been in essence executed: Euler's definition of a function has taken a strong place in school and university mathematical curricula. The second part – taking into account the development of mathematics after Euler and use of set-theoretic concepts has not been actually used until now at the either school or undergraduate level.

HISTORY OF TEACHING THE CONCEPT OF FUNCTION IN RUSSIA

In this preliminary survey of teaching the function concept we restricted the scope mainly by textbooks. Practices of teaching the notion of function have been largely determined by presentation of the subject in textbooks. These practices (of the last decades of 20-th century) have been partly described, e.g., by Dorofeev (1991).

Most probably, the first to mention the term "function" in Russian mathematical textbooks was Kotel'nikov who published in 1771 a book "On variable quantities" that was essentially the concise translation of Euler's "Introduction to the analysis of infinitesimals" (Prudnikov, 1956, p. 76). Note that the first German translation of Euler's "Introduction to the analysis of infinitesimals" appeared later, in 1788. Thus, Kotel'nikov's textbook was essentially the first translation of Euler's book into modern language. In this book, the definition of function was given where functions should be represented by analytical expressions. The similar definitions were given in the 3-rd volume of the textbook "Fundamentals of pure mathematics" published in 1812 by Fuss who was the disciple and grandson-in-law of Euler (Fuss, 1812, p. 278), and also in the 3-rd volume of the textbook "Course of Mathematics" by Osipovsky (Osipovsky, 1823, p. 2).

Generally, throughout the 19-th century the definition of function as analytical expression representing a dependence of variables prevailed (see. e.g., Scheglov, 1853, p. 310; Chebyshev, 1936, p. 8). The situation was slightly improved in the beginning of 20-th century when, following to the Klein's appeal, prominent mathematicians called to reform the mathematics teaching and, in particular, "to permeate the entire exposition of elementary algebra, beginning with elementary grades, by the concept of functional dependence" (Grave, 1915, p. 1). The textbooks with definitions not reducing functions to analytical expressions appeared (e.g., Shaposhnikov, 1908, p. 92)

In Soviet schools, up to the middle of 60-th the textbook of algebra written by Kiselev (first published before the October Revolution) was used with the following definition of a function: "That variable whose numerical values change depending on numerical values of another one is called a dependent variable or a function of that other variable" (Kiselev, 1964, p. 25). In the textbook there was a talk about tabulated and graphical presentations of functions; however the emphasis was made on the analytical expression of a functional dependence.

Similar definition was contained in the textbook of Barsukov for grades 6–8 used from 1956 to 1967: "If two variables are connected in such a way that to each value of one of them a unique value of another one corresponds, one speaks that there is a functional dependence between these variables. … If two variables are in a functional dependence, the variable that can accept any (admissible) values is called an independent variable… Other variable, whose values depend on values of the former one, is called a dependent variable or a function…" (Barsukov, 1967, p. 250).

Still in 1970, in the algebra textbook of Kochetkova and Kochetkov for grade 10 that replaced Kiselev's textbook, the similar definition is given (in the slightly more precise form), essentially ascending to Euler's one: "If to every value of a variable x somehow a certain value of another variable y is put in a correspondence one says that a function is defined" (Kochetkova & Kochetkov, p. 127).

The same situation is observed in undergraduate textbooks. In the textbook on higher algebra by Shapiro (1935, p. 5) also the functional dependence is stressed: "If two variables *x* and *y* are connected in such a way that to each value *x* a certain value of the variable *y* corresponds, then the variable *y* is a function of *x*: $y = f(x)$".

Similarly, in Sushkevich's textbook (1941) it is supposed by default that a function is an expression f(x), where x is a variable (p. 86). At the same time in his textbook there is (in a little archaic language) the quite modern definition of a group homomorphism with the requirement that to each element of the first group one has put in a correspondence a unique element of the second group, i.e. with the requirement to a homomorphism to be a mapping in the modern sense (p. 353).

Uspensky (2002, p. 163) noted that in Great Soviet encyclopaedia in 1956 a function was defined as a dependence of variables on other ones. He also mentions similar definitions of a function in authoritative undergraduate textbooks on calculus.

We explored a number of undergraduate textbooks on mathematics. Here are some results.

In the textbook of Stepanov (1953) on differential equations the definition of a function is absent. On the other hand, in the second edition of the textbook of Pontryagin (1965) the special appendix was added containing the modern definition of function as a mapping (pp. 292–293).

Note that the greatest mathematicians of the level of Luzin, Kolmogorov, Aleksandrov, Pontryagin, were apparently, first to realize the necessity of the introduction of the modern definition of a mapping into the scientific and educational literature. Such definition of a mapping is used in books of Luzin (1948), Aleksandrov and Kolmogorov (1948), Kolmogorov and Fomin (1954). Note that all these descriptions characterizing a function as a rule of correspondence were not strict definitions and left the concept of a function (mapping) undefined.

At the same time some great scientists still did not introduce the general concept of a function and its definition, limiting themselves to special cases. So did Mal'tsev (1956) and Gel'fand (1971) in their textbooks on linear algebra. Apparently, it was implicitly supposed, that mastering special cases of the concept of a mapping is enough for mastering the appropriate themes of mathematics, and it is not necessary "to multiply entities". Dorofeev (1978, p. 21) expressed similar educational ideas when he in a discussion article even protected a thesis about uselessness of the definition of a function: "Pupils have, basically, the correct substantial view of a function as a mathematical object, but experience significant difficulties when they encounter the definition of this object... This situation, namely the possession of a concept without knowledge of its exact definition is not strange at all... it is typical in the majority of kinds of human activity...".

Kolmogorov (1978, p. 29) in his reaction, however, indicated: "...Dorofeev ... at school in general ... allocates to any version of the set-theoretical definition of function a modest place (basically only for optional lessons). I think, however, that for school textbooks ... rules (composing the definition of the concepts of a function. – I.S)... should be given to pupils early enough and should be coordinated with some certain final definition".

Beginning with 1960s, as many researchers observe, owing to "bourbakization" of mathematics, set-theoretical concepts and, in particular, the general concept of a mapping (function) entered into curricula of secondary and tertiary school.

Kolmogorov supervised the reform of school mathematics teaching at the end of 60s. However, in the textbook for upper secondary school edited by Kolmogorov (first editions appeared in 1960s) a concrete definition of function is used, and authors consider only numerical functions: "A correspondence with a domain D where to each number x from the set D a unique number y corresponds by some law, is called a numerical function" (Kolmogorov et al., 1990, p. 20).

Thus, "Kolmogorov" reform did not aim at giving to teaching of mathematics abstract and formal character of what it was severely accused by opponents. The purposes were to eliminate archaic language and character of teaching, to correct the scientific level of mathematical education. The great attention was given to the didactical maintenance of the reform.

The general definition of a mapping has been introduced into the first textbooks corresponding to reformed curricula and published under the edition of Markushevich (1975) – the prominent mathematician and educator, the ally of Kolmogorov in the reforming of school mathematics. In 1960–70-s didacticians have developed also methods of teaching the concept of function at school (Kolyagin et al., 1977), and concluded that it is expedient to study the concept of function at school, consistently introducing concepts of sets, ordered pairs, direct products of sets, and correspondences.

The "Kolmogorov" reform met strong resistance in the school environment. Many of innovations were not accepted. It seems that "Kolmogorov" reforms were doomed to failure in conditions of inflexible, uniform and authoritarian education system. Some prominent mathematicians such as Pontryagin in 1980, attacked Kolmogorov reforms. They used as their mouth-piece the official magazine "Communist". The article in that magazine (as well as in the newspaper "Pravda") was equivalent to the denunciation. As a result, the general concept of a mapping, as well as other general set-theoretic concepts, has been expelled from school curricula, and Euler's definition of a function occupied a strong position in school mathematics.

In our opinion, this was a mistake, because the absence of the strict definition often complicates mastering the concept of a mapping by students in their further study in universities (Kolmogorov, 1991; Carlson, 1998; Bardini et al., 2014). We believe that, whilst not demanding from pupils the faultless possession of strict definitions, it is still necessary for them to attain an awareness of the modern definition of function.

Further development of methods of introduction and teaching of the concept of a function became possible in 1990-s when it was allowed to use alternative textbooks at school.

So, in the set of textbooks of Mordkovich for grades 7–11 the dialectic approach to the introduction of mathematical concepts is applied: "...the concept of a function ... should not, in a deep belief of the author, be introduced strictly from the very beginning, it should grow" (Mordkovich, 1998, p. 6). Strict definition of a function is introduced only in grade 9. Nevertheless, A. Mordkovich also considers only numerical functions, defining them in the language of variables.

We see a similar picture in the textbook of Bashmakov (1992, p. 11): "The variable y is a function of a variable x if such dependence between these variables is defined that for each value x uniquely determines the value of y".

Thus, the most widespread textbooks of mathematics for the senior grades contained definitions of functions which are similar to Euler's definition, as mentioned by Klein. We note also that Klein's advice was to introduce these definitions gradually, through examples. We see, that the majority of mathematical and educational community in Russia admitted that it is inexpedient to study the modern set-theoretical definitions of a mapping at school.

In undergraduate textbooks, since 60–70-s, the strict definition of a mapping basically has gained a strong position: one may mention textbooks of Skornyakov and Kostrikin on algebra, of Arnold on differential equations, of Zorich on calculus. In some textbooks for pedagogical institutes (for example, in the textbook of Kulikov on algebra) the strictness and formalism have got excessive character, complicating the learning of a subject. Nevertheless, in some undergraduate textbooks of the prominent scientists of the senior generation (for example, of Faddeev on algebra, of Gel'fand on linear algebra) authors still tried to avoid the introduction of the general definition of a mapping.

Thus, the final opinion about the introduction of modern strict definition of a mapping is not reached concerning not only school, but also the undergraduate textbooks.

Using historical school book excerpts for the education of mature mathematics teachers

Ysette Weiss-Pidstrygach[1] and Rainer Kaenders[2]

1 Johannes Gutenberg – University Mainz, Institute of Mathematics, Mainz, Germany, weisspid@uni-mainz.de

2 University of Bonn, Institute of Mathematics, Bonn, Germany

The use of historical and cultural perspectives in university mathematics education can support the development of self-esteem and maturity. It can bring together students with similar interests. We present the concept of a seminar on the analysis of mathematical textbooks and of learning contexts based on the consideration of historical excerpts. Such a seminar can become a starting point for a community of practice with the potential to develop social recognition and personal appreciation of the individual interests and talents of its members and their joint activities.

Keywords: Historical school book excerpts, mathematics teacher education for secondary schools, community of practice, Bildung.

INTRODUCTION

The organizers (among whom were the authors) invited gifted student teachers in mathematics at mathematics departments nationwide to apply for a four-day spring workshop in beautiful surroundings in Bonn that was paid for by the university – including travel and entertainment expenses. Despite this exceptional opportunity, only a few students answered this call. A closer investigation of this fact informed the organizers that most students, even the best mathematics student teachers, do not feel particularly *gifted*. In individual cases, there might be individual reasons for this, but in general, we interpret this phenomenon by the fact that these students were brought up in a school system in which they had to produce a required output in situations that are created and determined by others. The students learnt to interpret the evaluation and assessment of the learning output as a degree of their own learning success – just as how they learn in social networks to take the number of 'likes' on their posted output as a degree of esteem.

Mathematics student teachers for the gymnasium usually study mathematics in courses together with mathematics bachelor students, who study only mathematics (and a minor) all day. In mathematical tests and evaluations, they often perform weaker. The student teachers in Germany study next to mathematics a second subject and pedagogy, where they learn completely different perspectives and methods. Instead of feeling like a jack-of-all-trades they experience their inferior results in mathematics assessments as inferiority in terms of their 'giftedness'. Other forms of assessment as well as feedback from fellow students and professors do exist, but it seems that they are not taken as much into account as written mathematics examinations, as far as the self-conception of the student teachers is concerned.

Notably the *von Humboldt Bildungsideal* is built on two notions: the *autonomous individual* and the *cosmopolitan or Universalist (Weltbürger)* – that is, a universally interested person that cares about the important questions of humankind. The university should be – both for students and professors – a place for autonomous individuals to become such a *Weltbürger*. Furthermore, how do we want the students to act later as teachers, when they educate their own students? What is their understanding of *Bildung* and education at school? Student teachers, who are about to become responsible experts for *Bildung* at school, not only need to get in contact with these ideas, but should also be given opportunities to work on their own *Bildung* and personal development.

These considerations constitute in mathematics education the need for appropriate learning opportunities. Working on *Bildung* has an impact on one's whole personality and is therefore likely to last longer in professional practice. Here the history of mathematics plays an important role in mathematics teachers' education.

Several projects use historical themes for an autonomous study of student teachers or teachers. There are classical seminars, where students give talks on historical themes; there are websites to supply students and teachers with historical sources that can be used for teaching at school[1]. In addition, there are book projects evolving from seminars with students on historical matters (e.g., Van Maanen, 1995).

In this article, we reflect upon the set-up of a seminar around historical excerpts from schoolbooks that allows a process of value creation in a community of practice. First, we explore this idea by conceptual considerations and secondly, we illustrate the concept using Euclid's proof of the irrationality of √2 and the development of analysis.

ENLIGHTENMENT IN MATHEMATICS TEACHER EDUCATION

How can we transfer the existing learning opportunities in the above-described direction of *Bildung*?

The normal procedure in academic studies for student mathematics teachers is that they follow basic courses in pure and applied mathematics, courses and lectures in mathematics education, courses in educational studies (pedagogy, psychology) and study a second school subject on equal footing to mathematics. Only in some universities (e.g. Mainz) are there general courses on the historical and cultural roots of mathematics, reading courses and seminars for chosen topics in the history of mathematics. Assessments in mathematics are mostly tests on problem solving and mathematical terminology. Assessment varies in the history of mathematics and in mathematics education – we find essays, coursework, oral examination, seminar papers, presentations and homework assignments.

The feedback and assessment provided is thus much broader than in written mathematics exams. The problem is not that these alternative forms of assessment wouldn't exist. In mathematics, students hand in weekly exercises (often duos or trios) that are not only discussed qualitatively with the collaborating fellow students but also in weekly tutorials. Moreover, the students give talks in seminars. In mathematics education, in the history of mathematics, and in pedagogy courses as well as in most second school subjects, students have to write homework essays and give presentations. All this seems not to essentially affect the student's sense of self.

To sum up, with respect to *Bildung*, we encounter problems partly related to the common practices of assessment in mathematics courses:

— Student teachers appraise their own abilities according to their results in mathematical tests.

— The categories *right* and *wrong* characterize the attitude to mathematics.

— Prerequisites for teaching new content in mathematics are thought of in the form of activity-free knowledge (the student knows...).

— The bureaucratic Bachelor-Master system insinuates that education is about measurable outcomes, credits, evaluations, quality management, etc.

Do we want our future teachers to have this attitude towards their students? What are they going to teach them? Here, enlightenment ideals can still make a difference to the by now common views on education or training.

Immanuel Kant gave "An Answer to the Question: What is Enlightenment?" (Königsberg in Prussia, September 30th, 1784):

> Enlightenment is man's emergence from his self-incurred immaturity. Immaturity is the inability to use one's own understanding without the guidance of another. [...] If I have a book to have understanding in place of me, a spiritual adviser to have a conscience for me, a doctor to judge my diet for me, and so on, I need not make any efforts at all. I need not think, so long as I can pay; others will soon enough take the tiresome job over for me. The guardians who have kindly taken upon themselves the work of supervision will soon see to it that by far the largest part of mankind (including the entire fair sex) should consider the step forward to maturity not only as difficult but also as highly dangerous.

In this quote, one can sense what the age of enlightenment intended by education. Since present ways of teaching leave the student's perception of self at the side of the educational system, the above-mentioned problems can be understood as a lack of enlightenment in mathematics teacher education.

What alternative ways and models are there to change the sense of self and the self-esteem of students in order to become individuals that are more autonomous?

COMMUNITIES OF PRACTICE AND A GROWING MATURITY

In order to become autonomous, mature individuals the students need to experience a sense of self in which their own personal values for their development arise, ones that are supported by a recognition of other like-minded people with similar developing interests – backed by universal values and rules. In that way, they can actualize themselves and determine their own actions.

Hence, we need a course that allows university teachers and students to develop a community of practice, which fosters their development as far as orientation, maturity, autonomy, emancipation, responsibility, self-actualization and self-determination are concerned. To this end, we withdraw our guidance in small steps and replace it by development through progress in the community. Such development of value systems has been described in the discourse on communities of practice. For instance in (Wenger, 2002; chapter 8), we find several procedures for measuring and managing the value creation of a community or network. Such value creation methods are nowadays widely used in management. When we compare the five cycles of value creation, we discover some similarity between this procedure and the five basic questions for the preparation of lessons as Klafki (1963) formulated them. We use the value assessment framework as tool to structure the seminar and its development. A constant reframing and reconsideration of how success, appreciation and development are defined characterize the framework.

A SEMINAR ON HISTORICAL EXCERPTS FROM SCHOOL BOOKS

Historical excerpts from schoolbooks form the basis for an activity in the framework of the seminar. The goal is to undertake small-step lesson planning, starting from the "historical" excerpt. How can such an existing historical excerpt be augmented to curriculum-relevant teaching that serves the *Bildung* of the students? In Germany, there are a handful of schoolbook series that are used extensively in school (Rezat, 2010; Otte, 1981). The historical insertions in these books are all of a similar kind. Since these historical references stem from books that teachers use in their daily teaching at schools, they constitute a link of this activity with the practice. Indeed, when the future teacher finds her or himself teaching with the help of such a schoolbook later, it might be an occasion to unfold the learned attitude again – together with students and colleagues. In addition, it would be possible to get teachers from school involved in the project. Therefore, the seminar at the university already has the goal of letting the participants find like-minded people, who are also interested in history of mathematics and the development of mathematical contents.

Designing the seminar and also tackling the aforementioned problems in self-esteem and predominance of normative results, means starting with sufficiently open but concrete tasks and leaving a lot of time for group discussions: "A key element of designing for value is to encourage community members to be explicit about the value of the community throughout its lifetime. Initially, the purpose of such discussion is more to raise awareness than to collect data, since the impact of the community typically takes some time to be felt." (Wenger et al., 2002, p. 60).

A motive of development and support for a community of practice uniting student mathematics teachers, mathematics teachers, mathematics educators, mathematics textbook authors, historians, educators, other social science people and workers in further education (teacher development) leads to various activities. This motive defines activities and possible actions during the running seminar as well as long term planning as the:

— organisation of student teaching to apply the developed material,

— establishment of connections to textbook authors,

— development of an internet page with additional materials to the historical excerpts,

- linking of related existing internet sources with the materials of the seminar,

- development of activities for teacher in-service training on the basis of the additional materials to the historical excerpts and some aspects of the use of history in mathematics classes.

For our project in Germany, the enormous influence of mathematics textbooks on teaching – especially at the beginning of the career – is essential. In other countries and periods, this might be different. For the development of a community of practice in the spirit we are aiming at, it is important that the joint activities generate joint creations, have a context that is relevant to the participants, are related to their personal experiences and manageable by any member (the excerpts are small – about one page). An important step in transforming the seminar into a community of practice is the emergence and display of immediate values and potential values of the community. Having this in mind, monitoring, structuring and back up of the first group's discussions are important.

The students work in groups on one excerpt. They choose the topic and the material from the books on different grounds, for example:

- individual historical or mathematical interests,

- relations to other school subjects,

- experiences from their practical lessons or teaching in school,

- experiences in tutoring students,

- the wish to be in a team with a best friend.

The activities and interactions between members of the seminar in the group discussions, the choice of the material and plans to unfold it are important for the immediate and potential value of the further community.

Intentions of the discussions are, for example for students to get to know their biases and preferences, to start a general discussion about the use of textbooks and the particular design of the textbooks they will deal with, the realising of interrelations between topics studied in history of mathematics courses, the introduction of existing materials related to the excerpts and the repetition of basics in lesson planning and textbook use.

According to Wenger and colleagues (2002), one of the tasks of the seminar leader is to understand which potentials and *knowledge capital* of the community can be put into use. It may be helpful to give introductory presentations to support structure and to display possible joint activities.

When dealing with a schoolbook there are essentially three perspectives that one can take: the high school student's perspective, the teacher's perspective, or the perspective of the schoolbook author. While being used to the first perspective, the students usually struggle with the two more mature ones. Here we see the major role of communities of practice.

The textbook analysis starts from the perspective of a student, e.g. reading of the chosen excerpts, solving related problems, clarifying prerequisites and presenting the results. The teacher's perspective comes with learning objectives, reflection on the assumed knowledge, time management, and representation of the solutions of the problems. The perspective of an author appears in questions about the way history is used, the accuracy of the presentation of the historical fact, the design of the historical excerpt and the learning objectives of the involvement of history.

The three perspectives are understood as levels of awareness (Mason, 1998). Cooperation of the students is organised by grouping around interests in mathematics, history or interdisciplinary questions related to concept development. For the analysis of the mathematical textbook students can take a historical perspective, asking questions related to the story of a mathematical problem, the history of an idea, the story of a mathematical area, the biography of a mathematician, the story of an institution, the history of a concept.

Questions arising from a mathematical perspective are:

- How do modern notations and representations differ from historical ones?

- Which problems led to the imposition of a term?

Examples	Proof that $\sqrt{2}$ is an irrational number. *Assertion*: $\sqrt{2}$ is irrational. *Proof by contradiction*: Assume the opposite is true.	
The proof on the right is the eldest historically handed down proof for the irrationality of $\sqrt{2}$. At the same time, it is an especially beautiful example of an indirect proof. 	Consequences:	Explanation:
	(1) $\sqrt{2}$ is irrational.	
	(2) $\sqrt{2} = \frac{p}{q}$	Can $\sqrt{2}$ be represented as simplified fraction $\frac{p}{q}$?
	(3) $2 = \frac{p^2}{q^2}$	squaring of the equation
	(4) $p^2 = 2q^2$	resolving to p^2
	(5) p^2 is even	property of even numbers
	(6) p is even	property of even numbers
	(7) $p = 2n$	p is even, hence divisible by 2
	(8) $p^2 = 4n^2$	squaring of (7)
	(9) $4n^2 = 2q^2$	inserting (8) in equation (4)
	(10) $2n^2 = q^2$	dividing the equation (9) by 2
	(11) q^2 is even	property of even numbers
	(12) q is even	property of even numbers
	(13) $q = 2m$	q is even, hence divisble by 2.
	(14) $\frac{p}{q}$ is not a completely simplified fraction	p and q are even, so both are divisible by 2 .
This is a proof by contradiction to the assumption that $\sqrt{2}$ is representable by a completely simplified fraction. Hence, $\sqrt{2}$ is irrational.		

Figure 1: Historical excerpt from a German schoolbook (Neue Wege, 9. Schuljahr)

— What is the mathematical statement of a historical mathematical text source?

The perspective involving reflection on historical, mathematical and cognitive development is the most complex and advanced. It includes theoretical frames for concept development with historical references; that is to say, a historiographic approach, a hermeneutic approach, mathematical awareness, use of history as a mathematical tool, 'Whiggish' approaches or cognitive genetic and historical genetic approaches.

Student work is organised in groups attached to an excerpt. There can be several groups working on one historical textbook excerpt. The joint product of the group activities consists of a joint essay and short lesson plan related to different perspectives, from a historical and from a mathematical point of view. Let us consider two examples.

Example from geometry – reproductions, excerpts from historical sources

Here, we consider a reproduction of a small part of a small historical source. We look (Figure 1) at the *historical proof* of the irrationality √2 from Euclid, which one can find in most textbooks in a similar way:

1) First students will study the proof from the perspective of a high school student. Corresponding mathematical questions from their perspective

could concern the logic of the indirect proof, the logic of the arguments, and proof of the used arguments, mathematical terms and notations.

2) From a historical perspective, it is natural to search for the primary source and to compare it with the reproduction. In this case, it leads to an interesting search for a translation, containing the mentioned proof. At this point, the discussion can be supported by translations with commentaries introducing the students to historical questions that are related to translations and the choice of documents we are referring to when citing Euclid.

3) From the perspective of a teacher, the students would discuss whether the presentation helps to support mathematical understanding, what additional materials with enactive and iconic presentations can be used, and how to evaluate the understanding of the proof. Historical questions could deal with the use of original sources, with additional materials about Greek mathematics, and interdisciplinary learning environments relating to history, mathematics and philosophy.

4) Taking the perspective of a textbook author one could start with the question of whether history in this excerpt is used as a tool or as an object (Jankvist, 2009). Looking at the presentation and the use of modern notations can lead to questions related to *Whiggish* (Fried, 2001) presentations and their justifications. Another aspect is the use of geometrical concepts in Euclid's books and their algebraization in modern school mathematics.

To support group discussions, the tutor could give introductions to Greek mathematics, an overview of Euclid's *Elements* or an introduction to Geometric Algebra. Both translations and secondary literature on Euclid are easily accessible to the students. In this case, one would initially not provide reading material but rather help students to organise and structure the found sources.

An example from analysis

We now have an example of another kind. The textbook authors give a historical overview over a longer period. This excerpt at hand starts with general remarks about the roots of mathematics and analysis. The first mentioned mathematicians reach from Archimedes to Riemann. The excerpt ends with general remarks on the contemporary role of analysis and its central place in the study of mathematics. The subsequent questions are challenging for high school students

Excursion

… After these preparations, in the 17th century, the Englishman Isaac Newton and the German Gottfried Wilhelm Leibniz independently laid the foundation for analysis with infinitesimal calculus.

Newton assumed variable magnitudes to be time-dependent and called them "fluents" (flowing ones). By the derivative with respect to time, he denoted their instantaneous velocities ("derivative"), which he called "fluxions" and marked them with a dot (e.g., $\dot{x}$).

Newton calculated the fluxions by limit considerations. Since such a practice did not fit to his own methodological ideals, at first he did not publish his results, but just mentioned them indirectly while arguing with time-independent geometrical magnitudes.

In that way, it happened that the Germen Gottfried Wilhelm Leibniz developed about ten years later his own theory for the notion of derivative. Leibniz regarded a curve as an "infinity-gon", such that a tangent would intersect the curve in an infinitely small line segment. Here he built, amongst other things, on the insights of Cavalieri. Leibniz introduced the notion of "differentials", which brought forth the notion of "differential calculus". The quarrel between Newton and Leibniz, about which one of them would first have discovered the notion of derivative, has found its way as priority dispute into history of mathematics.

In the course of time, analysis was first further developed without really substantiated foundations. Only in the 19th century could one work with it in a way that fits today's standards, for only since then have notions like function, limit or integral been clarified precisely. To this end, the mathematicians Joseph Louis Lagrange (1736–1813), Augustin Louis Cauchy (1789–1857), Karl Weierstraß (1815–1879), Carl Friedrich Gauß (1777–1855) and Richard Dedekind (1831–1916) contributed in crucial ways.

The integral, in the form it is taught nowadays at grammar schools, goes back to the German mathematician Georg Friedrich Bernhard Riemann. Riemann determined the area that is bounded by the x-axes and the graph of a function by the help of easy to calculate areas of rectangles. The idea of the so-called "Riemann integral" was later further developed by the French mathematician Henri Léon Lebesgue (1875–1941). …

Figure 2: Historical excerpt from a schoolbook (Lambacher Schweitzer, pp. 165–166)

... Prepare a presentation about the history of analysis. To this end, read up on more contributions of the mathematicians that are introduced in the excursion. Take the following points into account:
Which mathematician is credited with the discovery of the exhaustion method? How did Galilei determine the velocity resp. the acceleration of a ball rolling down an inclined plane? What is understood by the theorem of Cavalieri? Explicate Newton and Leibniz's approach to the notion of derivative, giving examples.

Figure 3: Exercise related to the historical excerpt in Figure 1

and for the student teachers in the seminar too. In the case of an overview, a restriction on a well-selected aspect is helpful. In the case of the development of calculus, Barrow-Green (2008) and Blåsjö (2015) give wonderful examples of how to illustrate development.

For the development of the perspective of a teacher or even a textbook author additional help by the tutor is necessary.

The excerpt offers at several places the opportunity to go deeper into history. This single excerpt can supply the seminar with questions and aspects to be explored for many semesters. For our example we restrict ourselves to just one of them.

RESUMÉ

We are aware that the development of a community of practice of mathematics teachers and mathematics educators interested in history is a long-term task.

At the present economising of university life and the strong dominance of normative value systems we consider this experiment nevertheless particularly important.

“It is necessary to understand where we have come from so that we can further the journey”: History of mathematics in the formation of teacher identity

Maurice OReilly

St Patrick’s College Drumcondra, CASTeL, Dublin, Ireland, maurice.oreilly@dcu.ie

The author draws on his work with pre-service mathematics, physics and chemistry teachers taking a capstone module including six hours of History of Mathematics (HoM). He reflects on this experience using two perspectives: Clark’s application of Ball’s mathematical knowledge for teaching (MKT) in the context of prospective secondary mathematics teachers (PSMTs) use of history, and ongoing work on both teacher identity and ‘Mathematical Identity’.

Keywords: History of mathematics, prospective secondary mathematics teachers, mathematical identity.

SUMMARY DESCRIPTION

Initial teacher education is an activity that necessarily occupies a hybrid space, drawing on several epistemologies. The tension between pedagogy/didactics, on the one hand, and the ‘disciplines’, on the other, is ever-present. In the HPM community, we believe that HoM should play a central role in teaching mathematics (e.g., Kjeldsen, 2012) and yet we struggle to find where and how to locate HoM in practice (e.g., Guillemette, 2012).

The context of this reflection involved 34 students in the second semester of their final (fourth) year of the BSc in Science Education at Dublin City University, meeting once a week for a 3-hour session background in over a period of twelve weeks in the spring semester of 2014. All students had significant background in mathematics, physics and chemistry (and majoring in two of these) and involving substantial school placement. The author accepted the invitation of the module coordinator to prepare and deliver two 3-hour sessions on HoM, and to design assessment associated with these sessions.

Students were required to choose a ‘fact’ from the MacTutor HoM Archive and respond to one of two questions online relating to their chosen fact, in fewer than 100 words. The first 3-hour presentation followed this exercise immediately, the intention being that students would have some short, yet intense, engagement in HoM in advance of a substantial presentation. The second more extensive exercise required students to make a connection between one reading (from a choice of seven) and one (or two) web links (from a choice of twenty) to HoM topics ranging in time from Plimpton 322 to the fundamental theorem of algebra. The second 3-hour session comprised a presentation on these twenty topics and a group discussion, and immediately followed the second exercise.

Details of the range of student responses emphasising their mathematical thinking and their expectations of using HoM in their teaching are presented. This discussion relates to the aforementioned work of Clark (2012) which uses Ball’s MKT framework.

It also draws on the author’s own work and that of his collaborators (Eaton, Horn, Liston, Oldham, & OReilly, 2014) on Mathematical Identity to give a different perspective on the data arising from the second exercise just outlined. Mathematical Identity developed out of the works of several researchers such as Wenger (1998), Sfard and Prusak (2005) and Kaasila (2007). Initial consideration of these data, through the lens of Mathematical Identity, indicates a promising approach to encouraging PSMTs to take HoM seriously in their future careers.

In keeping with the work of Eaton and colleagues, attention is drawn to the narrative elements of the data and in particular to the evolution of students' perception of mathematics and their experience of learning/teaching it over time. It seems that the inclusion of HoM can be a catalyst to enrich such narrative and consequently strengthen students' Mathematical Identity.

Primary sources in the elementary school

Vasiliki Tsiapou

University of West Macedonia, Kozani, Greece, vana@semiphoto.com

The poster reports on the design and the implementation of a pilot teaching intervention – part of my ongoing research – with two historical texts. The sample was a small group of Greek students of the 6th grade. On the poster I present the texts, the design, and photos of student's activities.

Keywords: Primary historical sources, elementary education.

The historical texts belong to Liu Hui, a renowned Chinese mathematician of the 3rd century CE. The first one is his commentary (Lay-Yong & Tian-Se, 1986) on a problem of a circular field which is included in the ancient Mathematical Canon *'The Nine Chapters on the Mathematical Art'*. The area of the field is the unknown, but the data assumed π to be 3. The Canon offered four algorithms and the solution. Liu Hui proved the correctness of the first algorithm and gave a more precise value of π. The second text is the preface of Liu Hui's commentary on the canon. In this text Liu Hui reveals his reasoning and pedagogical considerations (Siu, 1993).

OBJECTIVES – DESIGN AND IMPLEMENTATION

The objectives are for students to: 1. make a transition to the more theoretically oriented geometry of middle school; 2. appreciate mathematics as a human creation and of different cultures; 3. engage in meta-level discussions about in issues and meta-issues of History (Jankvist & Kjeldsen, 2010). For addressing the objectives I designed a historical module (Jankvist, 2009) with the use of MKT (Ball, Thames, & Phelps, 2008) as the overall framework under which I tried to coordinate domain specific frameworks (i.e. proof in the elementary school's settings).

The implementation of the module had three phases: Introduction, Analysis and Synthesis (Jahnke, 2000). In the *introductory part*, I provided historical information about the socio-historical context and the mathematics at the time of Liu Hui. The use of History was under the conceptual dipole *'History as a goal'-'History'* (Tzanakis & Thomaides, 2011) and partly the second objective was addressed. In the *analysis part*, and for the first objective (*'History as a tool'-'History'*), students were reading small excerpts of the first text, and were decoding the commentator's guidelines. During the teaching students were encouraged to develop reasoning and communication skills (i.e. to explain and justify using deductive reasoning). In order to prove the geometrical face of the proof (the correctness of the first algorithm) students had tactile experiences and constructed geometric figures with conventional and digital tools. For the arithmetical face of Liu Hui's proof (the reason that π is 3.14), which is not highlighted in the Greek textbook, students made process pattern generalizations and filled in and interpreted tables and spreadsheets. In the *third part* I tried to address the last two objectives. I gave information about the commentator's philosophical context and with a more playful activity under the name 'the cards of philosophy', I engaged students in meta-issue discussions about the relationship between Liu Hui's work and philosophy *('History as a goal'-'History')*. In this activity I incorporated the second text and students discussed about Liu Hui's internal factors, by reflecting on the first text's activities. Also, following Liu Hui's concept of the discipline of mathematics as a 'tree', students created their own 'tree' connecting mathematical topics that they had used while they were dealing with the proof. In the end students presented to peers a synthesis of their work.

The integration of primary sources in the elementary school's mathematics may seem challenging for various reasons. Yet, if we want to stay true both to the commitments of mathematics education and of the History of mathematics (Fried, 2007) it is worthwhile to explore the possible ways to do so.

INTRODUCTION

The aim of the Early Years Mathematics working group is to share scholarly research related to mathematics education concerning children aged 3–8. This age group spans preschool through the early grades of primary school, and takes into consideration that in different countries children begin primary school at different ages. During CERME9, there were approximately 30 participants (authors and co-authors), with 20 accepted papers and 7 accepted posters. Of the 20 papers, one paper was a literature review paper on early childhood education (Alpaslan & Erden); the rest were empirical studies (12 related to preschool and 7 to primary school). There were 6 posters reporting empirical studies conducted within the preschool environment and one poster which described a STEM project promoting popular science which involved both mathematicians and scientists (Sorokina)[1].

The structure of the timeslots was designed in order to stimulate interaction and collaboration among participants and was as follows. Related papers were paired and after a short presentation of the first presenting author, a prepared question was posed by the second presenting author which initiated a general discussion. The roles of the presenting authors were then exchanged. Each pair of papers was allotted nearly 40 minutes. Posters were also allocated a few minutes of presentation time within the working group. One timeslot was devoted to small group discussions about general issues that had been raised during the papers and posters presentation. This report draws on the outcomes of these small group discussions and of an extra meeting of co-leaders with a few participants who had volunteered to help in the preparation of the report. On the last day of the conference, our room was visited by more than twenty colleagues from other working groups, where a lively discussion ensued.

In addition to the presentations, we had the privilege of visiting a local preschool. Very early in the morning, a group of participants visited the *Materska Skola, Opletalova 14, Praha 1*, directed by J. Moravcova, accompanied by Michaela Kaslova, one of the participants of the TWG. This visit was really interesting as it explained, better than a report, the organization of preschools in the Czech Republic.

IS EARLY YEARS MATHEMATICS "MATHEMATICS"?

The above question was raised and discussed in the first session of the TWG and continued to be in the background of many discussions throughout the conference. Our shared answer was positive. Early years mathematics is mathematics when it fosters the development of mathematical processes. We can study the construction of mathematical meaning at each age. Some of the participants preferred to use the terms pre-mathematics or prepa-maths (see Fuchs et al., 2015; Kaslova, 2010) in order to emphasize that during the early years, the concern is for the processes which enable construction of mathematical meanings as opposed to the rote learning of terminology, techniques and calculation. It is important to raise public awareness about early years mathematics (e.g., through informal mathematics or new STEM projects). The papers and posters presented during

1 These short references hint at the authors of papers/posters in the TWG.

TWG13 sessions offer a wide variety of examples of mathematical meanings to be constructed during those early years.

Preschool mathematics

The construction of mathematical meanings in preschool was presented by several authors in a variety of cases: the give-N task (Rinvold & Erstad); comparison of whole numbers (Tubach); conceptual subitizing (Rodrigues, Cordeiro, & Serra); the meaning of double (Björklund); mathematical discourse (Lavi); the coordination of the audible, the visible and the tangible (Pimm & Sinclair); unsolvable problems (Tirosh, Tsamir, Levenson, Tabach, & Barka); measurement (Erfjord, Carlsen, & Hundeland; Skoumpourdi), shapes (Erfjord, et al.; Pettersen, Volden, & Ødegaard), and symmetry (Demetriou).

While discussing the various mathematical activities described in the studies, it became aparent that different countries have different curricula with specific mathematical goals for preschool. The group expressed the need to know more about the organization of preschool in each country. Two cases were explicitly discussed – Italy and Sweden – observing that in both cases the preschool curriculum had been developed (in Italy in 1991, in Sweden in 2010) following Bishop's (1991) analysis of the universal activities for mathematical enculturation: counting, locating, measuring, designing, playing, explaining (Svensson). In addition, it was noted that programmes for preschool teacher education and development must be encouraged, where clear mathematical goals and ideas for learning trajectories for children are pinpointed. A specific example of a test for diagnostic purposes was analysed (Kaslova). The group discussed the risk that this kind of testing may introduce (e.g., teaching to test).

Primary school mathematics

Several authors offered examples concerning mathematics in early primary school:

Grade 1: inclusive definition of squares and rectangles (Bartolini Bussi & Baccaglini-Frank); conceptualizing parallel and perpendicular lines (Vighi).

Grade 2: multiplication tables (Maffia & Mariotti); magic squares (Maj-Tatsis & Tatsis).

Grade 3: patterns (Ferrara); fractions on the number line (Robotti, Antonini, & Baccaglini-Frank); employing the bar model for solving arithmetic word prblems (Koleza).

In most of the above examples, argumentation was also emphasized.

The teacher's role in promoting mathematics was the explicit focus of some contributions (Delacour; Erfjord et al.) but was also discussed in other cases. The group agreed that it is important to reach a balance between structured activities controlled by the teacher and fostering conditions which will encourage children´s agency. The issue of agency in preschool was the explicit focus of one contribution (Erfjord et al.).

CONTEXTS

Part of the time during small group work was used to discuss the issue of different contexts. Without entering into a review of the related literature, there is a risk of misunderstanding the notion of context. However, defining what is meant by context that was not the aim of this working group. Instead several papers and posters related to context either when describing a specific task, a specific piece of mathematics knowledge or a specific intention of the teacher/researcher. More generally, there are also institutional contexts (see, for instance, the short reference above on curricula in different countries) and the sociocultural contexts (Jaworski et al., 2015).

We collected meaningful examples of different contexts (in all of the above meanings) concerning

- outdoor activities in northern countries in the very cold winter (Delacour in Sweden and Erfjord et al. in Norway), which was quite astonishing for researchers from southern countries but are, on the contrary, a part of the shared values of their culture;
- families as places for mathematical play (immigrant families in Germany, Solmaz);
- informal (out of school) activities (Math circles, STEM camps, talks with a mathematician, Sorokina).

When the focus was on school mathematics, we had many examples of using manipulatives, either con-

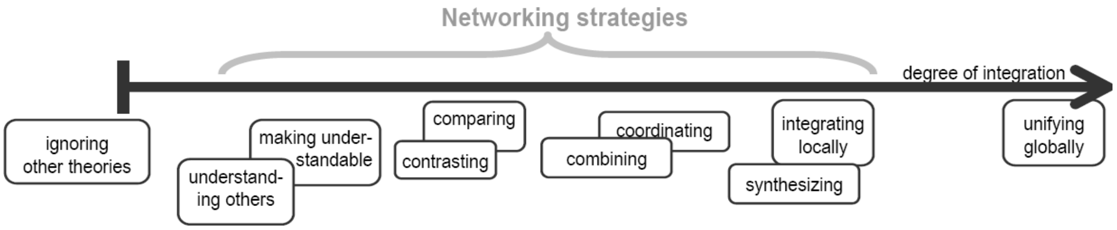

Figure 1: Networking strategies

crete manipulatives (cardboad collection, Demetriou; straws, Vighi; three dimensional models and folding solids, Pettersen et al.; blocks, Solmaz; virtual manipulatives (programmable robots, Bartolini Bussi & Baccaglini-Frank; softwares and apps, Pimm & Sinclair). Comparing concrete and virtual manipulatives was also investigated and discussed (Demetriou).

THEORETICAL FRAMEWORKS AND RESEARCH QUESTIONS

Several different theoretical frameworks were mentioned:

- variation theory after Marton (Björklund);
- levels of artefacts after Wartofsky (Svensson);
- semiotic mediation after Bartolini Bussi & Mariotti (Bartolini Bussi & Baccaglini-Frank; Maffia & Mariotti);
- discoursive approach after Sfard (Lavi; Vighi);
- semiotic bundle after Arzarello and colleagues (Ferrara);
- theory of didactic situation, didactical contract after Brousseau (Delacour);
- theory of knowledge objectification after Radford (Rinvold & Erstad);
- Interactional niche after Krummheuer (Solmaz);
- grounded theory (Arnell);
- sociocultural theories after Rogoff (Erfjord et al.).

In most cases, it seemed that theoretical frameworks are chosen with reference to either authors or groups of authors from the same country; this choice could be misunderstood as patriotism, it is not necessary the case. For instance, the semiotic mediation theory is useful in countries where the focus is on long term studies, which in turn depend on the institutional role of a teacher working for more than one year with the same group of pupils (Italy: Bartolini Bussi & Baccaglini-Frank, Ferrara). Hence, we have another interesting example of the influence of cultural contexts research on early years mathematics.

The relationship between context and theoretical framework is a big challenge for the diffusion of findings and the possibility of exploiting findings from different cultural contexts (Bartolini & Martignone, 2013). The presence of different theoretical frameworks shows that it is timely to discuss networking theories, according to the vision developed by Bikner-Ahsbahs and Prediger (2014, p. 170).

This issue might be focused in CERME10.

According to different theoretical frameworks, the authors of papers/posters have developed different kinds of empirical studies:

- intervention studies (short term and long term studies; attention to the teacher's role or focused on learners; examples of STEM in informal education)
- observation studies (observing learners; observing teachers; observing classroom processes)
- studies on teacher education .

It is difficult in some cases to make this clear distinctions, as in developmental projects the main idea of the activities is a result of a process of the engagement between researchers and teachers.

CONCLUDING REMARKS

The discussion sketched above left a problem open. During the last meeting with visitors from other TWGs we realized that there was some overlapping between the TWG13 and other groups, for instance the TWG02 on *Arithmetic and number systems*, where a major focus was on primary school arithmetic. One possibility to avoid overlapping is to interpret *Early year mathematics* as focused solely on preschool. This choice might be problematic because of the different institutional interpretation of preschool and primary school in different institutional context (a relevant example was offered by Vennberg, with the "transition" year between pre-school and primary school in Sweden). One of the arguments for continuing the TWG13 on *Early year mathematics* with focus on both is the importance to study also continuity between the two kinds of schools. Participants of TWG13 added that the exchange between researchers of both levels contributed to the general understanding of issues related to teaching and learning mathematics during these critical years.

Research papers

Using pivot signs to reach an inclusive definition of rectangles and squares

Maria G. Bartolini Bussi and Anna Baccaglini-Frank

Università di Modena e Reggio Emilia, Dipartimento di Educazione e Scienze Umane, Modena, Italia, bartolini@unimore.it

We present some fragments of a teaching experiment realized in a first grade classroom, to sow the seeds for a mathematical definition of rectangles that includes squares. Within the paradigm of semiotic mediation, we studied the emergence of pivot signs, which were exploited by the teacher to pave the way towards an inclusive definition of rectangles and squares. This was done to favor overcoming children's spontaneous distinction of these figures into distinct categories, reinforced by everyday language. The experiment is an example of an approach towards the theoretical dimension of mathematics in early childhood.

Keywords: Bee-bot, first grade, pivot signs, rectangles, squares.

INTRODUCTION

Rectangles and squares represent a paradigmatic example of the conflict between the perceptual experience and the theoretical needs of a mathematical definition (on this persisting conflict also see Hershkowitz, 1990; Clements, 2004; Fujita, 2012; Koleza & Giannisi, 2013), where squares are to be considered as particular rectangles (we will refer to a definition of rectangles that includes squares as being *inclusive*). Mariotti and Fischbein (1997) claim that "from the figural point of view squares and non-square rectangles look so different that they impose the need of being distinguished at least as much as triangles and quadrilaterals" (Mariotti & Fischbein, 1997, p. 224). Actually the difficulty of naming and classifying geometrical figures (and, in particular, squares and rectangles), according to inclusive criteria, seems to depend on different reasons:

— the implicit constraints of everyday language: for instance, both in Italian and in English (as well as in other European languages) the names "quadrato" [square] and "rettangolo" [rectangle] hint at a complete separation of the figures into two different classes (square and not-square rectangles);

— some widespread improper practices in school which reinforce the separation between squares and rectangles (for instance, activities with attribute blocks, where squares and non-square rectangles are classified in different sets).

Hence, teaching needs to orient learning towards an inclusive definition. The question is: *at what age?* We claim that, although this choice may create a discontinuity between everyday language and school language, it is possible from early childhood to sow the seeds of an inclusive definition, focusing on the experience of walking along or drawing a rectangular path, where the change of direction in the four angle vertexes has the potential to attract the students' attention. In the following, we report on some fragments of a long term teaching experiment, carried out within the theoretical framework of semiotic mediation (Bartolini Bussi & Mariotti, 2008). Additional details are discussed by Bartolini Bussi and Baccaglini-Frank (2015).

THEORETICAL FRAMEWORK

In order to design and to analyze the teacher's role in the classroom teaching process, we adopted the theoretical framework of semiotic mediation (Bartolini Bussi & Mariotti, 2008; Bartolini Bussi, 2013). The design process is represented by the reciprocal relationships between the tasks, the artifact, and the mathematical knowledge at stake. In this relationship the *semiotic potential* of the artifact is made explicit. The artifact is the *bee-bot*, a small programmable robot represented in Figure 1 (also see the next section). When children are assigned a task they engage in a rich and complex semiotic activity, producing traces (gestures, drawings, oral descriptions and so on), that we refer to as "situated texts". The teacher's job is to collect all these traces (by observing and listening to the children), to analyze them and to organize a path for their development into "mathematical texts" that can be put in relationship with the fragments of mathematics knowledge that are to come into play.

Figure 1: Bee-bot's back

The process of semiotic mediation also concerns the functioning of semiotic mediation within the classroom. The teacher acts as a cultural mediator, in order to exploit, for all students, the semiotic potential of the artifact (the bee-bot in our case). In this last process, Bartolini Bussi and Mariotti (2008) identify three main categories of signs: artifact signs, pivot signs, and mathematical signs. *Artifact signs* "refer to the context of the use of the artifact, very often referring to one of its parts and/or to the action accomplished with it. [...]"; *mathematics signs* "refer to the mathematics context" and *pivot signs,* which "refer to specific instrumented actions, but also to natural language, and to the mathematical domain" (ibid, p. 757). *Pivot signs* can be particularly useful for fostering a transition from situated "texts" to mathematical texts. Pivot signs develop and are enriched by their relationships with other pivot signs, hence building a *network* of pivot signs. Mathematical signs are not intended to suddenly substitute artifact signs; in fact the latter may survive for some time, especially for lower achievers or in cases in which the formal mathematical definition and the reasoning of the corresponding concepts require long term processes to be achieved.

Within this framework, our study addressed the following research questions:

(1): How might a long-term process of semiotic mediation that exploits the semiotic potential of the bee-bot with respect to the development of an inclusive definition of rectangles look for first graders?

(2): In particular, which kind of pivot signs (if any) can be identified and exploited during such long-term process?

THE CHOSEN ARTIFACT: THE BEE-BOT

The bee-bot (Figure 1) is a small programmable robot, especially designed for young students. Its ancestor is the classical LOGO turtle, originally a robotic creature that could be programmed through an external computer to move around on the floor (LOGO Foundation, 2000). It is not necessary to have any additional computer to program the bee-bot; this can be done simply pressing a sequence of command buttons on its back. When the programme is executed, the bee-bot moves on the floor: the execution of each command is followed by a blink of the eyes and by a short beep-sound. The bee-bot hints at many sets of meanings and mathematical processes, partly related to mathematics and partly related to computer science, for instance: counting (the commands); measuring (the length of the path, the distance); exploring space, constructing frames of reference, coordinating spatial perspectives, programming, planning and debugging. In a long term teaching experiment, all these sets of meanings are at stake, sometimes in the foreground and sometimes in the background. Focusing on any set of them depends on the adult's teaching intention. The bee-bot walks on the floor and traces paths that can be perceived, observed, described with words, gestures, drawings, sequences of command-icons and so on. Paths (either traced or imaginary, when no trace mark is actually left) constitute a large experiential base to "study" some plane figures, that can be traced using the available commands. These are polygons with sides measured by a whole number of steps and with right angles only. With the additional constraint of being convex, the bee-bot can be programmed only to turn "left" or "right" (with respect to itself), and therefore the convex polygons it can trace are always rectangles (including squares). Moreover, in experiences where "pretending to be the bee-bot" is essential, children embrace the robot's perspective: they move with the bee-bot and they see through its eyes. In particular, when walking along a closed convex path and ending up where they started, the children turn 360° in four equal "chunks" during which their orientation is perceived as essential (they find it important to end up facing the same direction as when they started).

THE TEACHING EXPERIMENT

Above we have discussed some features that define bee-bot's high semiotic potential with respect to the emergence of an inclusive definition of rectangles, characterized by the property of four right angles. Our teaching experiment was designed to capitalize on bee-bot's potential of fostering awareness of the "four right angles" property of generic rectangles (including squares).

Several sessions (15) were carried out in a first grade classroom at the beginning of the school year, for 4 months (more or less once a week) either in the classroom or in the gym, with a careful alternation of whole class or small group activity (with adult's guidance) and some individual activity. Each session was carefully observed by the teacher, by a student teacher or by a researcher (the second author of this paper), with the collection of students' protocols, photos, and videos. The tasks were designed by the whole research team, drawing on the initial intention and on some changes implemented "on the fly" based on episodes that occurred during the experiment. Due to space constraints it is not possible to report on all the details, so we have focused on particular sessions where the production of signs was very rich and fundamental for preparing the final summary texts and poster for the students (see Figure 6 in this paper, and Bartolini Bussi & Baccaglini-Frank, 2015).

Observing programmed bee-bots

In this session, students were given two bee-bots that had ahead of time been programmed with the same sequence. The task was: *Describe what they do*. The students watched the twin bee-bots move together, starting facing in the same or in different directions, and then moving separately. Then the memory of one of the bee-bots was erased (CLEAR command-icon) and the students were asked to reprogram it so that it would move just like the other bee-bot. The students' productions concerned both global and local aspects. Global aspects refer to the perception of a path as a whole (as if bee-bot had drawn it on the floor), whilst local aspects refer to special points of the path. An example of the former is the expression "it did an L"; an example of the latter is "they switched the turn". Both aspects also appeared in gesturing: the path is represented by a single pointer finger tracing a path in the air (tracing gesture), whilst turning is represented by moving the right hand (for a right turn) or left hand (for a left turn) up and to the right or left in a rotation (turning gesture). The *turning gesture* was mirrored by the student-teacher, as a pivot sign with respect to the notion "angle" in a path.

Pretending to be a bee-bot

During this session the students were asked to work in pairs: one pretended to be the bee-bot and the other gave the first commands to move according to some undisclosed (to the first student) path. The intention was to guide the children to focus their attention on the turn command. Typical words used were be "Straight Ahead" "Left" "Right" "Backwards" usually without quantifying the number of steps, and frequently combining a translation with a change of direction (rotation). For example, when a student said "left" the bee-bot student frequently would not only turn left, but s/he would also take a step in that direction, or even just take a step to his/her left without even turning in that direction. The student-teacher's intervention here was fundamental in focusing the children's attention on "turn" commands, which led to their beginning to explicitly consider rotations as important elements per se, without having to associate them to steps.

Constructing paths

Several activities were designed around tracing different kind of paths on the floor. When the aim was to produce particular letters of the alphabet, the students' attention was focused mostly on the "possible" and "impossible" letters: they empirically discovered that some capital letters (e.g., L, T. I) could be traced out, whilst others could not (e.g., B, A, D, O). In fact, neither acute angles ("sharp points") nor circular arcs ("fat curves") could be traced by the bee-bot. Children produced many examples of combinations of words, gestures and drawings, aiming at distinguishing the shapes (letters) which could or could not be drawn. There was a particularly rich production of words such as "angles", "(fat) curves", "diagonals", "(sharp) tips/points", "broken lines" and of related gestures and drawings. Suddenly, within this experience, an important event took place; this will be the seed of an inclusive definition of rectangles.

The main pivot sign: the "squarized" O

In a small group the following exchange occurred:

Student-teacher: ...Did you do an O?

Student: No. Then it could do like this this this and this [he gestures four consecutive right angles] a squarized O. Ah, then it can make a square!

We have translated a non-existing Italian word (*quadratizzato*) into a non-existing English word (*squarized*). Other students started talking about "squarized Os" and other possible "squarized letters", intending letters that include one or more squarized Os within them (e.g., P, B). These squarized 0s were acknowledged by the teacher and the research team as pivot signs, hinting at both the perceived path produced by the bee-bot (*artifact sign*) and at a *square* (a figure, interpreted as a *mathematical sign*). The importance of the four consecutive right angles suggested to orient children's attention towards this feature, that seemed to put in shade the length of each piece of the traced path (the sides) and to put in the foreground the four changes of direction, common to all squarized Os.

Focusing on the four right angles

In the students' complex experience, each right angle appeared with seemingly different meanings, that also affected the signs used. These, initially, were mainly dynamic and related either to the student pretending to be a bee-bot or to the bee-bot:

a) *Dynamic change of direction of the student pretending to be a bee-bot;*

b) *Dynamic change of direction of the bee-bot under the effect of the turn command.*

In both these cases, however, the angle was the external angle, i.e. the region swept by the gaze of either the student or the bee-bot while changing direction. When the researcher proposed to draw the paths in a "faster way: using a mark like the one the bee-bot

Figure 2: Sign for the right angle

would make if a marker were used", she chose to mirror a sign produced by a student "a turn like this" close to the turning point of the path (see Figure 2).

The sign had the potential to become a pivot sign with respect to the notion of "angle" (external angle): it recalls the command-icon on bee-bot's back, but it is somewhat decontextualized, since there appears to be no explicit mention to the bee-bot
In addition to these dynamic signs, as the teaching experiment went on, the children developed other signs, which lacked such dynamic components:

c) *Hands-meeting gesture referring to the point in the path traced by the bee-bot;*

d) *Gestures to interpret a static figure (referring to a dynamic experience);*

e) *Verbal utterance of the list of commands (uttered during or after the programming of the bee-bot);*

f) *List of commands written horizontally.*

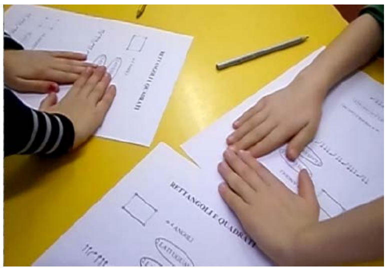

Figure 3: The students' gesture

First we describe the hands-meeting gesture (*type c*). While exploring figures that represented rectangles, including squares, a powerful gesture was realized by one of the groups of children and rapidly imitated by others: the two hands coming together at a right angle (Figure 3). The gesture emerged as the students tried to explain the property that all squarized O's (be they "allungati" [stretched] or "perfetti" [perfect]) had in common: all the four angles (internal angles) are equal and right. Moreover the gesture stresses the vertex as an important feature of the angle. Signs of *type d* were identified, for example, in the argument presented below (Figure 4), on how the angles of a square or rectangle have to be (as opposed to angles such as the ones of the parallelogram that was included in one of the worksheets).

Figure 4: Veronica's gestures

Veronica: "[in a square or rectangle] the angles go down straight...[in the parallelogram] they are a bit down to the right and a bit down to the left. It has to go straight, not like this and down, it shouldn't be a bit down like this one [she moves her pencil in the air along a slanted line with respect to a horizontal bottom line]. Instead it has to go straight like this and like this...it has to be straight like the line but a bit lying down [she marks the lower horizontal line]."

Signs of *type e* appeared when the students' attention was drawn to the "length of the path". Sometimes the turn command was in shade, as it did not lengthen the path perceived while the bee-bot spun around. However the number of commands for paths with angles, was not the same as the number of steps forward. So sometimes the turn command was still skipped (children 1, 2, 3, below). While in some of the children's utterances it was acknowledged (child 4, below) as a command like the others (it is represented by a similar button and it is executed with by a beep and a blink of bee-bot's eyes).

Child 1: Three steps then three then three then three we make a square, because it is the same ends, the same length.

Child 2: Instead, the other one has 1, 2-1, 2, 3-1, 2-1, 2, 3, it has two the same and two the same.

Child 3: The other was three, two, three, two. Not all equal.

In contrast

Child 4: Two forward, turn right, two forward, turn right, two forward, turn right, two forward, turn right. The segments have to all be equal.

Type f emerged in activities in which children had learned to represent traced paths as written sequences of commands, typically in a horizontal line, from left to right. Within these sequences they searched for regularities allowing them to distinguish different types of "squarized Os". Figure 5 shows signs left on the interactive white board after a discussion on "stretched squarized Os" (non-square rectangles) with respect to "perfect squarized Os" (squares). We note here how some students' language (in this and other occasions) seemed to be evolving into condensed pre-algebraic forms, such as a+b+a+b, that could eventually become expressions like 2a+2b for the rectangle and 4a for the square (a particular case in which a=b). In this teaching experiment, however, we did not pick up on these expressions, leaving them only as little germs to be nurtured by the teacher in future years (perhaps even during the second grade).

Focus on the shapes as wholes

Shapes as wholes were focused on from the very beginning of the teaching experiment, with either verbal descriptions alone or also with hand gestures. After the introduction of the idea of squarized Os, the adults involved in the experiment started mirroring students' utterances involving the words "rectangles"

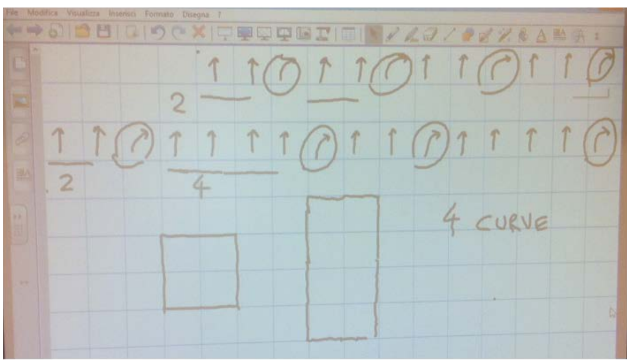

Figure 5: Agreed-upon signs for the programmed sequences and the paths

and "squares". As expected, when the attention was not brought to the word *squarized O* students spontaneously tended to partition the two situations, implying that "rectangles" had pairs of sides with *different* lengths ("equal in front of each other") while "squares" had sides that were "all equal". For some children this property seemed to persist when talking about "stretched squarized Os" with respect to "perfect squarized Os", while other children seemed to only differentiate "perfect squarized Os" from all other squarized Os, since they were special, being "all equal".

The shared meanings

We chose to build on what seemed to be the idea of this second group of students to reach a summary of the shared meanings. The most important step in this direction was a poster of "our" discoveries, a first step towards the development of "mathematical texts".

In this poster (Figure 6) several signs produced in the classroom are reconsidered, constructing a text where artifact signs (e.g. the figure of the bee-bot, the recollection of "giving it" a sequence of commands, the turns), pivot signs (e.g. the squarized Os, the small arrow to represent the external angles, and mathematical signs (e.g. squares; numbers; rectangles) are included.

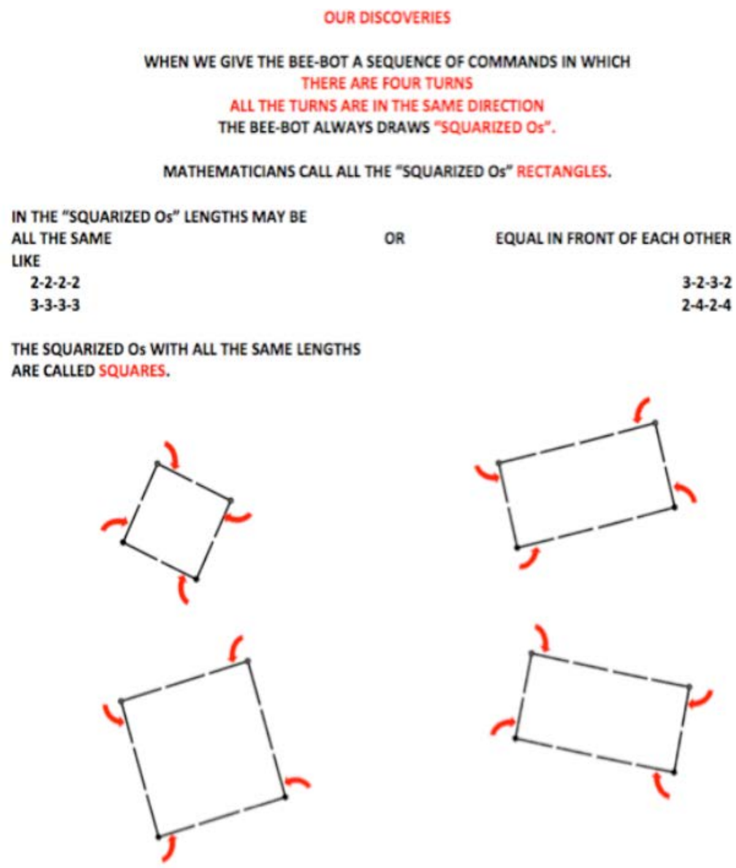

Figure 6: Poster of "our" discoveries

Is this text a mathematical text? Not yet: it is still a hybrid text, where the richness of the exploration remains present. What is important in this phase is that *all* of the students could identify this poster as having been produced by the whole class as a community. The choice of which signs to include was discussed by the research team, trying to collect signs that hinted at the individual and collective processes. The poster was discussed in the classroom; the students seemed very happy to find their ideas made public and to receive a reduced-size copy to glue on their notebooks. Some months later, a follow up questionnaire confirmed that (at least some) students had appropriated, and transferred it to a mathematical context, an inclusive definition of rectangles (other students were still on their way along this process). As mentioned before, the process is not to be considered finished. The teacher has planned to go on with the same group of students and deepen the inclusive definition for which she planted the seeds during this teaching experiment in the first grade.

DISCUSSION

The teaching experiment fruitfully exploited the semiotic potential of the bee-bot, joining different ways of representing the paths traced by the small robot, as sequences of commands, as wholes, as either physical or mental drawings, in both dynamic and static ways. During this long term process the students approached several pieces of mathematics knowledge, including counting (the commands), measuring (the length of the path, the distance), exploring space, constructing and changing frames of reference, coordinating spatial perspectives, programming, planning and debugging. The approach towards an inclusive definition of rectangles is only one aspect of this long and complex process.

A final comment on language. We do not claim that the inclusive (and decontextualized) definition of rectangles is already accepted by all the students (in fact we saw that this was not the case). Rather we find it important that students started becoming aware of the fact that theoretical mathematical needs may be different from everyday life needs. Moreover, we do not believe that the inclusive definition should be used also in everyday life. Rather it seems that, with this experiment, we have put the students in the situation of potentially seeing squares and rectangles within a same "family". What happened, indeed, was that the idea of "square" seemed to be overarching, in spite of the mathematical choices. The students seem to speak of the squarized O as the ancestor of rectangles (including squares) but, from the perceptual point of view they need to distinguish "perfect squares" from "stretched squares". This reminds us of the Chinese way of naming squares and rectangles: the sequences of ideograms for the words "square" and rectangle" contain two out of three of the same ideograms. Those that indicate "sides" and "shape" are the same, while the first indicates "exact" (for the square) and "long" (for the rectangle). This is represented in Figure 7.

正方形　長方形

Figure 7: Chinese characters for "square" and "rectangle", respectively

So, linguistically, a square is seen as a "shape with exact sides" and a rectangle as a "(same) shape with long sides". In this case language makes explicit that squares and rectangles are two kinds of a same thing, deeply related to each other and not partitioned into categories. The Chinese choice of the square as the most important shape may be related to the Chinese ancient culture, where it represents the Earth and the circle represents the Sky. This Iconic cosmology is shared by other ancient cultures.

ACKNOWLEDGEMENT

This teaching experiment was carried out within the PerContare project (ASPHI, 2011), with the support of the Fondazione per la Scuola of the Compagnia di San Paolo di Torino.

The trouble with double: Preschoolers' perception and powerful teaching strategies

Camilla Björklund

University of Gothenburg, Gothenburg, Sweden, camilla.bjorklund@ped.gu.se

This is a study of three teachers working with the notion 'double' with 4- and 5-yearolds. The purpose is to analyse what aspects that are critical for children to develop conceptual understanding of the notion. Data for analysis consists of video documentations from the teachers' authentic work that is driven by the theoretical framework of Variation theory of learning. The results show that children perceive the notion as an operation, either absolute 'add one' or relative 'add equally many', but there are also children expressing awareness of the part-whole relationship. These qualitatively different ways of perceiving the same notion give valuable insights of emerging mathematical abilities and the analysis of the teaching acts reveal powerful strategies for learning the notion, in terms of simultaneous discernment of critical aspects.

Keywords: Mathematics, double, preschool, variation theory of learning.

BACKGROUND

This study is part of a developmental project conducted in Swedish preschool (National Research Council, grant nr 724-2011-751). The general aim of the project was to enhance preschool teachers' awareness of mathematics as a content and goal in early years education, and to find pedagogical strategies that are in line with both the traditional way of working with children in Swedish preschool, which is heavily appreciating play as children's natural way of learning and being, and with contemporary research and theories on children's mathematical development.

This study is a contribution to the field of knowledge concerning early mathematical learning and teaching. The notion chosen for inquiry is 'double', which is regarded complex in its own simplicity, as double means not only an operation on a quantity, but also a description of the relationship between quantities and is relative in its nature.

CHILDREN DEVELOPING CONCEPTS

Mathematics in the early years is often considered close to the child's experienced life, not least because of the common notions used on a daily basis to describe numerical and spatial relationships in the surrounding world.

Piaget, Inhelder and Szeminska (1981) studied young children's conception of parts and fractions, which showed that notions such as half and double are fairly difficult to operate with. The notion double seemed to be very hard to grasp. This was confirmed by Holmqvist Olander and Nyberg (2014) whose study of 6–7-yearolds revealed that children usually failed to separate the concept from the base amount. One interpretation was that the operation 'to double' demands reasoning on quantities that are not present.

Numerical abilities and understanding are according to Piaget (1952) built on earlier acquired competencies, where the most basic competence is to abstract the perceived properties of objects (such as color, shape or size) and perceive objects as parts of a set that can be compared to other sets of same or different number of items. Piaget (1952) claimed that children develop concepts from the concrete towards the abstract. In order to learn to calculate and manipulate quantities, the child is thereby often supported by concrete referents (Mix, Huttenlocher, & Levine, 2002). Simultaneously, these concrete referents have to be considered as neutral counters, meaning that features of the objects do not interfere with the numerical relationship. Vygotsky (1987; 1998), on the other hand, described concept development as beginning with abstraction that is enriched and further developed as the child encounters and makes meaning of the concept in more complex settings. This latter way of seeing concept development broadens the view of children's meaning making as they use notions according to their current understanding, which in itself is an abstraction based on the child's logical reasoning.

Concepts such as 'double' are consequently troublesome to deal with for young children and for teachers to organize learning for. Considering these conjectures outlined above, there is a need for a study that describes children's perception of this kind of concept. A theoretically driven analysis will then contribute to our understanding of how children learn and develop their concept knowledge and how to facilitate deeper concept development.

THEORETICAL FRAMEWORK

The theoretical framework chosen for this study was the Variation theory of learning. This pedagogical theory (Marton & Booth, 1997; Marton, 2014) is based on empirical research of learning activities within multiple knowledge areas and school forms. The theory contributes to our understanding of learning, in that it focuses on the object of learning, what is made possible to learn and how this is orchestrated in powerful ways. Variation theory unfolds aspects of a learning object that the learner needs to discern in order to understand a phenomenon in certain ways. In teaching acts, these aspects are put into play within carefully developed patterns that enables the learner to explore the learning object in ways he or she has not previously been able to. Such patterns are contrast, generalisation and fusion (Marton, 2014).

According to the Variation theory, the learner cannot explore for example the number three if there are no numerical contrasts present, such as groups of two or four items. Generalization further means to implement an idea to other phenomena, meaning for example that there may be three of different kind, but still remaining its numerical meaning. In order for learning to occur, aspects of a learning object have to be differentiated through contrast and then brought together as a coherent whole, in other words fused together. Variation and simultaneous discernment are thereby necessary conditions to organise for in any teaching act.

This theoretical framework has been successful in both theoretical analyses and empirical studies in different kind of knowledge areas. Most research has been conducted in classroom settings, but there are also studies from early childhood education, where traditional lesson plans are exchanged with play and routine care situations (Björklund, 2013, 2014; Reis, 2011). Variation theory of learning was considered a relevant approach to studying young children's concept development when the interest is a specific new notion, such as 'double', due to the analytical framework and the pedagogical focus.

AIM, DESIGN AND METHODS

In focus for inquiry was the notion 'double' and those dimensions and aspects that are critical for preschool children to discern the nature and complexity of. A design study driven by the theoretical conjectures outlined above was carried out where the learning object was explored in authentic preschool activities.

Three preschool teachers participated in the empirical study. They planned and conducted one pedagogical activity each for the 4- and 5-yearolds they were working with (4 children participating with each teacher, a total of 12 participating children). The activities were designed in accordance with the theoretical framework, in other words enabling aspects of the notion 'double' to be explored through patterns of variation (Marton, 2014). In all learning sessions, the children were encouraged to talk and explore the notion by themselves and together with peers under the guidance of their teacher, in order to facilitate so called meta-cognitive dialogues (Pramling Samuelsson & Asplund Carlsson, 2008).

The acts and interaction between teacher and children are documented with video. The video documentations constitute data for analysis and interpretation, consisting of the three activities (12, 17 and 23 minutes of video data) conducted by the three teachers in different child groups. The various expressions of the children, both in verbal and non-verbal manners, are analysed as expressions of their understanding. The data is further analysed for revealing which aspects that are enabled to discern in the teaching acts, hence considered critical to elaborate in order to develop the children's understanding. The study is thereby two-folded: first to find out how children experience and understand the notion and second to discuss implications for the teaching act.

RESULTS

The purpose of this inquiry is to discern critical aspects of the notion 'double' as they are expressed by preschool children in designed but authentic learning situations in preschool. Further, the analysis will reveal teaching strategies that appear to be powerful for concept development.

Two dimensions, *operational* and *part-whole relationship*, are found to be emphasized in the learning act. This is unfolded by the directed attention that the designed activities and the interactions enable. Within these dimensions, aspects of the learning object are brought fore, giving a broader picture of how the children perceive the notion and why difficulties may appear. This will be discussed in the following text.

Operational dimension

The notion 'double' may be interpreted as an action or operation. The study gives evidence of children perceiving the notion as an operation, either absolute 'double means you add one' or relative 'equally many'. When analyzing the effects these conceptions may have on children using and communicating this notion, we can see where some challenges may appear.

Excerpt 1: You add one

Maria (teacher): From the beginning we had one (pointing to a stick on a sheet of paper). We were about to double that one, then you went to get one more (pushes two paper sheet with one stick on each towards one another). And together they make two. Pretty easy, don't you think?

Niklas: If there is three, it will turn to four (showing three fingers on one hand, then four fingers).

The children are listening to the teacher's explanation of how to 'double' a quantity. They perceive that it has to do with an operation on a quantity. However, as shown in Excerpt 1 above, there seems to lack some aspects of the notion, as the child expresses this operation in terms of 'adding one', and offering a logical solution to what happens when you double the quantity of three, which according to this line of reasoning would end up four. One critical aspect seem to be the number of the added unit, which should be perceived as a whole unit, equally large as the original one.

Excerpt 2: You add equally many

Isabella (teacher): Now it is Elias' turn. You will get three camels, Elias (puts three camels in front of Elias). And then you can pick out any ones you want from this pile (pushes the pile closer to Elias), 'til you have twice as many [in Swedish, the same word is used for 'twice' and 'double'].

Elias picks out a blue figure, then a green one, he hesitates and looks up on the teacher.

Isabella: How many did you have from the beginning? Do you know, when you only had the camels, do you know how many you had then?

Elias: Three.

Isabella: And if you are about to double that, then it means that you need to add equally many.

Elias: I have only taken two! (Elias leans forward and grabs one more figure, leans back again and smiles)

Isabella: You had only taken two. Now...

Elias: I have equally many.

Isabella: Do you have equally many there? Good, then it turned out twice as many.

Elias: They are six together.

Elias seems to be occupied by the thought of adding items to solve the task, in other words, he perceives the notion as an operation on quantities. He thus becomes unsure of how many to add and gets support from the teacher who directs attention to the original quantity. Further it becomes necessary to recognize the aspect of equally many that is to be added, which we can see that Elias has acquired. He also perceives the original and added sets as one whole, as he sums them up, regardless of their original belonging or visual features.

Some children comprehend the idea of 'equally many' and are even able to reason about this aspect on a generalized level, thereby accounting for the relativity in the meaning of the notion. The number of objects that are to be added are depending on the original quantity. This aspect, the relativity of the phenomenon, is with high probability a necessary aspect to discern in order to develop conceptual meaning in line with the conventional way of defining 'double'.

Excerpt 3: Relative sets

Isabella (teacher): Let me ask Brenda, what did you have in the beginning, how many did you have?
Brenda: I had four in the beginning, those (pointing along the row of camels).
Isabella: How did you know how many to take to get the double?
Brenda: I knew because I looked at them (pointing at the camels), that I'd take four.
Isabella: Yes, you had four and thought you'd take another four. Exactly. And how about you Elias, which ones did you have or how many did you have from the beginning? Can you remember?
Elias: Three.
Isabella: Three. And how many more did you take?
Elias: Three.
Isabella: And Tindra, how many did you have from the beginning?
Tindra: Two.
Isabella: And how many more did you take then?
Tindra: Those two (pointing at the outermost two figures).
Isabella: That means that when you have three items, like Elias has, you add equally many and then it is double. And Tindra had two and took equally many and Elias had three and took equally many.

The teacher in excerpt 3 is summarizing the tasks and solutions that the children have just completed. Attention is directed towards the added set and the teacher tries to generalize the relative aspect of the notion by pointing out examples of 'double'. This does however not seem to be sufficient, as one child responds by pointing at specific items as an answer to the question 'how many', indicating that the child reasons about what they just did, not on the operation and its impact on the quantity.

Dimension of part-whole relationship

When encountering the notion 'double', there is one aspect that becomes very important to account for: What set is the question aiming at? This is apparent when children and teacher are giving different suggestions for how to solve the doubling problems. In other words, are teachers and children focusing on the original quantity (that is to be doubled) or the result of the operation? This addresses the part-whole relationship, which is essential in all phenomena of numerical character.

Excerpt 4: Two or one and one?

Maria (teacher): Now there are equally many [one] on each paper. How many are there together?
Nora: Two (showing two fingers on one hand).
Amanda: One.
Maria: How many are there together? (pushes the paper sheets next to one another)
All children: Two.
Maria: Two.
Amanda: And if they are not together it is one, one (showing both index fingers).

This excerpt shows that children may focus on either the new whole constructed by the two parts together or on the set that is added to the original quantity (see also excerpt 5). The teacher in excerpt 4 and 5 tries to visualize the idea of 'double' as an addition, constructing a new whole. Amanda's focus seem though to remain on the parts that were added, not necessarily on the sum of the parts. This visual way of combining units by pushing paper sheets closer together seems to facilitate the children's attention to the result of an act, but at least one child's responses in the excerpts reveal that the perception of separated parts is dominating. It is thereby important to recognize possible different perspectives, as they may have impact on how the children continue to follow a line of reasoning.

Excerpt 5: Subsets by features

Maria (teacher) empties the paper sheets and pulls them apart. She puts a boat and a pig on one sheet, then adds a stick and another stick on the same paper sheet.

Niklas: Now it is two. Now they are three. Now they are four.
Maria: How many items do we have on the paper?
Niklas: Four.

Agnes and Nora point at each item and count out loud.

Maria: And if we are doubling four, how many items do we have to put on that paper then? (pointing at the empty paper sheet)
Nora: Four!

Amanda: Two and two.

This dialogue is interesting in several ways. The answer to the teacher's question may be 4 or 8; she asks how many they should add to get double, but she does not point out if the intention is to double the original quantity or to compose a unit consisting of equally many as the original one. Anyway, the children seem to direct their attention to the 'equally many' aspect and answer, according to that, 'four more'. One child, on the other hand, expresses her understanding of the task as a part-whole relationship, though focusing on the features of the objects, rather than the numerical relation, since she groups two sticks into one whole unit and the other two objects as another whole unit 'two and two'. The features of the objects that are used interferes with the numerical reasoning (see Piaget, 1952; Mix, et al. 2002) and emphasize grouping of items according to their physical appearances. This draws attention from the numerical relationship and limits the child's opportunities to get involved in the line of reasoning about the meaning of the notion.

The challenge of the notion 'double' is probably the shift from perceiving a set of items as a whole unit, to being a subset of a new whole that is doubled in number. It is probably easier to explore notions such as 'half' that includes manipulation of a whole visible quantity, dividing it into subsets. Double indicates on the other hand manipulation towards an unknown quantity that is difficult to imagine without concrete manipulatives. This result confirms the statements of preschoolers' perception of the notion as shown by Holmqvist Olander and Nyberg (2014).

Fusion of operational and part–whole relationship dimensions

The use of 'double' as a description of a quantity is in fact quite complex. It includes a relativity, which means that the quantity has to be related to another quantity and it is this relationship that the notion describes, not any one particular quantity. One can see the complexity that lies within this in the children's attempt to describe in words what double means, such as 'that you want a lot', 'very, very much' or suggesting to use a measuring tape to know how much double is. However, these are expressions of some insights to the notion that it is not an absolute number of added items and it would consequently be powerful to introduce and pay attention to the idea of 'equally many'.

The following excerpt is an example where both dimensions are present and used deliberately in the teaching act to bring out those aspects that are necessary for the children to discern simultaneously.

Excert 6: Making play-dough

The teacher Julia has prepared two identical recipes but instead of measuring units such as decilitre or table spoons she offers blocks. The task is to double the recipe. They have started by putting blocks for each amount of measuring unit on the original recipe.

Julia: How many were there on the flour? They [the blocks] can remain there.
Hugo: Two.
Julia: Now you should put twice as many here (pointing at the recipe sheet).

Hugo puts two blocks on the recipe.

Julia: How many are there (pointing at the original recipe with two blocks)
Hugo: Two.
Julia: And how many there (pointing at the recipe Hugo put two new blocks on).
Hugo: Two.
Joseinfe: Are they equally many?
Hugo: Yes.
Julia: Are there twice as many then?
Hugo: No.
Julia: They are equally many. How many do you think we should put here to get twice as many?
Emelie: Three there and two there.

The teacher follows Emelie's suggestion, which gives two blocks on the original recipe and three on the doubling-recipe.

Linus: No, I think you should put like this (puts one block above each of Hugo' blocks, then starts to do the same on the original recipe)
Julia: But you cannot put any here (pointing at the original recipe).
Linus: (throws away the block he had put on the original recipe) This is how I think.

Julia and the children continue comparing the original with the recipe with added blocks, altering taking away and adding blocks on the double-recipe to see the relationship between equally many and twice as many. They work in similar way with groups of one and two units through the whole recipe.

The excerpt above shows a way of teaching where bringing in contrast is used to support children's directed attention towards aspects that the teacher has considered necessary to explore. The starting point is the children's suggestions, which are explored and then challenged by other children's suggestions. Critical in this teaching act seems to be the simultaneous visualization of the original quantity and the double, combining the idea of adding 'equally many' with the comparison of quantities. The simultaneous discernment of equal and double is a powerful strategy that seems to enable the children to make sense of the troublesome notion, troubles that are likely due to the ambiguous nature of the notion in that it includes both a dimension of operation (adding) and a dimension of part-whole (comparing sets).

SUMMARY

The notion 'double' is complex in its own simplicity. 'Double' includes not only an operation on a quantity, but also a description of the relation between quantities. The notion is also in this sense relative in meaning, as the number of objects are not fixed rather depending on the observed number of objects in a particular set. These aspects are critical to discern, but as this study has shown, they challenge the children's perception and understanding of said aspects. In the teaching act, the teachers become aware of the nature of the notion, in that it includes both a description of a quantitative relationship between sets and an operation on a set. This insight is valuable, since it gives a reasonable explanation for children's actions and interpretations of the notion explored in an activity.

Important for the development of conceptual understanding is presumably a simultaneous discernment of the operational dimension of the notion 'double', which can be seen when children are talking about effects of doubling a quantity, and the relativity of the part-whole relationship of the notion, meaning that the number of added units of a set is related to the original set, not an absolute number. The teachers tend to use the expression 'equally many more' to emphasize this, indicating (perhaps intuitively) that there has to be a differentiated set to depart from.

Pedagogical implications of the findings point attention to the question: Are the children focusing 'double' as a comparison of two quantities or an additive operation that changes a quantity. Or, is it how the teacher offers these dimensions to be discerned that becomes critical? This is put to the test by one of the teachers who design an activity where the children are enabled to compare 'equally many' with 'original whole unit' and 'doubled whole unit'. The children participating in this activity seem to be given better opportunities to follow the line of reasoning and explore the nature of the notion in powerful ways. This is conjectured by the theoretical framework (Marton, 2014), but more empirical research will be needed to confirm this.

It is worth noticing that children who are expressing their solutions in verbal terms show variations in abstraction. Even though they solve a problem ending up with the right number of objects, some children are very attached to the concrete objects, expressed in terms of '*these two* were added' aiming at two specific objects that were picked out to double the original quantity, even though the numerical abstraction of the notion would suggest that the specific objects or features of the objects are irrelevant for the quantity that is described (Mix, et al., 2002; Piaget, 1952). Other children creates their own line of logical reasoning and implement ideas that may also be considered abstracted, such as 'you add one'. In Vygotsky's terms, children are developing their already existing concepts and implement their logical reasoning in new settings which will develop their concepts even further and towards feature-independent reasoning (Vygotsky, 1987; 1998).

Results from this study help us to better understand the very basic conceptual knowledge and abilities necessary for developing understanding of the notion double. The study also indicates that pedagogical strategies start from which dimensions and aspects that the learning object contains and further which of these the children are enabled to discern.

How the role of the preschool teacher affects the communication of mathematics

Laurence Delacour

Malmö University, Malmö, Sweden, laurence.delacour@mah.se

The purpose of this article is to study and analyse how two teachers implement an outdoor situation for children aged 4–5 in a Swedish preschool. The analysis and interpretation of the data in this paper has been influenced by situation theory and by the use of the didactic contract as a key concept. The term didactic contract is seen as a metaphor; consequently, I use a broader definition of the didactic contract to illustrate how the role of the teacher affects the communication of mathematics with children. Most of the text in this paper is adapted from my thesis (Delacour, 2013) and articles (Delacour, 2014a, b).

Keywords: Kindergarten, teacher, didactic contract, mathematics.

INTRODUCTION

During recent years, preschool mathematics has been on the national agenda. In 2011, a revised preschool curriculum was introduced in Sweden (National Agency for Education, 2011), in which the goals for children's mathematical development were made clearer both in scope and in content. How children are to create, explore, and use mathematics is not specified in the curriculum, however, as it is a goal-oriented document and is not concerned with teaching methods that can lead to different ways of communicating mathematics (Delacour, 2013).

In this study, two preschool teachers implement a situation in which the children investigate properties and what belongs together. I describe the situation, and compare the roles of the preschool teachers to analyse how they affect the communication of mathematics with the children. The following research question has been formulated: how do preschool teachers' implicit expectations affect children's motivation to participate in mathematical activities?

THEORETICAL FRAMEWORK

First, I take up the didactic perspective of the study, highlighting the theory of didactic situations. The key concept here is the didactic contract.

Theory of didactic situations

According to Brousseau (2000), it is common to see teaching as a transfer of a special knowledge to children, and to see the didactic relation as a communication of information. Teachers try to plan their lessons so that the children get as much out of them as possible. Brousseau states that in order to succeed, it is necessary to consider the factors that may contribute to the teaching of mathematics. Brousseau (1998) developed the *theory of didactical situations* (TDS) to highlight the didactic relation between the teacher, the children, and the mathematical content. This relation is termed the *didactic triangle*. The theory of didactical situations offers a model of knowledge, teaching situations, and the roles of the teachers and children in the classroom. Knowledge cannot be transmitted merely through explanation but, according to Brousseau, the teacher orchestrates learning and teaching in order to increase the child's knowledge. Knowledge needs to be learned through different contexts, and teachers can organize specific situations that lead to children's learning of a particular piece of knowledge (Perrin-Glorian, 2008). Teachers often try to find activities to introduce a new item of mathematical knowledge to children. When a teacher focuses on the "why" aspect of teaching, he/she will see a problem or a situation, not as a simple reformulation of knowledge, but as an environment that offers answers to the children, according to certain rules. What information do children need from the "milieu" to make choices, and to use one specific piece of knowledge rather than another? (Brousseau, 2000).

The didactic contract

Brousseau (1988) introduced the concept of the didactic contract as part of his work in the theory of didactical situations, and defined it as the teacher's behaviour (as expected by the child) and the child's behaviour (as expected by the teacher). Brousseau studied how the didactic contract affects mathematical learning. Teachers usually develop different practices to give children the exact assistance they need, while children try to meet their teachers' requirements by interpreting the teachers' signals. However, teachers should not provide detailed instructions on how to solve mathematical problems, because this practice results in children not learning what the teacher expect them to learn (Delacour, 2014b). Brousseaus famous example shows how teachers can arrange a situation to help children gain a greater understanding of numbers. The teacher takes up five tanks (more or less depending on the child's number perception) and ask the children to pick up as many brushes as there are containers. The child should collect all the brushes at one time. The teacher does not tell children what to do but it is the children who must find a strategy to solve the problem. Some children will use their fingers, others draw on paper, others use blocks. How the teacher is planning the "milieu" is important. How far brushes are from the containers, for instance, will affect how the children act. Eventually, the children will understand that counting is a useful strategy.

During a situation, the preschool teacher repeats, clarifies, or asks questions that allow the didactic contract to progress in a direction that the teacher has in mind. Sometimes it is the children engaged in the contract who influence the change, when they make a discovery or get an understanding of something and share it with the group (Garcion-Vautour, 2002). My interpretation of the preschoolers' expectations is that these are connected to the procedures related to the situation (Delacour, 2014a). The didactic contract is often invisible until one breaks it. A child may break the contract when he or she accepts learning or playing the game, as Chevallard (1998) called it, but does not fulfill the teacher's expectations. Learning is only obtained under the breach of the didactic contract according to Brousseau (1998). When children sit around a table and play memory game for the first time for instance, they turn upside down on the pictures without really understanding what will happen. They turn on the pictures they can access from their seats. Children believe that the teacher expects them to remain in their seats as they usually do when they eat, for instance. When a child breaks the didactic contract, getting up from his chair to reach the pictures that are further away and manage to get a couple, an individual learning occurs which then becomes collective.

DATA PRODUCTION AND ANALYSIS METHOD

This article is based on data collected for my thesis (Delacour, 2013) between the spring of 2011 and the autumn of 2012. The preschool teachers in this study were videotaped while they implemented a mathematical situation outdoors. They have been previously interviewed about their interpretation of the curriculum which have influenced my analyses of the video.

The teachers in this study work in two different preschools in a group consisting of four-year-old and five-year-old children. The preschool teachers were videotaped while they implemented a mathematical situation outdoors. In this article, two of these mathematical situations (filmed material) were analysed in terms of a didactic contract. The selection of the first video is based on the richness of the material, and the selection of the second is due to its variation from the first.

The preschools included in this study are located in two small communities of the same municipality. The schools show no major differences in staff composition, group size, or children's socio-cultural and economic background.

To analyse and interpret the data, I made a reflexive interpretation of the preschool teachers' implementation of a situation, and used an abductive analytical method, which meant that the reflection moved between data and theoretical analysis (Alvesson & Sköldberg, 2010). In the preschool teachers' implementation of the situation, my focus was on highlighting the relation between the teachers, the children, and the mathematical content. The analysis shows that the teachers had similar expectations about how the children should communicate, but obtained different reactions from the children.

ANALYSIS

In this part, I describe how two preschool teachers introduce a mathematical situation for the children, and highlight how the communication between teacher, children, and learning object progressed. I describe in which situation the groups was engaged in before the situation I analyses in this paper because I believe it affect the outcome. As the objectives in the Swedish curriculum are formulated as goals that the preschool should strive towards and there are no specific goals for the children to achieve I will focus mostly on the participation of the children rather than on the knowledge they acquired.

The mathematics situation

The preschool teacher Lotta collects four children in the schoolyard. She tells the children that she has found a lot of garbage in the forest, and asks them what they think about this. The children propose to remove the garbage from the forest, and then want to sort the garbage items in different piles according to their characteristics. Now the children are sitting around a white cloth that Lotta has laid on the ground. Lotta's situation is based on a play in which children present four items individually. The video shows how Lotta makes a window out of sticks, and puts four items in it. She uses the garbage that the children have already sorted. She asks the children to point out one item that is not associated with the other three. Lotta introduces a new concept: *having something in common.* She lets the children tell each other which one of the four items they think does not have something in common with the other items. The children argue with each other about the items they have chosen, and about how they are thinking. Lotta follows the discussion and asks an occasional question. Once the children understand the rules of the game, they take turns to choose four items.

The preschool teacher Malin asks eight children to sit on two logs in the forest facing each other. Malin has laid a white cloth on the ground. The children had previously been working with patterns. During the work with patterns, Malin had sent the children to collect a leaf and a pinecone each. Then she asked each child to tell what he or she had collected, and to lay one leaf, one pinecone, one leaf, one pinecone, and so on, on the white cloth. For the next situation that I will analyse for this paper, Malin has collected materials from nature in a box. She picks up one item at a time, and asks the children to tell what it is, what color it is, which tree it comes from, etc. Then she asks the children to come, one at a time, and choose two things and tell why they think the two things belong together.

The rules of the didactic contract

There is a strong tradition of morning meetings in Swedish preschool, when the children and teacher sit in a circle and do different activities (Rubinstein Reich, 1993). The children have been instructed in the preschool's rules, and know what is expected of them in a meeting. When Lotta and Malin laid a white cloth on the ground, the children expected that what was about to happen would be different from the meetings that take place in the morning and indoors. The children knew that free play was over, and that a teaching situation was beginning. The white cloth also provided an indication to the children about what was expected, and where they were expected to turn their attention. These rules were implied, as the children have been through similar situations in the past and can now recognize the teacher's actions, body language, and voice.

When Lotta introduces the situation, she does not need to tell them that they are allowed to talk, move, and exchange thoughts and ideas. There is an implicit understanding here of what mathematics is, as the teacher has previously communicated in this way to the children in this group. Mathematics in this preschool is something you do in groups, in which people help each other to solve various problems in a playful way related to the theme currently being worked on. This group has been working with environmental issues throughout the semester. When the preschool teacher asks questions, makes small comments, and calls for the children's attention on what is being said, the children are seen, and their actions are approved. They are encouraged to take the initiative and to listen to each other. The didactic contract is characterized partly by explicit rules but primarily by implicit rules. How the situation will proceed and what the children should do is not pronounced verbally. Lotta does not tell the children to come up with proposals of their own, or which garbage pieces they have to choose. In Lotta's group, once the children are involved in the situation, they introduce mathematical concepts, while noting properties of the items such as flat and thick, and different sizes, shapes, and materials. There may be concepts that some but not all of the children know. The children can then learn from each other. Lotta encourages the children to be active and investigative. She would rather offer realistic problem situations in which many solutions are possible according to Lotta. She encourages them to find their own way, to explore rather than to find an answer. The children's responses and behaviour are valued and praised with words like "good" and "talented." Both individual children and the entire group receive praise and encouragement.

David (5 years) puts three metal cans and a plastic bag in the window that Lotta (teacher) has made from sticks.

Olle (5 years): "This one, this one, this one." (pointing to the plastic bag)
Klara (5 years): "These two should be removed," (showing a can and a plastic bag) "for they are like that." (showing two jars, turned upside down)
Olle: "This one, this one, this one, this one." (plastic bag)
Lotta: "How were you thinking, Olle?"
Olle: "For it is metal, this one is not!"
Klara: "I think like this," (putting her hands on the plastic bag and showing a jar) "this one will be removed because they are the same thing," (the other jars) "for they are so." (showing that the two jars are upside down)

Olle takes a jar that was removed by Klara and turns it.

Olle: "But if you turn it right side up, what is it then? It will be the same, right?"
Klara: "But look, they are golden, so it should not be. It is silver."
Lotta: "Mmm right, and you think this one. What do you think, Eric?"
Eric (5 years): "Plastic and not plastic, and this one will be removed." (pointing to the plastic bag)

During the situation, the children reflect and draw their own conclusions. The children are given the opportunity to experiment with the items and discuss with each other.

This situation can be interpreted as the preschool teacher creating a situation in which the children can communicate. The children's diverse knowledge of the materials offered creates a dynamic. When they express their thoughts verbally, the children reflect with the help of their fellow students and the preschool teacher's questions.

Malin introduces her situation to the children by giving instructions on what they have to do. During the first part of the situation, in which the children work with patterns, they have to follow the teacher's instructions step by step, and no individual proposals are expected of them. In the part I analyse, Malin starts by asking the children to tell the names of the items she picks up from the box. She also asks different questions about the qualities of the items. Again, no initiative or individual proposals are expected. The answers children give can only be right or wrong. Next, when Malin asks the children to come one by one, pick up two items in the box, and explain their choices, she is expecting them to take initiative and come up with individual proposals.

Malin (teacher) calls the first child, Richard (5 years).

Malin: "You can pick up two things."
Malin: "You can stand there and tell what you chose."
Richard: "A berry and a leaf."
Malin: "A berry and a leaf. Why do you think the berry and the leaf belong together?"
Richard: "Because both are red."
Malin: "Because both are red. Thank you very much, Richard."

Six of the eight children use color to motivate their choice. Malin does not value or praise the children's motivation. She thanks them for their participation.

According to Blomhøj (1995), the teacher usually develops different forms of work in order to give children precisely the assistance required, and the children try to meet the teacher's expectations by interpreting the teacher's signals. The teacher cannot give detailed instructions on how the children should solve mathematical problems, because under this circumstance, the children do not learn. Instead, Lotta uses different signals to confirm that the children are acting as expected: She uses linguistic signals, such as telling the children they are doing well, repeating what the children say, asking them if they hear what a child says, and telling them that it is exciting to see how many solutions they can find; or she uses body-language signals, such as putting her hand on a child's arm, nodding, and looking satisfied. Lotta often uses the pronoun "we," as in, "We have to think now!" to signal that they will reflect all together. She sits with the children around the white cloth.

On the other hand, Malin gives complete instructions to the children, and tells them exactly what they have to do. She stands a bit back from the children, and calls one child forward at a time. It seems difficult for the children to suddenly start thinking by themselves. My interpretation is that the children are confused about what the teacher is expecting of them, and try to give a right answer, as they were previously required to do. Most of the children use the same motivation: "Because they are the same color." Malin uses signals and asks further questions to invite the children to talk, but the questions she asks require a right answer: Is it the same kind of leaf? What kind of leaf is it? What color is it? These questions may prevent the children from daring to come up with their own proposals. Malin does not involve the other children by asking them if they can see a different similarity than the one proposed by the child standing in front of them. Malin only involves all the children when she asks *right and wrong answer* questions. Her way of meeting the children does not seem to encourage discussion.

In Lotta's group, when the children do something other than what the preschool teacher has shown from the beginning, the situation evolves as the children want it to, and the teacher follows the children's behaviour. Lotta initially asks the children to point out one item that is not associated with the other three. After playing for a while, the children begin to point out two items that belong together. Lotta responds that it is true that the two items belong together, and the play continues with the new rules for the rest of the situation. Here, the children's actions govern the rules. Lotta's response can be interpreted as not wanting to inhibit the children's creativity by telling them to point out only one item, because she has designed the situation to get the children to explore, and not to judge their competency.

The didactic contract becomes visible

According to Brousseau (1998) and Blomhöj (1995), the didactic contract is not visible until it is broken. There is a difference between not following the didactic contract and breaking the didactic contract: The one who breaks the contract is involved and interested but does not act as expected, whereas the one who does not follow the contract loses concentration or is uninterested. When Lotta communicates mathematics with the children, she wants the children to discover that there may be many different solutions to the same problem. However, she does not communicate this to the children before one of them breaks the contract:

Olle (5 years): "Yeah but what is this? This one should be removed; they are not the ones."

Lotta (teacher): "It is great thought. And you others have also found a solution. Great God, how good, oh, great. What do you say? Should we collect?"

Olle: "What did you think? Did you think it was a bit difficult? You thought it was easy, and it wasn't."

Lotta: (puts her hand on Olle) "There are several different solutions. It was great."

Olle: "Did someone guess the right solution?"

Lotta: "There are many right solutions. You had a great explanation of how you thought, Olle, and David, you too, you also thought very well. And Eric, you were thinking the same way, and Klara too. Really good."

Olle thinks that the other children may have had difficulty guessing what he was thinking.

Olle does not accept the rules. He does not accept that there can be many solutions to the same problem. He thinks that the others should try to guess what he was thinking. He breaks the didactic contract, and when Lotta explains that there are many right solutions, the contract becomes visible.

Lotta makes the didactic contract visible when she repeats that there is more than one solution.

CONCLUSION

Preschool teachers prepare for a situation with an intention in mind. In one of the types of situation above, the children control the content of the situation and introduce various concepts. It is in the children's interests for them to control the shape of the situation when mathematics is being communicated. According to Lange, Meaney, Riesbeck, and Wernberg (2014), the teacher should be able to listen very carefully in order to build her suggestions on the children's interest. The preschool teacher reinforces what the children say by repeating and by asking questions that challenge them to explain, listen to each other, and move on. The teacher's scaffolding by using different feedback strategies, such as putting her hand on a child's arm, nodding, and looking satisfied; or by asking open-ended questions rather than giving instructions, will support children's learning (Bäckman, 2014). The preschool teacher's ability to follow the children's interest is critical in the establishment of a didactic contract by which both students and teacher are able to accept the rules of the game. The two videos examined here (and my previous interview) show a difference between the attitudes of the teachers and the responses they get from the children. Many factors can affect children's motivation to participate in a mathematical situation and it is difficult to know based on two observations how the "milieu" affects the children's motivation. In Malin's group, although the children did what they had to do, they were not motivated. My interpretation is that the kind of questions Malin ask confused the children about her expectation but I am aware that other factors can affects the outcome of the situation. The fact that eight children have to wait for their turn for instance, be quiet, sit still, and listen to each other can affect the communication in Malin's group. *Instruction*, which refers to experiences aligned primarily with the teacher's goals, and *construction*, which refers to processes young children actively engage in to acquire concepts and skills, should be integrated, according to Jie-Qi Chen (2012). However, this study shows that young children who are initially engaged with instruction may have difficulty then engaging with construction; and that the teacher needs to be clear about her expectations in order to help the children to break the didactic contract formed when instruction is used.

The use of virtual and concrete manipulatives in kindergarten school

Louiza Demetriou

University of Cyprus, Department of Education, Cyprus, dimloui@hotmail.com

This study aimed to explore kindergarten students' ability in solving symmetry tasks. Specifically, I wanted to investigate how the use of virtual and concrete manipulatives can improve kindergarten students' (4,5–5,5 years old) ability and representations in symmetry geometry tasks. For this purpose, I used two intervention programmes. In group A (n=25) students used virtual manipulatives and in group B (n=25) concrete manipulatives. Three types of symmetry tasks were used. Analyses of the data showed that both virtual and concrete manipulatives can help students move to a higher level of structural development. Additionally, students improved their ability to a greater extent with the use of virtual manipulatives.

Keywords: Kindergarten, symmetry, virtual manipulatives, concrete manipulatives.

INTRODUCTION

The increased emphasis that has been given to the geometry during the last decades, has changed the content of traditional Euclidean Geometry by introducing new types of geometry (Jones, 2002). According to Sinclair (2008) one of the impacts of Euclid's Elements in school geometry is that symmetry plays a peripheral role in the curriculum. Furthermore, additional to the mathematical motivations for increased emphasis on symmetry, the psychological research suggests that young children show a strong capacity for attending to and identifying symmetry. According to Vurpillot (1976) the ability to detect symmetry develops early. This strong capacity for attending to and identifying symmetry should be developed through their school geometry experiences (Sinclair & Kaur, 2011). Additionally, the use of technology is growing within schools and gives teachers the opportunity to differentiate their lessons and children's experiences. Computers are important tools for exploration and discovery of mathematical concepts (Burns & Hamm, 2011). Nevertheless, Burns and Hamm (2011) found little research that supports the use of virtual manipulatives over concrete manipulatives and according to Steen, Brooks and Lyon (2006) research on the impact of virtual manipulatives is limited.

As a result, the purpose of this exploratory study was to investigate kindergarten students' ability in symmetry tasks as well as the role of virtual and concrete manipulatives in solving the specific tasks. Consequently, the research question addressed in this research is:

How can the use of concrete manipulatives and virtual manipulatives contribute to the understanding of symmetry by kindergarten students?

LITERATURE REVIEW

Students' understanding of symmetry

Children have intuitive notions of symmetry from early years. As Sarama and Clements (2009) argued, symmetry was the easiest transformation regarding visualization to young students. Additionally, according to Seo and Ginsburg (2004), pre-school children spontaneously constructing symmetrical figures in informal play. Vertical bilateral symmetry remains easier for students to handle than horizontal symmetry (Genkins, 1975) which in turn is easier than diagonal symmetries (Palmer, 1985). While Boulter and Kirby (1994) argued that analytical strategies may lead students into successful answers, Tzekaki and Christodoulou (2000) found that symmetry can be accessed by five and six year old students in a holistic manner. At the same time they found that five and six year old students were able to distinguish symmetrical and non-symmetrical shapes, but on the other hand they were unable to draw symmetrical shapes taking into account their relative position and size.

Virtual and concrete manipulatives

Virtual manipulatives are interactive, web-based virtual representations of dynamic objects that present opportunities for constructing mathematical knowledge. Learners could gain insight into mathematics using visual representations of concepts and relations. Results of available research on virtual manipulatives, offer potentially beneficial uses of technology in mathematics classroom. For example, in a study with two treatments, in order to teach symmetry and congruence, Johnson – Gentile, Clements and Battista (1994) found that Logo-based version enhanced the construction of higher level conceptualizations of motion geometry. Additionally, more recently, Sinclair and Kaur (2011) found that kindergarten children were able to develop an understanding of symmetry that showed awareness of the properties of reflectional symmetry through the behaviour of dynamic images.

Even though studies found many perceived benefits on the use of virtual manipulatives, Burns and Hamm (2011) found little research that supports the use of virtual manipulatives over concrete manipulatives. Concrete manipulatives are objects used as tools that allow students to experiment and explore mathematical concepts. Burns and Hamm (2011) found that fourth graders, who were just beginning a unit on symmetry, realized larger pretest–posttest gains when concrete manipulatives were employed.

Theoretical perspectives

In order to analyze the geometric learning of students interacting with virtual and concrete manipulatives I adopted the levels of structural development as proposed by Mulligan, Prescott and Mitchelmore (2003). Young children, who have learned to look for mathematical similarities and differences within and between patterns, will tend to look for similarities and differences in new patterns and broaden their structural understanding accordingly. In contrast, students who tend not to notice salient features of structure are likely to focus on idiosyncratic, non-mathematical features in all situations. Children's representations may classify into the following four broad stages of structural development:

- Stage 1 – Pre-structural stage: Most examples show idiosyncratic features and representations lack any evidence of spatial structure.
- Stage 2 – Emergent (inventive-semiotic) stage: Representations show some relevant elements of the given structure, but their spatial structure is not represented.
- Stage 3 – Partial structural stage: Representations show most relevant aspects of spatial structure, but the representation is incomplete.
- Stage 4 – Stage of structural development: Representations correctly integrate spatial structural features.

METHODOLOGY

The sample of this study consisted of 50 kindergarten students (4,5–5,5 years old) in an urban middle SES district in Cyprus. There were 25 children per class, with a wide range of academic abilities. The method of convenience sampling was used. In group A (n=25) students used virtual manipulatives, while in group B (n=25) students used concrete manipulatives. Firstly, students complete a pre-test in order to determine their initial notions on symmetry. After this, two intervention programmes followed. Students in group A were taught with the use of virtual manipulatives in groups of five students. Nine virtual math applets were used, with three kinds of tasks: recognition of symmetrical and non-symmetrical shapes and images b) positioning axes of symmetry and c) completing shapes and images in order to be symmetrical. The activities used in group B were the same as in group A but in this case students used concrete manipulatives. Equal opportunities were offered to all students to get involved and touch real materials such as geoboards, symmetry mirrors, cardboards, pattern blocks, folding papers.

Each teaching lasted 80 minutes and there were a total of 4 lessons for each group. At the end of the interventions the same test, as the initial, was given to students in order to see if they had an improvement. The test consisted of three parts. Figure 1 presents the three parts of the pre/post-test. Firstly, children were asked to identify symmetrical images and put them in a circle. Secondly children had to put symmetry axes in nine images. Finally, in the third part, children were asked to complete 8 shapes and images in order to be symmetrical. Data were collected in a quiet part of students' school environment in the form of personal interviews and the interviews were audio-recorded.

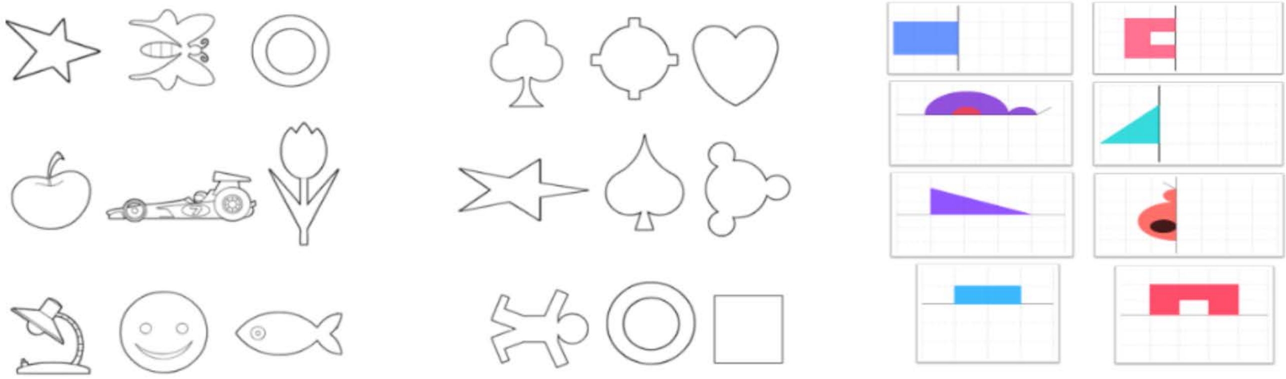

Figure 1: Pre/Post-test

Data analysis

Regarding the first part of the test, 0 was given to incorrect answers and 1 point to correct answers. At the second part of the test 0 was given to incorrect answers, 0,5 points to mainly correct answers and 1 point to correct answers. Coding for the third part of the test was based on the classification of representations according to the levels of structural development as proposed by Mulligan, Prescott and Mitchelmore (2003). The analysis of the data was qualitative and quantitative. Due to the limited size of the sample descriptive statistic (means and standard deviations) was used.

RESULTS

Means and standard deviations of pre-test are presented in Table 1. As we can see, the activity where children asked to complete symmetrical shapes have the lowest mean ($\bar{x}$=0.43, SD=0.23). In addition low performane appears in tasks where children asked to put axes of symmetry. Children seem to perform better in symmetry recognition tasks.

As mentioned above, the lowest performance appeared in tasks where children had to complete shapes and images in order to be symmetrical. The most difficult task in this category was task 5 where students asked to complete a symmetrical shape to create a triangle over a horizontal axis of symmetry.

Table 2 presents students' classification of representations in each task according to the level of the structural development. As we can see a large number of students seem to be at stage 1 (pre-structural stage) and stage 2 (emergent structure) since their representations do not present evidence of mathematical structure. Additionally none of students were at stage 4.

Post-test

As we can see in Table 3, after the teaching interventions mean of both groups was increased. Specifically in group A, the mean increased from 0.50 to 0.70 and in group B from 0.53 to 0.60. As it revealed students in group A improved their performance to a greater extent compared with students in group B.

	Number of students	Mean	Standard Deviation
Identify symmetrical images	50	0.64	0.17
Axes of symmetry	50	0.46	0.17
Completing symmetrical shapes	50	0.43	0.23

Table 1: Means and standard deviation of the three tasks in pre-test

	Task 1	Task 2	Task 3	Task 4	Task 5	Task 6	Task 7	Task 8
Stage 1	19	25	26	25	32	24	21	25
Stage 2	26	15	15	16	14	15	23	15
Stage 3	5	10	9	9	4	11	6	10
Stage 4	0	0	0	0	0	0	0	0

Table 2: Students' classification of representations in pre-test

		Number of Students	Mean	Standard Deviation
Group A	Pre-test	25	0.50	0.20
	Post-test	25	0.70	0.13
Group B	Pre-test	25	0.53	0.17
	Post-test	25	0.60	0.16

Table 3: Means and standard deviations for group A and group B

Noticeable seems to be the effect of teaching interventions in the third part of the test. Table 4 and 5 presents the number of students in each stage at pre and post -test.

Students in both groups moved from a lower stage of structural development in a higher level. In group A number of students which categorized at stage 1 and 2 at pre-test was between 19–23 while number of students which categorized at stage 3 and 4 was between 2–6. After the teaching intervention with the use of virtual manipulatives the number of students which categorized at stage 1 and 2 reduced (between 9–15) while the number of students which categorized at stage 3 and 4 increased to 10–16.

Additionally in group B, before the teaching intervention, number of students which categorized at stage 1 and 2 was between 20–23 while number of students categorized at stage 3 and 4 was between 2–5. After the teaching intervention the number of students categorized at stage 1 and 2 reduced to 13–20 while the number of students categorized at stage 3 and 4 increased to 5–12.

As we can see, students in group A increased their ability in completing symmetrical shapes to a greater extent than students in group B.

Qualitative data analysis

Through a qualitative analysis of the pre-test we can see some difficulties that students faced. Firstly in the first part of the test students ignored some aspects of the original shapes, which determined whether a shape was symmetrical or not, in at least one image. In the second part of the test, where students asked to put axes of symmetry, students were able to put vertical axes of symmetry but unable to put horizontal axes. Additionally only 2 of them were able to understand that shapes may have more than one axes of symmetry. In the third part, a large number of students at pre-test, transferred the initial shape in at least one task. Furthermore, they ignored some aspects of the original shapes. For example in task 2

	Tasks 1		Task 2		Task 3		Task 4		Task 5		Task 6		Task 7		Task 8	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post
Stage 1	11	3	12	3	14	9	13	5	17	5	14	2	11	4	12	5
Stage 2	12	9	8	9	6	5	8	10	6	4	5	9	12	10	7	6
Stage 3	2	9	5	11	5	8	4	8	2	10	6	9	2	8	6	9
Stage 4	0	4	0	2	0	3	0	2	0	6	0	5	0	3	0	5

Table 4: Students' classification of representations on each task: Group A

	Tasks 1		Task 2		Task 3		Task 4		Task 5		Task 6		Task 7		Task 8	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post
Stage 1	8	4	13	7	12	8	12	7	15	10	10	5	10	4	13	7
Stage 2	14	13	7	6	9	8	8	10	8	10	10	8	11	14	8	10
Stage 3	3	7	5	10	4	7	5	7	2	3	5	9	4	6	4	6
Stage 4	0	1	0	2	0	2	0	1	0	2	0	3	0	1	0	2

Table 5: Students' classification of representations on each task: Group B

and 8 they ignored the empty square. At the same time in tasks 4 and 5 students ignored the diagonal line segment that they had to bring in order to complete the symmetrical triangle. At the same time, a large number of students seem to ignore the relative size and position of original shapes.

The qualitative analysis of the post-test showed that the biggest improvement was achieved by a girl in group A. During the intervention Maria faced many difficulties. Originally, she completely ignored the instructions and as she said, she was just trying to make images "to look good." In another attempt to complete the shapes, she ignored the initial position and the size of the shapes. However, at the end of those activities, she was able to complete symmetrical shapes with vertical and horizontal axes. In addition to this she was able to take into account the initial position and size of most shapes. In Figure 1 we can clearly see an example of Maria's improvement.

As we can see in Figure 2, at pre-test, Maria transferred all initial shapes. Most of her representations were categorized at the pre-structural stage. However, after the teaching intervention, Maria's representations improved significantly. In tasks 1, 2, 7 and 8 Maria's representations manage to reach the stage of partial structure. In tasks 3, 5 and 6, Maria's representations were classified at emergent structure stage.

The use of virtual manipulatives generated enthusiasm and motivated most of the students. For example John, a boy from group A, set more difficult tasks for himself. During an activity called "Creating Symmetrical Pizzas" John tried to complete a pizza (Figure 3) with a diagonal axis of symmetry even though he was not successful at it.

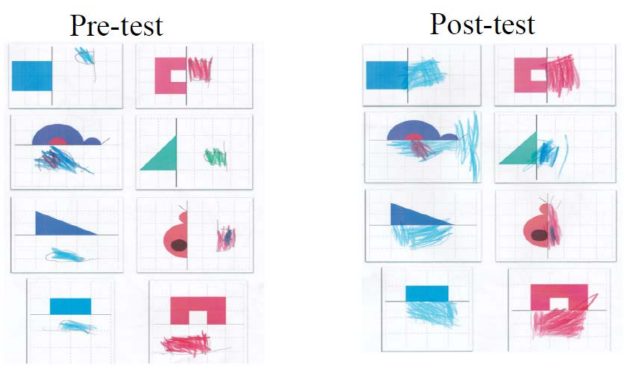

Figure 3: Pre/Post-test

John seemed to understand those activities from the very beginning. He was able to complete more complicated shapes with vertical and horizontal axes of symmetry without facing particular difficulties. Figure below presents two examples of John's activities.

John seemed to adopt an analytical strategy in order to complete those activities.

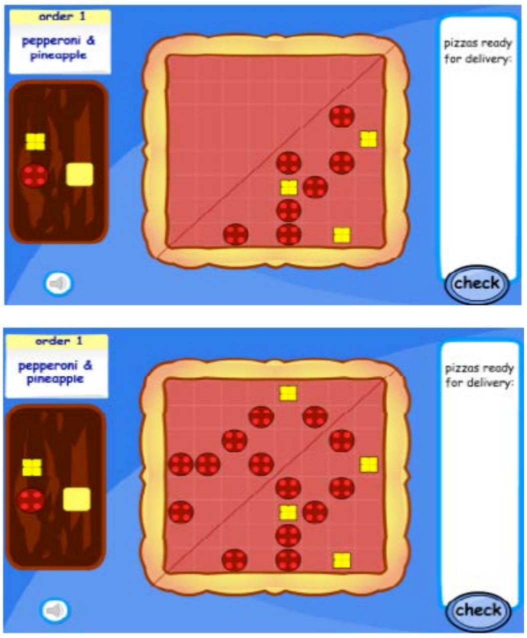

Figure 4: "Creating symmetrical pizzas"

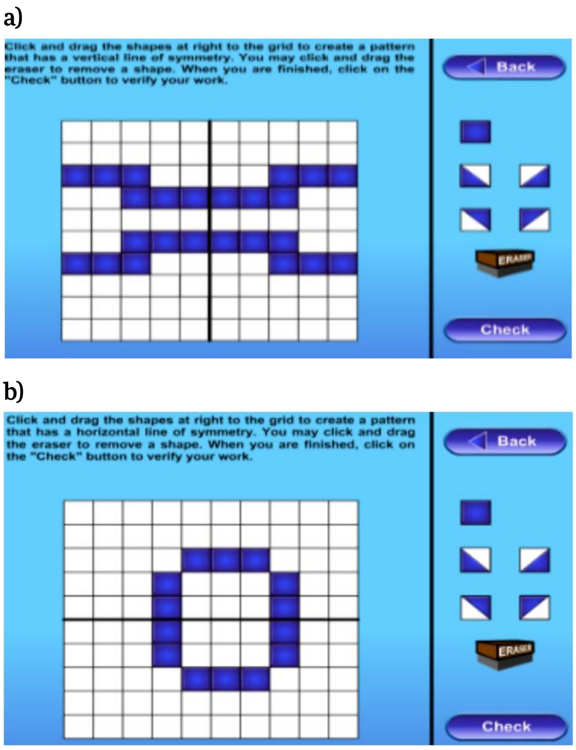

Figure 5: John's activities

Researcher: Can you tell me the way you think in order to complete this shape?

John: First, I count how many squares are painted on the one side.. at this line... 1, 2, 3 ... 4. So, on the other side I should put 4 squares. I have to put them next to the black line.

Researcher: Why you have to put those squares next to the black line (axis of symmetry)?

John: Well, since in the given example the first square is next to the black line, I strongly believe that I have to put another square to the other side right here (next to the black line). So when I have to fold this picture (he joined his hands and fold them) I am trying to imagine if the one side touch the other side. I remember the video we saw with the butterfly when the one side touches the other after we fold the picture.

CONCLUSIONS

As it revealed from the data analysis, kindergarten students had higher performance in identification of symmetrical images and lower performance in tasks where they had to put axes of symmetry and complete symmetrical shapes. These findings seem to be agreed with previous findings (Sarama & Clements, 2009; Tzekaki & Christodoulou, 2000). According to Tzekaki and Christodoulou (2000) kindergarten students, seem to access symmetry concept in a holistic manner. This is something that is confirmed in this study. During recognition activities, students ignored important details which determine if a shape is symmetrical or not. As a result, they made wrong recognitions. In the third part, most of the students transferred the original shapes and this is something that supports the holistic manner that students faced symmetry concepts. Additionally our findings seem to be in agreement with Genkins (1975) who argued that vertical bilateral symmetry remains easier for students to handle than horizontal symmetry since students at this study faced difficulties in putting horizontal axes of symmetry. As Tzekaki and Christodoulou (2000) argued children of 5 and 6 years old were unable to draw symmetrical shapes taking into account the relative position and size of shapes. This is something that is confirmed in our study since a large number of students from both groups were categorized at pre-structural stage and emergent structural stage according to Mulligan, Prescott and Mitchelmore's (2003) classification.

Even though both teachings improved students ability in symmetry, the results of our investigation, suggest that the use of virtual manipulatives can improve students' performance to a greater extent than the use of concrete manipulatives. As Yerushalmy (2005) argued computers may provide representations that are just as personally meaningful to students as physical objects. These results seems to be in agreement with Sinclair and Kaur's (2011) findings who found that kindergarten children were able to develop an understanding of symmetry that showed awareness of the properties of reflectional symmetry through the behaviour of dynamic images. At the end of the computer session, students in group A were able to recognize symmetrical and non-symmetrical shapes and images, to place axes of symmetry and to complete shapes and images. The number of students which classified at stage 1 and 2 reduced after the teaching intervention with the use of virtual manipulatives. Additionally, more students from group A moved to stage 3 and 4 according to Mulligan, Prescott and Mitchelmore's (2003) classification of representations. Char (1989) argued that a computer environment offered students greater control and flexibility comparing with the concrete materials. The flexibility of computer manipulatives allowed students to mirror mental "actions on objects" better than concrete manipulatives do and probably this is the reasons for the better students' performance in group A.

The results reported in this paper should, however, be interpreted with some caution. This study suffers from some limitations. First of all it is a study with small sample, so it is difficult to draw firm conclusions or to generalize the findings to other students or context. Also another limitation of our study is the limited time horizon. This study measured the impact of virtual manipulatives on a short term. As a result the real impact of virtual manipulatives may not become apparent during this short term. As a consequence we can see multiple directions for follow-up research. For example further research is needed to analyze the impact of virtual manipulatives with the use of high level statistical analysis, in large scale studies. These studies should also measure the impact of virtual manipulatives on a long term. Additionally another direction for future research consists of examining the applications of more recent technologies in kindergarten students such as touch screens.

Distributed authority and opportunities for children's agency in mathematical activities in kindergarten

Ingvald Erfjord, Martin Carlsen and Per Sigurd Hundeland

University of Agder, Kristiansand, Norway, ingvald.erfjord@uia.no

The aim of this study is to investigate to what extent authority is distributed and opportunities for children's agency in mathematical activities. We are drawing on a sociocultural perspective on learning to analyse the distribution of authority among kindergarten teachers and children and exercise of agency in various mathematical activities in the kindergarten. Our analyses show that authority is distributed to some extent, through questioning and opening for children's contributions. Moreover, opportunities are given in which children exercise conceptual agency with respect to mathematical reasoning concerning geometrical shapes and measurement.

Keywords: Kindergarten, agency, authority, mathematics.

INTRODUCTION

Mathematics has not been explicitly mentioned in Norwegian curriculums for kindergartens until 2006 (Ministry of Education and Research, 2006). The 2006 curriculum emphasises that the children are supposed to develop their mathematical competence through play, experimentation and daily activities, and that the kindergarten teachers (KTs) are to facilitate and empower children's mathematical explorations. Today the KTs are supposed to be able to address mathematics as a subject in their daily enterprise. It is therefore of interest to study in what ways kindergarten teachers orchestrate mathematical activities in order for the children to engage in the mathematics.

This was the background for our investigation of how mathematical activities were organised, to what extent mathematics was the core of the activities, who was in charge of the mathematical content of the activities, to what extent the children had opportunities to appropriate mathematical concepts, and so on (see, e.g., Carlsen, 2013; Hundeland, Carlsen, & Erfjord, 2014). We have documented elsewhere (Erfjord, Carlsen, & Hundeland, 2012) evidence of a shift in the studied kindergartens regarding the didactic triangle characterising the kindergartens' enterprise; from a situation where a pedagogical activity (PA) was initiated with minimal mathematical input, to a situation where mathematics became the focal point in the activity – a so-called mathematical pedagogical activity (MPA). One important argument for this shift was found in the KTs' roles as mathematically competent adults and leaders of these activities.

In the study reported here, we thus had an initial hypothesis: In order for the mathematical activities to become effective with respect to mathematical outcome and experience on behalf of the children, the KTs have to distribute authority and facilitate children's exercising of agency in the adult-child interaction. Furthermore we had an initial hypothesis that if the KTs distributed authority amongst themselves and the children, the learning activities may gain flexibility and children initiatives, but may suffer from less mathematically goal-directed actions. This may lead to a situation where a planned MPA in effect becomes a PA. From these hypotheses we formulated the following research question:

> In what ways is authority distributed amongst kindergarten teachers and children in the observed mathematical activities, and in what ways are opportunities created for the children to exercise agency?

Agency is something that constricts or permits what one is free to do in a given situation. This question thus addresses an under-researched and important area in mathematics education, both the focus on distributed authority and exercising of agency as well as our focus on mathematical learning activities in the kindergarten setting.

Several studies during the last decade have documented the mathematical learning opportunities offered for children when they are participating in MPAs (see, e.g., Carlsen, 2013; Clements & Sarama, 2009). These studies document that learning opportunities are indeed offered for children in the kindergarten setting. Moreover, the children are nurtured in their ongoing process of appropriating mathematical tools when participating in MPAs. However, none of these have focused particularly on the interaction between KTs and children with respect to distribution of authority and agency.

AUTHORITY AND AGENCY

In order to address the research question, we adopt a sociocultural perspective on learning and development (Rogoff, 1990; Wertsch, 1998). Within this perspective interaction amongst adults and children as well as the use of tools are acknowledged as fundamental elements constituting the learning process. Tools such as mathematical language, paper and pencil, concrete materials, etc. are used as mediating artefacts in order for persons to communicate and interact in collaborative settings. In our study there are thus two main concepts that need a clarification, authority and agency. Cobb, Gresalfi, and Hodge (2009) define authority as "the degree to which students are given opportunities to be involved in decision making about the interpretation of tasks, the reasonableness of solution methods, and the legitimacy of solutions" (p. 44). Authority is thus a term used to address who is responsible when it comes to making mathematical contributions to an on-going problem-solving process. In our use of the term agency, we are following Lange (2009), that human agency is a term used about a child's "faculty to act deliberately according to one's own will and thus to make free choices" (p. 2588).

In order to align the view of authority, agency and a sociocultural perspective on learning, we are drawing on the work of Cobb and colleagues (2009) and their analysis of students' possibilities to exercise agency in particular classrooms. According to these authors, there are two aspects that are of importance when it comes to effectiveness in supporting mathematics learning; distribution of authority and opportunities for students to exercise agency. Furthermore, Cobb and colleagues (2009) argue that authority is closely connected with students' possibilities to exercise agency. According to Pickering (1995), agency concerns in what respect an individual's actions are emerging from free will or are influenced by others. Attributes of classic human agency are thus choice and discretion. Cobb and colleagues (2009) follow Pickering (1995) and differentiate between two forms of agency, i.e. conceptual agency and disciplinary agency. Conceptual agency is about "choosing methods and developing meanings and relations between concepts and principles" (Cobb et al., 2009, p. 45), that is attributes familiar within human agency. Pickering (1995) introduced the term disciplinary agency to emphasise that agency, when exercised within a conceptual practice like mathematics, is closely connected to the discipline in which it unfolds. In mathematics it is about employing established methods. According to Pickering, disciplinary agency is thus a specific disciplined pattern of human agency, e.g. routines with respect to symbol manipulations like $a(b + c) = ab + ac$. The notion of disciplinary agency then describes human passivity within a conceptual practice. Disciplinary agency thus "leads us through a series of manipulations within an established conceptual system" (p. 115).

Based on these notions of conceptual agency and disciplinary agency, Cobb and colleagues (2009) argue that in order for mathematical learning processes to be supported effectively, authority has to be distributed and students ought to be given opportunities to exercise conceptual agency. This argument is supported by Boaler and Greeno (2000) as well. Their study reveals that students need to be given possibilities to participate as creative agents in the mathematics classroom in order for mathematics teaching to be effective. Moreover, Boaler and Greeno argue that students need to be given possibilities to use their own language, to be given chances to think for themselves, to be given chances to make own interpretations and decisions.

Additionally, Cobb and colleagues (2009) argue that experience in exercising conceptual agency is needed in order for students to be able to reason about the usefulness of disciplinary tools in problem-solving processes. If authority is kept with the teacher, students are only offered possibilities to exercise disciplinary agency. Within a conceptual practice, like doing and learning mathematics in a kindergarten setting or in a mathematics classroom, there is therefore what Pickering (1995) refers to as a dance of agency. Conceptual agency and disciplinary agency may be intertwined and alternately take a lead. In our study the KT, the child, and the conceptual practice, i.e. a mathematical pedagogical activity (MPA), influence one another. We thus suggest talking about such activities as situations where authority may be distributed amongst the actors, giving each of them opportunities to act and exercise agency. When orchestrating a MPA, the KTs may have intentional learning goals of their mathematical activities. But since authority is distributed amongst adults and children, opportunities may be given for children to participate and possibly exercise conceptual agency.

The notions of authority, conceptual agency and disciplinary agency are used by Cobb and colleagues (2009) within a school context. As argued elsewhere (Erfjord et al., 2012), the Norwegian school context and kindergarten context differ to a large extent, both with respect to the nature of the two curriculums and with respect to organisational and structural nature. It is thus relevant to discuss how these notions may be employed in a Norwegian kindergarten context. Since kindergarten children are young and less autonomous than their counterparts in school, a KT may distribute authority in a different way than a teacher in school. The KT orchestrates mathematical pedagogical activities and she thus has most of the authority. However, she may ask the children several questions, suggest actions, asking for their opinions, their thoughts and ideas, asking for arguments and so on. In doing that some of the authority is distributed to the children, putting them in the position of being in charge for the mathematical interaction, how and in what direction this process may evolve. Nevertheless, as we will see from the analyses below, there is no doubt that the KTs have most authority in the cases we present.

To sum up, we use the term authority in line with Cobb and colleagues (2009), as something that may be given to others. In our case authority is given by the KTs to the children. When authority is given, opportunities are created in which children may exercise agency. However, as we will see, the children do not always take advantage of those opportunities to unfold their agency.

METHODS

Our study may be described as having a collective case study design (cf. Stake, 2000), because we study a number of cases in order to investigate the phenomenon of distributed authority and exercising of agency within MPAs in kindergartens. We were invited to kindergartens when the KTs argued to be orchestrating MPAs. These activities were videotaped. We analysed data from three kindergartens, and in this paper we present four illustrating excerpts to address the research question formulated for this study. We studied situations that from the outset were orchestrated by the KTs. Thus, the planned activities were led by the KTs and it was primarily the KTs that had the authority in the activities. Hence, the children's opportunities to exercise agency were limited. However, we seek to analyse to what extent authority was distributed, even though authority was mostly kept with the adults.

Our analytical process may be described in the following way: Firstly, we carefully analysed the conversations and actions between the KT and the children, paying attention to how the MPAs were orchestrated by the KTs. In doing that, we had the following questions in mind: Did the KTs invite the children to interpret the tasks? Did they accept and use the children's own wording of the situations, choices and actions to solve the tasks? The KTs actions indicate to what extent they distributed the authority in the MPAs to the children. Secondly, after having identified occasions where authority was given to the children, our next step was to analyse whether the children used their freedom to handle the situation based on their own free will. That is, whether they were able to exercise their agency in order to solve the tasks. Our attention was now particularly focused on the children's actions, whether they responded orally with own thoughts and actions or whether they only waited for the KT's suggestions. Thirdly, in order to study the distribution of authority, we paid particular attention to the teachers' conversations with the children. Did the KTs use suggestions or instructions? Did the KTs organise the MPA in a way that gave the children opportunities to act based on their own ideas? How did the KTs respond when the children presented their own ideas and acted in their own way? Fourthly, our analysis of the children's exercising of agency included paying attention to what the children did in the situations where authority was distributed. Did the children solve the problem using their own ideas? Did the children use their own language in their problem-solving process?

ANALYSIS AND RESULTS

The analyses in this study comprise excerpts from three kindergartens. The first excerpt is taken from Duckling kindergarten in which four children and one KT participate and where the mathematical theme is measuring. Excerpts 2, 3, and 4 are taken from Pinocchio kindergarten. Six children of age 4–5 years and three female adults were involved in planned activities with the children. The common theme for these activities was geometrical shapes: triangles, quadrilaterals and circles.

Excerpt 1

A group of 4–5 year-old children went on a forest trip together with their KT. When they arrived at the place where they used to stay, the KT gave four children the task to find themselves one tree each. Then she asked:

KT: Whose tree do you think is the thickest one?
Birger: Pedro's (5 sec.)
KT: Pedro's. Maybe you can try to hold your arms around the tree, like this (holds her arms as if she is folding a tree). Which one do you think it is? Do you think it is Pedro's tree? Can you imagine how we may find out whether it actually is Pedro's tree that is the thickest one?
Lisa: Because it looks so big
(The four children are holding their arms around their tree)
KT: Because you think it looks so big.
Birger: I fold the tree like this (he holds his hands around the tree)
KT: You fold it like that. Do you think there are other ways to find out whose tree is the thickest? How can we find out whether your tree is the thickest (Looks at Pedro)? Because that was what the others thought, that your tree is the thickest. How can we find out whether Pedro's tree is the thickest? Do you have any idea?

In this excerpt the KT seeks to distribute authority amongst her and the four children. She invites them into a discussion where they are supposed to reason about thickness of trees. The KT challenges the children to come up with their own ideas and opinions. The problem is how to compare thickness of trees. It is apparent from the excerpt that the children experience difficulties in responding to the KT's question. However, Lisa argues that it is Pedro's tree that is the thickest one because it looks so big.

The KT invites the children to contribute with their opinions. Authority is to some extent distributed between her and the children, when she asks the children to come up with their ideas with respect to deciding whether Pedro's tree is the thickest one. The children are supposed to compare thickness of the trees with their arms.

The children are given authority at various occasions. However, the children do not seem to exercise agency due to the difficulty level of the challenge given by the KT.

Excerpt 2

This dialogue took part in a sharing time with the children and the adults in a reserved small room. After a brief introduction where the KT gave the theme for the day, triangles, quadrilaterals and circles, she started off by giving the children a task:

KT: Can you see any shapes in this room? (The children move their heads and look around in the room)
Clara: I can see a "rounding" (The child points to one of the walls in the room)
KT: Where can you see a "rounding"?
Clara: There! (She points to a transparent plastic box, where a cross section of a rolled up poster has a circular shape)
KT: Yes. Great.

This kind of interaction pattern, with suggestions from the children and confirmation or clarification questions from the KT continued for a while. The authority is handled by the KT in the sense that she has organised the activity, and she takes decisions during the session concerning what are being discussed and how the topic is investigated. Also the agency is mainly with the KT. However, the KT's acceptance of the child's vocabulary, as for example the use of words as "rounding" for circle and "circle" for a cylinder, indicates that she transferred authority concerning way to express mathematics from her to the child. In opposite way she could have corrected the child's incorrect mathematics naming of the figures. The KT's invitation to the children looking for geometric shapes in the room, also gives some authority to the children in the meaning that they can select what to point at. As a consequence the object that is being discussed and interpreted as a triangle, quadrilateral or circle are chosen by the children.

Excerpt 3

This excerpt is from an activity that took part on the floor. The KT had prepared a closed cardboard box containing different shapes. On the floor three A4 sheets with big sketches of respectively one triangle, one quadrilateral and one circle were placed. The task for the children was to put their hand into the box and choose one of the shapes, describe the selected shape without looking at it, and finally place the shape on one of the sheets according to its shape. The KT asked one child at a time to do the task, and she interacted with questions to the child. One example of such interplay is the following:

KT:	It is your turn, Vicky
Vicky:	(Uses a couple of seconds to select one item from the box)
KT:	What have you found, Vicky? (She holds a ball in her hand within the box)
Vicky:	A bouncing ball (She shows the ball and bounces it at the floor)
KT:	What kind of shape has the bouncing ball?
Vicky:	A rounding
KT:	A rounding, yes. Can you place it on the "rounding" at the floor?

Compared with the activity analysed in Excerpt 2, this activity gives less possibility for alternatively solutions. In this sense the KT keeps her authority. However, the activity gives the children a possibility to describe the geometrical shape, firstly based on their tactile sense and secondly based on what the child see and is doing with the shape. Thus, the children have some freedom to describe this shape with their own wording. Similar to the activity above, the KT accepts the child's vocabulary when the child labels a spherical ball as being "a rounding". The KT also uses the child's label when she asks the child to place the "rounding" on the floor. The fact that the KT had selected a spherical shape, despite asking them to categorise the shapes as two dimensional (triangle, quadrilateral and circle), indicates that the KT probably intended the child to categorise the ball as a "rounding" or "circle".

Excerpt 4

This excerpt is taken from an outdoor activity which involved a walking trip up to a church close to the kindergarten. The children got one sheet of paper each with three columns headed with pictures of respectively a triangle, a quadrilateral and a circle. The children were asked to put a vertical mark in the correct column each time they discovered a thing with the particular shape. A road sign outside the kindergarten was one of the first thing noticed by the children. The road sign had a quadrilateral form with an inscribed triangle. The following talk took part between two of the children and one of the adults:

Clara:	See the road sign
KT:	Yes, What kind of shape is this?
Clara:	A quadrilateral.
KT:	Yes. Put a mark there (The KT points with her finger at the column "quadrilateral" on their sheets. The two children make a mark on their sheets in the correct column).
KT:	Can you see any more shapes on the road sign? (The children remain quiet for four seconds)
KT:	One – two – three (while the KT counts loudly, she points counting with fingers headed to the road sign). Can you see the shape within the road sign?
Ida:	A triangle.
KT:	Yes. Great. Put a mark under «triangle» on your sheets. (The two children put a mark on the correct column in their sheets)

In this activity we observed several similar examples to the one above where one or two children talked and got some help from one of the adults. In the activity, the children had been offered authority in deciding shapes and categorisation in the three types suggested by the KT in the sheet. The interaction pattern is similar to what we found in Excerpt 2, However, the outdoor area opens up for more options of things to categorise than the small room in Excerpt 2. The children's possibility to take the agency is bigger, and the KT has less possibility to prepare the activity in the open outside environment. However, several times during the outside activity, the KT asked the children as a group to look at particular things like a circular brick area outside the church. Such interventions gave more authority to the KT with an emphasis on particular things shaped as triangle, quadrilateral or circle.

DISCUSSION

We set out in this study to answer the following question: In what ways is authority distributed amongst kindergarten teachers and children in the observed mathematical activities, and in what ways are opportunities created for the children to exercise agency? The four excerpts show how the authority is distributed between the KTs and the participating children. The excerpts also exemplify how the children exercise their agency by participating in the mathematical learning opportunities that occur in MPAs.

In excerpt 1 the KT collaborates with the children in order to find out whose tree is the thickest one. The children come with various responses and the KT notices them and gives a response back, as paraphrasing and with a new question. The excerpt is characterised by the children's involvement in the activity, even though they are not so verbally activity. The KT lets the children imagine what they think, to estimate thickness of trees, as well as to come up with reasons for their ideas. This shows that the children are given mathematical authority in this case and that they exercise conceptual agency. They are given opportunities to participate and to give directions for the MPA. At the same time we observe that the KT is in charge of the activity. She controls the activity by actively asking questions to all children at the same time, but also individually.

However, our observations show a variety concerning the KTs' distribution of authority to children and to what degree children exercise agency during their participation in learning activities. In excerpt 2, 3, and 4, the distribution of authority is limited inside a planned frame for the activities. It concerns children's oral response to questions, selections of certain objects or participation in well-defined physical actions. The KT invites the children to take part in these actions, and it seems reasonable to argue that the children perceive this participation as voluntary. In that way we conclude that the children seem to exercise agency. However, it is also clear that the KT controls the activity, and does only allow responses that support her goals for the activities.

In the situations where authority is distributed to them, the children get opportunities to exercise conceptual agency. That is, the children contribute with ideas and arguments that may strengthen their opportunities to develop mathematical meanings and relations (cf. Boaler & Greeno, 2000; Cobb et al., 2009). As we saw, there is not so much disciplinary agency to be found in the analysed cases. That is, however, not surprising, given the Norwegian kindergarten's enterprise of being process oriented and situated within a social pedagogical tradition. Thus, disciplinary agency as the use of "established solution methods" (Cobb et al., 2009, p. 45) is not that prevalent in the kindergarten since these methods to some extent do not exist in any readymade matter.

We argue that authority, and hence, agency, ought to be distributed carefully within MPAs in order for the children to become supported in their mathematical learning process. Opportunities to exercise conceptual agency are needed, but the KTs need to orchestrate the MPA in such a way that the children are able to exercise agency. At the same time the KTs ought to control the activities in order to possibly reach mathematical learning goals. This is needed due to the limited mathematical experience of the children.

Perceiving and creating in the mathematics classroom: A case-study in the early years

Francesca Ferrara

Università di Torino, Torino, Italy, francesca.ferrara@unito.it

This paper draws on recent research on the theorizing of embodiment in mathematics thinking and learning to adopt a non-dualist perspective that challenges the view that mathematical concepts cannot be perceived and created. This perspective brings out the intensive and immersive aspects of mathematical activity that feed the potential and the mobile in the classroom. Through the analysis of two 8-year old children, who reason on a figural pattern, I show how their ways of talking, moving and feeling allows them to mobilise and invent the mathematics they are learning. In so doing, I propose that perceiving is conceiving and creating is learning.

Keywords: *Creativity, embodiment, mathematics learning, materialism, perception, virtual.*

INTRODUCTION

In the last decade or so, lots of studies of embodied mathematics focused on the role and relevance of bodily activity in mathematics teaching and learning. Far from being an emergent generation of research, this corpus of work has started offering attempts to talk about and understand mathematical activity in *non-dualist* ways. Examples are studies of researchers like Nemirovsky, Radford, Roth and, more recently, de Freitas and Sinclair. No matter what their theoretical stances are, whether phenomenological, semiotic, philosophical, etc., they all embrace visions of a 'multimodal' or 'sensuous' mathematical cognition that recognise a special place to physical bodily aspects in the classroom, without assuming the existence of "two distinctive planes, one internal and one external" (Radford, 2013, p. 144). They all pursue a *participationist* view of teaching and learning that moves away from the constructivist tradition started with Piaget, which considers the mental schemas that students are expected to acquire. And beyond the mechanistic view still present in Lakoff and Nùñez's (2000) seminal embodied cognition theory, which fails to escape the mind/body split by inferring metaphorical mappings in the mind as sites of/for knowledge. Acquisitionist theories, based on structural concept formation, also entail levels of abstract thought confining mathematical concepts to abstractions, to de-personalised intangible and immaterial entities that *cannot* be perceived. Sfard's (2008) communicational theory shares the participationist commitment, by focussing on the ways in which students and teachers change their mathematical discourses, and conies the term 'commognition' to stress how thinking *is* communicating. But, sort of struck by all the 'fuss' about the body, and gesture in particular, it resists discussions about its participation in mathematics classroom discourse.

In this paper, I adopt a non-dualist participationist position that pursues a different vision of perception and creation in mathematics, according to which bodily activities are ways of thinking as well as of communicating (and feeling, I argue). In this way, I hope to contribute to the theorizing about the embodied nature of mathematics and of its learning.

THEORETICAL PERSPECTIVES

Sheets-Johnston challenges our ways of theorizing embodiment in thinking, shifting attention to "our being the animate organisms we are" (2009, p. 397) and "living moving bodies", which "*feel the dynamics*" of their everyday tactile-kinesthetic/affective experiences (2012, p. 393, emphasis in the original). There is no question then but that animate beings are not "*embedded* in the world" or "*embodied* in their actions, their emotions, their cognitions"—as Freedberg and Gallese (2007) would suggest on the basis of research on the mirroring system of the brain, which is in turn rooted in the realities of movement (Sheets-Johnston, 2009, p. 397, emphasis in the original). Animate beings, claims Sheets-Johnston, "are already living, and being already living, are already making sense of themselves and of the world in which they find themselves and of which they are a part." (p. 397). She is here suggesting a new image with respect to the 'I think therefore I am' *à la* Descartes. One that we might refer to as 'I move therefore I am', which entails that moving *is* thinking, so gesturing *is* thinking—as much as communicating *is* thinking (the other way around in the commognitive perspective).

Nemirovsky and colleagues (2013) stress a resonant point of view when they make a parallel between music and mathematics to investigate kinesthetic activity in museum exhibits where learners 'play mathematical instruments'. Fluent use of the instrument involves an interpenetration of perceptual and motor aspects of playing it. Kinesthetic activity is relevant here in two ways: "motor activity is involuntarily enacted as part of perceiving", and "partial motor and perceptual components have the power to elicit the activity as a whole over time" (Nemirovsky et al., 2013, p. 380). Working from a non-dualist approach to tool use, the authors again trouble the dichotomies between thinking and acting, *perceiving and conceiving*. In my own study on multimodality in mathematical activity (Ferrara, 2014), I examine kinesthetic activity in the context of motion detector use and I propose to see mathematical thinking in terms of floating intricate intensive entanglements of ways of perceiving, moving and imagining. Here, I follow Burbules (2006) in claiming that experiences engage our imagination "when we can interpolate or extrapolate new details and add to the experience through our own contributions", so that we may be "making guesses about things that are not immediately present to us" or "anticipating what will happen next in some sequence or development." (p. 41). Imagination, depending on students' active response and engagement in the activities, triggers feelings of *immersion*, senses of "as if", which make the experiences virtual experiences for the students. A key dimension of this quality of immersion that, for Burbules, "makes the virtual seem or feel "real" to us" at that moment, are "our posture, body tension, and startle responses" or "our relaxation, rhythmic movement, and kinesthetic sensations" (p. 42)—and he takes here any truly educational experience as being immersive, or virtual, as much as watching a film, hearing a story and listening to music. As I have stressed, this sense of immersion reconfigures mathematics learning as an alive and *genuinely creative* adventure.

A way of re-framing creativity in the mathematics classroom is offered by the new inclusive materialist approach of de Freitas and Sinclair (2013, 2014; see also Sinclair et al., 2013). Creativity is not studied here as

> a property or competence of a learner, as suggested by approaches that seek to measure the flexibility or fluency of a child's thinking. It does not exist independently of its exercise. In other words, it is not that individuals are creative or not creative, but rather that creativity flows across the learning assemblage in a somewhat impersonal way. (de Freitas & Sinclair, 2014, p. 86)

This conception of creativity is not bound to a "personal creativity as a characteristic that can be developed in schoolchildren" (Lev & Leikin, 2013, p. 1204). Indeed, it shifts attention away from the doer, and from the idea of giftedness and high ability in mathematics, to focus on the doing, without lapsing into reading actions as reflections of mental states. It "treats creativity as *an action taken* that emerges in context, without being exhausted by it" (Sinclair et al., 2013, p. 241, emphasis in the original) and *bringing forth the new*.

Thus the inclusive materialism centres on the process of creation of something new, looking at students' actions, with the other material actions in the classroom, as an expression of creativity. Interestingly, it relies upon a re-configuration of the contours of the learners' body, which enables to talk not only about the body *in* but also *of* mathematics. In fact, inspired by the French philosopher Gilles Châtelet and his notion of the virtual, de Freitas and Sinclair explore "how mathematics partakes of the material world" (2014, p. 1) and how this occurs "in operative, agential ways", troubling the tacit belief that "the mathematical concepts (multiplication, cube, zero) are taken for granted, while students collaboratively move towards them." (p. 40). Within a tradition that assumes that abstract thought and materiality are entwined, their philosophical position looks for "how bodies are assembled through activity" (p. 15). For de Freitas and Sinclair, "the body is an assemblage of human and non-human components, always in a process of becoming that belies any centralizing control." (p. 25). Their perspective "moves away from a theory of power as a totalizing, external force and follows power as it flows through sensation and affect, across the surfaces of bodies as they emerge in relation to these flows." (p. 41). In so doing, they open room for post-humanist discourses of subjectivity and agency, for which students are always in a process of *becoming* mathematical subjects through agential relations with the diverse dynamic materialities in the classroom, including the mathematical concepts.

Thus mathematical creativity (or inventiveness) is materially conceived of in terms of the process that "expresses and captures the temporal and dynamic moment when the new or the original comes into (*in-venire*) the world at hand", for example in terms of "the dance between the gesturing and drawing hand" (de Freitas & Sinclair, p. 88, emphasis in the original). Other than bringing forth what was not present before—a feature stressed by Châtelet (1993/2000) in his analysis of inventive moments in the history of mathematics, a creative act has also other characteristics (Sinclair et al., 2013). It is unusual: it does not align with current perceptual habits or practices that are taken as norms and the extent to which it is recognized as creative, depends on the context where it occurs. It is unexpected or unscripted: it is not directly of formally determined by the intentions of the individuals involved. It changes the way language and other signs are used and alters the meanings that circulate in a situation, so that its meaning cannot be exhausted by existing meanings. These qualities "point to the centrality of the body and its movement (actions)—rather than internal mental disposition—in creative acts." (p. 242). De Freitas and Sinclair (2014) discuss how "gesturing and diagramming can together bring about new ways of thinking, moving and imagining, and thereby give rise to inventive processes." (pp. 109–110).

In a different work, de Freitas (2014) claims that Châtelet shows us "how we might study a particular practice for how its lines of flight flourish and act generatively in unfolding new *intensive* dimensions." (p. 290, emphasis in the original). She draws on contemporary theories of perception to focus on the way the student's body, together with its potentiality, can be reconfigured, and the contours of the sensible and the intelligible recoded. She argues that we need to unpack the provisional nature of perception for emphasizing its *virtuality*, or virtual movements: "We never just register visual information from that which is in front of our eyes:", says de Freitas,

> we see potentiality, relationality, mobility, occurrence. [...] In other words, we live on "speculative investments," as though we were surfing "the front edge of a wave-crest" [...]. Perceiving an object entails a prehending of our body's potentiality to walk around the object, to reach out and touch the object, to see the object, to weigh it, to smell it. (p. 298)

In this paper, I want to use these arguments to focus on the *immersive* and *animated* ways in which children talk, move and feel in mathematical activities. These become means to look at how the children *perceive* and *create* in the mathematics classroom, giving rise to inventive moments that mobilise their doing mathematics as much as the mathematics they are doing. My non-representational monist view—aligning with those that challenge the body/concept and matter/thought dichotomy—questions the binary divide between perceiving and conceiving, creating and learning.

METHODOLOGY

In the analysis, I have chosen to focus on a particular pair of 8-year old children, Lara and Filippo, who deal with pattern activities to develop early algebraic thinking. The whole elementary class participates, during regular mathematics lessons, in a 5-year longitudinal study concerning the introduction of the concept of function and the use of variables. Thus the children had already worked on patterns in the previous grades. The selected data refers to the beginning of grade 3, when they are divided into pairs

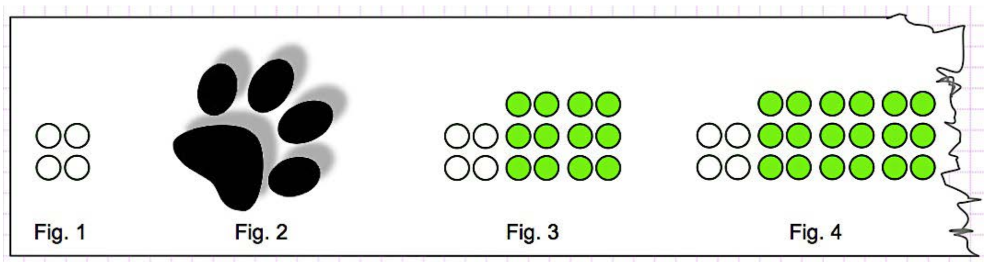

Figure 1: The figural sequence of the activity "Do you remember of Tobia?"

to face an activity called "Do you remember Tobia?", which re-presents a figural sequence to them. Tobia is the name of the imaginary dog that left the track on the ripped paper, having covered up term 2 of the sequence (Figure 1).

In grade 2, the children were asked to extend this sequence up to its sixth term and to find the second term. In grade 3, the purpose of the activity is to shift attention to the relationship between any term of the sequence and the term number—its position in the sequence. To this aim, the pairs are given the task of noticing any regularity in the pattern, and of explaining it.

Lara and Filippo sit on a desk, one in front of the other and turned around to face the other in the discussion. A master degree student, who participates in the lessons as an observer, films them by using a mobile camera. Data of their discourses come from the video-clips, while additional material is given by their written productions. A university researcher (the author) and the teacher are also present in the classroom. The researcher (labelled by R in the data) consistently takes on the role of the guest teacher, teaching the lessons in collaboration with the regular classroom teacher (T below), who has the role of an active observer. In the activities, phases of individual work alternate with pair work and collective discussions.

RESULTS AND ANALYSIS

The results are divided into three sections. The first two focus on the discovery of a remote term within the figural sequence. The last section centres on the way in which Filippo solves the new task about the position of a given total number of circles.

Perceiving numerosity in the particular: What about position twenty-five?

The activity began with Filippo and Lara examining the pattern of Figure 1, with the instruction of looking for regularities. Filippo started by focussing on the bottom row of term 3 and seeing that the number of circles there relates to the term number. In particular, he has found that if one counts the circles on the bottom row and divides this number by 2, one gets the position of the term in the sequence. This introduces in the discourse the new operation of division by 2, which Filippo and Lara share with the researcher as soon as she comes to the pair.

Filippo: For example, you look at this [*Points to term 3 of Figure 1 with the pen in his right hand*], you do, you count the circles below [*Runs the bottom row*], one, two, three, four, five, six [*Counts the circles*], then you do six divided by two [*Looks up at the researcher*] that gives, oh

Lara: Three [*Looks up at the researcher*]

Filippo: And this is, is [*Moves the pen twice around term 3*], oh, the position

Lara: Or you also take this [*Overlaps Filippo's voice. Points to term 4*], you can also take this [*Points to term 4 again*]

R: Oh, and does it also work here? [*Indicates term 4*]

Filippo: This one is equal. One, two, three, four, five, six, seven, eight [*Counts with the pen the circles on the bottom row of term 4. Lara joins him in counting*]. You do eight [*Looks up*] divided by two

Lara: It gives four [*Looks at the researcher*]

Filippo: And this one [*Moves the pen twice around term 4*] is in position four. This one [*Shifts the pen to term 1*], one, two, two [*Looks up at the researcher*] divided by two gives one [*Points with the pen to expression "Figure 1" below term 1. Looks up at the researcher. Smiles*]

R: Very Good! Oh, now I tell you: What about position twenty-five?

Lara: Twenty-five divided by two! [*Laughs. Looks at Filippo*]

Filippo: [*Looks at Lara surprised, looks up at the researcher, looks back at the sequence. Keeps thinking in silence for some seconds, suddenly mimes with his left hand a small rotation towards his torso. Looks up*] you do twenty-five, oh, times two

R: What do you use twenty-five times two for? Explain me.

This short passage shows that Filippo and Lara perceive the first structural relations in the figural sequence, between the numerosity of circles and the number of a given term like 3 or 4 – the children move the discourse beyond the recursive "adding six circles" (that emerged in grade 2), towards looking at the sequence in a functional way, by talking (for example using "position") and gesturing (around the term, to its bottom row). What they perceive is of a very different nature, since it introduces reasoning on the pattern in terms of whole numbers (numbers of circles), even if still per rows, but no longer strictly related just to the spatial structure. Dividing by 2 also comes to the fore as a means to manage the relations between numbers. A certain satisfaction can be grasped in Filippo's explanation about term 1.

Hoping to encourage the children to perceive more than one relation in the sequence, the researcher then introduces a new task for a new (remote) term: the "position twenty-five" task. Lara hurriedly says "Twenty-five divided by two", but Filippo keeps silent, marking his struggle (also expressed by his repeatedly changing gaze). The mathematics of the figural pattern is mobilised. Filippo responds thinking about multiplying by 2, but he gets confused about the kind of numbers in use when invited to explain. Thus he inquires "but do you say position twenty-five or the number twenty-five?". The situation breaks through with the answer "No, the position twenty-five", which prompts Filippo to insist on "you do twenty-five times two". When the researcher then asks "And what do I find?", discourse moves on.

Filippo: You find the number, the number of, of, oh, to put below [*Runs the bottom row of term 4 many times with the pen in his right hand*]. And you put them, at the beginning [*Moves left hand to term 4*] you put two of them and then two [*Indicates the bottom row with the pen, looks up*], then you put two of them and you go by two [*Jumps along the middle row*], and then you don't put any here [*Points to the empty space on the top row with left index finger*] and you always go by two [*Jumps along the top row with the pen*]

Filippo reasons in terms of numbers of circles on the 4th term of the sequence to think about the shape in a remote term like 25. In perceiving the row disposition and composition in term 4, gesturing on its rows with both hands ("always" referring to groups of "two" circles), he conceives of the structure in term 25 in terms of the spatial similarity that is granted by the algebraic structure of the pattern. Through gestures, the circles begin to be mobilised together with the numbers in the sequence.

Creating the new term: You skip the first two and you go

The teacher gets close and Filippo, excited, wants to tell her about term 25.

Filippo: In position twenty-five, you do, to discover that one [*Moves the pen many times around term 4 of the sequence*], this one [*Runs the bottom row of the term*], you do twenty-five times two, twenty-five times two, oh, then you put [*Points to term 4*], oh, wait, twenty-five times two, and, this number, oh, wait, I do no longer remember [*Smiles*]. You do twenty-five times two [*Pauses. Looks around, beats his head*], oh, what did I say? [*Looks at Lara, looks at the sequence*]

Lara: Twenty-five times two [*Pauses, looks at Filippo who points to term 4*], one, two, three, four, five, six, seven, eight [*Counts the circles on the bottom row of term 4*], you do eight divided

Filippo: Ah! You do twenty-five times two [*Looks at the teacher*], and you put the result here below [*Mimes with the pen the arranging of the first circles on the bottom row of term 4. Looks up at the teacher. Figure 2a*], you put the circles, all, of the result [*Continues the gesture outside of the paper. Figure 2b*]. When you arrive at the result with the circles, there [*Shifts the pen to a position towards the desk side. Figure 2c*], you stop and you go above [*Shifts the pen to indicating the middle row of term 4, keeps reference to it with left index finger*] and you always put twenty-five, no, always the result [*Mimes the arranging of circles on the middle row, moving to the desk side. Figure 2d*]. Then here [*Points with index finger and pen to the initial empty space on the top row of term 4*], you skip this, you skip the first two and you go [*Keeps the finger as a reference, mimes the arranging of the circles on the row with the pen. Figure 2e*], oh, and you put, you do [*Looks at the teacher*], oh, you take two away from the result and put those ones! [*Repeats the miming of the top row. Looks at the teacher, smiles*]

Figure 2: (a-c) miming the bottom row of term 25; (d, e) miming the other two rows

Filippo thinks of the pattern in terms of numbers as results of operations (no longer just numbers of circles). He uses his hands and fingers to enact the exact shape of the figure in the 25th position, with the reference of the 4th term. But he also gestures outside of the paper to talk about/imagine a term that would appear after the sequence––and, in any case, would be made of longer rows. Filippo mobilises the static diagram on paper through his gestures as a form of diagramming. He actualizes the virtual movement of the sequence, rather than only realising its logical possibility through numbers (that exists in the given only). Thus the circles are mobilised and the mathematics of the pattern is invented in the moving assemblage of the child, the pattern and the mathematics. This allows the creation of new mathematics as the new term is figuratively brought forth through Filippo's gestures.

Without distinguishing between perceiving and conceiving, as I am encouraged to do in materialist terms, I might say that, for Filippo, term 4 *is* term 25 here. In a similar way, without distinguishing between creating and learning, we might say that Filippo is starting to reason in algebraic terms and the children's discourse is moving to a more functional one compared to the previously discussed.

Perceiving and creating the unknown: What position is?

Filippo explains to the teacher the term in position Pippo that was introduced by the researcher as a challenge after term 25. The children faced the task with some tension with respect to using expressions like "the result of Pippo times two". During this interaction, the teacher poses the new task of having the total number of circles in a term: "I have a position, which I don't know, which has twenty-two circles, how can I discover what position is?", specifying that she means "as a whole".

Filippo: Twenty-two, oh, you take away four from twenty-two [*Mimes the operation moving his hands together in front of his torso from right to left. Figure 3a*] and you get eighteen, and it's the first group [*Mimes a grouping. Figure 3b*] of four [circles], eighteen. Then, you take away six from eighteen [*Mimes a block, with a vertical movement of his right hand. Looks at the teacher. Figure 3c*] and you get twelve [*Shifts right hand on the right, moves closer*] that, so, are four and a row of six [*Mimes the grouping again and a new block. Looks at the teacher. Figure 3d*]. Then [*Moves on the right again with both hands open to mime the remaining circles, bends his head*], take away six from twelve and it gives six, so they are four [*Marks a grouping with left hand*] and two rows of six [*Mimes a block with right hand*]. Then [*Pauses*], take away six from six, so it gives three rows of six [*Keeps still left hand, mimes the three blocks with right hand. Looks at the teacher. Figure 3e*], plus four [*Marks the grouping again with left hand. Look at the teacher. Smiles. Figure 3e*], and then, oh, there are no more [*Turns more towards the teacher*], you do, they are four plus three rows of six [*Mimes the grouping with left hand, the blocks with right hand*]

R: Ok, so what position is?

Figure 3: (a-c) miming the first operation; (d, e) miming the resulting blocks

Filippo: So, it's, one, two... three, four... five, six... four! [*Mimes the counting of the circles on the bottom row of the term, moving from left closer to the camera up to disappear almost entirely from its view. Smiles*]

This short episode shows how Filippo's ways of talking and moving become ways of diagramming the specific term in the sequence, and of imagining its position. It is as if Filippo had the term (big) in front of his eyes, could touch it and see it from various points of view, moving around it. His gestures, gazes, postures, smiles, all creatively tend to the term, with his body clearly marking the position and making space for the teacher. Like in the case of term 25, the invention of new mathematics is allowed as the given circles are mobilised, the imaginary blocks are animated and their position is created in the evolving body-material assemblage, through gestures of repeatedly subtracting six and the body shift closer and closer to the camera.

CONCLUSIONS

My goal in this paper has been to examine the children's ways of talking, moving and feeling as immersive and animated ways of perceiving and creating in mathematics, *the* mathematics. In a monist materialist perspective, the episodes have shown that the children's gestures play relevant roles as for the claim that their perceiving *is* conceiving and their creating *is* learning. Filippo and Lara begin to learn to think algebraically in the first and second episodes, when they create the shape of term 25 using the reference of term 4 of the sequence. Filippo sometimes gestures on the 4^{th} term as if the 4^{th} term was the 25^{th}, in other times he gestures beyond it for reaching the new imaginary term. Without these gestures, the diagram would stay static and the children would only use numbers to realise the possible given in the figure. In the third episode, Filippo is learning that a given total number of circles (not only the number of circles on the bottom row) can have a position in the figural pattern, when he creates the position for twenty-two circles without any reference to specific terms on paper. In the episodes, the child's hand gestures are never iconic representations of one term in the pattern. Rather, they are conceptions and creations that allow reducing distance between the physical and the mathematical. They transform what is static/possible towards the mobile/virtual––algebraic thinking here. At the heart of this virtuality, the figural pattern is a part of Filippo's body––and feelings––and *is* the mathematics in that mathematics is implicated by the pattern. As a consequence, the duality of the child-pattern and pattern-mathematics can be rethought of as *one*, the child-pattern-mathematics, which is a learning assemblage in the classroom.

The status of early childhood mathematics education research in the last decade

Zişan Güner Alpaslan[1] and Feyza Tantekin Erden[2]

1 Bülent Ecevit University, Faculty of Education, Zonguldak, Turkey, zguner@metu.edu.tr
2 Middle East Technical University, Faculty of Education, Ankara, Turkey

This study explores early childhood mathematics education research from 2000 to 2013 in major journals of mathematics education and prior CERME-Early Years Mathematics papers. The comparison between the studies published in the journals and in CERME uncovers some interesting results: i) the majority of studies are from English-speaking countries in the journals whereas the majority of CERME papers are from non-English speaking countries, and ii) the focus of research topics in the journals seems to be significantly different than that in the CERME papers. Moreover, there are more empirical studies than any other types of research and studies mainly focusing on children appear to be more popular. Accordingly, there should be more diversified papers (e.g. regarding research topic) to deepen and enrich this field.

Keywords: Early childhood mathematics education, research trend, systematic review.

INTRODUCTION

Early childhood mathematics education (ECME) which refers to the education of the ages of 3- to 6-year-old children (NAEYC, 2010) is significant for young children (Clements, Baroody, & Sarama, 2013). The study of Clements and colleagues (2013) briefly positions its reasons in two main frames by stressing the benefits of early childhood mathematics (ECM) for minimizing the achievement gap among students from different backgrounds, and for being a precursor for children's further achievement. The studies also indicate that ECME enables children's acquisition of mathematical understanding and skills (Perry & Dockett, 2002) as well as their gaining positive attitudes towards learning mathematics (Stevenson & Newman, 1986). The contributions of early years to children's cognitive and affective domains play an important role for their further mathematics success (Campbell et al., 2001). Furthermore, its significance is stressed through perceiving early years as an opportunity to support and improve children's readiness for the learning of mathematics (Clements & Sarama, 2010). Hence, ECME has major interrelated goals concerning children. The first is related to content related goals, namely children's gaining a mathematical understanding and thinking. The second goal of ECME is about process goals, which include mathematical skills such as reasoning and predicting. The last one is about affective goals like enjoying learning mathematics (Clements et al., 2013). The above-mentioned outcomes and goals of ECME can undoubtedly be achieved through the high quality educational practices which rely on the research based policies, guidelines, and practices (Fox, 2007). In this sense, Sarocho and Spodek (2009) argue the significance of increasing number of research studies in early childhood education on the growing interest in ECME. Thus, the contribution of published articles in ECME research cannot be undermined because getting to know about the research trend becomes a priority for ECME researchers especially for the novice ones in terms of their guidance for the future of the field. However, the majority of these review papers reflect the status of this research field from a national perspective such as Australasian (Fox, 2007; Highfield & Goodwin, 2008), and American (Hachey, 2013). Besides, the remaining review papers seem controversial since they do not investigate the research papers on a certain database/journal and for a certain time period (Sarocho & Spodek, 2009). Rather, they examine the development of this field from a historical view. Therefore, this study aims to reveal the status of international ECME research from 2000 to 2013 in highly refereed mathematics education journals [i.e. Educational Studies in Mathematics (ESM), Journal for Research in Mathematics Education (JRME), For the Learning of Mathematics (FLM), Mathematical Thinking and Learning (MTL), The Journal of Mathematical Behavior (JMB), Journal of Mathematics Teacher Education (JMTE), and ZDM: The International Journal on Mathematics Education (ZDM)] and Early Years Mathematics WG papers in CERME6, CERME7 and CERME8. The review is guided by the following questions: (a) What were the nationalities of authors contributing to ECME research during these fourteen years? (b)What were the types of research design in ECME research during these fourteen years? (c)What were the research topics in ECME research during these fourteen years? (d)What were the research samples in ECME research during these fourteen years? In this way, the findings of this study will guide ECME researchers to better plan and improve the research field relying on the information about under-researched areas and also will call the need for the collaboration between policy makers and teacher educators to sustain the quality in this field.

METHOD

This review study was carried out in Turkey. The journals were selected considering the ranking of European Mathematical Society (EMS) in terms of some criteria such as recognition and citation of the journals (Törner & Arzarello, 2012). Therefore, this study only focused on the journals ranked as A plus and A category which are ESM and JRME in A plus journals; and FLM, MTL, JMB, JMTE, and ZDM in A journals. Among these journals, FLM was not included into analysis due to the limitation of online access. Besides, CERME papers were examined since the first meeting of Early Years Mathematics Working Group (WG) in CERME6. For the purpose of this study, the age interval for ECME (3 to-6-year-old) in NAEYC (2010) report was considered. Therefore, the papers that studied first and/or second grade children were not included. As a result, 49 published articles in the journals and 35 papers in CERME were analysed.

The nationality of contributing authors was quantitatively analysed in order to reveal the contributing countries to this research field. In this sense, the formula of Howard, Cole and Maxwell (1987) was utilised. According to this formula, each paper was given one point. In the case of multiple authors from different countries, the order of author (*i*) and the total number of countries (*n*) in the study were taken into consideration.

$$\text{Score} = \frac{(1{,}5^{n-i})}{\sum_{i=1}^{n} 1{,}5^{n-i}}$$

Research type of the published articles were determined based on the previous review study of Tsai and Wen (2005) which categorized the papers as empirical (e.g., quantitative and qualitative), position (i.e., advocating a certain issue related to the topic under investigation), theoretical (i.e., proposing or generating a theory the related field), review (i.e., summary of the previous research studies), and other papers (e.g., clarification of a specific curriculum or programme for the related research field). The interrater reliability was calculated by the authors of the study and it was found as .95.

Research topic was determined considering the working group names of the Eighth Congress of the European Society for Research in Mathematics Education (CERME, 2013). Whereas some of the WG names such as university mathematics education and history in mathematics education were not included, the determined sub-titles in Early Years Mathematics WG were additionally used. The adapted version of research topics were as follows: Teaching and Learning of Number Systems and Arithmetics (Topic1), Algebraic Thinking (Topic2), Geometrical Thinking (Topic3), Mathematical Potential, Creativity and Talent (Topic4), Affect and Mathematical Thinking (Topic5), Mathematics and Language (Topic6), Comparative Studies in Mathematics Education (Topic7), The Role of Natural Language in Early Years Mathematics (Topic8a), The Role of Play in Early Years Mathematics (Topic8b), The Role of Manipulatives and ICT Tools in Early Years Mathematics (Topic8c), The Transition between Manipulation and Different Kinds of Representation (Topic8d), Designing and Implementing Tasks for Early Years Mathematics (Topic8e), The Transition between Pre-primary and Primary School in Early Years Mathematics (Topic8f), Ways to Learn to Become a Learner at School (Topic8g), Early Years Mathematics and Learning Disorders; Early Identification and Intervention (Topic8j), Teacher Education and Development in Early Years Mathematics (Topic8k), Theoretical Approaches in Early Years Mathematics (Topic8l), Technology in Early Years Mathematics (Topic9), Social, Cultural and Political Challenges for Mathematics Education (Topic10), Stochastic Thinking (Topic11), and Argumentation and Proof (Topic12). The interrater agreement for research topic of the published articles was calculated as .90.

RESULTS

The results indicated that there were 49 published articles about ECME in the investigated journals during the last fourteen years. The distribution of published articles was respectively provided by year and journal. Besides, there were 35 papers in Early Years Mathematics working group in prior CERME conferences.

(For further details about results: https://www.academia.edu/7957956/CERME-9-_Appendix).

Contributing Countries

The formula of Howard and colleagues (1987) revealed the countries' contribution to ECME research in the selected journals from 2000 to 2013. The scores of the countries were analysed in terms of year and journal. There were totally 18 contributing countries to this research field during these fourteen years. The analysis by year indicated the high ranking contributing countries as the USA, Germany, and the UK. There was not any study about ECME in the years of 2000 and 2006 in the investigated journals. Although the total scores of the US, the UK and Germany were striking when compared to other countries, only the research articles from the USA were published during almost each year. As for Germany, the year of 2013 was efficient in terms of the increased number of published articles when compared to previous years. The analysis of contributing countries by journal indicated that the variation of the countries was higher in ESM (44.4%) and MTL (38.8%) than other journals. Authors from five countries contributed to ZDM, JRME and JMB, while JMTE had publications from four countries. Although the dominance of English-speaking countries appeared in each journal, the top ranking countries were from non-English speaking countries such as Israel, Germany, and Turkey in ESM and JMTE. Furthermore, the number of articles from Germany (40%) and Israel (26.6%) was striking in ESM. As for the contributing countries in previous CERME conferences, there have been eleven countries since the first emergence of Early Years Mathematics WG. As opposed to the majority of English-speaking countries in mathematics education journals, the top countries were Germany (37.1%), Israel (20%), and Norway (14.2%). The major contributing countries consistently continued to participate in CERME which is biennially organized. Although the number of countries in CERME6 and CERME7 was five, it increased to eight different countries in the recent CERME.

Research type

During the last fourteen years, almost all of the published articles were in the empirical category (87.75%). In particular, all of the published articles were empirical between 2001 and 2009. Among these empirical papers, qualitative research paradigm was the most popular (46.51%), and this was followed by quantitative (30.23%) and mixed type research designs (23.25%). Yet, other research types such as review (2.04%), theoretical (2.04%) and position (2.04%) were rarely presented in 2001, 2011 and 2013. As for the other research types, there were totally three papers published in 2010 and 2013 in order to provide an introduction into a mathematics education programme and/or a curriculum. The research type by mathematics education journals showed similar consistency in terms of the majority of empirical papers per journal. All of the papers were specifically empirical in JRME, MTL and ZDM. Each investigated journals published studies with different research paradigms including qualitative, quantitative and mixed research design. Among these papers, the dominance of qualitative research paradigm continued in ESM (54.5%), JRME (44.4%), JMB (66.6%), JMTE (66.6%), and ZDM (75%). However, the number of quantitative (50%) and mixed design research papers (40%) was interestingly higher than qualitative research papers in MTL. Other research types such as review, theoretical, position and other were published in ESM, JMB and JMTE. The dominance of empirical research papers (91.4%) was still seen in previous CERME Early Years Mathematics WG papers. Most of the papers were qualitative (80%) and it was followed by quantitative (17.14%), and mixed design (2.85%) studies. Besides, there were three research papers in the category of other to describe a certain curriculum or a programme. But, there were not any review, theoretical and position papers.

Research topic

From 2000 to 2013, the mostly investigated research topics were about number systems and arithmetics (22.44%), algebraic thinking (16.32%), teacher education in early years mathematics education (12.24%), designing and implementing tasks for early years mathematics (10.2%), and comparative studies in mathematics education (8.16%). The studies about number systems and arithmetics insistently became frequently explored topic almost each year except for 2000, 2002, 2005 and 2006. Even though the frequencies of popularly investigated topics varied, the studies about teacher education reached its highest proportion in 2011 (40%). Other research topics about geometrical thinking (6.12%), language and mathematics (6.12%), the role of play (4.08%), manipulatives and ICT tools (4.08%) in mathematics, theoretical approaches to early years mathematics (4.08%), affect in early years mathematics (2.04%), stochastic thinking, social and cultural challenges in mathematics education (2.04%) were not drawn attention by the researchers as much as popular topics. Furthermore, there were not any published articles about the role of natural language in mathematics, representations in early years mathematics, transition between preschool and primary school mathematics, technology in early years mathematics, ways to become a learner at school, and disadvantaged students in early years mathematics and intervention. As for the research topic by journal, the dominance of the research topics about numbers and arithmetics and algebraic thinking permanently continued as top research topics in JRME, JMB, and MTL. However, the top research topics per journal showed variance. For instance, designing and implementing tasks for early years mathematics got the highest proportion in ESM (20%) and JRME (22.2%), whereas all of the published articles in JMTE were about teacher education and half of the articles in ZDM were about geometrical thinking. There were CERME papers about various research topics. Although some of the popular topics in CERME papers were consistent with the publications in mathematics education journals, some of them were strikingly different. Among these papers, the most prominent ones were about the role of play in early years mathematics (14.2%), teacher education (14.2%) and designing and implementing tasks for early years mathematics (11.4%). It was followed by some of these research topics including geometrical thinking (8.57%), mathematics and language (8.58%), and the role of manipulatives and ICT tools in early years mathematics. On the other hand, the top research topics showed variance per each CERME conference. To be more specific, the top topic was designing and implementing tasks in early years mathematics (33.3%) in CERME6, teacher education (20%), the role of play (20%) and the role of natural language (20%) in early years mathematics became popular in CERME7. As well as the popularity of the role of play (18.7%) continued in CERME8, the use of manipulatives and ICT tools in early years mathematics (18.7%) were drawn attention.

Research sample

Research sample refers to the participants (e.g. children and teachers) of the studies in the investigated journals and proceedings. Considering the research sample in published articles, only empirical papers were further examined and analysed by year and journal respectively. The results illustrated that studying with children (74.4%) was the most popular method in early years mathematics education research during these fourteen years. The number of the studies with children has increased since 2010. Even though other samples were not preferred as much as children, there were studies conducted with pre-service teachers (6.9%) and the combination of children and teachers (6.9%), teachers (4.06%), the combination of children and parents (4.06%) and other (2.3%). The results for research sample by journal provided that studying with children continued its popularity in ESM (90.9%), JRME (77.7%), JMB (83.3%), and MTL (80%). Moreover, there were published articles in JMTE conducted with pre-service teachers (75%) and as well as the combination of children and parents (25%). As for ZDM, this journal published the studies conducted with children (50%) and teachers (50%). As for the combination of teachers and children, such studies were published in JMB, JMTE, and MTL. Similarly, the substantial part of the studies in prior Early Years Mathematics WG was conducted with children (60%) and the sample of children continued to be the mostly preferred one in all previous CERME conferences. Other research samples were not studied as much as children. But, there were studies conducted with teachers (14.2%), and the combination of children and parents (11.4%).

DISCUSSION AND CONCLUSION

This study presents the major contributing countries to this research field as English-speaking countries in the context of mathematics education journals. This may be related to the benefits of reporting the scientific papers in a more efficient way than the way non-English speaking researchers do. Yet, the contributions of non-English speaking countries particularly Germany and Israel were striking. Furthermore, these countries became the top countries in previous CERME conferences in terms of their contribution to the research field. Moreover, they provided a significant contribution to the field through their being a research community since the publications of such countries were constructed through a collaborative work.

In this study, majority of the published articles and CERME papers were empirical. Among these papers, qualitative research paradigm was the most utilized one. This may be related to the research sample of the published articles because another finding of this study indicates that studying with children was superior to studying with other kind of samples. Furthermore, using qualitative research methods is the most common way to study with children (Trundle & Saçkes, 2012). This trend was followed by quantitative and mixed research design. Although almost all of the quantitative studies were conducted with children, they mostly preferred to collect data in accordance with the target age group through using mathematical tasks and materials. As for the research type by journal, the majority of the empirical papers adopted qualitative research methods. Yet, the number of quantitative papers was higher than others in MTL. Moreover, as opposed to the dominance of empirical papers, other research types like review papers were rarely presented during these fourteen years and they were published in ESM, JMB, and JMTE. The difference among journals may be related to their aims and scopes. Although CERME accept various research types, there were not any review, theoretical and position study among the CERME papers.

The results also announce the top research topics in ECME research. These top research topics were different in the investigated journals and CERME papers. In the mathematics education journals, the top topics were about teaching and learning of number systems and arithmetics, algebraic thinking, teacher education, designing and implementing tasks for early years mathematics, and comparative studies in mathematics education. Its reason may be related to the goals of ECME such as promoting mathematical thinking and learning and improving qualification through various ways like teacher education and the implementation of tasks (e.g., Clements et al., 2013). Besides, these research topics consistently remained the top topics almost each year. This shows us the insistence of the researchers on these research topics to reach the stated goals of mathematics education. In spite of the significance of teaching various content areas such as geometry and measurement in ECME (NCTM, 2013), learning of number systems and arithmetics and algebraic thinking were the most frequently investigated topics. This may be related to the broad focus of 'numeracy' in early childhood curriculum rather than process skills and affect (Ginsburg & Golbeck, 2004) and as well as its misinterpretation as generally dealing with numbers (Sarama & Clements, 2004). However, other research topics such as geometrical thinking and affect in early years mathematics were not studied as much as the top topics. Besides, there was no study about remaining topics like technology in early years mathematics, and learning disorders; early identification and intervention in the selected journals and CERME papers though these topics are highlighted to achieve ECME goals, and to provide high-quality education to meet the needs of all learners (Highfield & Goodwin, 2008). Moreover, the top research topics varied per journal. For example, the topic of designing and implementing tasks for early years mathematics was the mostly studied one in ESM. This may not be surprising because the journal focuses on the practitioners in mathematics education through dealing with didactical, theoretical and pedagogical issues. The top research topics (e.g. the role of play and the role of natural language in ECME) in prior CERME were in general different from the investigated journal articles. This may be related to the dynamic in Early Years Mathematics WG and the research interests of group members. Furthermore, CERME papers filled the gap in terms of investigated research topics since there was not any study about the role of natural language in the journals examined. Last but not least, the top ranking research sample was children in both mathematics education journals and CERME papers. Moreover, it is good to reach the studies conducted with other samples. The combination of both children and parents and children and teachers is particularly a good indicator of understanding the relevant research topic through considering the context because the need for such research which explores parents' educational interactions with their children and the role of parents' on children's learning mathematics is pointed out (Ginsburg & Golbeck, 2004). Moreover, the results per journal indicated that some journals like JMTE and MTL publish the studies conducted with the combination of various sample. The findings of this study for each journal particularly introduce the aims and scope of each major journal in the field for ECME researchers who would like to contribute to this field. Thereby, this may play a facilitator role for future studies to fill a gap in the field as well as to determine the right journal in accordance with the kind of topic, design and sample of the studies. In spite of the evolution of this research field in the past decade, the results may also suggest some further research directions for the improvement of this research field. First of all, the research community in ECME should be internationalised through increasing the number of studies from various countries. Besides, cross-national and cross-cultural studies may contribute to the advancement of this research field. Second, other research types should be drawn attention by the researchers as well as empirical papers because the position, theoretical and review papers play an important role in contributing to the research field. Third, the goals of ECME should be accomplished through studying various research topics rather than the research topics focusing on only some goals of ECME. Particularly, there should be more research topics such as "technology education" for the improvement of children's mathematical learning, and "transition between preschool and primary school mathematics" for the development of mathematical proficiency (NAEYC, 2010). Last, there should be more studies conducted with various participants like children and parents based on the contributions of family environment to children's ongoing mathematical learning (Ginsburg & Golbeck, 2004). Furthermore, there is a need for studies conducted with pre-service and in-service early childhood teachers since the findings of such studies may guide teacher educators for the professional development of early childhood teachers in ECME (Lee & Ginsburg, 2007). The findings of the study were limited to the investigated journals in mathematics education and CERME Early Years Mathematics Working Group (WG) papers. Therefore, further review studies could be replicated through including highly refereed early childhood education journals and other international mathematics education conferences as well.

The bar model as a visual aid for developing complementary/variation problems

Eugenia Koleza

University of Patras, Department of Primary Education, Patras, Greece, ekoleza@upatras.gr

In this paper, we report the preliminary findings of a study that considered how third grade students represent multiplication and division problems using the bar model as a tool. Initial results indicate that students are able to create visuals, representing problem's structure, and based on these visual representations they can formulate division problems given a multiplication one.

Keywords: Multiplication, division, complementary problems, bar model.

INRODUCTION

Use of diagrams is considered an efficient strategy in teaching and learning mathematics and especially in mathematical problem solving. "From the most elementary class to the most advanced seminar, in both introductory textbooks and professional journals, diagrams are present, to introduce concepts, increase understanding, and prove results. They thus fulfill a variety of important roles in mathematical practice" (Mumma & Panza, 2012, p. 1). Diagrams make plain the quantities in the story context and the relationships that exist amongst them, limit abstraction and thereby aid in the problem-solving process (Bishop, 1989). *Draw a diagram* is a well known strategy for mathematical problem solving (e.g., Polya, 1957; Schoenfeld, 1985), grounding in the belief that generating a diagram enables deeper understanding of the situation described and facilitates the conceptualization of the problem structure (van Essen & Hamaker, 1990). Not all diagrams are beneficial or can easily be used by the students. Vosniadou (2010) distinguishes between external representations that are *perceptually based* (grounded on everyday observations) *depictions* and those that represent *conceptual models* (theory –based). Pictures used in mathematics and science textbooks, number lines and bar models that are usually used on mathematical problem solving, are conceptual models.

In our study, we used the bar model as a visual support for the resolution of simple (one operation) multiplication problems and the formulation of the two corresponding division problems.

Children's difficulty to understand the close relation between multiplication and division was a problem noticed very early in mathematics teaching literature. Nevertheless, in most western curricula, multiplication and division, as well as addition and subtraction are taught separately. Paraphrasing Herscovics (1989), it is as if students are taught the syntax of operations, without the semantics. In other words, students know the algorithms (the rules of the 'grammar') but they do not understand the meaning and their relations. This situation explains the difficulty that pupils often face when solving equations in algebra with an operational view of equality (Wagner & Parker, 1988). "The 'one-thing-at-the-time' design, provide fewer opportunities for 'making connections' compared to those adopted in eastern cultures" (Sun, 2013, p. 13). "In Chinese elementary schools, addition and subtraction are introduced simultaneously, and subtraction is introduced as the reverse operation of addition. Division is also introduced as a reverse operation of multiplication" (Cai, 2004, p. 110). As Cai refers (p. 112), "representing quantitative relationships in different ways will not only help students develop deeper understanding mathematics, but also will help them develop their flexibility of using equations to solve application problems". Giving an example of a variation in a multiplication problem, Sun (2011, p. 104) explains that "within the problem set, there are two concepts of multiplication and division behind three similar problems made with 4, 6, and 24. Example problem: How many trees do 6 lines need so that each line can have 4 trees? Variation problem 1:

How many trees will each line get if we plant 24 trees in 6 lines? Variation problem 2: How many lines do we plant if we plant 24 trees in order so that each line has 6 trees? Clearly, the intent of One Problem Multiple Changes is to enable students recapitulate the general relationship of multiplication and division, and the meaning of equal from the problem set 4 × 6 = 24, 24 ÷ 4 = 6, 24 ÷ 6 = 4 [...]. The task draws students into a space of relations as opposed to directing attention to the object itself."

THEORETICAL FRAMEWORK

The 'model method', also known as graphical heuristic, consists of the use of rectangular bars to represent numbers rather than abstract letters to represent unknowns in word problems. This method is often used in education systems of many countries under various names: tape diagrams – in Japan (Murata, 2008), strip diagrams – in US (Beckmann, 2004), or bar models – in Singapore (Hoven & Garelick, 2007). This special kind of diagrams "are clearly designed *to help children decide which operations to use*. Instead of relying on superficial and unreliable clues like key words, the simple visual diagram can help children understand why the appropriate operations make sense" (Beckmann, 2004, p. 43). Cai and colleagues (2005) consider the 'model method' as one of the big ideas related to algebraic thinking in the Singaporean elementary curriculum. "Children solve word problems using the 'model method' to construct pictorial equations that represent all the information in word problems *as a cohesive whole, rather than as distinct parts*. To solve for the unknown, children undo each operation. This approach helps further enhance their knowledge of the properties of the four operations"(p. 8). In other words a basic property of the bar model is that it can support an exploration and visualization of the 'doing' and 'undoing' processes in mathematics. According to Hall and colleagues (1989) when the structure of a problem is recognized, a formal representation of this relationship may be constructed. Departing from meaningful tasks, students may construct personal meanings by the use of the bar model. In an initial phase the bar model may serve as a *model of the mathematical structure* of a word problem. Later, through a process of vertical mathematization, reflecting on the relationship between their actions upon a diagram and the effects of those actions, students may generalize and abstract those actions to successfully solve problems of the same semantic structure. In this way, bar model becomes, to those students, a *model for the mathematical structure.* Bar model is particularly useful for problems that involve comparisons, part-whole calculations, ratio and proportion.

In this paper, we will restrict to the use of the bar model as a visual support in order to formulate multiplication and division problems.

The Singapore education system's approach concerning the use of diagrams, has close relation with the one several soviet researchers (Bodanskii, Mikulina, in Davydov, 1991/1969) has used in their studies concerning algebra word problems. For example in Figure 1 (on the left) is the diagram of the problem: "*In the kindergarten, there were 17 more hard chairs than soft ones (labeled M). When 43 more hard chairs were added, there were 5 times more hard chairs than soft. How many hard and soft chairs were there?"* as presented in Bodanskii (1991/1969, p. 302), and on the right the bar model representation.

In both cases, the common element is the concept of "unit". Units are not simply single discrete entities, but instead may be composed of one or more 'shapes' (in the diagram) of various types (Davydov et al., 2000). Taking as a "unit" the number of soft chairs, the sum 17+43=60 is translated as 6 units, giving, thus, the answer of the problem. The problem solver is able to reason from the very diagram that was created as a *model of* the situation given. The algebraic equation that correspond to this visual solution- the *model for* this kind of relations- is just a step further.

The research question behind our study was:

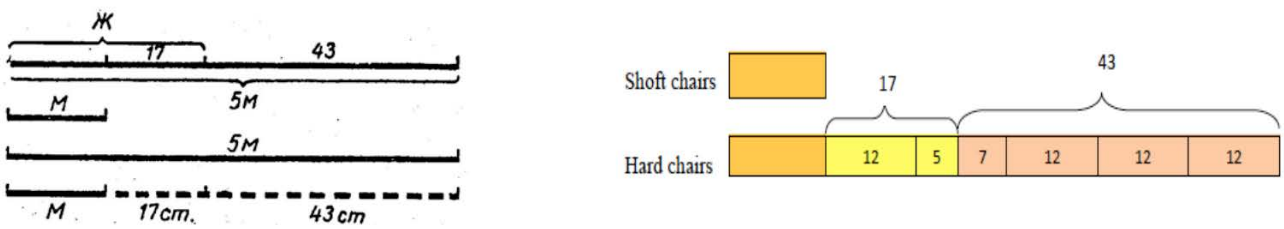

Figure 1: Similar representations of the same problem

Can the bar model support students in the resolution and formulation of multiplication and (complementary) division problems?

METHOD

In this study, 19 third graders (aged 8) were involved, belonging in a class of a primary school in Patras. During a period of eight 45-minutes sessions the students followed the regular lessons (teaching of the multiplication table) that were enriched by the bar model as a way to solve and represent problems, and mainly as a way to connect multiplication and division, in a unified scheme. This connection was designed only for the needs of our experiment, given that these two operations are taught separately in the Greek mathematics curriculum. Tasks given during instruction were arithmetic and algebraic tasks (given a problem, the task asked for his complementary ones-focus on relations) with three (group, restate and vary) of the five semantic relations (the other two were change and compare) identified by Marshall (1995). Data was collected and analyzed from field notes, photos, pupils' written work, and final tests. Learning gains were assessed by means of a word-problem test just after the end of instruction and a second one a month later.

Hereafter, the problems given in the tests.

Vary-problem in the short-term test: *Grandma has in her sac 45 sweets in 5 bags. How many sweet are there in each bag?*

Vary-Problem in the final test: *Grandpa gave to each one of his 5 grandkids 12 euros. How many euros he gave in total?*

For each problem was asked to the students: "*Departing from the problem, with the same story and the same numbers make two other problems and 'design' them*".

Teaching students for short periods of time could not serve as a basis for a solid understanding of their thinking and how it might be influenced by the use of a certain visual representation. Our 'teaching experiment' has not the characteristics described by Steffe and Thompson (2000), but it was an exploratory one which aimed only to the evaluation of the bar model as a visual aid for the resolution and formulation of complementary multiplicative-structure problems. "Any researcher who hasn't conducted a teaching experiment independently, but who wishes to do so, should engage in exploratory teaching first. It is important that one become thoroughly acquainted, at an experiential level, with students' ways and means of operating in whatever domain of mathematical concepts and operations are of interest" (Steffe & Thompson, 2000, p. 274). In other words, we wanted first to explore the role this specific visual representation may have in helping students to understand how multiplication and division are connected, and their eventual difficulties, in order to design our 'teaching experiment'. Because "incomplete understanding [...] can result in inappropriately designed artifacts or artifacts that result in undesirable side effects."(March & Smith, 1995, p. 254)

DISCUSSION

The first of the 8 lessons (the corresponding textbook objective was the multiplication table of, 2, 5 and 10) began with a teachers' question.

T: *What is a problem? Who can make a problem?*

S: *I have 80 candies and I give 10 candies to each one of 8 children*

T: *Is this a problem? What are you asking? In order to have a problem you must ask for something. For example, 8 children bought 10 candies each one. How many bought in total? Lets make a picture of the problem.* (The teacher designs the bar model). *In order to have a problem, we must 'hide' something.*

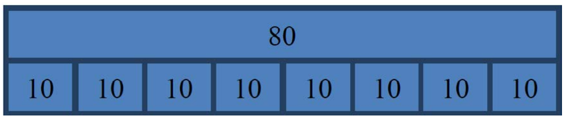

Figure 2

T: Can someone else make another problem, with the same story?

S: We can 'hide' the number of candies that each child will take.

(The teacher changes the previous model)

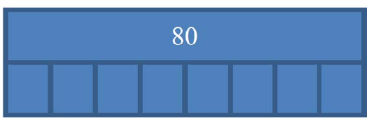

Figure 3

T: *Another problem?*
S: *We can 'hide' the children.*
T: *So, I will delete the squares.*
T: *If I had 40 candies, and 10 children, how many candies could have each child?*
S: *4*
T: *Can you 'design' the problem?*

During the next 2 sessions students worked with the multiplication table (according to the official schedule), and solved multiplication problems following a 'didactic contract' of 4 precise steps that had emerged from the previous lesson: (1) we read first and we 'design' (make a representation of) the problem, (2) in order to make the 2 'inverse' (complementary) problems, we "hide" a number from the design, (3) we write (in words) the 'inverse' problems, and (4) we solve the problems.

The complementary/inverse problems were introduced by the teacher as the two variations of an initial problem, and the bar model was presented as a tool of organizing problems' data. Each complementary/inverse problem was creating by 'hiding' a number on the bar.

During this process, students faced two major difficulties: (1) Expressing in natural language the problem that they had already represented by the bar model, and (2) representing by the bar model the quotative/measurement division problem-variation. For example, while the multiplication problem «*If I save 8 euro in a week, how many euros I will have after five weeks?*» and –'hiding' the 8- the corresponding partitive division problem "*If I saved 40 euros in 5 weeks, how many euros I saved in a week*" were easily represented by the bar model, it was not the same for the 'quotative division' problem. The rule of 'hiding' could not be applied: while in the "partitive division' problem they had to 'hide' the numbers, in the 'quotative division' one, they had to 'deconstruct' the bar model. In the following pictures (Figure 4) we see (to the left) the incomplete diagram made by a student (reproduced in the middle), and the one suggested by the teacher (to the right).

Teacher's proposition in order to face the difficulty was to reformulate the problem as "*How many 8s we want in order to make 40?*"

We present three different treatments of the "quotative division" problems representation during instruction

a) An arithmetic treatment: no use of the bar model

"*30 ducks fly in groups of 5. How many groups of ducks are there?*"

Figure 5

b) The 'quotative division' as a subtraction: A "filling-in" use of the bar model. "*I have 45 stamps in pockets of 9 stamps. How many pockets I have?*" The thought behind the model was:

"*I take off each time 9 stamps from the 45 stamps*"

Figure 6

The 'quotative division' as the inverse of the multiplication: An 'algebraic' use of the bar model.

Figure 7

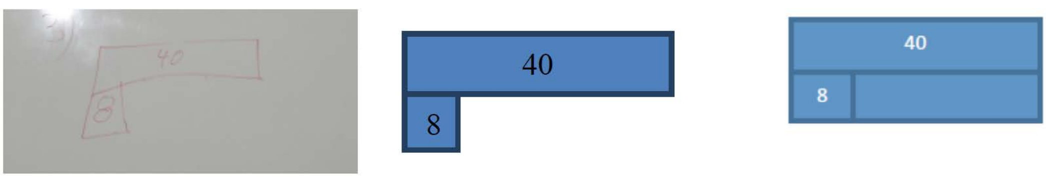

Figure 4

After instruction a final test was given. Hereafter, we comment students' competency in using the bar model for the resolution of the 'vary-problem' given in this final test (see page 4).

From a total of 19 students,

a) 13 students formulated correctly the two division-problems. The two main strategies observed during instruction, appeared also in the final test:

— a mixed ('filling-in' and algebraic) strategy -MS(10 students), and

— an 'algebraic' strategy -AS (3 students).

We give an example of each case.

(MS) *Fey*

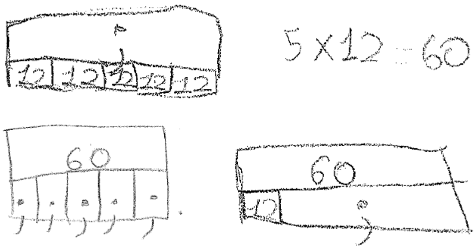

Figure 8

(AS) *Joseph*

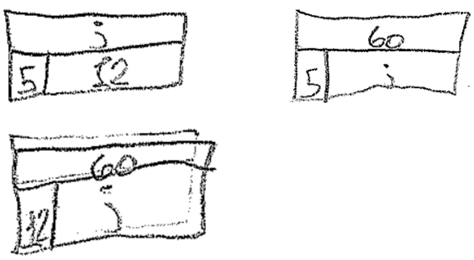

Figure 9

The 3 students who used the 'algebraic' strategy were the higher achieving students of their class. This outcome confirms similar results by Booth and Koedinger (2007) according to which, higher-achieving middle school students do benefit from the diagrams while low-achieving students perform better on story problems that do not have accompanying diagrams.

b) 3 students formulated only the partitive-division problem.

"*Grand papa has 60 euros and he wants to distribute them to his 5 grandkids. How many euros will have each one?*"

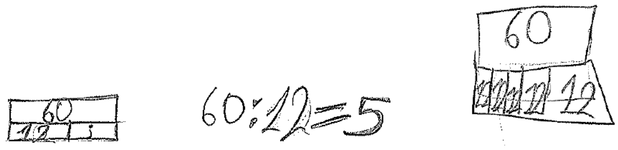

Figure 10

c) The rest 3 students were not able to use the bar model at all. For example for the multiplication problem the diagram proposed was

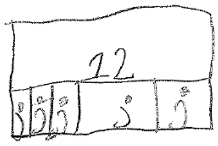

Figure 11

or

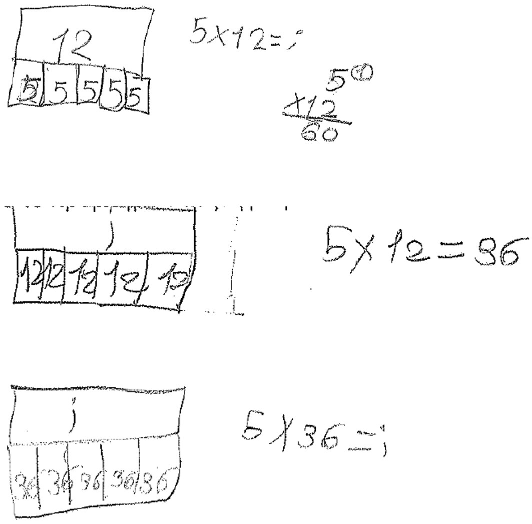

Figure 12

CONCLUSIONS

The results has shown, that the bar model is an effective model, but only for multiplication and partitive division problems. Though most students (13/19) after a relatively short term instruction (eight 45-minutes sessions) could formulate and represent by the bar model a multiplication and the corresponding division problems, further research is needed about the kind of representation that is more appropriate for the quantitative division problems.

The fact that a representation may be "clear" for a multiplication problem does not mean that it would be a useful tool for the formulation of the corresponding division problem. For example, lets take the array model.

This model in a concrete (on the left) or in a more abstract (on the right) version, under certain conditions may be useful for students to understand the relation between a multiplication and the two complementary-division problems. It is useful, if all information is on the representation, but not if the students must construct the representation by themselves, especially in case of big numbers.

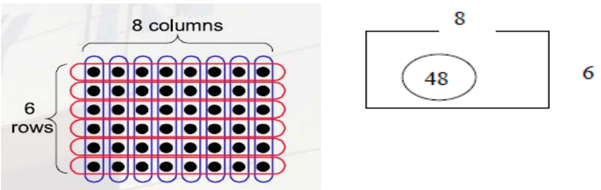

Figure 13

On the other hand, the use of the bar model, as our research has shown, is a high demanding task, because the level of abstraction needed. For example, in the problem: *Sarah made 210 cupcakes. She put them into boxes of 10 each. How many boxes of cupcakes were there?*, students must put on the representation information that does not exist.

The mathematics symbolization "…..?….", is not evident for the young students.

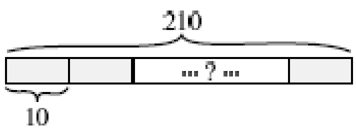

Figure 14

A combination of an array and a bar model representation could be eventually easier to use for students. For example, in the problem: *Sarah had 12 apples to hand out to her class. Each group of students in the class got 3 apples. How many groups were there in the class?* This kind of representation would be:

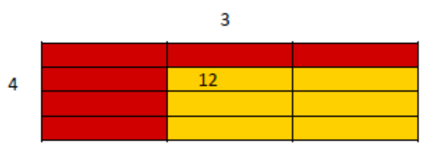

Figure 15

The data collected do not permit us to know if the students who had used the algebraic strategy (AS) were acting in a pure algorithmic way, or 'with understanding'. Eventually a confrontation with the strategies used by the same students in additive-structure problems may offer a more complete explanatory framework. A more accurate analysis of the relationship between the instrument and students' meanings is required, and that is what is going to be done with the data analysis of the whole teaching experiment.

Introduction to arithmetical expressions: A semiotic perspective

Andrea Maffia[1] and Maria Alessandra Mariotti[2]

1 University of Modena and Reggio Emilia, Modena, Italy, andrea.maffia@unimore.it

2 University of Siena, Siena, Italy, mariotti21@unisi.it

An early introduction to arithmetical expressions is realized in a teaching experiment involving an artefact based on the rectangle model for multiplication. Children elaborate signs, strictly related to the activity with the artefact, which evolve to mathematical ones: the enchaining of different representations in many semiotic systems is described according to Theory of Semiotic Mediation. In particular the teacher role in selecting and elaborating specific personal signs, in order to make them pivot signs, results as crucial. Elaborated tasks reveal to be good triggers for a relational approach to arithmetical expressions.

Keywords: Arithmetical expression, multiplication, rectangle model, distributivity, semiotic mediation.

DISTRIBUTIVITY IN GRADE 2

In Italy there is a long tradition for which students are expected to know all the times-tables from 1 to 10 at the end of grade 2, often justified with sentences such as "if they do not learn times-tables in the second year, they will never learn them". It is well known that recall of results of one-digit numbers multiplications is more difficult when the operands are closer to ten. Psychologists refer to this phenomenon as *operand size effect* (e.g., McCloskey, 1991). Operations' properties can be used to reconstruct more difficult results relying on easier ones ($8 \times 2 = 2 \times 8$; $3 \times 8 = 3 \times 5 + 3 \times 3$), this kind of strategy could be particularly useful when times-tables have not yet been memorized completely. In other words an early introduction to operations' properties may promote flexible calculation strategies instead of rote memorization.

The use of operations' properties requires a relational approach to calculation in order to establish the equivalence between different calculation procedures; establishing such an equivalence requires to grasp the relationship between two arithmetical expressions organizing the relationship between two operations (i.e. multiplication and addition) in a highly structured way. The classic symbolic representation seems hardly accessible to very young children, thus distributive property is often introduced by graphical representations (Ding & Li, 2014; Izsák, 2004): rectangles have been largely used as model for multiplication (for a large review see Izsák, 2005) from Euclid's *Elements* since more recent western textbooks (Ding & Li, 2010).

The aim of this paper is to describe the emergence of symbolic arithmetical expressions as numerical representation of the distributive property: working with a specific artefact (a rectangular model for multiplication), pupils begin using the artefact, pass through an iconic representation and arrive to make sense of a structural relationship between different numerical expressions.

THEORETICAL FRAMEWORK AND METHODOLOGY

The work here presented is a part of a wider teaching experiment on multiplication, implemented in a grade 2 class in Italy. The general theoretical framework is the Theory of Semiotic Mediation (TSM) (Bartolini Bussi & Mariotti, 2008) and the teaching sequence is centered on the use of an artefact called "geometrical times-table". In this table, rectangles are organized, increasingly, in columns and rows as showed in Figure 1.

According to the TSM approach, the didactic intervention was implemented in *didactical cycles*, comprehending individual activity with the artefact, small group work and whole class *mathematical discussion*.

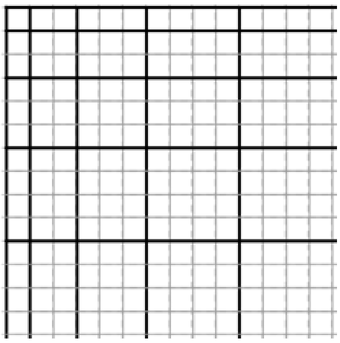

Figure 1: Geometrical Times-Table with five columns and rows

An artefact is defined as a *tool of semiotic mediation* when the teacher uses it intentionally to mediate a mathematical content to students (Bartolini Bussi & Mariotti, 2008). The artefact is both related to the personal meanings of its user while solving a particular task and to the mathematical knowledge underpinning the task and/or the construction of the artefact itself. This double relation is called *semiotic potential* of the artefact (ibid, p. 754). When students accomplish a task using the artefact, they produce signs strictly related to this activity; those signs, to which we refer as *artefact signs*, can be very different from the ones usually used by mathematicians while working with the mathematical knowledge related to the task, because pupils can be unaware of this knowledge. Anyhow students are expected to become able in using culturally determined *mathematical signs*. According to TSM we expect an evolution from artefact signs to mathematical ones. In order to describe such evolution we use the notion of *semiotic chain*, the set of dynamic relations among artefact signs and mathematical ones. In the description of the evolution through semiotic chain, a specific role is played by another type of signs named *pivot signs*. These signs are defined with respect to their function in promoting the relationship between the other two categories of signs (ibid, p. 756).

In the case of geometrical times-table, each one of the rectangles can represent a multiplication: the sides are the factors and the area is the result. Rectangles can be cut, moved and pasted and, in particular, some of results of these actions can be related to specific operations' properties. For instance, commutative property can be related to observation of different positions of rectangles with sizes of the same length. In the first part of the teaching sequence, children explored the artefact and were asked to explain how numbers and operations could relate to it. Finally, after a couple of months, a didactic cycle was released aimed at introducing pupils to the distributive property.

In the first task, students are asked to cut two pieces of paper with the same dimensions of two rectangles of the same row (both sides smaller than five). They also have to paste the two pieces of papers along one of the sides in order to form a new rectangle, then they are asked to look for a rectangle with the same dimensions into the table. Children are expected to use the obtained rectangle dragging and rotating it on the table, trying to fit it inside the borders of one of the rectangle in the table. We imagine a relation between the pasting of two rectangles in a bigger one as the sum of two multiplications to obtain another one, i.e. it is a transformation of an arithmetical expression according to the distributive property: $a \times b + a \times c \rightarrow a \times (b + c)$. In our a priori analysis we expected that pupils notice that all the rectangles have the same height and that the final rectangle has a width that is the sum of the two of the others, this constitute the germ of the mathematical meaning of the distributive property. In order to work on the other direction of the transformation ($a \times b + a \times c \leftarrow a \times (b + c)$), a second task has been implemented: each student received a copy of a letter by Giovanni, an imaginary child who lives in another city. In his letter, Giovanni explains that he has to calculate 3×7 but he only remembers multiplications with factors smaller than five. In our a priori analysis of the task we expected children to use the signs produced during the past activities to decompose 3×7 in two smaller multiplications, eventually using the table to find the right ones.

Using TSM lens, we analyse the activity of children in the progression of the didactic cycle, while facing the two tasks involving the use of the geometrical times-table and in the following collective discussions. According to TSM, we will look for semiotic chains, identifying the three different types of signs and their mutual relations, in order to describe the development of the semiotic mediation process. Thus our research questions can be articulated as follows:

(1) which semiotic chains can describe the semiotic mediation process from the use of geometrical times-table to symbolic representations of the distributive property?

(2) What is the role of the teacher in triggering this process?

The two tasks have been implemented in a grade 2 class of 20 students, in Tuscany in a period of two weeks. All lessons have been videotaped by the first author who, even if he was not the teacher, interacted with the pupils during the different work phases. Following the analytical model for studying videotape data by Powell , Francisco and Maher (2003), all videos have been viewed several times and a description of the events has been written. According to a priori analysis of the semiotic potential of the artefact, we selected critical events, then transcribed and coded. The different signs produced by teacher and students have been classified according to TSM (artefact signs, pivot signs or mathematical signs) and semiotic chains identified. Videos and written productions made us able to reconstruct the storyline interpreted in the next section.

DATA ANALYSIS

Combining tiles of the same row: the emergence of a semiotic bundle

After a previous activity, pupils became familiar with the artefact, with cutting and moving rectangles and recognizing them on the table. A shared system of artefact signs was established around the key word 'tile' that, at this point, has a complex meaning: it refers to one of rectangles (either on the table or cut on the paper), but also to the multiplication between the two numbers that represents the dimensions of the rectangle, specifically it refers to both the multiplication and the result. The first task of a new cycle asked to select two tiles in the same row of the table, to cut them and to combine them into a new tile and to identify on the table a rectangle that corresponds to this new tile. Working on this task children engaged in finding where their rectangles (to which they refer as "tiles") were inside the table. When all the students completed this task, the teacher asked for comments. A child made an intervention:

Lor: That…when two tiles are far (he points at the table) you can calculate the result and then you know it.
Researcher: And how do you calculate the result?
Lor: Between these two (he points two rectangles in the fourth row) you do nine times four, it is thirty-six (he points the 4×9 rectangle) plus twenty (he points the 4×5) it is fifty-six.
Researcher: […] Well, Lor gave an example and he said that when the results of two tiles are known, it is possible to discover the result of another tile. I have understood this way, you have to say to me if I understood correctly. You said that if I know the result of two tiles (he does the gesture in Figure 2a), I can do the addition (gesture in Figure 2b). Isn't it?
Lor: No. It is that, if you do these far two, you calculate them!

(a) (b)

Figure 2: Researcher gestures during discussion

The researcher elaborates the statement of Lor generalizing it, and also passing to the interpretation of the calculation – addition of multiplications – as the combination of tiles. The semiotic process of interpretation is accomplished by enchainment of words, graphical representations, mathematical symbols and gestures. The word "addition" is combined with the gesture of joining the fingers, with the intention of relating the combination of tiles (gesture) and the operation of adding numbers. The pupil seems not to follow the researcher comment and repeats his statement stressing the fact that he is referring to tiles which are far one from the other. Maybe this child looks at the pragmatic scope of the activity as to find the results of the union of two tiles which cannot be compared directly (because they are far). He is able to produce a new personal example without cutting new pieces of paper and using numbers which lead to a multiplication out of the table. The researcher continues the discussion trying to change signs and to work on another, simpler, example.

Researcher: What do you obtain?
Lor: Fifty-six.
Researcher: And what do you need this number for? What does it represent?
Lor: A tile.
Researcher: It is another tile, it is what I was saying: if you put together two tiles, then you find another one. Let's do an example […] if I, for instance, take the tile two

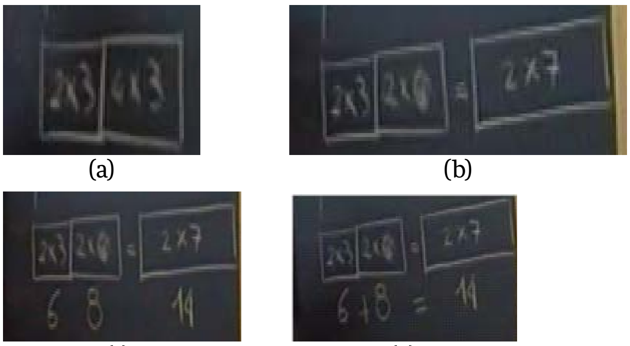
times three (he draws a 2×3 rectangle on the squared blackboard, he writes "2×3" inside it). Do you all agree that this is the two times three tile?

Chorus: Yes!

Researcher: And I put together the four times three tile (he draws a second rectangle juxtaposed to the previous one, Figure 3a) this is big as which tile? Putting all together?

The sign "addition" has been replaced with the artefact sign "put together" which refers directly to the activity done (i.e., the pasting of the pieces of paper) with the aim of bridging the gap between the idea of combining the tiles and that of adding multiplications. It is also introduced a graphical icon (Figure 3a) together with written and oral mathematical signs. The researcher refers to the graphical representation using the word "tile", an artefact sign. Arzarello (2006) defines a *semiotic bundle* as a collection of semiotic sets (set of signs, modes of producing, relationships with meanings) and relationships among them. In the last excerpt there is a system of different related signs involving the ones used by students and new ones introduced by the researcher, it can be described as an example of semiotic bundle. In particular we observe a *genetic conversion* (ibid, p. 281), namely the oral and gestural signs, produced in the previous part of the discussion, are converted in new graphical ones enlarging the bundle.

After these transcribed episodes, the researcher changes the example and asks children to develop the interpretation process, focusing on the dimensions of the rectangles, then on the height and width of the resulting rectangle. When they agree on the answer, he synthesizes their intervention saying that the two tiles, together, equal [1] the two times seven



(a) (b) (c) (d)

Figure 3: Graphical signs on the blackboard

tile and he draws it (Figure 3b). Finally, the researcher asks the children to say how many squares there are inside each one of the rectangles and he writes these numbers under the drawing, obtaining the signs represented in Figure 3c.

Some students begin to notice that six plus eight is fourteen. The researcher decides to rephrase one of his previous sentences.

Researcher: So, when I put together the squares inside this tile (he points the 2×3 tile) with the squares of this tile (he points the 2×4) I obtain the squares of this entire tile (pointing 2×7). Isn't it?

Non: It is true!

Researcher: Which operation does "put together" correspond to?

Chorus: Six plus eight!

Mab: Equals fourteen.

Researcher: (writes the symbol + and = between the numbers, Figure 3d) So, what does this mean? If I know the results of two little tiles (he points 2×3 and 2×4), I can put them together (he points the numbers 6 and 8) and what do I find? (he points 14) The result...

Chorus: Of a tile!

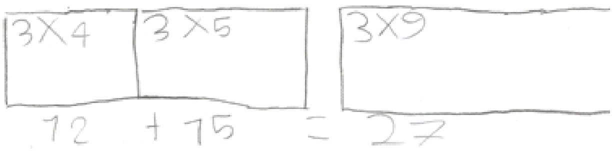
Researcher: And how do we find this tile? It has the same height, and this? (he points the base of the rectangle)

Sim: It is large as the two together.

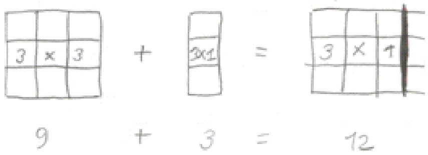
Researcher: It is large as the two together. Do you all agree?

Chorus: Yes!

"Put together" becomes a pivot sign that is explicitly related to the operation of addition, but in the same time it is related to the combination of tiles and more specifically to the addition of the width-dimension of these tiles. As suggested by the children, the researcher also introduces the symbol + in the discourse, it is not between the operations of multiplications but between the respective results. At the end of this discussion, the children are asked to produce some personal examples. Two children cannot find a way to accomplish this final task, another child just copies the example on the blackboard. The others give one or even more original examples imitating the pivot sign of Figure 3c to represent the distributive property (Figure 4a). Four children transform the drawing adding the sign + between the rectangles (Figure 4b). All these texts are made of two lines: the first line is composed of pivot signs and the second one of mathematical signs, as each text were a kind of Rosetta Stone: establishing an explicit relationship between the two lines they solicit the translation of artefact signs into mathematical ones, and so they may function as a resource for the unfolding of the semiotic potential of the artefact. The different texts produced by the pupils show interesting differences; for instance, the kind of text in Figure 4b (where the first line text includes both artefact and mathematical signs) presents an hybridisation between the different semiotic systems that provides evidence of the movement from personal meanings, strictly related to



(a)



(b)

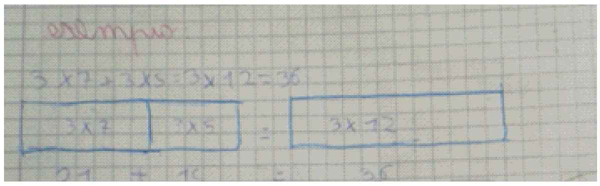
Figure 4: Fra's (a) and Mal's (b) productions after the class discussion

the use of tiles, to mathematical meanings expressing the relationship between operations. In the following days the teacher asked the students to give examples using the version with the + between the rectangles (Figure 4b). The teacher recalls this bundle, used by some students, and decides to foster the sharing of this type of signs that has the potential of linking the text composed of artefact signs with the text made of mathematical signs.

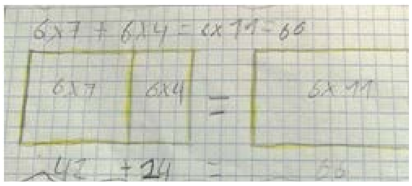
Translating rectangles into arithmetical expressions

After a couple of days, the teacher proposed a variation to the task: she gave them an example writing it on the blackboard, saying them to copy it on the notebook (Figure 5a) and then to invent some personal examples. In this way the teacher enriched the text introducing a new line of mathematical text, in parallel with the previous ones. Such a text is provided as an alternative 'translation' of both the artefact text and the mathematical text. Though at this moment just few students create new text including this new expressions (Figure 5b), the availability of a translation key from a semiotic system to another will play a crucial role in the further activity.

A week after, the second task was given. The students were asked to read the letter, discuss some possible answers in small groups and then to report their solutions to the whole class. A proposed solution consisted in decomposing the rectangle 3×7 in 3×4 and 3×3 or in 3×5 and 3×2 using the graphical pivot signs developed in the previous activities to represent this process. It is interesting to notice that, while reporting this second solution, Fra comes to the blackboard and begins from the expression 3×5+3×2 (written just in symbolic mathematical signs) and only after he completes it drawing rectangles (with the same height) around the two multiplications, without caring about their lengths.



(a)



(b)

Figure 5: Mir's copy of the teacher example (a) and Lor's personal production (b)

A while after, Mir asks to go to the blackboard saying that he would like to try a new different solution (Figure 6a). As matter of fact, from the mathematical point of view, what Mir writes does not differ from Fra's proposal; the difference is only in its representation: Mir's representation eliminates any reference to the artefact using genuine symbolic register, as it is confirmed by the following exchange.

Researcher: Ok, Mir can you explain me a thing. What do all that equal signs mean?
Mir: Three times five equals fifteen. Three times five plus three times two equals fifteen plus six.

The new signs are strictly related to the signs used till this moment, as shown by the activity of Fra, but

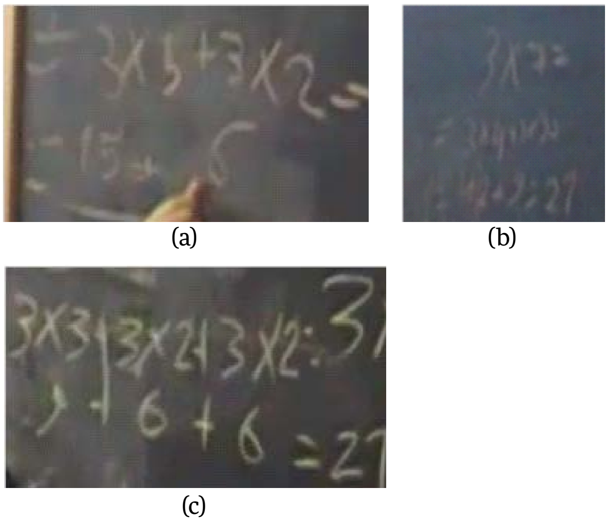


Figure 6: Arithmetical expressions are used to represent the proposed calculations

have lost all the graphical qualities shared with the artefact. The text now relies completely on mathematical culturally determined signs, its meaning is not explained but the direct linkage with previous signs, condensed in our Rosetta Stone, allows students to interpret it. When Mir receives a good feedback for his representation, other students ask to come to the blackboard to use the same representation (Figure 6b), among them, at the very end of the discussion, Lor comes to the blackboard and suggests another solution (Figure 6c).

After this discussion, students are asked to write individually a letter to answer to Giovanni. The majority of the given examples about the order in which Giovanni has to perform his calculation are expressed by arithmetical expressions, only three students just use a representation with rectangles. In many productions the two kinds of representation appear together (Figure 7), showing evidence of the process of appropriation of a relational meaning of arithmetical expressions and its relation with the use of the artefact.

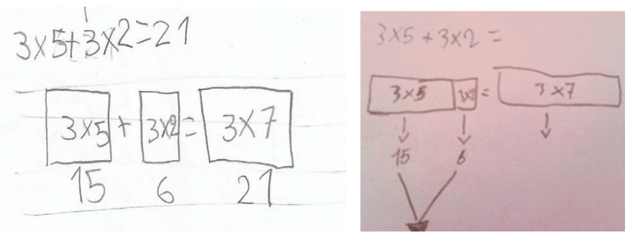

Figure 7: Sob's and Sim's combined usage of expressions and rectangles

DISCUSSION

The usage of artefacts to introduce the distributive property is a diffused approach: in some studies it is possible to find pre-constructed paths implemented in textbooks (Ding & Li, 2014) or in instructional materials (Izsák, 2004). However "how students might be supported to make transitions from concrete to abstract representations remains largely unknown" (Ding & Li, 2014). Our study shades light on such a complex process, showing the crucial role played by the semiotic dimension as it is modeled by the TSM. In our experiment we introduced an artefact with strong representative features based on the rectangular model for multiplication, with different tasks specifically designed for this experiment. The analysis of the data shows the expected process of semiotic mediation. The transition from artefact signs to arithmetical expressions is guided by the teacher and the researcher choosing tasks and orchestrating the mathematical discussions.

From a theoretical point of view, TSM gave suitable aids to design the activity with the artefact and provided useful analytical tools. In particular the distinction of different kind of signs gives many insights on the evolution of students' productions and on teacher's interventions. As clearly shown in the previous analysis, a sensible handling of the pivot signs in the collective discussion allows the teacher to foster the development from personal meanings to mathematical ones. It has to be noticed that many different kinds of signs go under the label "pivot signs". These signs are more or less related to the artefact or to mathematical symbols and they belong to different semiotic systems, sometimes used in parallel or generated one from the other, briefly they constitute a semiotic bundle (Arzarello, 2006). This construct grasps this semiotic richness that may explain the potential move from representing the combination of rectangles (tiles) towards representing the relationship between arithmetical expressions. Moreover, the use of semiotic bundles as pivot signs aimed at relating the activity with the rectangles to mathematical signs, was intentionally exploited by the teacher through the production of hybrid texts explicitly relating – as in a Rosetta Stone – the two different systems of signs.

It is also meaningful to remark how asking for individual productions after the first discussion allowed the teacher to observe emerging personal representations produced and shared by the children; these signs (specifically the introduction of the sign + between the rectangles), appropriated by the teacher, became fundamental to foster the evolution towards mathematical signs.

The proposed kind of tasks seems to be very promising for introducing the usage of expressions in very first grades. The selection of appropriate signs leaded to a quite natural introduction of this mathematical representation in a context in which it is useful and meaningful. Moreover, the need of conventions about the order of operations computing appeared as natural in this context and children showed a good structural control of the expressions. We have also to stress that, even if it was a minority, there were children who had difficulties in following this approach. It is needed further research and more cases to give more relevance to these findings.

Investigations in magic squares: A case study with two eight-year-old girls

Bożena Maj-Tatsis[1] and Konstantinos Tatsis[2]

1 University of Rzeszów, Rzeszów, Poland, bmaj@ur.edu.pl

2 University of Ioannina, Ioannina, Greece

The paper presents the results of a case study of two eight-year-old girls working together on an activity involving – among others – two magic squares. During the activity we have observed the girls' participation in the task, which led them to the discovery of some properties of operations and, moreover, to mathematical reasoning. Additionally, there were differences in the way the two girls perceived the given activity at particular moments, a fact that may be related to their general views of mathematical activity.

Keywords: Mathematical reasoning, investigations, magic square.

INTRODUCTION

Mathematics teaching and learning is a process that begins from the early years of childhood and takes place in formal and informal settings. Children, even at a small age have access to powerful mathematical ideas, such as mathematization, connections, argumentation, number sense and mental computation, algebraic reasoning, spatial and geometric thinking, data and probability sense (Perry & Dockett, 2002). During most of their time, and especially during play, children are engaged in informal mathematical thinking, which may include reasoning and argumentation (English, 2004). Although there is a consensus on the importance of that informal mathematical knowledge and its contribution to the child's further development, the research on reasoning processes in informal settings is rather limited (e.g., Ginsburg, Inoue, & Seo, 1999). Having in mind these considerations, we designed a case study aiming to study the reasoning processes that will occur, together with the mathematical concepts that may evolve by engaging two girls in a series of mathematical tasks. Particularly, our research questions were the following:

- What aspects of mathematical reasoning can be observed during the particular activity?
- In what ways has the particular activity contributed in the girls' understanding of properties of mathematical operations?
- Which were the characteristics of the girls' participation in the activity?

THEORETICAL FRAMEWORK

The process of learning mathematics can be viewed by many different perspectives. Among them, there are those that focus on the child's activity while doing mathematics and comparing that activity with that of a mathematician. Ponte (2001) talks about "a parallel between the activity of the research mathematician and the activity of the pupil in the classroom" (p. 53).

One of the important activities of the students who are doing mathematics is the mathematical investigations, in which the students rather than solving a problem with clearly-framed questions, are faced with a situation in which the conditions might not be completely clear, thus they might have to search for regularities and relations or even formulate some questions by themselves (Ponte, 2001). During these processes it is highly probable that the students will use some mathematical reasoning in their work. Lannin, Ellis and Elliot (2011) connect mathematical reasoning with nine essential understandings. Among them we find developing conjectures, generalizing to identify commonalities, generalizing by application, investigating why, justifying based on already-understood ideas, and validating justifications. This framework has proved much helpful for the purpose of our research.

Mathematical activities like those described before can be also observed in students at the early stages of their education. In NCTM's (2000) *Principles and Standards of School Mathematics* in the "Reasoning and Proof Standard for Pre-K through Grade 2" we read that the ability for mathematical reasoning "develops when students are encouraged to make conjectures, are given time to search for evidence to prove or disprove them, and are expected to explain and justify their ideas" (p. 122). It is also a known fact that children do use mathematical notions in their informal everyday activities before they enter the formal school system (Ginsburg et al., 1999). English (2004) claims that children during their play are engaged in mathematical reasoning; moreover, from a researcher's perspective, there is an interest towards "the thinking behind children's mathematical responses" (p. 14).

The importance of children's reasoning processes lies in the fact that they are strong facilitators of their learning, even more than specific contents of mathematical knowledge (Perry & Dockett, 2002). But we have to stress here that none of the previous can be achieved without the help of the teacher who – among other actions – has to ask the right questions and choose the proper tasks. Ponte (2001) offers a detailed description of the expectations for the teacher in an investigation class. These vary from the careful selection and design of tasks to decisions concerning time management and class organisation. What is important, however, is that the tasks should be designed in such a way that conjecturing, justifying, generalising, etc. will come up naturally during the students' participation in the activity.

DESIGN OF THE STUDY AND METHODOLOGY

The design of our study was based on our theoretical framework; most of the tasks were taken by a textbook which is aimed to promote interest in mathematics (Lankiewicz, Sawicka, & Swoboda, 2012). Our choices were driven by the following assumptions: the problems should be accessible to a wide range of students on the basis of their prior knowledge; they must be solvable, or at least approachable, in more than one way and without the use of tricks; they should illustrate important mathematical ideas; they should serve as first steps towards mathematical explorations and be extensible and generalisable (Schoenfeld, 1994).

The students were given seven tasks in total and the session, which took place in one of the students' house, lasted for two hours. Both the authors of the paper were present in the session and both were known to the two girls. The first author, who will be referred to as Researcher in the transcripts, was the one who provided help and guidance to the students. Her roles were consistent with those described by Ponte (2001) and NCTM (2000) and can be summarised in the following:

a) propose challenging questions for the students;

b) support and evaluate students' progress by promoting a balanced participation in the activity;

c) think mathematically by asking new questions and by becoming involved in mathematical reasoning;

d) supply and recall information;

e) promote students' reflection.

The two students, Ania and Magda, were both eight years old at the time of the study, and they were fellow-students in the second grade of a public primary school in Rzeszow, Poland. They both had good marks

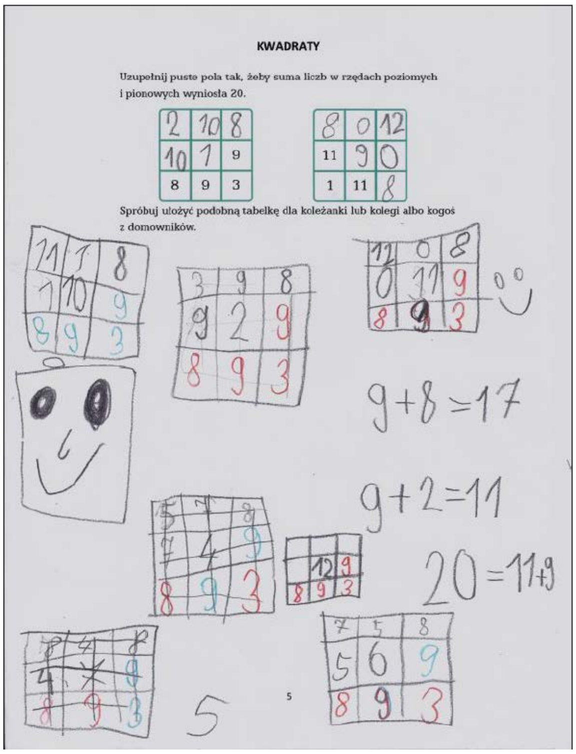

Figure 1: The worksheet containing the magic squares and part of solutions

in mathematics and they volunteered to participate in the research.

The analysis in the present paper focuses on a task related to a particular type of magic squares, which are partially filled, contain equal sums horizontally and vertically (but not diagonically) and the same number can appear more than once. This task was chosen because it fulfils the assumptions mentioned before and, particularly it is aimed to promote conjecturing and justification. Moreover, it has led to a rich discussion and engagement of our students. This was the fifth task in the row and Figure 1 shows the worksheet that was given to the students, together with some of the girls' solutions.

In the top of Figure 1 we read: "Complete the empty fields so that the sum of the numbers in rows and columns is 20". And then: "Try to create a similar table for your friend or somebody from your family".

The analysis of the girls' activity was done according to our research questions and was based on our theoretical underpinnings. Particularly, we firstly tried to locate any manifestations of Lannin and colleagues' (2011) essential understandings that are related to mathematical reasoning:

— developing conjectures,

— generalizing to identify commonalities,

— generalizing by application,

— conjecturing and generalizing using terms, symbols, and representations,

— investigating why,

— justifying based on already-understood ideas,

— refuting a statement as false,

— justifying and refuting the validity of arguments,

— validating justifications.

The analysis of the episode has shown that not all of the above were manifested in our students' interactions, which was somehow expected, since some of these understandings (e.g. generalising by the use of representations) were rather advanced for our eight-year-old participants.

Another useful analytic framework was Brandl's (2011) mathematical giftedness model, which consists of abilities specific to mathematics and general personality traits. The former include mathematical sensibility, memory, structuring, generalising and the reversion of mathematical processes. The latter include intellectual curiosity, willingness of exertion, joy in problem solving, perseverance and frustration tolerance. Although the model refers to mathematical giftedness, we have found it useful for characterising the participation of our students. Finally, throughout the discussion we have located the conjectures that are related to properties of the specific magic squares, as well as numbers and addition.

RESULTS

The task which is the focus of the study was the fifth in the row. For the purpose of the present paper we focus only on the first part of the task, which was to fill in the missing fields of the two magic squares. Mathematical activities of particular interest for our research are written in italics. Our notes are written in brackets. The discussion that follows took place few minutes after the worksheet was given to the students, since they needed some time to comprehend the task:

Ania: It will be here 12, for example 12 [the sum of 9 and 3 which are in the last column], 2 plus.... in order to be equal to 10, then 2+8. We have to put 8.

Magda: And here we can [put] 1 and add 10 [in the middle column].

Ania: [checking] Uhm. Yes. And here 8 [writing what she calculated before]. And here it would have to be 2 [in the top left].

Magda: and 10 [writing 10 in the last field, i.e. the middle in the first column].

Researcher: Is it ok?

Ania: Yes. 8+9+3 equals 20; 10+1+9 also equals 20; 2+10+8 also equals 20.

Researcher: Magda, how did you know that there [in the middle field] has to be 1?

Magda: Because I knew here and here I knew that it will be [showing the middle row and middle column]

Ania started with the last column in which only one number was missing; thus, she chose to begin with the easiest part of the task. Magda focused on the middle field; in this case the situation was open because both middle row and column had two empty spaces. Magda probably chose 1 because that was the number that added up to 10 (because of 9 in the bottom field). She *made a conjecture*, while Ania *validated* it. Both girls were engaged in solving the task and were *monitoring each other*. The researcher asked the question "why" in order to make Magda justify her choice. But she had difficulties in expressing her way of thinking. Up to that moment the girls were not aware that 1 in the middle field is not the only solution.

Thus later on, the question of the researcher "Can another number be in the middle?" surprised the students, since they thought that they had completed the first square. It created a cognitive conflict, since they were probably never faced a problem with more than one correct solution. It made them thinking for a while and the first answer of both of them was "no". After that, Ania had a second thought. She *made the conjecture* that in the middle you can put the number 2. But she quickly *refuted the hypothesis*: "If here would be 2, then not. Here has to be like that". She showed the other numbers in the middle column: 9 and 10 and she *concluded* that 2 does not fit to them. Because the completed square was misleading the students, the researcher asked them to draw another one – the same with the one given in the task. Then she repeated the question: "Can something else than 1 be in the middle?"

> Ania: No, because for example if here was 2...
> Researcher: yes...? [showing interest]
> Ania: then here it would equal 11 [with 9]... [thinking for a while] ... and here (the last column) you have to add 8 for sure. Here you have to add 8 for sure! [repeating and writing 8]
> Researcher: Yes..?
> Ania: And if here was 11, then 11, then you would have to add nine...? [unsure]

Ania was engaged in solving the problem. It was a real *challenge* for her and she demonstrated *intellectual curiosity*. She was not convinced that number 2 is not adequate although she had *rejected* it before. Therefore, she wanted once again to check if number 2 can be put in the middle of the square. This resulted in *discovering* that in the last column has to be 8 "for sure", which is later expressed in the sentence: "Here always has to be 8, because it can't be a different number". This is an expression of *generalization* accompanied by an *explanation* which is not justified. While Ania was trying to *investigate* the situation with number 2, Magda seemed to not be interested in the problem anymore. She proposed to move to the second magic square given in the task (see Figure 1). Ania firmly answered: "No, Magda. Wait, now we do that" which showed her *perseverance*. This happened few times during that task, which demonstrates Ania's *willingness of exertion*.

After filling the square the researcher wanted to engage Magda, so she asked "When are we sure that the square is correctly filled?". This provoked a *justification* by Magda: she drew lines on all columns and rows and *explained*: "When all squares [she means sums] will be correct. You have to make operations". After that the girls were convinced that number 2 can be put in the middle of the square. Ania also added: "But 1 also can be" by which she wanted to stress that there are two correct solutions. After that Magda proposed to check number 4. The solution made them enthusiastically state: "Here can be 4 as well!" Another discovery encouraged their further investigations: Magda noticed that she can use the previously filled squares to fill the next ones:

> Magda: [filling the square with 7 in the middle filed] It's so easy. Look [writing 4 and 8 at the top and showing the previous square with 4 in the middle; laughing]: From that. Because here everything is opposite!

By *identifying commonalities* she made a *conjecture* which later resulted in *generalizing by applying* it into another pair of squares (2 and 9 in the middle). The outcome inspired her to continue. Ania *developed* Magda's *observation* and "Everything is opposite" was elaborated to:

> Ania: ... every number is changing with something. (...) for example 7 with 4, 4 with 7 [showing squares with 4 and 7]; 9 with 2, 2 with 9 [showing the squares with 2 and 9] 1 with 10 [the first square with 1 in the middle], 6 with 5 [the square with 6 in the middle]".

The researcher moved their focus to the sum of these pairs of numbers and this led them to a common *discovery*:

Magda: 7+4 is 11 [square with 7 in the middle]. Here is also 11 [square with 4 – showing 7 and 4]
Ania: Every square 11, 11 here also 11. All it has 11.

The second cognitive conflict appeared when the students were discussing what numbers could be put in the middle of the square. The first ideas that "all" numbers can be put (Ania) and "even 100" (Magda) as a synonymous of a big number were quickly *rejected* and *reformulated* into "all up to 10!", which was clarified by Ania: "it means all one's [she means one-digit] numbers together with 10". To the researcher's question about number 11, both girls answered "no". The justification of Magda was that "If in the middle would be 11 and here 9, then it would already be equal to 20 [in the middle column] ... and here [empty field] we have one more. It seems that zero is not treated by the students as a number: you have to add something in the field, but there is nothing to add. But as soon as they realized that zero can be put in the empty field, they *applied* that understanding: "And 11 will be changing with 0!":

Researcher: So, can 12 be in the middle?
Ania: yes
Magda: yes
Ania: And 11 will be changing with 0!
Researcher: Uhm. And what will 12 be changing with?
Magda and Ania: hmm
Ania: 12? So I will do it a small one [drawing a new square]
Researcher: Ok, so quickly and then we will move to the next task
Ania: it's a pity. It's so nice that task... 12. But 12 cannot be because...
Researcher: Why 12 can't be?
Ania: Because ... because 12+9 is already 21!
Researcher: ok...
Ania: So 12 can't be
Researcher: Magda, can't it be?
Magda: No
Researcher: Hm. So what numbers can we put there in the middle?
Ania: up to 11.
Magda: from 1 to 11 [simultaneously]

Number 11 in the middle was immediately rejected, while with 12 they were more cautious. Only the thought about exchanging with another number made them remember the initial condition about sum of 20 which was used by Ania in her *argumentation*. The work at the first square was completed by the range of numbers that can be put in the middle in order to fill the whole square. The range was partially complete, since it did not include zero, although it was mentioned and used.

In the second square the students mainly *applied* their own *discoveries* (with some modifications according to the new conditions) and used the *argumentation* developed in the first one. It is interesting that Magda started filling the square by number 9 (which means that you have to add 0) which was the extreme case in the first square and it took them some time to accept it. Generally, they were working with a big enthusiasm and *complemented each other*. After filling the given square they did not draw any other squares because they expressed everything verbally:

Magda: Here for example 8 [in the middle] and add here 1 [above 8]
Researcher: Aha (...)
Researcher: And if here we put 7 [in the middle], then what will be here? [above]
Magda: 2
Researcher: And if 6?
Ania and Magda: [loudly] 3!
Researcher: How do you know that 3?
Ania: Because when it was 7 then it was 2. And if we decrease it more then it will be 3
Researcher: And if we put 5?
Magda: Then 4 (...)
Researcher: What's the biggest number we can put in the middle?
Ania: 20?
Researcher: Can we put 20 in the middle?
Magda: For me 9, because 10+11 it would be already 21.

We can notice that both students made a significant progress; they were more confident in *making conjectures* and *giving justifications*. Moreover, their discoveries gave them satisfaction which can be described as *joy in problem solving*.

Summing up, the particular activity had invoked many aspects of mathematical reasoning, which may be categorised according to our methodological framework into understandings related to mathematical reasoning (Lannin et al., 2011) and general personality traits which support mathematical activity (Brandl, 2011). The former may be further categorised into *interactive understandings*, which are directly oriented to the partner and *personal understandings* which have a more personal character (although they might be also directed to the partner or the researcher). Characteristic cases of interactive understandings in our study were the monitoring of each other and the development/elaboration of the other's observation; personal understandings included the development of conjectures and the generalization by application. During the episode that we analysed a number of conjectures were articulated, validated and eventually elaborated:

1) In the middle field you can put 1.

2) In the top right field always has to be 8.

3) In the middle field you can put 2 (in the sense of another solution for the square)

4) "Everything is opposite" – the addition of two numbers is commutative.

5) The sum of the two numbers in the upper fields of the middle column is constant and equal to 11.

6) 11+0 equals 11. Any number plus zero equals that number.

7) In the middle field of the first square you can put all numbers from 0 to 11.

8) The sum of the two numbers in the upper fields of the middle column is constant and equal to 9. Decreasing one number makes the second increase.

9) The biggest number we can put in the middle of the second square is 9.

It is obvious that some of them are related to properties of the specific character of our magic squares and some properties of addition: identity property, commutative property and associative property.

The personality traits that we located in our mathematical activity were: perseverance, willingness of exertion, intellectual curiosity and joy in problem solving. Moreover, we have noticed significant differences in our students' participation regarding not only their understandings of mathematical reasoning, but also the personality traits. Particularly, Ania was more willing to investigate the situation, developing new conjectures and perseverant. Magda, on the other hand, usually wanted to move on when she was faced with a novel situation; however, whenever she developed her own conjectures she experienced satisfaction. Summing up, we may say that Ania was better in proposing new ideas, while Magda was better in justifying their conjectures and monitoring Ania.

CONCLUSIONS

Our case study has provided us with interesting and valuable data that go in line with the relevant literature. We have observed that our students have been able to articulate sound mathematical conjectures, which supported their mathematical reasoning. Moreover, both students were engaged in the task and have demonstrated signs of mathematical sensibility and intellectual curiosity, but in a different degree. As we mentioned, Ania was better in proposing conjectures, while Magda was better in monitoring; thus, it seems that the students' roles although not identical, were somehow complementary to each other. This fact was very helpful for the "flow" of the activity and the outcome of their investigations. The researcher's interventions, mostly in the form of questions, were also vital for the girls' investigations, promoting their mathematical reasoning and fostering their reflection.

The magic squares have thus proved a useful tool for promoting our students' investigations and we believe that it can also be used for the discovery of properties of numbers and addition.

“How do you make numbers?”: Rhythm and turn-taking when coordinating ear, eye and hand

David Pimm and Nathalie Sinclair

Simon Fraser University, Burnaby, Canada, djp3@sfu.ca

In this paper, we examine an environment involving a young girl, an adult and a touchscreen application (TouchCounts), in which engagement with number draws on all of the audible, the visible and the tangible. We broadly frame our analysis in terms of the conversation (both verbal and non-verbal) that occurs, seeking to gain insight into the nature of number – and in particular of its ordinal aspect – in this complex assemblage. We propose that much can be learned from our analysis about the nature of counting in more traditional environments, as well as about the particular forms to which TouchCounts may give rise.

Keywords: Kindergarten, touchscreen application, audible, visible, tangible.

INTRODUCTION

Over thirty years ago, Stephen Brown observed, “One incident with one child, seen in all its richness, frequently has more to convey to us than a thousand replications of an experiment conducted with hundreds of children” (1981, p. 11). Nowhere, perhaps, is this as true as in the arena of early number. Our starting point here is with such an incident, involving a five-year old girl – for argument’s sake, we’ll call her Katy. But the full encounter, which lasted just over an hour, also involved an adult, Nathalie (second author), some geometry tasks with pencil and paper, and, from about half-way through, an iPad with the numerical App *TouchCounts* (Sinclair & Jackiw, 2011), the pertinent aspects of which we describe briefly in this paper (see also Sinclair & Pimm 2014). We wish to explore the potential of framing this interaction as a *conversation* about number, albeit one involving an entanglement of the audible, the visible and the tangible.

We are also interested in examining how children’s number activities within this particular entanglement relate to findings from prior research on children’s development of number. Elsewhere, we have described how the design of this App supports the development of subitising (Sinclair & Pimm, in press) and finger gnosis (Sinclair & Pimm, 2014), in addition to offering more expected opportunities for children to work with cardinal aspects of number (Sinclair & Heyd-Metzuyanim, 2014). In this paper, we follow the suggestion of Coles (2014), who argues for the importance of ordinality in the early development of number, based on recent neuro-science findings, as well as on the work of Caleb Gattegno (1974). [1] Ordinals convey a sense of time and sequence, of ‘the next one to be named’ and ‘the one to be said after that’. Success with intransitive counting primarily involves being able every time to generate stably the same set of words in the same order. Transitive counting, which may be over-emphasised in early schooling (see Tahta, 1991), relies centrally upon intransitive counting and can actually be seen as a ‘mere’ application of it, a subordinate practice. Among other things, ‘ordinality’ refers to the capacity to place numbers in sequence: for example, that 4 comes before 5 and after 3 in the symbolised sequence of natural numbers, as well as in the parallel ordering of the number words. We here interpret attending to any kind of sequencing of numbers (not just counting by ones) to be attention to the ordinal.

In particular, Coles points to the need for research to explore the potential of an increased emphasis on ordinal aspects of number with children of primary school age, or younger. In current classrooms in Canada (and elsewhere), children are generally offered concrete resources and materials (such as Dienes Blocks, a move which Tahta, 1991, terms *metaphoric*). The neuro-science suggests such schoolwork on linking symbols to objects may reinforce the very way of thinking that underachieving students need to overcome in order to become successful at counting and arithmetic. Coles hypothesises that what these students need is support to work with number words and symbols in their relationship to other number words and symbols (which Tahta terms *metonymic*). Our research focus and central question involves understanding better the particular entanglement of the audible, the visible and the tangible plays out in young students' developing ordinal sense of number.

THEORETICAL FRAMING

In Jackiw and Sinclair (2010), user interaction with *The Geometer's Sketchpad* is discussed in terms of a pedagogic conversation, one in which it makes far greater sense to frame the student as the *teacher* rather than the software acting as one. The authors rhetorically ask, "If *Sketchpad* cannot speak, in what sense can it participate in discourse?", yet go on to claim, "there is a coherent and well-defined linguistic trajectory to users' interactions with *Sketchpad*, an explicit interplay and evolution of language [...]" (p. 159). The 'language' they discuss is all written and the user issues commands by means of verbal menu selection, mouse play and/or keyboard entries.

In the excerpt we discuss here, we wish to go further and examine the 'coherent and well-defined linguistic trajectory' we see in Katy's interactions with *TouchCounts* broadly inspired by the field of Conversation Analysis (see, e.g., Sacks, 1992), specifically focusing on sequential aspects of turn-taking, the core characteristic of naturally occurring conversation. The focused conversation (in the conventional sense) between Katy and Nathalie in the first part of the encounter proves Katy to be well-accustomed to taking turns and a respecter of that: indeed, there are almost no instances of overlapping speech. But when she 'converses' with *TouchCounts* on the iPad, she takes most of her turns with her index finger, changing things significantly.

This latter 'conversation' is about the spoken sequence of number names in English, as well as the visual numerals on the discs that are generated by her finger in the varying rhythms she adopts. Unlike with the *Sketchpad* setting mentioned above, there is no written language here: the only visible symbols (which are not part of the English language) are the numerals appearing on the successively generated discs. But the associative *rhythm* – parallel structure in the number words said, repetition in her finger touches, pulse in her attention – is so evident that it becomes for us one of the main phenomena of interest in this episode. Temporality and sequentiality lie at the heart of ordinal awareness. As Tahta (1989) claims, "Time becomes manifest [...] in the experience of rhythm and repetition. The medium for language, and so eventually for counting, is at first *sound*" (p. 20). Staats (2008) convincingly argues that, "repetition creates ideas that transcend the sentence", a phenomenon she links to Roman Jakobson's poetic function of language, one where "the form of the message calls attention to itself" (pp. 26–27). [2] While 'the number poem' [3] may be used as informally to refer to the sequence of number words, we doubt users of this expression are attending to Staats' assertion "Any time a repetition causes listeners to attend to the form of the statement, or to use the form of the statement to construct meanings, the poetic function of language is in play" (p. 28).

METHODS

The encounter at the heart of this paper occurred in an elementary school in a rural part of British Columbia, where the second author worked for about an hour with each of five kindergarten children, in a one-to-one setting separate from their customary classroom and teacher, which was videoed as part of the research project. The first part of each clinical interview focused on symmetry tasks, while the second part involved the use of *TouchCounts*, which was new for each student. Because this was the beginning of Katy's work with *TouchCounts*, it gave us an opportunity to see her first encounters with counting tasks on the iPad, seeing how she made sense of the App and how that interacts with her feel for number. Katy was the first student to be interviewed, as well as the youngest (having recently turned five). Although portions of this session have been analysed in a paper for the previous CERME (Sinclair & SedaghatJou, 2013; there is also more discussion of methods there), that paper focused on cardinal aspects of number. Here we offer a more ordinal focus and closer attention to the entanglement of the audible, visible and tangible.

Brief description of TouchCounts

We briefly describe only the Enumerating World of *TouchCounts*, which starts almost blank, except for a horizontal bar representing a shelf (Figure 1a). In this world, a user taps her fingers on the screen to summon numbered objects (yellow discs). The first tap (when initially turned on or after pressing Reset) produces a disc containing the numeral "1". Subsequent discrete taps produce sequentially numbered discs. As each tap summons a new numbered disc, *TouchCounts* audibly speaks the English word for its number. As long as the learner's finger remains in contact with the screen, it 'holds' the numbered object, but as soon as she "lets go" (by lifting her finger), the numbered object falls to and then "off" the bottom of the screen, as if captured by some virtual gravity. If the user taps and releases a numbered disc above the shelf, it falls only to the shelf, and comes to rest there, visibly and permanently on screen, rather than vanishing out of sight "below". (Thus, Figure 1b shows a situation in which there have been four taps below the shelf – these numbered objects are in the process falling – and then the "5" disc was placed above the shelf.)

Discs dropping away (under 'gravity') mirror the way spoken language fades rapidly over time, with no trace left – the impermanence of speech. Also, with discs disappearing, any sense of cardinality goes too: the disc labelled '2' is simply the second one to have been summoned (in the absence of the presence of the disc labelled '1'. So the Enumerating World with 'gravity' enabled (it is an option) is almost entirely an ordinal one. However, the shelf feature allows the

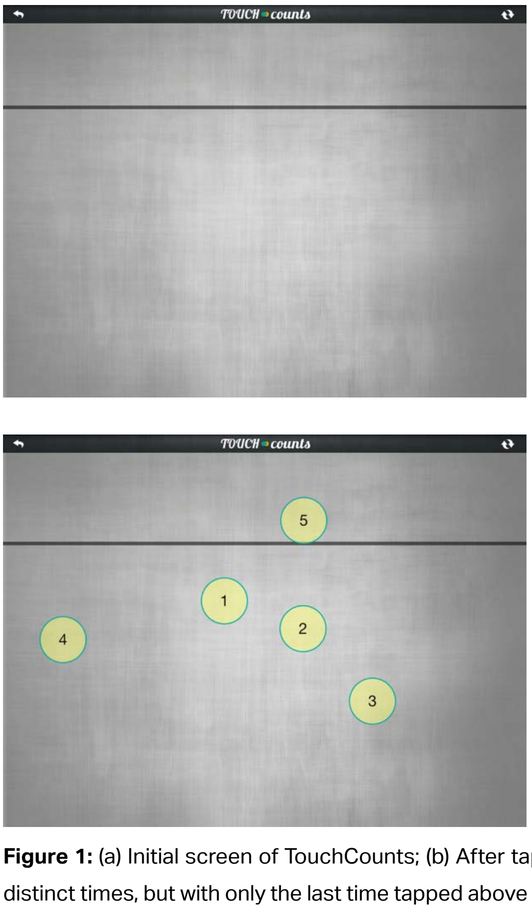

Figure 1: (a) Initial screen of TouchCounts; (b) After tapping five distinct times, but with only the last time tapped above the shelf

user to 'store' some objects for longer. Since a new numbered object is created each time a finger is placed on the screen and then lifted, one cannot 'catch' or reposition an existing numbered object by retapping or dragging it. Depositing discs on the shelf are as if they have been written down, inscribed on the screen as one might write on paper.

Fingers can be placed on the screen either one at a time or simultaneously. Thus, with five successive taps, a user sees five sequentially numbered objects appear one after another on the screen and hears these numbers announced by their English number name one by one. [4] However, if she places two fingers on the screen simultaneously, she sees two numbered objects appear simultaneously, but only hears the higher-numbered one explicitly named ("two," if these are the first two taps). Thus, repeatedly tapping two fingers on the screen produces the sequence of number names "two, four, six, eight, ...". This feature is barely drawn on in our excerpts.

Notably, *TouchCounts* 'takes care of the counting', both in terms of making sure that the sequence of numerals is given correctly on the screen and in terms of ensuring that the number names are said in the requisite order, in response to the fingered requests of the user.

DATA, ANALYSIS AND RESULTS

In engaging with the data, we looked for interaction in conversation (including the iPad as converser) as well as elements of rhythm and repetition. The ten-minute sequence from which the excerpts discussed in this paper have been taken begins:

Nathalie: Let's do some, just some numbers first, OK?
Katy: Numbers.
Nathalie: Yeah.
Katy: OK.

From strokes to pops

Without prompting, Katy's hand then approaches the screen and the index finger of her right hand touches the top of it and then slides down to the bottom (we call this a 'stroke'). A yellow disc appears under her finger with the numeral '1' on it and at the same time "one" is spoken by the iPad. Her finger moves back to the top of the screen, before touching again and slowly stroking downwards. The iPad says "two", followed by

Katy's echo. This happens repeatedly for three, four and five, while for six, seven and eight she says the number simultaneously with the device (Figure 2a).

She says nothing for nine (and it subsequently becomes clear she is not always sure nine follows eight). The appearance of the disc bearing '10' attracts her attention, perhaps because of its double digits. Katy bends over to look closely at the screen and she then says "ten" *after* the iPad and with a rising intonation (Figure 2b). She keeps her head down while continuing to make subsequent numbers at a good speed, but now only the iPad recites them: she is so quick that the iPad only gets to say the 'four-' of "fourteen" before "fifteen" comes. After "seventeen", several fingers fall on the screen at once, and then 'twenty-one' is heard. This produces a pause in the action and Katy's lips spread into a smile. All her other fingers are tucked away, as the rhythmic stroking continues along with the chorus of named numbers, which Katy begins to repeat with the iPad at "twenty-three" (only she consistently says "tenny" for "twenty"). At "twenty-seven", Katy looks up, no longer watching the screen (see Figure 2c), while she continues stroking and saying numbers.

Even in this first small episode, some transcription issues are evident, mostly concerning the coordination of ear, eye and hand. Each of the elements is a material event occurring in time in the world. Consequently, each of them occurs in time and takes a certain length of time and can occur in conjunction with the others. To transcribe them there would need to be a 'channel' (or 'register', though not in the technical, linguistic sense) for each, arranged horizontally (like a musical score for several instruments), where time is calibrated across them, but even then it would be difficult to show shifting subordination of one to the other (as occurs when Katy looks nonchalantly up while continuing to swipe). What we have had to attempt here is a narrative retelling, making observations about our linked phenomena of interest.

The *TouchCounts* timings are predictable, in that the numbered disc appears virtually instantly when the finger is lifted from the screen, while each number word takes a certain length of time to say. The words above twelve are generated syllabically, e.g. fif-teen and fif-ty, while "twenty-three" uses the same "three" as "three". There is an appreciable gap between, for instance, the "twenty" and the "seven" in the saying of "twenty-seven", a material fact that Katy makes good use of later by inserting her finger stabs to prevent the second part of each number word being said aloud.

Nathalie asks her to tap above the shelf, which she does, swiping her finger down to make 'thirty-one'. After 'thirty-two', Nathalie asks Katy to let go of the disc above the shelf (not *on* the shelf), which Katy does, noting that "it stops the number". When she taps again (above the shelf) she says "pop", and then taps several times again. At 'thirty-nine', she starts placing the discs on the shelf side by side, going from the left to the right, until she gets to 'forty-six', at which point she returns to the left edge of the line, makes 'forty-seven', looks up at Nathalie and puts her hands on her lap. Nathalie asks Katy to reset. Instead of hitting the reset button, she creates numbers in quick succession, so that the iPad says "forty-eight, forty, fifty, fifty, fifty".

Nathalie asks Katy to put "just five" on the shelf. Katy tries several times, without success, then puts her head down and taps intently on the screen below the shelf, saying the number names aloud with the iPad (one, two, three, four), then moving her finger up to place five on the shelf. Nathalie asks Katy to put "five and ten up here". On her first try, she places five below

Figure 2: (a) Katy stroking; (b) Attending to the disc; (c) Stroking while looking up

the shelf, so has to begin again. On her next try, she very quickly taps four times below the shelf and once above. She then puts 'eight' above the shelf and realises her mistake, but continues tapping quickly on the screen, so that the iPad says "twenty, twenty, twenty, twenty, thirty, thirty, thirty, thirty, thirty, thirty, thirty, thirty, thirty, thirty-nine, forty, forty, forty, forty, forty, forty, forty, forty, forty, forty, fifty, fifty, fifty, fifty, fifty, fifty-five". Katy smiles. We conjecture reassurance can derive from the regularity of repetition and rhythm.

The language of 'friends'

In the moment, Nathalie spontaneously tries to 'humanise' the mathematical task she wants Katy to attempt, namely to produce all the multiples of five alone on the shelf. She does this by saying, "Imagine five and ten are your best friends and they're the only ones you want to come over to your house (*points to the region above the line*). So you just want five and ten and not the other people in your class." The language of friends and home and the translation of what is happening on the screen into these terms, however, is precisely the sort of metaphoric shift that Tahta suggested can take attention away from the ordinal, away from links between the number words and symbols themselves. Additionally, this move transfers the 'I want' framing of the task into what 'you [Katy] want'. After a few tries, Katy succeeds in placing just five on the shelf (Nathalie: "Five is your friend."), then taps below the screen to make six.

When Katy spontaneously asks, "What kind of number is going to come after?" (there had been no talk about 'kinds of number' prior to this), we assume she is asking 'friend or not friend', but it could also signal that, at the moment at least, she is unsure that "seven" follows "six". Also, following the placing of "eight", Katy asks "Is nine going to come after?". She eventually places 5 and 10 above the shelf successfully. She stops. Then Nathalie asks her which other numbers are her friends. She mentions several (seven, one, two, "all of the numbers") and then starts tapping, making eleven, twelve, thirteen, four, fif, six, twenty, twenty, twenty, twenty-five.

From "pop" to "drop"

She starts at one again above the shelf, puts two below the shelf saying "drop", then places three above the shelf and four below (repeating "drop") and continues going over and under the shelf until she gets to seventeen above, pauses then continues until she reaches twenty-two. She then returns to the left side of the shelf, having filled the shelf with (mostly) odd numbers and continues to tap-drop, seemingly more focused on the rhythmic motion of her hand than on the specific value of the number names. She starts going very quickly, saying "drop" again so that only "forty, forty, forty, forty..." can be heard from the iPad, then "fifty, fifty, fifty...", then "sixty, sixty, sixty...". Katy says, "I'm doing a pattern", but does not go into any more detail, alas, as to which pattern she is seeing. She continues in this way into the seventies, the eighties and the nineties, until the iPad crashes. After this, Nathalie shows Katy how to use many fingers at a time to make "friends". She gets to two hundred and five, says "I don't want no friends" and presses reset while smiling. She then says she knows how many friends she wants, and makes one, two, three, four, five, six successively with her finger, then stops, saying, "That's how many friends I want."

DISCUSSION

Rhythm is the essence of counting, its heartbeat. It is there from the beginning, but changes over time. Katy's first rhythms are the slow strokings of the screen with her index finger, which she watches swim down the screen, as if each numbered disc were worthy of her attention. Here, she seems to be in conversation with the motion of the discs, more so than with the iPad's oral naming. Indeed, she notices the shift from single to double-digit numerals at ten (commenting "a one and an o"). Then tactile rhythm turns into taps, a new gesture that seems less interested in the individual number than in the succession – and this is where Katy starts chiming in with the voice of the iPad, no longer even needing to see what she is making happen. With the task of placing five on the shelf, a new rhythm develops over time, which is the four quick taps below the shelf and then a fifth above, this perhaps giving rise to the rhythmic 'above then below' alternation with which she will later play.

Rhythm is also there in the structure of the number names. It is there in Katy's large, alternating rhythmic gestures, gestures that are binary. The odd and the even, we might think: it is there in her gestures, but we hear none of it in what is said, merely in the pattern of the 'pops and drops', to use Katy's words. Were she attending to the numerals on the discs that were alternately produced above and below the shelf, she might have seen something recurring in the digits' place, attending to what changed, but changed regularly (but there would have been ‘noise’ here, as she occasionally places her finger on top of an already existing disc, which then does not make a new one). Had she allowed the iPad to say every number fully, she might have heard something similar: the same stem, first by itself, then followed by the number words one to nine, before the next stem changed, a decimal rhythm underlying a repeating refrain. But no, instead she edited [5] the conversation by means of her own interruptions, only allowing the iPad room to say the same thing each time: sixty, sixty, sixty, ... (ten times), “seventy” (ten times), “eighty” (ten times), then “ninety”.

Gattegno (1970) claimed, “To stress and ignore *is* the power of abstraction that we as children use all the time, spontaneously” (p. 12; *italics in original*). This episode with Katy illustrates his claim consummately: she consistently *stresses* the common decade stem and consistently *ignores* the variation that follows (by editing it out of the conversation, by making in vanish, aurally) and does so across more than sixty numbers one after another. She manages to do this by complex finger movements deployed in a highly rhythmic manner. Hers is no small achievement. In relation to Staats’ comment about language drawing attention to itself, we assert that Katy’s dextrous manipulation of her side of the ‘conversation’ does precisely that (namely drawing attention to the repetitive pattern of the number words in the decades).

CONCLUSION: THE TRIPTYCH OF THE SENSES

Deleuze (1981/2003), at the end of his book on the art of Francis Bacon, offers a brief discussion of the interaction between the hand and the eye, as well as degrees of subordination of one to the other. Deleuze distinguishes four ‘values of the hand’, which he terms the *digital*, the *tactile*, the *manual* and the *haptic*, teased out first along the degree of subordination of the hand to the eye (*digital* more subordinate than *tactile*, where the hand is reduced to a finger). With the *manual*, the direction of subordination is reversed (Deleuze writes of “the insubordination of the hand”, p. 155) and with the *haptic*, the link between eye and hand are relatively severed.

But it is not so much in the detail of these distinctions that we wish to dwell. Rather, it is that here, with *TouchCounts* present, we are looking at dynamic interactions *among* hand, eye and ear. And we are concerned with numbering not painting. But Deleuze’s idea of mutual entanglement and relative subordination among senses and their organs remains. We are interested in the particular way that this specific entanglement is shaped, which is distinct from other counting environments, and we can extend Deleuze’s concern with the hand and the eye to include the ear also. The lifting of Katy’s eyes while still making numbers provides a clear instance of a subordination of the eye to the hand and ear, one that is easy to observe (whereas instances when the ear is or is not attending are less apparent).

Nowhere in this episode does Katy seem to be counting objects, but rather is simply counting [6]: the ‘number poem’ is being made by her index finger – *TouchCounts* answer to Katy’s question as cited in our title. This one-to-one correspondence, in which *TouchCounts* takes care of saying the number names in the correct order, releases Katy from having to worry about *what*, if anything, is being counted, allowing her to dwell in the rhythmic succession that *is* counting. Later, the eye and the hand are both subordinated to the ear (in the same way that Hewitt, 1996, speaks of subordinating and coordinating actions and attention to achieve a central goal), as Katy achieves the (presumably desired) repetitive aural effect of the exaggerated looping back and forth tapping of her hand.

To return to Coles’ work and renewed attention to ordinality, not only does number involve coordination of the audible, the tangible and visible, as illustrated in this episode, but *TouchCounts* affords the stressing and ignoring of each of these aspects in various ways. In particular, it allows the subordination of the aural to the tactile – with the IPad ceding conversational ground to her with every tactile interruption – with the possible exception of when it ends the conversation abruptly, by crashing just prior to the unspoken “ninety-three”.

ENDNOTES

1. Such ideas are also present in Walkerdine (1988) and, particularly, Tahta (1991).

2. Jakobson's poetic function relates to his metaphoric and metonymic 'axes', as drawn on in Tahta (1991) by the latter's use of these terms, as mentioned above.

3. Sometimes, 'the number poem' refers to rhymes like 'One two, buckle my shoe' or 'One, two, three, four five, once I caught a fish alive', that incorporate the number words in order as part of the text, while sometimes this expression simply refers to the number words being recited in order by themselves (see also Tahta, 1991).

4. Other language options are available with *TouchCounts*, including French and Italian.

5. For more on editing, see Hewitt (1997), although he sees it as a teacher function to affect student attention.

6. In *Symbols and meanings in school mathematics*, Pimm (1995, pp. 64–66) distinguishes between *transitive* and *intransitive* counting – the former connecting the counting of things to the fact that the verb 'to count' can take a direct object (an answer to the question 'What are you counting?'), while the latter label refers to counting (reciting the number words in order) where there is no such direct object (where the answer to the same question is "Nothing").

Learning interventions supporting numerosity in three year old children

Reinert A. Rinvold and Hans Erstad

Hedmark University College, Elverum, Norway, reinert.rinvold@hihm.no

This paper reports from a preliminary qualitative case study and accompanying theoretical considerations in preparation for a study of interventions designed to support the learning of numerosity in three year old children in a Norwegian kindergarten. Teaching interventions are analysed and discussed both from the perspective of children's learning and the teacher's mediation. Luis Radford's theory of objectification is used as theoretical framework. This is a new approach, as most research papers in the field use quantitative methods and a cognitive approach. Our study indicates that preschool teachers face challenges in taking the perspective of the children they teach, and that knowledge of children's learning phases and assessment of children is needed to improve teaching.

Keywords: Numerosity, objectification, give-N task, parallel individuation system.

INTRODUCTION

Already at the age of about two children begin to learn the sequence of counting words, but further development takes time. More than a year is often needed from when children can count small sets of objects properly until children respond correctly to questions involving the use of numbers (see Sarnecka & Carey, 2008, p. 664). We hypothesize that this time can be reduced by planned learning interventions conducted by preschool teachers or other competent persons. In a preliminary qualitative case study over a period of three months we followed learning interventions in a Norwegian kindergarten conducted by a preschool teacher who was supervised by two researchers. Twelve children took part more or less throughout the study. We emphasised activities which use and give meaning to counting and number, but also the learning of counting skills. The interventions in the preliminary study started up with low quality. During the study we observed improved instruction and many signs of learning. Interventions of mixed quality proved much better than no interventions at all. A follow up study is planned and will build on the findings from the preliminary study.

Norwegian children can attend kindergarten from the age of one until they start school the year they turn six. As much as 90 % of Norwegian children between one and five years old, attended kindergarten in 2013. As remarked by Hundeland, Erfjord and Carlsen (2013), "the Norwegian kindergarten is regarded by OECD (2006) as situated in a social pedagogy tradition, i.e. an educational institution where core enterprises are upbringing, care, play and learning". Norwegian preschool teachers usually do not support children's learning of counting and number through planned and systematic interventions. Now and then they initiate simple counting activities, and sometimes they initiate conversations about numbers with children based on free play situations. The preschool teacher in our study does not have mathematics as a subject in his education. However, since 1995 mathematics has been compulsory in preschool teacher education in Norway.

From the adult expert perspective, numerosity is the same as the cardinality of sets, but we use the former term to underline the very different perspective of the child and the educated adult. The learning of numerosity means to catch the meaning and cultural use of number. This is complex and diverse, starting early in children's lives. In the research literature, the understanding of the numerosity N has been operationalized by the so called give-N test (Wynn, 1990; 1992; Sarnecka & Carey, 2008). In give-4 the child is asked to retrieve four objects, for instance plates, from a heap or a larger set. Research has shown the give-N tasks to be far from obvious for the child. Wynn (1992) found a progressive development in children from first managing give-1, then give-2 and so on up to give-5 or give-6. This has been confirmed by several others (see Sarnecka & Carey, 2008). When give-5 or give-6 is mastered, children seem to respond correctly to give-N, for N as large as the child is able to count. We will analyse excerpts of interaction of such challenges both for the children and for the preschool teacher trying to support them. Finally, possible improvements in the design of interventions will be discussed.

RADFORD'S THEORY OF KNOWLEDGE OBJECTIFICATION

The research literature on young children's acquisition of number has been dominated by psychologists, cognitive scientists and neuroscientists. Their perspective is cognitive with emphasis on understanding, mental models and what happens in the brain, and they use quantitative methods. The give-N activity has been seen as a test of "understanding the cardinal principle" or being a cardinal principle knower, Sarnecka and Negen (2012). The cardinal principle was introduced by Gelman and Gallistel (1978), and states that the last counting word in a correct applied counting procedure, is the cardinality of the set. The latter refers to a concept as possessed by mature adults. We claim that the child does not experience concepts, but activities which gradually become mastered and turned into procedures. To possess numerosity as a concept comes much later in the child's development. In place of speaking about understanding, the noticing of regularities in and connections among the activities is emphasized. This approach is based on Luis Radford's variant of cultural historical activity theory. In his theoretical framework, mathematical objects exist in the culture among us. According to Radford (2008, p. 222), "[...] mathematical objects are fixed patterns of reflexive human activity incrusted in the ever-changing world of social practice mediated by artifacts". Both counting and give-N activities are examples of cultural activities. Objectification is the crucial moments of the child's learning when the child notices important aspects hidden in cultural activities.

> The term objectification has its ancestor in the word *object*, whose origin derives from the Latin verb *obiectare*, meaning" to throw something in the way, to throw before". The suffix – *tification* comes from the verb *facere* meaning "to do" or "to make", so that in its etymology, objectification becomes related to those actions aimed at bringing or throwing something in front of somebody or at making something apparent – e.g. a certain aspect of a concrete object, like its colour, its size or a general mathematical property. (Radford, 2006, p. 6)

The child does not notice an abstract property, but a pattern or regularity in a cultural activity involving language, physical actions and artefacts. An example is the give-3 activity where a child is asked to fetch three plates from the shelf. A child can take part in such activities before being able to do it alone. During the learning process what children have objectified can vary significantly. Following Radford (2005), we use the concept 'layers of objectification' to classify alternative objectifications of the same activity. The original use by Radford was to study how students in school objectify the generality of geometrical number patterns. Later on Lorange and Rinvold (2014) have applied the theory to the study of students' strategies in expanding fractions to a common denominator. One layer of objectification of give-3 is when a child is using 1–1 matching to take one plate for each member of his family. A more advanced layer of objectification for the same activity is to remember the number word three and take one plate for each of the three first counting words. Different layers correspond to different strategies for doing the task depending on the regularities, skills and semiotic tools the child has grasped. Counting aloud, silently or using their fingers, are variants which give rise to more finely grained layers of counting. Layers are not necessarily linearly ordered. We have seen the same child demonstrate different layers of objectification of counting within one learning session. An example is perfect counting of six toy cars and recital of the counting words one-two-three when asked how many noses the boy has. Fragile and uncertain mastery and understanding in a learning phase is one possible explanation, but also social uncertainty in responding to demanding tasks together with other children.

Children who master the give-N task for all N, or in practice 5 or 6, are called cardinal principle knowers or CP-knowers. According to Sarnecka and Negen (2012), recent empirical studies have found that CP-knowers show an implicit understanding of succession and equinumerosity. The competency of succession is described as knowing that adding one item to a set, means moving one word forward in the counting sequence. Sarnecka and Carey (2008) found that CP-knowers performed well on two tasks intended to operationalize this competency, and that the non-CP-knowers performed only slightly better than chance. Sarnecka and Wright (2013) came to a similar conclusion for a task intended to measure the competency of equinumerosity. The latter means that two sets with a 1–1 correspondence must be labeled with the same number word. These results indicate that objectification of give-N is an important milestone in the learning of numerosity.

THE PARALLEL INDIVIDUATION SYSTEM

Children younger than one year have been shown to be sensitive to small numerosities. This ability does not, however, mean that the children posit the concepts of the numbers one, two and three. Visual discrimination does not by itself gives understanding of language. *Verbal subitizing* (Benoit, Lehalle, & Jouen, 2004) in which a child immediately gives a number word when shown a set of one, two or three concrete objects has to be learnt. This learning process does not have to be difficult, but is complicated by the fact that many children meet the number words only in counting and not in number talk. Some children may never have been shown for instance three dolls and told that this is three dolls. Subitizing is believed to be based on what is called the parallel individuation system in the brain. According to Sarnecka and Negen (2012, pp. 247–248), this system represents and tracks individuals (objects, sounds, or events). Concrete objects and their properties are represented, so the parallel individuation system is not an abstract number system.

> This system privileges spatiotemporal information to initiate a mental index, or object file, for each item. Although inherently non-numerical in nature, these representations afford numerical content by retaining information about numerical identity – mentally stored items can be compared on a one-to-one basis with visible objects in the scene to detect numerical matches or mismatches. (Hyde, 2011)

Learning the colour red is mediated by pointing to red things and saying for instance “this apple is red”. We expect that verbal subitizing can be learnt similarly, but that generalization is somewhat more demanding than for colours. The parallel individuation system does not let the child see twoness, but the mental image of for instance two dolls. The possibility of comparing a given set of concrete objects to some standard visual representation makes generalization possible. Mental images also let the child solve some matching tasks without numerical thinking.

METHODOLOGY

In the preliminary case study we followed twelve children in a Norwegian kindergarten for a period of three months. The kindergarten was chosen because it is located in reasonable distance from the university college where the researchers work, and has a preschool teacher interested in cooperating in this project. The participants were all the children between three and five years with no known learning difficulties who wanted to take part and whose parent granted permission. At the start of the study the ages varies from 3 years 2 months to 5 years 7 months. The children took part in weekly intervention sessions of 10 to 20 minutes duration. In the first part of the study as many as seven children took part in each session. Later on some sessions had only three or even two children. All sessions were videotaped and observed by at least one of the researchers. An experienced male preschool teacher conducted all the sessions. Sometimes an assistant was present too, whose contribution was limited. Before each session the researchers gave the preschool teacher an outline of what to do, but he had quite a bit freedom and was not given precise instructions. The content of the sessions were different kinds of counting tasks and activities. Most often one child at a time completed a task or answered a question. In the paper we study samples with the four youngest children, two boys and two girls. They were Siri: 3 years 2 months, Nina: 3 years 6 months, Ole: 3 years 7 months, and John: 3 years 10 months. No testing or systematic assessment of the children was done, but all of them had some previous experiences with counting. Already in the first session we noted that Ole and John were relatively poor in counting.

ANALYSIS OF LEARNING INTERVENTIONS

We present selected excerpts from three sessions, focussing on one task from each of them. Each excerpt is a dialog between the teacher and one child. Information about movements, gestures and other relevant facts is put in square brackets. The tasks are analysed from both teacher’s and child’s perspective.

The pure give-N task

In this task a piece of paper with a numeral printed on it is laid on the floor. One of the children is asked to say which number it is, and then the teacher repeats the number. One child is asked to collect that number of plastic bears from a bucket and then place the bears beside the numeral. We follow the first give-N task given to Siri.

Teacher: It's the number four. Can you fetch that many bears?
Siri: [Collects two bears without any signs of counting and puts them on the floor]
Teacher: How many bears have you put on the floor? [He moves one of them a bit and makes counting gestures towards each bear] How many is this?
Siri: [after some silence] Two [without visible or audible counting]
Teacher: one – two [while pointing to each of the bears]
Siri: two – three

The teacher thinks that counting will help the child, but Siri resorts to a more primitive objectification layer of counting. When the teacher says one – two, she turns back to the practice of reciting the number words. The teacher emphasises counting, and he probably expected her to count aloud before answering "two". But, her answer was satisfactory. Both verbal subitizing and counting internally are legitimate strategies. He could have challenged her better by taking away the bears and giving her a give-2 task.

The collecting plates to the bears task

One week later Nina is part of the group in place of Siri. Now the children are given a situation which is modelling an everyday activity. This enables them to rely on information and strategies they already know.

Teacher: In one of the houses live a mammy bear, a daddy bear and a tiny baby bear. [moving the mammy bear] Now you must come and eat. Can you Nina come and fetch a plate to each of the green bears. The green bears must have one plate each. [while holding a transparent plastic bucket with small circular plastic pieces]
Nina: [Takes four plastic pieces from the bucket, one at a time, without looking at the bears. She loses one piece on the floor, begins to retrieve it, but stops.]
Teacher: They must have one plate each.
Nina: [She lays down one plate for each bear] porridge [takes the last plate and gives it to a bear belonging to another family of bears]

Nina is not looking at the bears while collecting plates, so she either takes them randomly or relies on some other information. The former is less probable, since she is taking time collecting the plates. The individuality of the bears can be remembered by the names mammy, daddy and baby or their medium, large and small sizes. This is within the limit of the parallel individuation system, so 1–1 matching based on memory is possible. That she takes one plate too many, may indicate that she relies on numerical information, but has not developed a firm grasp of numerosity.

As number words are not mentioned, this is not really a give-N task. It could have been so if the teacher had introduced number words, for instance by asking the child how many bears there are in the family and how many plates are needed. Later on in the same session Ole gets a give-2 task in which the number word 'two' is used both before and after the task.

Teacher (T): The bear family got visitors. [He places two bears beside the green family] The mammy bear asked if the two visitors also wanted porridge. Can you put on plates to them Ole?
Ole and T: [Ole takes some plastic pieces from the bucket. Simultaneously, the teacher repeats "place plates to the two, two".]
Ole: [Ole looks at the bears and returns some plates to the bucket until he has two. Then he walks to the bears, takes one plate in each hand and places one plate in front of each bear.]
Teacher: Excellent. There they got two plates.

That Ole first collects several plates in the bucket, may be because the visual presence of five bears overrides the number word 'two'. The teacher's repetition of the question initiates a change to collection by visual 1–1 matching. One week previously Ole was successful with give-2 tasks without direct visual support. The available visual resources lead Ole into a more primitive layer of objectification of give-2.

In the same session, John, the mathematically weakest child, gets a give-4 task.

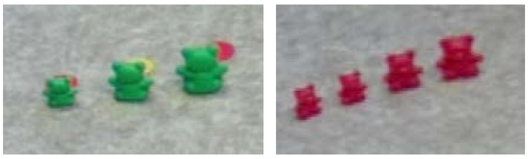

Figure 1: The green and red bear families

Teacher: John, the red ones must also have plates. [points to each of the plates in front of the green bears]

John: No. [takes three plates one by one from the bucket, staring into the bucket, places one plate carefully in front of three of the bears]

Teacher: How many have you there? Can you count them?

John: [points twice to the plate in front of the first bear]

Teacher: You must count them. [Counts to three aloud while both he and John point to each of the three plates] How many more plates do you need then? One [while John is taking one plate from the bucket]

John: [Places the plate in front of the fourth bear, then looks at the teacher]

Teacher: Good!

Since John is weak in counting and numerosity, it is unlikely that he relies on numerical information when taking out three plates. The sizes of the red bears (Figure 1) indicate that the family has two adults and two children, but this information does not seem to be used. A likely explanation is that the parallel individuation system is utilized, but that the capacity limit of three makes John unable to take four plates at first. The second time he correctly takes one plate, but this does not necessarily mean that John is a 1-knower. The teacher's utterance 'one' comes while John already is about to take one plate, so it is likely that John's action is based on spatiotemporal memory.

The garage task

In a session more than one month later the teacher has placed a heap of cars on the floor beside a garage. Ole, John and Siri are sitting on chairs placed so that they see both the garage and the heap of cars. The garage task is a challenging give-N task giving less support and meaning. Parking places and cars are part of daily life, and children enjoy playing with toy cars. However, it is not natural at all to park a given number of cars, randomly chosen from a larger set. The children's interest in toys cars can also be a distracter. The attention of some children was lead toward the cars themselves rather on the numerical information they were given.

Teacher: Then I first want that John takes two cars [taps three times with his hand on top of the garage] and puts them on top here. Can you take two cars and put them on top of the car house?

John: [gets up, walks to the heap and almost without hesitation takes three cars one by one into his left hand. After a very short break he takes another car and holds the cars to his chest. Then he continues and takes a last car. Then he takes a long break while looking at the last car.]

Teacher: Two cars do we want up there [taps three times with his hand on top of the garage] two cars.

John: [rises and walks to the garage, then places all the five cars one by one carefully on top of the garage, then turns in the direction of his chair.]

Teacher: [gestures John to return] Can you count how many cars there are here? Can you count them together with me? [Takes John's finger] one – two – three – four – five [while he moves John's finger to each of the cars]

John: [starts moving towards his place]

Teacher: Wait a moment. How many should you have? Two cars

John: [Begins to take up one car from the heap.]

Teacher: [Stops him] We must take away some cars. [Takes away three cars] Can you count now? How many cars are placed on top of the roof now?

John: one – two [while pointing to the cars one by one. Then looks at the teacher]

Teacher: Two, yes. It was this you should have. Exactly, two cars

Possible explanations for John's inappropriate response to this give-2 task are that he ignores the word 'two', or that he interprets it as 'many'. He may also take the cars he liked, or he takes into account how much space is available on top of the garage. The teacher's question of counting the cars is intended to draw attention to the numerical aspects of the task. John, however, again tries to return to his place, so this does not seem to be of any help. The next action by the teacher is to remind John that it is two cars he should have. This initiates John to start a new give-2 attempt by picking up a car. Unfortunately that attempt is refused by the teacher before we know what John would have done. John seems to have objectified give-N as a procedure for selecting some objects and putting them in a given place. If John had not been stopped, he may have taken up two cars and been rejected again because five cars already are on top of the garage. The teacher's strategy of reducing a larger set into a set of two members is far above the level of the child, and shows that he is not able to take the perspective of the child.

DISCUSSION

The most striking observation from the selected excerpts is the challenges the preschool teacher meets in mediating the children's learning. The same is true also for the rest of the videotaped interventions. When he tries to meet their needs, his response is often irrelevant and leads the children into more primitive layers of objectification. The level of tasks is not adapted to what each child has managed earlier. In order to help children struggling with the most basic tasks, the teacher should systematically remember or make written assessments of what each child has achieved so far regarding counting and give-N. More basically, the teacher needs to be aware that the child experiences cultural procedures and does not possess conceptual knowledge of numbers.

One conclusion is that give-N tasks are of different kinds and of varying difficulties. In the most demanding give-N tasks numerosity is given by a number word, and the child has to rely on that information in order to carry out the task. For the most demanding give-2 and give-3 tasks, verbal subitizing is a possibility if mastered by the child. In the easier tasks, the objects are visible to the child or have names supporting 1–1 matching while the child collects the objects. In the follow up study we plan first to give a child the easy type, but will also challenge the child with pure give-2 and give-3 tasks as preparation for the mastery of give-4. While working with the easy tasks, the teacher has to support the connections to audible and visible counting, but also give praise and appreciation to children who can tell the number of objects in sets by internal processes. Both internal counting and verbal subitizing are competences which are valuable in the learning of numerosity. Beyond the limits of the parallel individuation system, counting is indispensable. This is in accordance with Sarnecka and Negen (2012, p. 252), who claim that it is not possible to learn the meaning of large numbers in the same way as the small numbers have been learned. Similarly, Sarnecka and Carey (2008, p. 664) report that children who only master give-1, give-2 or give-3 (subset-knowers), do not use counting when solving these tasks, even when asked to do so.

In a follow up study we will take into account both the findings from this paper and other results which were not included here due to considerations of space. We will try both collaboration between children and more physical activities. Give-N has been described as collecting a set of physical objects. A variant of give-N is to repeat some physical movement a given number of times. This is used in collecting N objects, as the child fetches an object N times. Non-collecting examples are jumping N times or clapping N times. Board games in which the player moves a piece as many steps as a dice shows, is another possibility. Such a game may be tried with children who do not master the collection form of give-2 and give-3, by using a dice showing only one, two or three. To show the actual number of spots on a dice is an easier alternative than communicating N by a number word. Three different approaches can be combined by first asking a child to say the number of spots on a dice, and then apply counting to move a piece that many steps on a playing board.

The aim of this paper is to present a didactical sequence that fosters the development of meanings related to fractions, conceived as numbers that can be placed on the number line. The sequence was carried out in various elementary school classes, containing students with certifications of mathematical learning disabilities (MLD). Thus, our didactical aim was to make accessible to all the students of the class, including MLD students, meanings related to fractions using a common didactical sequence for the entire class. Our research is based on a range of different perspectives, from mathematics education to neuroscience and cognitive psychology. We discuss how such perspectives can be combined and provide the theoretical bases to design the didactical sequence, which will be outlined, and which allowed us to implement and strengthen inclusive education.

Keywords: Fraction, number line, artifact, mathematical learning disabilities.

INTRODUCTION AND LITERATURE

The concept of *fraction* is a very difficult one to master: frequently students are unable to reach an appropriate understanding of it, as described for example by Fandiño Pinilla (2007), and they can even come to fear fractions (Pantziara & Philippou, 2011). When children encounter fractions – typically in Italian school this happens in third grade (at 8–9 years of age) – it is the first time they have to treat sets of digits differently than how they treat those given in decimal positional notation representing positive integers. The numerator and denominator of a fraction are two numbers, each of which is bound by the rules that apply to positive integers, but that together represent a new, *single*, number. Learning to see the numerator and the denominator of a fraction together, as a single number is one of the most difficult – if not *the* most difficult – cognitive aspect of fractions (Bobis, Mulligan, & Lowrie, 2013).

Others disciplines, besides mathematics education, such as cognitive psychology and neuroscience, have also been very active in investigating the phenomena of (difficulties in) understanding mathematics (incuded fractions), even if the different interested fields of research have not yet reached sufficiently common grounds for conducting scientific and interdisciplinary studies. In this paper, we consider some results from research in neuroscience and cognitive psychology to ground important design decisions taken during the elaboration of a teaching experiment constructed around the learning of fractions in primary school. In the following paragraphs we will illustrate reasons why it is important to learn (and therefore teach) fractions, both from a didactical (math education) point of view and from the perspective of cognitive science.

IMPORTANCE OF FRACTIONS AND DIFFICULTIES IN LEARNING THEM

From the logical and epistemological points of view, the notion of *fraction* can be seen in different ways: as a linguistic representation of the decimal number obtained from the division indicated (but not calculated) by the number corresponding to the numerator and the one corresponding to the denominator; as an operator where the denominator indicates in how many equal parts a given unit is divided (*each part is called a unit fraction*) and the numerator indicates the number of these to consider.

$$3/4 = 3 \textit{ times } 1/4 \rightarrow 3 \times 1/4$$

Frequently, at least in Italian education, the conception of fraction as an operator is not explicitly identified as a rational number. Only when it is transformed into a decimal number is it placed on the number line.

From the point of view of learning mathematics, fractions constitute an important leap within domain of arithmetic because they represent a first approach to the idea of extension of the set of Natural Numbers. In this sense, fractions need to assume a specific position on the number line (Bobis et al., 2013; Bartolini Bussi, Baccaglini-Frank, & Ramploud, 2013). Teaching the notion of fraction is, therefore, a quite delicate issue and it is ever so important to explore insightful ways of structuring didactical activities around it. In this respect, particularly insightful approaches have been provided, for example, by Bobis, Mulligan and Lowrie (2013). Even if certain basic aspects of the concept of fraction, particularly when seen as the perception of the variation of a ratio, seem to be innate (McCrink & Wynn, 2007), the learning of fractions presents obstacles, not only of a didactical nature. In fact, research in mathematics education (e.g., Bartolini Bussi et al., 2013), has shown how learning about not only the semantic aspects but also the lexical and syntactical ones of fractions involves the overcoming of different epistemological and cognitive obstacles such as:

— Assuming that the properties of ordering natural numbers can be extended to ordering fractions (e.g. assuming that the product/quotient of two fractions makes a greater/smaller fraction).

— Positioning fractions on the number line using the pattern of whole numbers (Iuculano & Butterworth, 2011).

From a cognitive point of view, fractions seem to demand more working memory resources than representing whole numbers (Halford, Nelson, & Andrews, 2007). Moreover, fraction knowledge also requires inhibitory control and attention (Siegler et al., 2013), so that the numerator and denominator are not treated as independent whole numbers (Ni & Zhou 2005). With this in mind, it is clear that for a student with MLD (even when “D” stands for “difficulties” instead of “disabilities”) the learning of fraction will be a particularly arduous task. In fact, recent studies suggest that dyscalculia, a particular kind of MLD, is rooted specifically in weak visual-spatial working memory and inhibitory control (Szucs et al., 2013).

Our present work on fractions is part of a broader body of research (Robotti, 2013; Baccaglini-Frank & Robotti, 2013; Baccaglini-Frank, Antonini, Robotti, & Santi, 2014) that has the objective of building inclusive curricular material, grounded theoretically in research in mathematics education and in cognitive psychology, appropriate for *all* students, including those with MLD.

CONCEPTUAL FRAMEWORK

A large number of studies associated short-term memory (STM) and working memory (WM) with mathematical achievement for students and expert (see reviews in Raghubar, Barnes, & Hecht, 2010). Moreover, non-verbal intelligence, addressed to general cognition without reference to the language ability (DeThorne & Schaefer, 2004) also seems to be strongly related to mathematical achievement (Szűcs et al., 2013). These (and similar) findings suggest that non-verbal intelligence may partially depends on spatial skills (Rourke & Conway, 1997). Thus, spatial processes, performed on the base of spatial skills, can be potentially important in mathematical performances, where explicit or implicit visualization is required. Moreover, research in cognitive science (Stella & Grandi, 2011) has identified specific and preferential channels of access and elaboration of information. For students with MLD these are the visual non-verbal, the kinesthetic-tactile and/or the auditory channels.

Studies in mathematics education as well, although with different conceptual frameworks, have highlighted how sensory-motor, perceptive, and kinaesthetic-tactile experiences are fundamental for the formation of mathematical concepts – even highly abstract ones (Arzarello, 2006; Gallese & Lakoff, 2005; Nemirovky, 2003; Radford, 2003). In this regard, within a semiotic perspective, Bartolini Bussi and Mariotti (2008) state that the student’s use of specific artifacts in solving mathematical problems contributes to his/her development of mathematical meanings, in a potentially “coherent” way with respect to the mathematical meanings aimed at in the teaching activity.

Thus, in this paper we aim to describe examples (activities) of inclusive math education (Ianes & Demo, 2013), constructed referring to the math education domain as well cognitive psychology and neuroscience domains.

The goal of the activities we will describe, was to realize a sequence that would favor, for *all* children (including those with MLD) the development of mathematical meanings of fractions as numbers that can be placed on the number line. The sequence of activities was designed, realized and analyzed taking into account the following principles:

— the importance of an epistemological analysis of the mathematical content

— the role of perceptive and kinesthetic-tactile experience in mathematical concept formation as well the visual non-verbal, and auditory channels of access and elaboration of information, in particular in children with MLD

— the role of social interaction, verbalization, mathematical discussion;

— the teacher as a cultural mediator.

Following these principles, as we will describe later, particular artifacts (like paper strips, rulers and scissors) were identified with the intention of using them to help mediate the meanings at stake in the activities.

METHODOLOGY AND SEQUENCE OF ACTIVITIES

The sequence of activities was designed by 22 primary school teachers and 1 supervisor (the first author) composing a study group. The activities were carried out during a pilot experimentation, which involved 22 classes (nine 5th grade classes, six 4th grade classes, and seven 3rd grade classes), before being revised for an upcoming full-blown study. In this paper, we will report on the pilot experimentation carried out in the 3rd grade classes. Students worked in small groups.

The sequence of activities asked to work with differents artifacts such as A4 sheets of paper, squared-paper strips or represented squared-paper strips in notebooks. At first, students were asked to represent fractions on squared-paper strips, then to represent squared-paper strips in their notebooks and to represent, upon these strips, fractions. At last, students were asked to represent fractions on the number line (see below). As described below, the teachers also included moments of institutionalization and discussion (Bartolini Busssi & Mariotti, 2008) based on some critical episodes.

The activities concerning the sequence are:

1) Partitioning of the A4 sheet of paper: this activity involves dividing the A4 sheet of paper, chosen as a unit of measure, in equal parts, by folding and using the ruler; the procedure allows for the introduction of "equivalent fractions" as equivalent surfaces, and of "sum of fractions" for obtaining the whole (the chosen unit, that is, the A4 sheet).

2) Partitioning of a strip of squared paper. This activity involves three sessions:

    A) Given a certain unit of measure, position it on the strip; then, position some fractions on the strip (1/2, 1/3, 1/4, ...) according to the given unit of measure (see Figure 1). The objective is to represent, on the same strip, different fractions, introducing reciprocal comparison.

    B) Given different units of measure on different strips, on each strip a same fraction is represented (1/2). The objective is to make explicit the dependence of the unit fraction upon the chosen unit of measure (1/2u).

    C) Given a squared strip, choose appropriate units of measure to represent different fractions on that strip (e.g., 1/3 and 1/5). The objective of this activity is to find the *lcm* (least common multiple) between denominators as the appropriate unit of measure.

3) Placing fractions on the number line. The fractions, considered to be lengths of segments with origin in 0, are placed on the (positive) number line using the idea at the basis of the operator conception of fractions (developed in point 2). Since the right endpoint of the segment on the number line is labeled with a fraction, it will also assume the meaning of "number", as do all the other whole numbers on the line. Different fractions will be associated to a same point on the line, and will be used to revisit the meaning of "equivalent fractions".

ANALYSIS AND DISCUSSION

In this section we present an analysis of points 2 and 3 of the sequence, and in particular the transition from point 2 to point 3, which we consider the most significant in order to place fractions on the number line. Our objective is to highlight how the meaning of fraction evolved, thanks to the use of the tools (squared strip of paper, and number line) and to the designed tasks.

ACTIVITY 2, SESSION A. A certain unit of measure is given (for instance, a unit measure corresponding to 15 squares). The students are asked to position it on the *strip of squared paper* and to place and color on the strip unit fractions like 1/5,1/3, etc.

Figure 1: Four strips of squared paper where students had postioned a certain unit of measure and had defined unit fractions and colored fractions (4/5, 2/3, 5/3, 7/5)

With respect to the kinesthetic-tactile aspects that characterize activity 1 (partitioning of the A4 sheet of paper in equal parts), the manipulation of the artifact "squared strip" becomes a prevalently perceptive experience, in which the main channel for accessing (and possibly producing) information is the visual non-verbal one. Therefore the task (implicitly) requires the use of a procedure in which the fraction is conceived as an operator: the students partition the strip and produce linguistic signs associated to the name of the fraction expressed in verbal language ("Un mezzo" – tr. "One half"), in verbal visual language (the writing "un mezzo" – tr. "One half") and arithmetical language ("1/2"). The teacher institutionalizes the relationship between the different signs (partitions of the strips, visual verbal, visual non verbal, and arithmetical signs) in terms of rational numbers. Thus, the construction of meaning related to the notion of rational number, is based on the interplay between different types of semiotic sets (Arzarello, 2006). Note that the task was completed by all groups of students.

ACTIVITY 2, SESSION B. Each group of students is asked to choose a unit of measure, reproducing it on a strip and placing the fraction 1/2 on the strip. Then, their strips are compared. The dependence of the fraction on the unit of measure, observed comparing the results of the different groups of students, becomes explicit during a classroom discussion, from which we include an interesting excerpt:

Student 1: Maybe we made a mistake.
Student 2: No, we did not make a mistake, I am sure I folded the unit in half, so it's ½.
Student 3: We shouldn't look at the length, because each group chose a different unit of measure. [...]
Students 4: Because doing ½ is cutting in half, so if the units are different the halves are different [...] we have to be careful because to understand which counts more we can't put them one on top of the other like we did for the placemats.

Here a shared meaning is being developed for the fraction as an operator on a chosen unit of measure (1/2u). Note that the kinaesthetic-tactile approach in which the strips were put one beside the other is no longer effective for comparing fractions.

ACTIVITY 2, SESSION C. The task asks to choose a unit of measure to represent on the same strip different unit fractions like 1/3, 1/6, 1/8, 1/2, 1/4.

The parameters defining the situations are such that the situation makes it necessary to choose 24 squares (corresponding to the *lcm* of 2, 3, 6, 8 and 4) as the unit of measure. In fact the children do not simpy looked for the unit of measure spontaneously, generally using trial and error methods, but they also check the efficiency of their choice. Moreover, positioning on a single strip different fractions, makes the ordering of fractions quite similar to that of the other numbers that are perceptively evident (Figure 2).

We note here that for the different fractions on the strips (Figure 2), the teacher asks to also associate color to the verbal, figural and arithmetical representations. The reason is that, as suggested by Stella and Grandi (2011), the verbal channel is not the preferred one for most students with MLD. Color becomes a tool supporting working memory and possibly also long term memory, through which the meanings developed

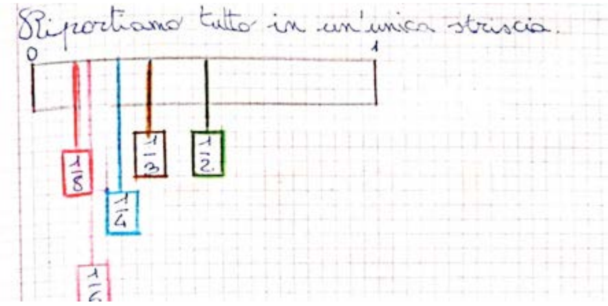

Figure 2: different fractions on the same strip

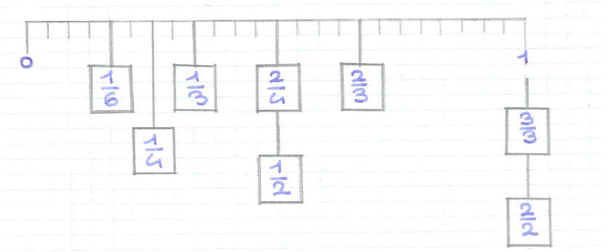

Figure 3: Fractions on the number line

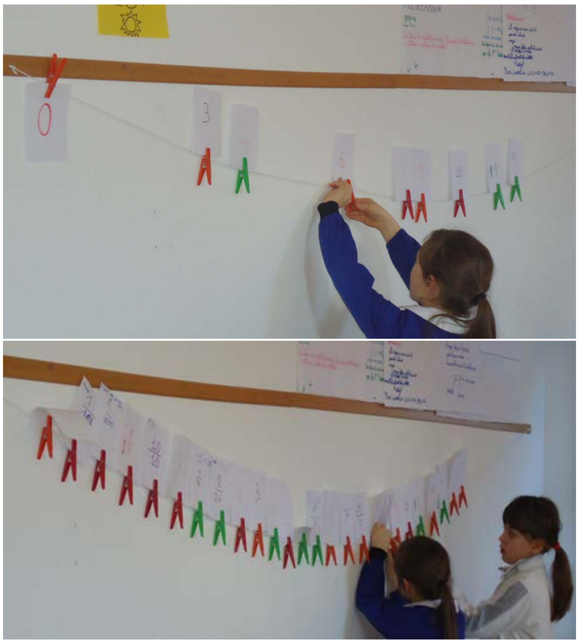

Figure 4: String on the wall where the position of the unit is made to vary dynamically sliding the corresponding label attached with a clothes' peg

can be recalled and used (Baccaglini-Frank & Robotti, 2013).

ACTIVITY 3. The objective of this activity is to place and order fractions on the number line (Figure 3) that has been partially constructed in Activity 2 and that is now used by the teacher as a tool of semiotic mediation (according to Bartolini Bussi & Mariotti, 2008). This transition is fundamental: the representation of the artifact "strip of paper" becomes a mathematical sign that represents the mathematical object "the number line".

Actually, from now on color is no longer used and the labels are referred to points on the number line. We can therefore claim that fractions here have assumed the role of rational numbers. The teacher could take advantage of this transition to construct a new tool of semiotic mediation, developed from the preceding artifacts. The "narrow strip" now becomes a concrete artifact (Figure 4): it turns into a piece of string on the wall, upon which 0 is placed at the left end and the position of the unit is made to vary dynamically sliding the corresponding label attached with a clothes' peg. The dynamic component of this artifact recalls certain software (such as AlNuSet, GeoGebra, Cabri2...) of course with evident differences, including the fact that as the unit (the position of the paper card with written "1") is made to vary, the positions of the other whole numbers and fractions do not vary dynamically at the same time or automatically, as a consequence of the new placement of the unit: their motion requires a specific action in order for the numbers on the line to maintain the desired mathematical relationships. This feature can actually be exploited to foster the students' appropriation and *active control* of important mathematical meanings at stake, such as the density of rational numbers or the ordering of fractions on the number line during activities like this one.

CONCLUSIONS

We have outlined particularly significant (and delicate) passages of the sequence of activities, showing how the transition was guided. Initially the students were exposed to a somewhat traditional conception of fractions as operators in the context of partitioned areas (the "part-whole" meaning described in Bobis et al., 2013). This idea was soon re-invested in a slightly different context: the areas became strips that gradually lost their "fatness" and were narrowed down until they become (oriented) segments indicating distances from the origin of the number line. The power of an approach like the one described resides in how such a transition can be gradual and continuous, if the teacher manages to keep alive the situated meanings that emerge throughout its unraveling. This is in fact what happened, and the children (including those certified with MLD) came to deal with fractions as numbers on the number line, without hesitating to compare them, place equivalent fractions on the same point, and add them, according to meanings they had developed using the strips of paper that still had an area.

In summary, the analysis of the teaching intervention has shown that students have elaborated personal meanings consistent with the mathematical meanings related to fractions. In particular, the strip was used as instrument of semiotic mediation to develop the meanings related to fractions as operators and, then, to the ordering of fractions, to equivalent fractions and finally to equivalence classes. The use of the strip, the string and color (for a certain period of time), has had a key role in favoring the construction of the number line as a mathematical object. On the number line fractions, associated with points, could assume the role of rational numbers being representatives of equivalence classes. Finally, it is possible that this kind of construction of meanings related to fractions might also support the management of procedural aspects involved in operations with fractions, as various researches both in mathematical education and in cognitive science have already suggested (Siegler, 2013; Robotti, 2013; Robotti & Ferrando, 2013). Further studies are needed to explore and to confirm this hypothesis that we consider significant both for research and for teaching.

We would like to greatly thank all the teachers of the "Questione di numeri" project who have realized, together with the first author, this research study.

Although the trends seem to be shifting, researchers have given far less attention to the work of teaching mathematics in kindergarten than to children's learning. This paper aims at contributing to this under-developed area by focusing on one particular task of teaching mathematics: asking productive mathematical questions. From analysis of a situation that involves Lego play, we attempt to decompose the different kinds of mathematical questions asked and thus contribute to the further conceptualization and understanding of this particular task of teaching mathematics in kindergarten.

Keywords: Kindergarten, mathematics, teaching, productive mathematical questions.

INTRODUCTION

Children's learning of mathematics has been studied for decades; the teaching of mathematics to children below school age has been studied much less. Whereas numerous theories have been developed in order to describe different aspects of mathematics learning, few theories describe mathematics teaching. Almost three decades ago, Lortie (1975) called for a language to describe the work of teaching, and a language and theory of teaching is still called for – especially in kindergarten.

When developing a practice-based theory of mathematical knowledge for teaching (MKT), Ball, Thames and Phelps (2008) focused on "recurrent tasks of teaching". In the work of teaching mathematics, teachers are faced with different challenges, and these are referred to as tasks of teaching. An example is "asking productive mathematical questions" (Ball et al., 2008, p. 400). Teachers are continually challenged to ask questions that stimulate further mathematical thinking among children. Is this challenge similar in kindergarten? Identifying and investigating such tasks of teaching might provide a common foundation for further conceptualizations of knowledge needed for teaching mathematics (Hoover, Mosvold, & Fauskanger, 2014), and this paper represents an attempt to further investigate the task of asking productive mathematical questions in a Norwegian kindergarten context. We approach the following research question: How can the task of asking productive mathematical questions be manifested in a Norwegian kindergarten context?

Based on studies in the US, Ginsburg and Amit (2008) argued that teaching mathematics in kindergarten is similar to teaching mathematics in school. Other studies suggest that the work of teaching mathematics differs across kindergarten contexts (Mosvold, Bjuland, Fauskanger, & Jakobsen, 2011). Further investigations of the work of teaching mathematics are thus needed, both in order to develop more comprehensive theories of teaching mathematics in kindergarten and to learn more about similarities and differences in the work of teaching mathematics in different kindergarten contexts. In our attempt to approach this challenge, we focus on the challenge of posing productive mathematical questions. This is arguably a central task of teaching mathematics – also in the kindergarten context – and we aim at contributing to the further unpacking of this task. We draw upon exemplary data from a Norwegian kindergarten context, where a kindergarten teacher interacts with six children in an activity involving Lego play. The activity is analyzed with a focus on tasks of teaching as conceptualized by Ball and colleagues (2008). In the following section, we present some trends from research on teaching mathematics in kindergarten as well as previous research and theories related to asking questions.

THEORETICAL BACKGROUND

Traditionally, research on early years mathematics has had a strong emphasis on children and their learning and understanding of mathematics. In the last decades, however, research on the early childhood mathematics teacher has flourished. Some studies focus on the knowledge and beliefs of the teachers (e.g., Schuler et al., 2013), whereas other studies investigate the actual work of teaching mathematics in a kindergarten context (e.g., Carlsen, 2013). In mathematics education, a large amount of research has focused on the knowledge needed for – or used when – teaching mathematics (see e.g., Rowland & Ruthven, 2011). Relatively speaking, much research has focused on mathematics teachers in school; far less research has focused on teaching mathematics in kindergarten. The study by Ginsburg and Amit (2008) represents one of few examples of the latter, and these researchers argue that teaching mathematics in kindergarten is mostly similar to teaching mathematics in school.

When investigating mathematics teaching, there are different possible approaches (for an overview, see Thames, 2009). One possibility is to identify and describe issues regarding the mathematical content of what is being taught; another possibility is to identify the work of teaching that is distinctively mathematical. Our study, although related to both of these two, represents a somewhat different approach in that we analyze the work of teaching in an attempt to identify the mathematical demands. In doing this, however, we also investigate the nature of the mathematical tasks of teaching that are involved in the work of teaching – in particular related to asking productive mathematical questions.

A goal with mathematics teaching at all levels is that children (or adults) learn to think mathematically; some describe this as a process of mathematizing. In order to reach this a goal, an environment needs to be created where conjectures can be put forward and discussed without fear of being ridiculed, and children need to be engaged in such mathematical discussions (Lampert, 1990). When creating this kind of environment, the kinds of questions mathematics teachers ask are of importance. By asking the right mathematical questions, the teacher can create a supportive atmosphere in which the children further develop their mathematical thinking and start thinking like mathematicians (Mason, 2000). In a mathematics classroom, teachers ask different kinds of questions. Some questions are open and aimed at stimulating further inquiry, whereas other questions are more closed – oftentimes serving as control questions (cf., Carlsen, Erfjord, & Hundeland, 2010). There also seem to be cultural differences in the questions mathematics teachers ask in classrooms. In their study of questions asked in 1st grade mathematics classrooms in Japan, Taiwan and the US, Perry, VanderStoep and Yu (1993) found that teachers in the Asian countries asked more questions about problem solving strategies and conceptual knowledge than their colleagues in the US. Subsequent studies seem to confirm these findings (e.g., Hiebert et al., 2003), and international assessments like TIMSS and PISA show that children from these Asian countries outperform children from most countries in the Western world.

In a kindergarten context, Carlsen and colleagues (2010) found that the kindergarten teachers' frequent use of questions enabled children's participation in the learning activities. They did, however, also find that kindergarten teachers often asked questions that were not true questions. This coincides with a more recent study where Carlsen (2013) found that a kindergarten teacher mainly used structuring questions in her orchestration of a mathematical activity involving the telling of a fairy tale. From these studies, it can be argued that the questions asked by kindergarten teachers oftentimes serve as a means of reaching joint attention, and numerous studies in psychology contend that joint attention is of vital importance in children's learning. When Bruner and his colleagues started investigating this issue in the late 1950's, they mainly analyzed newborn babies or young children with a focus on their eye gaze (Bruner, 1995). A narrow understanding of the concept of "joint attention" would thus simply be whether or not an individual is looking where someone else is looking (Sigman & Kasari, 1995). A broader definition includes responsive and initiating behaviors as well as facial expressions and gestures. Baldwin (1995) defines joint attention with the mutual awareness in mental focus that two or more individuals have when looking at the same thing. A key issue then is that the mutual awareness must be in the mental focus – not only that two people stare at the same thing. Sigman and Kasari (1995) argue: "joint attention must involve an integration of information processing and emotional responsiveness" (p. 190). Studies like that of Tomasello and Farrar (1986) show that joint attention has a central role in children's early language learning, but it is arguably important in early years mathematics learning as well.

Given that joint attention has a central role in young children's learning, a natural follow-up is to ask about the role of the adult in this. The process of reaching joint attention has been referred to as a tutorial process (Wood, Bruner, & Ross, 1976), where an adult or "expert" helps somebody who is less skillful. A crucial feature of such interactions, it can be argued, is the adult's ability to make joint attention (Bruner, 1983). In earlier works, Bruner focused on joint attention in relation to language development and learning (Bruner, 1983); later he described the role of the adult in terms of scaffolding (Bruner, 1995). In this study, we follow Baldwin's (1995) understanding of joint attention in that it includes a mutual awareness of mental focus. We suggest that the questions posed by kindergarten teachers – and thus also the task of asking productive mathematical questions – could be understood in terms of reaching joint attention. When we investigate the task of asking productive mathematical questions, we therefore suggest that the process of joint attention needs to be an integrated aspect.

METHODS

In order to investigate kindergarten teachers' mathematical questions, we asked a kindergarten teacher for permission to video record an everyday activity that involved something he associated with mathematics. The kindergarten teacher decided to organize a situation of Lego play with six children from his kindergarten class (his class included a total of 18 children aged 3–6 years). The kindergarten teacher and the children sat around a table that was filled with classical Lego bricks of different shapes and colors; the children could play freely with the bricks. The first author recorded the session as illustrated in Figure 1.

The kindergarten teacher had 17 years of experience, and he finished his education before mathematics was introduced as a required course in Norwegian kindergarten teacher education. The six participating children were between 3,11 and 5,4 years of age (the decimals represent months). We refer to the children by fictitious names; the kindergarten teacher is referred to as "Teacher". The Lego play activity lasted 22 minutes, and the researcher had the role of a passive observer. Neither the kindergarten teacher nor the children seemed to take much notice of the researcher or his camera. Afterwards, the video was transcribed verbatim, and the transcripts were coded by the use of conventional content analysis (Berg & Lune, 2012), where the unit of analysis was the kindergarten teacher's questions.

RESULTS AND DISCUSSION

The activity begins with the kindergarten teacher gathering the children around the table to introduce the Lego activity. He explains that they are going to play with the Lego bricks, and someone (the first author) is going to record the activity in order to learn more about what they are doing. The children eagerly start playing with the Lego bricks. Shortly after, a first question is posed to the teacher:

8. Kaja: (holds up one red and one blue brick and turns to the teacher) Have you found one of those or one of those?

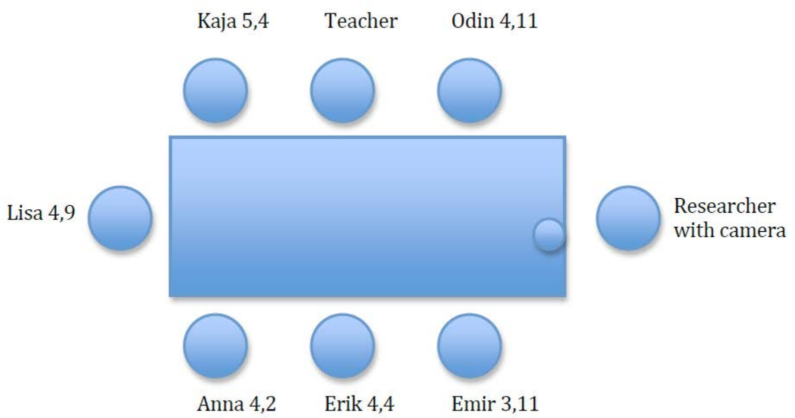

Figure 1: The placement of the participants in the Lego-activity

9. Teacher: One of those? (scratches his chin) What do you mean with "one of those"?
10. Kaja: Two of those (holds up the bricks again)
11. Teacher: Yes... (Odin hands the teacher a red brick, and the teacher holds it up) What does it look like?
12. Kaja: Table?
13. Teacher: Do you see what they look like?
14. Kaja: Triangle!
15. Teacher: Triangle, yes. But look, I'll show you something funny. If you ... put them together (puts two blue and one red brick together on the board). If we had one more of those, what would it have become then?
16. Kaja: Taaaaaable ... round [shape] (looks at the teacher)
17. Teacher: A round shape, or simply a circle.

Among the mathematical tasks of teaching, Ball and colleagues (2008) listed "responding to students' why-questions". The question posed by Kaja in the beginning (8) is not such a why-question, but we notice how the teacher uses the question as a starting point for posing another question (9) in order to direct the children's attention towards the mathematical concept that can be used to describe the bricks. His question can be described as an invitation to use more precise concepts than "one of those", and this could serve as an example of a productive mathematical question in a kindergarten context. When Kaja first responds by holding up the bricks instead of providing a more precise concept (10), the teacher asks her to describe what the brick looks like (11). As a response to this question, Kaja eventually says: "triangle" (14). The teacher confirms her answer and repeats what she said (15) – although the brick is not a triangle but a triangle-like shape with one round edge.

Even though there are six children in the activity, Kaja (5,4) is the only active participant in this part of the discussion; Odin (4,11) also contributes by finding the desired bricks, but his contribution is non-verbal. When Kaja responds to the teacher's follow-up question by saying that it would become a table (16), he introduces the concepts of "round shape" and "circle" as alternatives (17). This can be seen as an example of the task of using appropriate mathematical language, and we can also say that the dialogue in this excerpt indirectly contains the challenge of "choosing and developing useable definitions" (Ball et al., 2008, p. 400). Instead of using a more correct mathematical definition for a triangle – where the sides have to be straight line segments – the teacher decides to accept Kaja's description of the shape as a "triangle" (15).

Later in the discussion, when Kaja finished building her circle shape with two red and two blue bricks, Lisa (4,9) asks for the same kind of bricks:

41. Lisa: I need one more red and two more blue.
42. Teacher: Triangles like that? (points towards Lisa's board) But isn't it a little bit strange that ... they. How many are there here? (picks up Kaja's board to show)
43. Kaja: One, two, three, four (counts out loud while pointing)
44. Teacher: Four triangles. But isn't it a little bit strange that those triangles make a ...
45. Lisa: Circle
46. Kaja: Circle
47. Teacher: How is it that a circle can become a triangle? Or, triangles become a circle?
48. Kaja: We just ... (points to the board)
49. Lisa: The triangles have such round there.
50. Teacher: That edge ... side is a little bit round, yes.

We notice that the teacher follows up on Lisa's request by directing her attention using the word "triangle" and pointing (42) to reach joint attention. The teacher continues to ask questions while pointing at Kaja's board – which is finished – focusing on the quantity. We assume that the teacher is aware that the children know how to count, and his question about how many bricks can then be seen as an invitation to count. Ball and colleagues (2008) identified a similar task as: "connecting a topic being taught to topics from prior or future years". Kaja counts and finds out that four "triangles" are needed in order to build a circle (43).

Within a sociocultural kindergarten tradition (like the Norwegian kindergarten), the kindergarten teacher's knowledge and ability to ask questions are significant. Carlsen, Erfjord and Hundeland (2010) argued that the teacher's questioning is of vital importance for children's learning, and they found that almost half of the questions posed were open questions where the children are encouraged to present a solution themselves. The teacher in our study also poses a lot of questions, and through this questioning we gain knowledge of the children's development of number concept as well as their knowledge of shapes.

The teacher continues to pose questions, and his next question can be seen as an effort to re-focus the children's attention towards the seeming paradox that four "triangles" can make a circle (44). Both Kaja and Lisa are now referring to the shape as a circle (45 and 46) rather than table or round shape – indicating that they have adopted the kindergarten teacher's use of a more precise concept. When asked about how the "triangles" can become a circle (47), they do not respond verbally but points to the board instead (48). This situation could have been used to reach a more precise definition of a triangle, but the kindergarten teacher does not go in that direction. Instead, this part of the dialogue ends by the teacher confirming that the "triangles" have a round edge (50). Instead of stating that these particular "triangles" are in fact circular sectors – or quadrants – and four of them put together thus make a circle, the teacher leads the children into a mutual reflection about the shape of the bricks and how they can be used to create a new compound shape (circle). This also illustrates another task of teaching related to selecting representations for particular purposes – in this case using the Lego bricks to discuss shapes. Presentation and discussion of non-examples like this can be important in children's formation of solid concept images that go beyond the prototypical triangle (Levenson, Tirosh, & Tsamir, 2011). In this case, the children identified these particular Lego bricks as triangles although they are in fact non-examples. The children rely on visual reasoning, and the kindergarten teacher could have used the situation as a starting point for discussing more examples and non-examples and helped the children towards where they notice differences between shapes (ibid). From these examples, we have seen that the task of asking productive mathematical questions includes a number of intertwined challenges – or tasks – for the teacher.

CONCLUDING DISCUSSION

Ball, Thames and Phelps (2008) identified "asking productive mathematical questions" as one of the recurrent mathematical tasks of teaching. We argue that asking productive mathematical questions is indeed a relevant task of teaching mathematics also in a kindergarten context. From our analysis of this play situation in a Norwegian kindergarten, however, we suggest that the task of asking productive mathematical questions is highly complex. In this concluding discussion, we point at three issues that add to the complexity. First, there are different types of questions that might be asked to facilitate children's further reflection and exploration of mathematics. Second, there are different possible purposes that underlie the asking of questions. Third, the task of asking productive mathematical questions is often intertwined with other tasks of teaching, and the kindergarten teacher needs to address these tasks instantly as they appear.

In their analysis of kindergarten teachers' questions, Carlsen and colleagues (2010) found that the teachers posed open questions, asked for arguments, invited to problem solving, re-phrased children's utterances, and made conclusions. These types of questions could also be identified in the play situation analyzed here. When we have focused specifically on the mathematical demands, however, we can observe the following aspects in the questions:

- encourage use of more precise mathematical language
- confirm use of more precise mathematical language
- describe what children observe with their own words
- mathematical reflection about a more compound problem
- mentally complete an observed pattern or unfinished shape
- encourage reflection about observed patterns and connections
- invite to count

This list represents an attempt to decompose the task of asking productive mathematical questions, but it can also be seen as an attempt to identify the teacher's underlying purpose in asking these types of questions. It is difficult, however, to make conclusions about purpose from observations of activities and conversations only. In this study, our focus was on tasks of teaching that could be observed from discussions between the kindergarten teacher and the children. We have thus analyzed the observed work of teaching without bringing in the voice of the teacher concerning his intentions. Introducing the teacher's voice from a follow-up interview could have been interesting, however, but that would be beyond the scope of this paper – where our focus was strictly on unpacking the observed tasks of teaching. Interviews with the kindergarten teacher could, however, provide further information about teachers' beliefs and knowledge that would also be relevant to investigate.

Although we have investigated the data with a focus on the task of asking productive mathematical questions in particular, we have also seen that several other tasks of teaching are oftentimes intertwined in this task. When asking children to use more precise mathematical language, for instance, the kindergarten teacher could also face the task of choosing and developing usable definitions. Being faced with the apparent paradox of how four "triangles" could make a circle, the kindergarten teacher would have to make decisions about whether or not he should go into a discussion about the proper definition of a triangle. If he were to go into such a discussion with these children, however, he might also have had to deal with the concept of polygons and straight line segments, and this would probably be beyond the topics he intended to teach. On the other hand, avoiding the more precise definition at this stage could lead to misconceptions that would have to be dealt with later on, and this illustrates the complexities involved in the work of teaching mathematics in kindergarten.

An additional challenge that can be seen in several parts of this dialogue is related to joint attention. At all stages, but perhaps in particular with smaller children, the teacher is faced with the challenge of reaching joint attention. Several questions, comments and even gestures made by the kindergarten teacher can be seen as acts of reaching joint attention, and we argue that the issue of joint attention is embedded in all tasks of teaching mathematics in kindergarten.

In this paper, we have tried to contribute to the unpacking of one particular task of teaching mathematics: asking productive mathematical questions. We have seen that this task is complex, as we have already discussed, and we believe that it is also context specific. Asking productive mathematical questions to kindergarten children probably involves other kinds of challenges than asking such questions to children in lower secondary school, but the task of teaching is still relevant at all levels. We thus support the argument made by Hoover and colleagues (in press) that mathematical tasks of teaching "can serve as a common foundation for conceptualizing and measuring mathematical knowledge for teaching" (p. 101) – also in kindergarten – but we suggest that further studies are needed in order to investigate and unpack the tasks of teaching mathematics in different contexts and at different levels.

Kindergartners measuring length

Chrysanthi Skoumpourdi

University of the Aegean, Mytilene, Greece, kara@aegean.gr

The present paper will clarify kindergartners' informal ability and spontaneous strategies when using different materials in order to measure and quantify length. The results validated the fact that there are some sub components of young children length measure informal ability which are of some interest. These are kindergartners' strategies for measuring length, their confusion on the concept of length with the perimeter and the area, the nature of the measurement result, as well as, the relation between the measuring material and the measured object.

Keywords: Length measurement, measurement unit, measurement materials, kindergartners.

INTRODUCTION

Geometric measurement is a crucial topic in mathematics (Smith, van den Heuvel-Panhuizen, & Teppo, 2011) due to the fact that it connects mathematical domains with each other (number and geometry) as well as, real life. Length measurement is a fundamental concept for students' geometric measurement learning. On one hand it is a comprehensible attribute for young children and on the other hand numerous other concepts rely on it. Students' main ideas, concepts and skills on area and volume measurement are constructed through length measurement (Tan-Sisman & Aksu, 2012).

Learning length measurement is a slow and evolving process and young children do have the capacity to understand and learn this attribute (Sarama, Clements, Barrett, van Dine, & McDonel, 2011). There are eight main concepts that are fundamental for children's understanding of length measurement (Clements & Sarama, 2007): 1. Understanding of the attribute of length. 2. Conservation of length. 3. Transitivity. 4. Equal partitioning of the object to be measured. 5. Iteration of the unit; the placing of the unit end to end alongside the object and the counting of these iterations. 6. Accumulation of distance; the number words of the counted iterations signify the space covered by the units up to that point. 7. Origin; any point on a ratio scale can be used as the origin, 8. Relation between number and measurement. These concepts are developed according to age and in a sequence that is not commonly accepted yet, since they are influenced by instruction and experience.

Length measurement is included in most curriculums (ΠΣΝ, 2011; Smith, Tan-Sisman, Figueras, Lee, Dietiker, & Lehrer, 2008) from pre-kindergarten and its study usually promotes a sequence of instruction that is based on Piaget's theory of measurement. These series include: use of words that represent quantity or magnitude, (direct and indirect) comparison of length, measuring of length with nonstandard units and with manipulative standard units, as well as, measuring with a ruler and other standardized tools. However, recommendations to this progression, propose the beginning of the instruction with standard units and rulers, for an initial understanding of measurement, and a later introduction of nonstandard units (Clements, 1999), as a result of the fact that children are able to use standard measuring tools before they fully understand them (van den Heuvel-Panhuizen & Elia, 2011). Therefore, Sarama and Clements (2009) proposed an early childhood learning trajectory of length measurement, which follows a developmental progression: 1. Pre-length quantity recognizer. 2. Length quantity recognizer. 3. Length direct comparer. 4. Indirect length comparer. 5. End-to-end length measurer. 6. Length unit relater and repeater. 7. Length measurer. The revised learning trajectory proved that (Sarama et al., 2011) the 7th level does not exist and the 4th and 5th levels are developed simultaneously.

Most of young children pass into and through the end-to-end length measurer level in which they use several units or begin to iterate a unit while leaving gaps between units. The students' errors that are most reported (Tan-Sisman & Aksu, 2012), during the learning procedure of length measurement, are: overlapping units, mixing units of length with other units of measurement, confusing the concept of perimeter with area, incorrect alignment with a ruler, starting from 1 rather than 0, counting hash marks or numbers on a ruler/scale instead of intervals and focusing on end point while measuring with a ruler.

Research results, on what young children are able or incapable to accomplish in length measurement, are not always in agreement. Several researchers (Barrett, Jones, Thornton, & Dickson, 2003; Clarke, Cheeseman, McDonoug, & Clarke, 2003; Clements & Sarama, 2007) proved that children as young as preschoolers know about the existence of length, distance, area, weight etc and they have an informal understanding of them. They confirmed that kindergartners are capable to perform direct comparison of objects and order objects according to their length. They explained that preschoolers are not capable of reasoning about the attributes of length, distance, area, weight etc and measure them accurately and that kindergartners are not able to use units to determine the length of an object.

Sarama and colleagues (2011), demonstrates that although no pre-kindergartner was able to consistently measure objects end to end, or iterate a unit along a length, kindergartners were able to do it. They were capable of arranging units end to end (without spaces or overlaps between units), count the number of units, as well as to state correctly the total length measured in terms of that unit. On the contrary, none of the children of kindergarten used a ruler consistently to measure length, despite repeated introduction in various teaching experiments. A different study (Castle & Needham, 2007) indicates that, at the end of the first grade, less than half of the class demonstrated the ability to iterate units. The above results signify that research outcomes are not entirely consistent with young children's capabilities to measuring length.

Kindergarten children face a great difficulty in length measurement tasks when tasks are of high complexity and require the mental use of the length measurement unit and unit iteration, as well as, complex ordering abilities (van den Heuvel-Panhuizen & Elia, 2011).

In this paper, the informal ability and the spontaneous strategies of kindergartners to realize measurement tasks using a variety of materials are investigated. We wondered if kindergartners were able to use different materials in order to quantify length. The research questions were the following: 1. Have kindergartners the ability to use the provided materials to measure the length of an object? 2. Which strategies they use to measure length and how are they related to the different materials? 3. Which of the materials were used more effectively?

METHOD

In order to investigate kindergartners' informal ability and spontaneous strategies to quantify length with the use of various materials for measurement, data were collected from 20 kindergarten children (10 girls and 10 boys) (4 years and 9 months to 6 years and 6 months) from a public kindergarten in Rhodes, Greece[1]. This kindergarten was chosen for two reasons. The first was that there is a frequent cooperation with the teacher who likes integrating innovations in her teaching and her students are used in teaching experiments. The second was that the children in that classroom were able to compare two objects directly and recognise their equality or inequality and they were also able to order objects according to their length.

For the purpose of the study, kindergartners were asked to measure the length of several objects' iconic presentations by using eight usual measurement tools and to note on a piece of paper, their size. The images were related to a story familiar to students and had rectangle-like-shape (stair, paper clips, a part of a road, frame, mirror) or oblong irregular shape (tower, lighthouse, shark). The materials used for measurement, were nonstandard manipulative units, standard manipulative units and standardized measurement tools. Specifically, the materials were of four types: 1) discrete items, such as 1cm cubes, 2cm cubes, same sized matchsticks, paper clips and anglegs which may be considered as measurement units, 2) continuous material, such as a piece of string, in which the appropriate size must be generated by the child, 3) combined materials, such as Cuisenaire rods, which may be considered as measurement units or continuous material and 4) composite material, such as a ruler, in which its (conceptual) organization into units or 'chunks' may be used for quantifying the size

1 Kindergartens in Greece include students from 3 years and 9 months to 6 years and 6 months old.

of an object in a standardized way. The length of the different iconic representations was measured with different types of materials.

The tasks were the following:

Task 1: Can you measure the length of the shark with these (2cm cubes)?

Task 2: Can you measure the length of the stair with these (Cuisenaire rods[2])?

Task 3: Can you measure the length of the frame with these (1cm cubes)?

Task 4: Can you measure the length of the tower with these (anglegs[3])?

Task 5: Can you measure the length of the frame with this (string)?

Task 6: Can you measure the length of the lighthouse with these (matchsticks)?

Task 7: Can you measure the length of the road with these (paper clips)?

Task 8: Can you measure the length of the mirror with this (ruler)?

The research was a case study and the unit of coding was each child's strategy based on the type of material used. Each child was interviewed alone in a separate room and the process was videotaped. Principles of ethics were taken into consideration.

RESULTS

The students' strategy was recorded in relation with the type of the material used for the measurement of each object (Table 1).

In the tasks 1, 3, 4, 6 and 7, where discrete items were used, the students acted in three different ways, which were common in all five tasks: *linear placement* strategy, *perimetrical placement* strategy and *spatial placement* strategy. The *linear placement* strategy was of two kinds: *linear placement without gaps* and *linear placement with gaps*. In the *linear placement without gaps* strategy, the children arranged the discrete items, in a linear way, either end-to-end with the object (Figure 1 & 2) or not (Figure 3). In particular, they either connected them in a line before arranging them or just placed them linearly in a systematic way.

Figure 1

Figure 2

Figure 3

Although, there were children who measured length in a right way, not all of them gave the right quantitative answer. They noted other numbers or series of numbers. In these cases they tried to count the items they used, but not always in a systematic way. In one particular case, a child, while counting, unitized the object, along the anglegs, by rhythmic movements of his index, whereas not always in a constant way. Except the quantitative answers, children notated either the name of the object to be measured or letters. There were also children that did not answer anything or mentioned the colours of the items used. These types of answers were also provided in all of the following tasks.

The *linear placement* with gaps strategy was the same with the previous one, but students left gaps between the linear arranged items or they began placing the blocks below the top of the object and stopped just before the end of it. The gaps between the 1cm and 2cm cubes, in most of the cases, were due to the lack of cubes connection.

The position of the discrete items in a not linear, but perimetrical way, drove to the *perimetrical placement*

2 The Cuisenaire rods are math learning aids for students that provide a hands-on way to explore math concepts as length measurement.

3 The AngLegs come in different lengths allowing students to explore math concepts such as length measurement.

strategy in which object's perimeter was covered by the items (Figures 4–6). In some occasions, only a part of the object's perimeter was covered because of the items' limited number (Figure 7). A kind of perimetrical strategy was the *perimetrical dragging* strategy, used by only one child. She was always dragging one of the items perimetrically to the object.

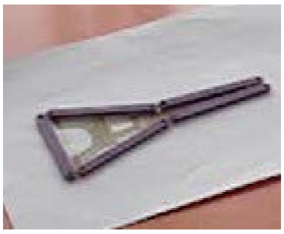

Figure 4

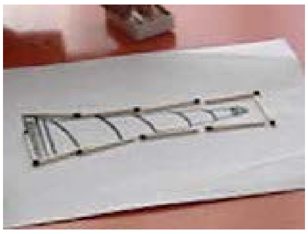

Figure 5

Figure 6

Figure 7

Children in many cases placed the items on the objects' surface instead of placing them linearly. Like perimetrical strategy, in *spatial placement* strategy, items were not adequate to fill the surface and for this reason kindergartners covered just a part of it (Figure 8). The spatial placement strategy differed when children measured with matchsticks and paper clips, due to the fact that their placements were of two kinds: horizontal (Figure 9) and vertical (Figure 10). These placements may have been favoured by the type

Figure 8

Figure 9

Figure 10

of material, which was not symmetrical, like cubes, but elongated.

In task 2, combined materials were used, and students acted in the same three ways as mentioned above: *linear placement* strategy, *perimetrical placement* strategy and *spatial placement* strategy. All strategies were as formerly described whereas with a significant differentiation. Since there was lack of materials in the same size, children had to decide what to select: a big one to manipulate it like a continuous material or small ones (with the same size or not) to manipulate them as counting units. The children chose one, two or three equal or unequal sized items that were: long as the object's length, smaller than the object's length, bigger than the object's length (Figure 11). Similarly,

Figure 11

Figure 12

Figure 13

there were occasions that the children chose many unequal sized items placed perimetrically to the object (Figure 12) or on its surface (Figure 13).

The children, in order to reply to the query, counted the pieces of the materials used. In one particular case, a child placed his finger at the one end of the object, while having underneath the already placed materials, counting 'one', then skipped his finger counting 'two', 'three', ... However, the distance skipped was not always stable. This student was the one who unitized the object, along the anglegs and the string. *Perimetrical dragging* strategy was used by a child, also in this task.

In task 5, in which continuous material was used, the students acted in two different ways: *linear placement* strategy and *perimetrical placement* strategy. In the *linear placement strategy*, the children, in most cases, left the string along the object without stretching it. The string was not placed end-to-end to the object but exceeded the length of it from both sides – *middle linear placement* strategy (Figure 14). In a case, a child put the string along the object's length from its end – *edge linear placement* strategy – and a pair of scissors was requested in order to cut the string. The lack of scissors made him unitize the object along the string by rhythmic movements of his index, which he simultaneously counted. This student was the one who unitized the object, along the anglegs. The *perimetrical placement* strategy was the positioning of the string on the object's perimeter. As with the other materials, here too, only a part of the perimeter was covered by the string, because of its limited length (Figure 15).

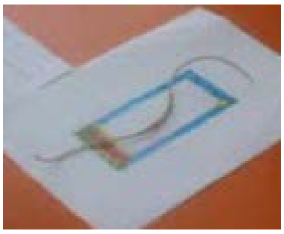

Figure 14

Figure 15

Figure 16

Figure 17

In task 8, a ruler was used as a composite material and students acted in the same way as before: *linear placement* strategy as well as *perimetrical placement* strategy. The *linear placement* strategy was of two kinds: *edge linear placement* strategy and *middle linear placement* strategy. In the former, the ruler was placed on the object's edge (Figure 16), and in the latter, in the middle of the object's length (Figure 17), just like the string's placement. In the perimetrical placement, two children placed the ruler in each side of the object. Students' notes in this task were in general arithmetic. Some children counted the ruler's units in a one to one correspondence with number words, usually inconsistently. In a case, the edge linear placement directed to the right answer – it was the student who unitized objects, along with the anglegs, the string and the cuisenaire rods. The rest of the students' noted a number by chance without counting, or a number that they noticed on the ruler.

Generally, students were consistent in both of the strategies they used and the kind of response they provided, sometimes regardless of the material used for the measurement and occasionally in accordance with the material used. For example, the child who dragged a single material and rearranged it perimetrically to the object performed it in all tasks. In addition, the child who unitized with his finger the

Tasks with discrete items	**Strategy**
1)'2cm cubes' to measure a shark 3)'1cm cubes' to measure a frame 4)'Anglegs' to measure a tower 6)'Matchsticks' to measure a lighthouse 7)'Paper clips' to measure a part of a road	*Linear placement (without gaps or with gaps): For 'Anglegs' Linear placement (with 2 pieces equal to tower's length or 2 pieces sorter than tower's length) *Perimetrical placement (or dragging) *Spatial placement: For 'Matchsticks' & 'Paper clips' *Spatial placement (horizontal or vertical)
Task with combined material	**Strategy**
2)'Cuisenaire rods' to measure a stair	*Linear placement (with 2 or 3 different size pieces equal to stair's length or with 3 different size pieces longer than stair's length) *Perimetrical placement (or dragging) *Spatial placement

Table 1: Tasks, types of material and strategies used for measuring length

linear placed materials, like counting discrete quantities of objects, was constant in his strategy no matter what the material was. Children who arranged items linearly performed it in all tasks. However, a child, who measured most of the objects in a correct manner and rightly quantified the lengths, was puzzled with the use of the string and the cuisenaire rods. He held the edge of the string at the edge of the object and could not decide what to do with the other end. Finally, he placed the string perimetrically to the object. Regarding the rods, he used three different sized items which in total had the same length with the object, while he answered "three". The same child placed the ruler correctly on the object, counted with his finger but his answer was wrong.

It was also observed that perimetrical placement strategy and spatial placement strategy were influenced by the object's image. In one case, covering the perimeter was the same as covering the surface of the object, due both to the objects' shape (shark) and to the material used for measuring (2cm cubes). Furthermore, when the image was rectangle-like and empty inside (stair, frame, mirror), children covered its perimeter whereas when the image was oblong irregular and coloured inside (tower, lighthouse, shark, a part of a road), children tended to cover its surface.

Children quantified length in two different ways: a) counted the (equal or different sized) materials, b) unitized materials by their finger. Their responses varied, except the quantitative ones, which represented the amount of materials used in measurement. The rest of their responses were related with the colours of the materials, letters of the alphabet, number series and the name of the object to be measured.

DISCUSSION-CONCLUSIONS

This study indicated that kindergartners have an informal ability and use several strategies when measuring with a variety of materials. There were children who used the provided materials and successfully measured the length of objects' image, as it is also reported by another research (Sarama et al., 2011). They aligned units that were of equal size without gaps and they counted them. Other times, they placed the materials linearly and unitized them in order to quantify the length. In the latter, the child coordinated discrete and continuous quantity, which is a high cognitive level.

Although research mentions that children are able to use standard measuring tools before they fully understand them (van den Heuvel-Panhuizen & Elia, 2011), in our research we clarified that the majority of students used the measurement materials and tools in a not systematic fashion and were not able to determine the length of an object. This finding is in accordance with other research results, mentioning that kindergartners are not able to use units to determine the length of an object (Barrett, Jones, Thornton, & Dickson, 2003; Clarke, Cheeseman, McDonoug, & Clarke, 2003). They measured length by placing multiple materials that exceeded the length of the object or by attempting to iterate a unit, leaving gaps between units. Some children arranged enough materials to lay from one end to the other across the object without being concerned about their size. When children laid units leaving space between them, they spread them out to make them reach from one end to the other. In many occasions, although all materials were enough to reach from one end of the object to the other, children semi-covered (or cross along) the perimeter or the surface of the object. Children's notes were numbers, letter expressions, colours etc. In a few instances, they combined the numerical data with the qualitative in their verbal communication, mentioning the unit of measurement.

Three were the main strategies that kindergartners used, in order, to measure the length: linear placement strategy, perimetrical placement strategy and spatial placement strategy. These strategies acquire special features depending on the material. With the use of discrete materials, the linear placement strategy was of two kinds: linear placement without gaps and linear placement with gaps. On the contrary when the materials were continuous, like string and ruler, the linear placement strategy was defined as: edge linear placement strategy and middle linear placement strategy. The perimetrical placement strategy was transformed in a case, to the perimetrical dragging strategy. Finally, the spatial placement strategy differed when children measured with non-symmetric items, creating two kinds of placements: horizontal and vertical. The measurement of length by outlining or filling the object by measurement tools has also been mentioned in a study (Castle & Needham, 2007) as a first graders approach. The researchers state that this strategy may indicate their confusion of the different dimensions or that it may be a result of their linear thinking and of a difficulty to conceptualize the object in more than one dimension.

The effectiveness or not of these strategies, seems to be an indicator that students possess an informal knowledge for measuring and quantifying length, in which the teaching process can be based in order to be developed in formal knowledge. The understanding of kindergartners' informal ability to cope with length measurement and the sub components of that capability, can inform teacher's instructional design, in order to support children's learning. This is a crucial point both for helping students to develop their length measurement ability and also to realize the importance of measurement unit, connecting a number to length and specifying what this number represents. For instance, they must understand that a length of 3 is different from the length of 3 cubes, different from the length of 3 anglegs and different from the length of 3 unequal rods: 1 red, 1 green and 1 yellow. Likewise, that the length of five 1cm cubes is the same as the length of 5cm on the ruler. Further research is required to investigate how children interpret their notes regarding the objects' length, should they understand what they have written and what is written by others.

The results of this study, although it was investigative in nature and involved just one kindergarten class, are interesting, because they explore some sub-components of young children length measure informal ability. These can improve our knowledge for kindergartners' ability to cope with length measurement, as well as, to understand why the research results often differ. These are, except of the most reported students' errors, the personal effective strategies that even a kindergartner can use for measuring length, the confusing of the concept of length with perimeter and with area, the kind of the measurement result and most important, the relation of the measuring material with the measured object.

Familial studies in early childhood that involve mathematical situations

Gizem Solmaz

Middle East Technical University in Ankara, Faculty of Education, Ankara, Turkey, gizem.solmaz@metu.edu.tr

This paper aims at giving information about "interactional niche in the development of mathematical thinking (NMT)" (Krummheuer, 2011b). Considering the benefits of playing games, some games were developed within the scope of erStMaL-FaSt that enable children to play with their families. The aim of this study is to analyze mathematical development of children with the immigration background. In a play setting, Tunç played with his father and mother. This paper provides a description of this play setting as well as its results. Based on empirical evidence of a familial play setting, the study provides further details of NMT. This study was conducted with a Turkish family that lives in Germany.

Keywords: Measurement, familial studies, interactional niche, immigration background, mathematics in early years..

THEORETICAL BACKGROUND

The place of geometry and measurement in our lives is unquestionable. Our environment is full of geometrical shapes and we measure objects around us in our daily life. Indeed besides matures even children who are two years old can use mathematical concepts. For instance, a child at the age of two can decide effortlessly whether his friends or his cookies are bigger (Heuvel-Panhuizen & Buys, 2008). No matter how complex these mathematical concepts can be seen, in fact they are used automatically. Children start to measure objects at very early ages (Clements & Sarama, 2007). While measuring, they use very different methods. For example, they make measurements with a ruler or compare objects by using their bodies (Clements & Sarama, 2007). In addition to these, by using their hands they can measure and comment about the length of a table (ebenda). When children engage in practical activities with support from adults, the mathematics embedded in the activities can be addressed and learnt by the children. Thus, it brings a question to mind "What is the role of the parents who spend most of their times with children?" In regards to children's experience with mathematics and geometry, Vygotsky states that, long before going to school children can improve their arithmetic skills and interact with people around them (Baroody & Wilkins, 1999). Children can make division, multiplication, addition, subtraction and can decide size of shapes, images and so on (ebenda).

METHODOLOGY AND THEORETICAL PERSPECTIVE

Considering the benefits of playing games, some games were developed within the scope of erStMaL-FaSt that enable children to play with their families. The aim of this study is to analyze mathematical development when children with immigration background and their parents play games. In order to achieve this goal, games were developed by using mathematical contents like shapes, patterns etc. The most important feature of these developed games was to explore how children learn mathematical subjects. Children were recorded with cameras while playing determined games within the scope of the project. Researchers later watched recorded videos and analyzed the play situations. Project erStMaL-FaSt is a project of the IDeA (Center for Research on Individual Development and Adaptive Education of Children at Risk). This research center is constituted by the German Institute for International Educational Research (DIPF) and Goethe University Frankfurt. The financial support is provided by the Ministry of Higher Education, Research and the Arts from the state of Hessen (for more information: http://www.idea-frankfurt.eu/de).

For the longitudinal analyses and comparisons among different mathematical learning situations, the concept of "interactional niche in the development of mathematical thinking" (NMT) (Krummheuer, 2011b), is used. Krummheuer interprets NMT as, "interactional niche in the development of mathematical thinking" (NMT) consisting of the provided "learning offerings" of a group or society, which are specific to their culture and will be categorized as aspects of "allocation", and of the situational emerging performance occurring in the process of meaning negotiation, which will be subsumed under the aspect of the "situation" (Krummheuer, 2012). NMT – Family, is an elaborated version of NMT offering analytical concepts to capture familial mathematical learning opportunities in early childhood and elementary school ages. Three components of NMT-Family are shown below, which will be elaborated later on, from the aspect of the design of FaSt. NMT-Fast, a developing subtopic of NMT, gives the opportunity to research the importance of families' attendance for pre-school children's learning of mathematical concepts. NMT-Fast consists of 3 components as outlined below in Table 1.

Content: The play situations by erStMal-FaSt are set up to elicit the families' chances for interactive negotiations. In these play situations, from the situational view, the rules of play and/or mathematical topics might be chosen as themes in the period of emerging negotiation.

Cooperation: The collaborating process of child and adult provides more opportunity to cleanse their thinking and to make their performance more beneficial and effective. A different leeway of participation comes up due to this cooperation. Krummheuer uses the term "Leeway" as a colloquial meaning of "room for freedom of action" (Krummheuer, 2012). "Leeway of participation" ("Partizipationsspielraum", Brandt, 2004) is one of the interactionist approaches by which child discovers and explores his/her cultural environment while co-constructing it. Therefore, this is a concept which belongs to the situational aspect. Brandt (2004) defines that the participants interactively fulfill varied margins of leeway of participation that are contributing or limiting the mathematical development of a child (see also Krummheuer, 2011a; 2012).

Pedagogy and Education: Learning paths are described and delineated with developmental theories and theories of mathematics education to study cognitive development. According to folk pedagogy, in the concrete interaction, the participating adults and children become situationally active and operant. Each individual's cognitive development is constitutively bound to the attendance in various social interactions. In the course of these interactions and participations in mathematical discourses, a "support system" which is called as "Mathematics Learning Support System" (MLSS) is proposed as a concept for the learning of mathematics evolving from Bruner's concept of a Language Acquisition Support System (LASS) (Bruner, 1986). MLSS occurs in different ways in the phases and routines of interactions between child and families. During these play situations they convey their knowledge by exemplifying explanation to the statements during negotiation of meaning. Either "the right given instructions" or "the wrong given instructions" by families bring about some different types of support. While the given instructions are being negotiated by children and their parents, they set new interpretations that support the development of the child or influence him/her unfavorably (see Acar Bayraktar & Krummheuer, 2011; Acar Bayraktar, 2014). In respect of all these three components, one

chosen scene will be introduced as an example to show how measurement abilities in the interactional niche in a familial context emerge. In this study, data was collected through video recording. This study is a part of a bigger project which is erStMal-FaSt.

THE PLAY: "WHO WILL BUILD THE HIGHEST BUILDING?"

The chosen play is from the mathematical domain of 'measurement', which is developed according to specific design pattern (Vogel, 2014). Aim of the game is to build the highest building. At the beginning, all blocks are placed on the table. All players take one dice themselves, on which pictures of blocks are present. The

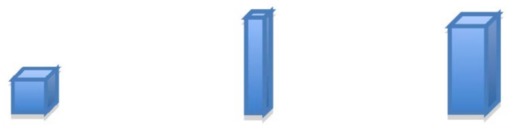

Figure 1

youngest player is to start first. He rolls his dice, then looks at the picture on the top of dice. The figure on the dice should be identified with the matching block from the pile on the table. The player is supposed to set each matching blocks on top of each other so that the highest building can be built without toppling down. In this way, all players try to set the blocks on top of each other by rolling dices in turns. In total, 6 rounds are played the blocks that are already placed cannot be moved or their places cannot be changed. During the game, if any of the player's building topples down, he/she fails and leaves the game. In the end, the player with the highest building wins the game. In the play setting at this study, Tunç plays with both his mother and father. Their play takes about 15 minutes.

The required information about Tunç's family is in the Table 2.

In the play situation, firstly, his father gives Tunç a little information about the game where he demonstrates for Tunç how to pick up the block from the box after he rolls the dice. Then he rolls the dice and asks Tunç about the figure that has occurred. Afterwards he asks Tunç to find this figure in the box, to show him the figure and to put the block on the table. Tunç puts the cube shaped block in front of him. His father wants him to re-roll the dice. He requests Tunç to put the new block onto the first cube shaped block. Then the father confesses to Tunç that they will build a big house by putting blocks on top of each other and that they will continue like this until the blocks drop onto the ground. Then his father explains to Tunç that he has to set the blocks by himself without any help from neither his mother nor his father. His mother adds that everyone will have their own blocks and whoever gets the highest one will win. Afterwards she asks who will start first. Tunç says "me" and starts the game by rolling the dice. Block A comes on the top of the dice. Tunç takes it from the pile and puts it on the table. Then, his mother rolls the dice, gets Block A and puts it on the table. Then father rolls the dice, gets Block B and puts it vertically on the table. Hereafter comes up the transcript of the chosen part of the scene: Table 3 on the next page.

Line 13, 14, and 15: Tunç, by showing a block that he picked up to his father asks him whether it is big. Tunç, by asking this question, may have tried to get a response to whether the block he found is appropriate or not. Or maybe he asked just because he waited to be approved by his father. A possible indication of the latter interpretation is that immediately after posing the question, he responded "Yes" without waiting for his father's feedback. Tunç has put his block horizontally just like his father did it with the previous block. The reason behind this may be that he thinks his father did right or that he may wait for his father's approval by putting it similar to the way his father put. If we look from another perspective, he may have behaved this way because his father did not listen to what his mother told him. In other words, he may have copied his father.

02	01:31	father	**yes**
03	01:32	mother	*looks at Tunç's father* it cannot be such high *takes a block b*
04			than *from the box, regulates* this is high now this is much
05			higher
06	01:37	father	but we must lay a strong foundation, don't we? If I put it so,
07			it can be easily dropped, can't it Tunç? *holds block b*
08			*vertically, makes it horizontally* because of this, father puts
09			so *puts block b horizontally on the table in front of him*
10	01:38	Mother	(not understandable)
11	01:50	Tunç	rolls the dice, handles the box and looks into takes one
12	01:52	Father	**yes!**
13	01:53	Tunç	is this big? No
14	01:54		*takes a block b sets horizontally on his first block a on the*
15			*table in front of him.*
16	01:56	father	ok... *looks at Tunç* it is your mother's turn
17	01:58	mother	*rolls the dice, picks a block b from the box, sets it on her first*
18			block on the table in front of the her
19	02:00	Tunç	*looks at his mother* you have two blocks
20	02:05	father	*rolls the dice* **yes!** *takes a block c, looks at it from side to*
21			side, smiles.
22	02:13	mother	you must put on it you cannot put next to it like that....
23	02:18	father	*put block c vertically next to his first block b*
24		mother	you cannot put two next to each other. like that
25	02:19	father	why cannot be next to each other?
26	02:19	mother	you cannot put two next to each other *hand up vertically* you
27			should put like that
28	02:24	father	why so that I win? *Smiles*
29	02:25	mother	no *smiles*
30	02:27	Tunç	rolls the dice, takes a block c , puts vertically on his corpus
31	02:28	father	**yes!**
32	02:29	mother	*points Tunç* look he does it right
33	02:30	father	**vaov Tunç!**
34	02:31	mother	*rolls dice* I get always small blocks *picks block a from the*
35			box, puts it
36	02:33	Tunç	*(german not understanble)*
37	02:36	father	it's my turn now *rolls the dice* **yes** *picks a block c from the*
38			box, put it vertically on his corpus
39	02:43	Tunç	*looks at his mother* you roll always small *rolls the dice* **yes**
40	02:47	father	what's it, Tunç?
41	02:48	Tunç	*shows figure on the dice to his father*
42	02:49	father	**huge! vaoov!**
43	02:50	Tunç	*looks for a blocks into the box*
44	02:51	father	*pushes the box to Tunç, asks to him* which block matches
45			with the figure
46	02:53	Tunç	*takes out a block c from the box, shows to his father* this
47	02:54	father	yes
48	02:55	Tunç	*puts a block c vertically on his corpus, regulates it*
49	02:56	father	**yes!**
50	02:57	mother	*looks at Tunç* make it robust then not to fall down *rolls dice*
51	03:03	father	but you cannot regulate it so much that Tunç after you put it
52			once, you cannot touch it again
53	03:08	mother	why not? *handles a block b puts it horizontally, then*
54			vertically, then horizontally again
55	03:17	father	*smiles* mother cheats Tunç

Table 3

Line 22: The mother says "you must put it on you cannot put next to it like that. The mother, by saying that, may have tried to remind the father of the rules of the game. The word "must" may cause one to think that there is a rule that has been mentioned. In other words, by saying "you must put on it you cannot put next to it like that" she may has reminded him that he is required to put them over each other. The mother, by doing so, may have tried to remind Tunç about the rules of the game again because as she was talking to his father, Tunç was also listening to them. So, with this reminder, it can be assumed that the mother may have opened up a leeway of participation for Tunç.

Line 25: The father asks the mother why he cannot put the blocks side by side. With this question, the father may have opened up a leeway of participation for Tunç because, through this question he could think about what possibly could happen if he puts blocks side by side. It can be supposed that there could be two reasons why the father asks this question. First, he may not have realized that he disobeyed the rules and tried Tunç to realize that also by waiting an answer from mother. Second, he may have thought that the way he placed the block is correct. This way, by asking the question, he may have wanted the mother to reconsider about the subject.

Line 28: The father asks the mother "Why? So that I win?" He smiles. With this question, he may have tried to tell Tunç that he could win if he places blocks vertically like himself. Another possibility for this situation is that he may have tried to encourage Tunç by acting like they are racing to win the game. On the other hand, the father may have tried to finish the discussion between him and the mother.

Line 34, 35: The mother rolls the dice and says "I always get small blocks". By saying this, the mother may have tried to get the attention of Tunç to compare the blocks with each other because the mother has got block A. In other words, Tunç could make the sense; block A was the lowest block, out of this. Namely, it could be assumed that the mother may have constructed a leeway of participation with this reaction. In contrast to this, the mother may have said this just to indicate which block she got.

Line 39: Tunç turns to his mother and says: "You always roll small". Then, he rolls the dice and says: "Yes". Tunç, by saying this, may have tried to show his mother that he knew the blocks coming to her were low. On the other hand, he may have tried to remind her that she always got low blocks and that she cannot win the game. In addition to these possibilities, it can be examined that, in line 34, by saying 'I always get small blocks', the mother could have opened up a leeway of participation for Tunç. Through this, Tunç thought about that what his mother tried to say and finally he decided that her mother got small blocks.

RESULTS

To sum up, I argue for indication of a developmental niche that has emerged for Tunç. His mother and father are reminding him about the rules of the game and even explaining why they put the blocks vertically or horizontally. Thereby it seems that Tunç has understood which way to place the blocks to get a longer structure. Also his father supported Tunç during the game by saying "yes". From this point of view, it can be said that the father's supportive actions increased Tunç's motivation.

Children at the age of 5 can easily decide which structure, created by placing objects over each other, and is longer than the others. Furthermore they can discover the connection between length and numbers. They can also perceive length differences between objects even though there is no discernible difference (Cross, Woods & Schweingruber, 2009). When this case is taken into consideration, it is possible to say that Tunç's perception about measuring has developed properly compared to his age. Also his mother and father have been helpful to him to apprehend the subject with their reminders and explanations.

Starting off from this analysis we can configure 3 components that we mentioned before:

Component "Content": There were 3 goals for the game, which are selected for Tunç: Measurement, matching shapes and figures and balancing the blocks statically. Pre-school aged children may have some difficulties with length measurement. They may not be able to compare the length of any object or building. But most of the children aged between 4 and 5 are able to measure with manipulatives, e.g. ruler, given to them. They can also make the connection between length and number of the components (Cross, Woods & Schweingruber, 2009) Based on this information it can be assumed that Tunç has succeeded in comparing the lengths of objects without using any tools. At this point, his mother and father remind him with examples when they place the blocks vertically. Therewith they will get a longer structure.

Component "Co-operation": During the game his mother and father accompanied Tunç. But the game has not been directed by a specific person. The father was generally quite dominant, and he gives some responses like yes, huge and vaov. In addition to the father, the mother was also considerably involved in the game. From time to time, they reminded each other about the rule of the game. The father gave suggestions to Tunç from time to time which seem to have encouraged Tunç. Also, when Tunç asked a question to his father, he gave time for Tunç to think and answer. For example, when Tunç asked his father if the block is big by poking the block at his father, the father waited for an answer from Tunç. Afterwards, Tunç found his own answer by saying "No". It can be said that the father has opened the leeway of participation of Tunç. On the other hand, the mother has succeeded getting Tunç's attention to the game by interfering with the father from time to time. Her action has caused Tunç to question the playing style of the father. Thus, he placed the blocks just like his father did. From this point of view, both the mother and the father have enabled Tunç to an opened leeway of participation.

Component "Pedagogy and Education": In the case of this selected game, Tunç has succeeded in building a long structure by observing his mother and father.. Vygotsky asserted that there is an important role of "social environment" in which child's cognitive development included (Kozulin, 2003). Children start to learn from people around them and their social world (ebenda). Starting off from this information, it can be said that Tunç has been able to explore how to build a longer structure with contributions from his mother and father. Studies have shown that preparation of learning and capacity of thoughts affect learning. This capacity (potential of learning) is shown with zones of proximal development, ZPD (Cook & Cook, 2007). French (2007) stated that with adult's help, children reach an extensive learning capacity which is different from the one earlier. At this point, we may assume tell that a child playing with an adult who directs him becomes effective in his learning period. If we analyze the example with Tunç and his parents in relation to ZPD, we see indication of such extensive learning possibility. Tunç has apprehended how to get a longer structure with support from his father and mother and in fact he even won the game by getting the longest structure.

All in all, in the chosen situation, it can be assumed that through his father's and mother's reminders, the developmental niche has emerged for Tunç.

Preschool teachers' understanding of playing as a mathematical activity

Christina Svensson

Malmö University, Malmö, Sweden, christina.svensson@mah.se

In this paper, preschool teachers' documentation of their learning about playing as a mathematical activity are examined using Wartofsky's three levels of artefacts, primary, secondary and tertiary. Playing is one of Bishop's six mathematical activities and was a new consideration for most teachers and in contrast to how play is generally conceived as a tool for learning. Wartofsky's three levels of analysis provided insights into how the teachers were able to visualize and understand playing as a mathematical activity.

Keywords: Artefact, mathematical activity, preschool, preschool class.

BACKGROUND

In this paper, I analyse preschool teachers' reflections on their learning about Bishop's (1988a) mathematical activity Playing using Wartofsky's (1979) three levels of artefacts. This investigation is a part of a wider study investigating preschool teachers' mathematical learning in a professional development project designed around the introduction of a revised curriculum (Skolverket, 2010). The project involved teachers completing written documentation about their reflections and this paper explores how this documentation was analysed. According to the Swedish curriculum (Skolverket, 2010), the preschool teachers are responsible for that activities in groups of children are performed in a way to stimulate and challenge children in their mathematics development. Skolverket (The Swedish National Agency for Education) (2008) highlighted how, ten years after instigating a curriculum for preschools, mathematics still had an inconspicuous position in preschools.

Previous research has suggested that preschool teachers perceive mathematics only to be about counting and measuring (Clements & Sarama, 2007; Ginsburg, Lee, & Boyd, 2008). Consequently, there have been suggestions that mathematics in preschool should include patterns (Björklund, 2008), and geometry (Clement & Sarama, 2007; Ginsburg et al., 2008). More broadly there is an argument made in favour of encouraging preschool children to think and make many mental relationships rather than to teach them specific subject content (Kamii, Miyakawa, & Kato, 2009). Counting, measuring, patterns and geometry are mathematical content and do not necessary include the expectation of mathematical thinking, such as Playing. This is in contrast to curricula such as the Swedish preschool curriculum (Skolverket, 2010) which emphasis mathematical thinking. In a background document to the curriculum (Utbildningsdepartementet, 2010), mathematics in preschool is discussed on the basis of Bishop's (1988a) six mathematical activities Counting, Measuring, Locating, Designing, Playing and Explaining, which perceive mathematics as a cultural activity, developed in all cultures. Bishop (1988a) considered the activities to be processes that lead to the development of mathematics. These six fundamental activities, he claimed are universal for two reasons. Firstly, because they seem to have been performed by each culture group that has ever been studied, and secondly because they are both necessary and sufficient for the development of mathematical knowledge.

Bergen (2009) asserted that Play can be defined as the medium for learning process for all ages because many qualities of play enhance learning process. She continues with saying that play is valuable for children primarily because it is a medium for development and learning, and it is important to understand that playing and playfulness is a quality which is valued by mathematicians, engineers and scientists. Helenius, Johansson, Lange, Meaney, Riesbeck, and Wernberg (2014b) also discuss that Play is an important means for learning and continues by saying that; with for mathematicians Play describes as a necessary component of their creativity in problem solving. Thus, enhanced playful learning at every level of education that prepares professionals for scientific, mathematical and engineering fields is warranted (Bergen, 2009). Playing is the mathematical activity, which deals with aspects of mathematical thinking. Bishop (1988b) considered that Playing involves designing and participating in games and pastimes, which have more or less formalised rules which all players must follow. Bishop (1988b) included games for adults and claimed that Playing is an important activity for developing mathematical thinking for all ages. He considered Playing as characterized by thinking hypothetically (imagining a potential action to take in the game and is the beginning to think abstractly), modelling (abstracting something from reality) and abstracting (identifying the relevant features to focus on within a situation), guessing, estimating, assuming or adopting.

The role of play in education is a major concern of early childhood educators (King, 1979) and so even in Sweden. Play has a long history in preschool curriculum in Sweden, which could be the means of that preschool teacher are unlikely to naturally connect it with mathematical thinking. Wernberg, Larsson and Riesbeck (2010) claimed that the early learning of mathematics needs to be problematized so that it not only consists of numbers and calculations. They argued that the learning of mathematics in preschool should be based on playing. They considered Playing to be the most important means for learning in preschool, because it promoted interactions between teachers and children or between children and children. But the concept of learning by Playing needs to be more nuances to be categorized as a mathematical activity Playing (Bishop, 1988b). Helenius and colleagues (2014b) mean that, for play to be considered mathematical, it must include all or most of the following three parts. The first is that the participants must abide the implicit or explicit rules of the play. The second is that if the rules change there needs to be negotiation by participants. The third is that negotiating the rules contributes to forming the boundaries of the play situation and thus what aspects of reality can be suspended and what aspects are modelled in what ways. "However, young children are unlikely to know the rules of mathematics so for play to count as mathematical, there must be abiding by group negotiated rules, but these may not necessarily be about mathematical content knowledge per se" (Helenius et al., 2014, p. 7).

As a result, it is possible that Swedish preschool teachers have difficulties understanding Playing as a mathematical activity. In research about the impact of a professional development project based on Bishop's (1988a) six mathematical activities, Helenius, Johansson, Lange, Meaney, Riesbeck & Wernberg (2014a) noticed that preschool teachers focused more on counting and measuring. Very few teachers labelled the activities that they described as Playing. They argued that changes in teachers' understanding take time and "a more explicit discussion of Bishop's six activities could be beneficial for future professional development programs" (p. 10).

Previous research on professional development in Sweden shows that, teachers claimed that they wanted to acquire extended knowledge and understanding of representations, and ideas in many different areas in mathematics (Doverborg, 2006). Furthermore, she found that continuous reflection with colleagues about videos, photographs, observations and interviews contributed to teachers' extending their knowledge and views on mathematics and pedagogical discussions. Alnervik (2013) focused on sharing and discussing pedagogical documentation between colleagues as a tool for visualising and developing their teaching practices. Pedagogical documentation is mentioned in the foreword of the curriculum as a way of making preschool practices visible and subject to discussions and evaluations of the quality and quantity of preschools (Skolverket, 1998). However, it is only when documentation is used for reflection that it becomes pedagogical, which has also been emphasized in published literature to provide guidelines for the use of documentation (Taguchi, 1997).

This research investigates teachers' documentation of their reflections on their learning about Playing as a mathematical activity. In the next section, Wartofsky's (1979) three levels of artefacts are discussed, as Alnervik (2013) used this in analysing the pedagogical documentation of preschool teachers in her research. The professional development was a project for developing preschool teachers' understanding of mathematics, including Playing as a mathematical activity. The project provided data for my research when it was necessary to determine whether teachers faced a conflict between Playing as a mathematical activity and other conceptions of play in order to improve the possibilities for learning opportunities within the professional development. Thus, the research question is: *How can Wartofsky (1979) three levels of artefacts in the analyses inform how preschool teachers developing understanding of Playing as a mathematical activity?*

WARTOFSKY'S THREE LEVELS OF ARTEFACTS

Wartofsky's (1979) three levels of artefacts have been used as tools for understanding the learning that occurs in mathematics classrooms (Hemmi, 2010; McDonald, Le, Higgins, & Podmore, 2005; Radford, 2008). There are several ways to classify artefacts (Säljö, 2005; Wartofsky, 1979). Säljö (2005) defined artefacts as tools that mediate between the individual and the social practice. He divided artefacts into two groups: *intellectual tools* like discourses and systems of ideas and *physicals tools* like texts, maps and computers. He also classified them into *primary tools* like a hammer and *symbolic tools* like those used for communicating ideas. Radford (2008) argued that we think with and through cultural artefacts, like the wooden ruler, the number line, and the mathematical signs on a piece of paper. A similar argument can be made for pedagogical documentation. Alnervik (2013) used Wartofsky's (1979) three levels of artefacts, primary, secondary and tertiary, to analyse teachers' pedagogical documentation to identify different perspectives. Artefacts, such as a die, a photograph or a film about a mathematical activity are unlikely to support changes in teaching practices without a task, a reflection and a conversation between colleagues and a re-reflection for reconstructing or developing the educational work focusing on the activities (Alnervik, 2013).

Following the Soviet tradition, Wartofsky (1979) focused on historic-cultural objects as artefacts. His interest was to define the ways humans worked to create cultural artefacts. He claimed that perceptions are culturally conditioned and represent a person's internal mental model which, through different representations, indicates that possible changes have occurred. Wartofsky (1979) connected the function of tools for use in internal mental models of human understanding by going from the practice and use of the tool to the theoretical and imaginative understandings of the tool. He provided a strategy to do this by separating artefacts into three levels, primary, secondary and tertiary, although he also acknowledged the importance of linking the three levels. The artefact or tool itself does not determine whether it is primary, secondary and tertiary, but rather how it is used.

Primary artefacts: These are tools, which are being used, in a special context. To utilise the tools means possessing the knowledge of how the tools operate, including the skills needed to operate them.

Secondary artefacts: These tools act as a model or pattern in which the artefact is used to describe how people are supposed to do something i.e. seeing something that was not apprehended earlier.

Tertiary artefacts: These are tools or aids for thinking, where the artefacts help people to see the environment in a special "new" way. These artefacts can be considered as a way to "create, understand and analyse the world" (Säljö, 2005, p. 98). Hence, new ways of viewing the world can be discovered and these can contribute to altering and understanding a practice in a new way (Alnervik, 2013).

METHOD

This paper reports on a part of a larger study aiming at investigating how preschool teachers use their understandings of the six mathematical activities (Bishop, 1988a) in their teaching practices during a professional development programme. This programme was part of Matematiklyftet (Skolverket, 2013) and used materials developed specifically for teachers in preschool and preschool class. Preschool class is a "bridging" year between preschool and school and school starts in the year when children turn seven, preschool is for one to five year olds. The material is based on collaborative learning (Timperley, Wilson, Barrar, & Fung, 2007) and Bishop's (1988a) six mathematical activities. Ninety preschool teachers and preschool class teachers, divided into four groups, actively participated in this project during a period of eighteen months, 2013–2014. The mathematical activity Playing (Bishop, 1988a) was the focus of three meetings with the teachers. The teachers were given mathematical tasks and questions to discuss, in order to develop their understanding of Playing. Before the first meeting the participants were supposed to have read the prescribed texts and looked at video(s), from the professional development material. During the first two meetings, the texts and videos were discussed and between the meetings the teachers implemented tasks in their preschools that could be linked to *modelling, abstraction* and *hypothetical thinking*.

Following Helenius and colleagues' (2014) advice about the need for more explicit discussions of Bishop's six activities, teachers got the opportunity to discuss mathematics in preschool and preschool class with their colleagues at the professional development. To base the discussions on teachers' own practices, the teachers brought with them documentation in the form of photographs or videos. Every third meeting was a reflection meeting where the teachers discussed their documentation. During these discussions the teachers used a reflection protocol as support for their discussions so that they could further develop the mathematical activities. As one of the facilitators of the professional development, I kept my own notes of the meetings and these were also analysed.

In this paper, the purpose is to look at how Wartofsky's (1979) three levels of artefacts were used to identify what understanding of Playing as a mathematical activity teachers displayed in their documentations during the professional development. Bishop's (1988b) description of modelling, abstraction and hypothetical thinking as key features of Playing was used in identifying how teachers visualises this mathematical activity in their work in preschools. Wartofsky's (1979) three levels of artefacts were chosen as a way of seeing whether a conflict between understandings of Playing and other conceptions of play in the Swedish preschool was evident in the teachers' pedagogical documentation. In order to operationalise Wartofsky's (1979) three levels of artefacts so that they could be used in analysing the teachers' documentation, descriptions of how they could be used in the data analysis were developed:

Primary artefact: Tools as a photograph, video recording or a note from the teacher to visualise Playing as a mathematical activity.

Secondary artefact: Tools in the documentation from the teacher, where the notes described what occurred in photographs or video recordings in form of the three concepts; modelling, abstraction and hypothetical thinking.

Tertiary artefact: Tools that aid teachers' thinking to see the environment in a special "new" way of Playing as a mathematical activity.

ANALYSIS

In the following sections, I provide a description of a teacher's documentation and how it was analysed using Wartofsky's (1979) three levels of artefacts.

Pedagogical documentation as a tertiary artefact

A teacher in a preschool class chose to video record a play situation where three children, six years old, played "doctor". This is a common play situation in preschools and preschool classes and models children's perceptions of a real hospital. Consequently it was considered to be an example of the *modelling* component of Playing as a mathematical activity. In the video, one child is a patient, one child was a doctor, and one child was a nurse and secretary. The teacher talked to the children and asked them questions during the episode captured on the video.

The teacher discussed with the children different aspects of Playing by asking questions. From this, she then added comments to the documentation.

The teacher asked the children question about objects they were using as part of their hospital game but which did not necessarily look like they did in reality. Such a situation occurred when the child, who acted as a secretary, sat down at the table and pressed the buttons of a calculator. The child answered that the calculator was a typewriter on which he wrote prescriptions. This was analysed by the teacher as illustrating the *abstraction* component of Playing because the child had only focused on specific aspects of a typewriter, the buttons, as being important for what he was doing. After that, the teacher asked the doctor about the patient's condition. The doctor informed the teacher the patient had a very high heart rate, so he had to stay at the hospital for a few days. When the patient heard that his condition was very serious, he lay down on the sofa again. The child who was acting as the patient imagined what it was like to have such a bad condition so he followed the rules of the game situation in order to ensure that he received further treatment from the doctor. This was considered to be an example of *hypothetical thinking* because he had to work out what would be expected of him, if he really was a patient with a bad heart condition the rules changes and there was negotiation by participants.

In her documentation, the teacher showed how her choice of implementing this situation and her conversation with the children, illustrated how she had perceived and worked with the three components of Playing as a mathematical activity. At the reflection meeting, my notes suggested that she had observed this play before, but had not seen it as a mathematical activity. During the reflection meeting, she also, of raised how she felt about her own presence during the children's "free play", and how this affected her further development and planning of this situation.

Her documentation of Playing was analysed as a tertiary artefact, as the teacher showed that she had gained new understanding, that might contribute to her changing how she saw this situation in the future Playing by providing her with new ways of understanding what she did.

Pedagogical documentation as a secondary artefact

The example of a secondary artefact comes from the documentation of two teachers who decided to work together. They took turns in participating in the children's free play and simultaneously photographing it. The teachers provided texts to accompany their photographs about what the children said and did.

However, they did not mention modelling, abstracting and hypothetical thinking (Bishop, 1988b) in their documentation. The children did discuss how chairs should be placed in order to resemble a ferry and in so doing organized the chairs from a model they had been aware of earlier and the rules contributes to forming the boundaries of the play situation. This situation could have been identified by the teachers as *modelling*. The children also put toys in a swimming pool to represent a pool on the ferry that could give massages. This second situation could have been identified by the teachers as *abstraction* like aspects from the reality. Later, the children informed the teachers that a chair was missing and it meant that not all the children could get a massage at the same time. This last situation could have been identified by the teachers as *hypothetical thinking* because of how the children pretended that the game could not continue if not all of the children participated.

This documentation was categorised as a secondary artefact because an individual reflection from the teachers on their roles, which was present in the first pedagogical documentation, was left out. The notes that they made allowed them to explain what the children had done but not reflect on it, thus making it a secondary artefact. Without the reflection component, it seems that teachers can remain unaware of how the components of Playing were present in the situation. It is interesting to note that when the teachers presented their documentation to their colleagues at the reflection meeting, they then could discuss the different aspects of Playing in the situation but this was not part of their documentation.

Pedagogical documentation as a primary artefact

In this documentation, the teacher video recorded a situation where a four-year-old child was supposed to sort material, containing teddy bears in different colours and sizes. The teacher asked questions during the documentation, which were related to the numbers and the sizes of the teddy bears, such as "how many teddy bears do you have?" and "do you have more orange teddy bears than red?" However, the child played with the material and responded with statements such as "this is a ring [of teddy bears], dancing around a Christmas tree". However, this situation could be an example of *modelling*, as the child presents a possible model of a real-world situation. The child continued with "I get to do this instead when I throw out the Christmas tree" which could visualized be a *hypothetical thinking* as she presents a possibility of something occurring. The teacher used the video camera, as a direct tool to produce a description of a mathematical situation or a play situation with math material. In the documentation, the situation was neither explained nor reflected upon. Hence, it was categorised as a primary artefact, a tool as a video used in a specific context to visualize mathematic in an organised situation.

COMPILATION OF THE RESULTS

A total of thirty-seven sets of documentation were collected from the teachers. Several teachers chose to do the documentation together, others chose to resist. About a quarter of the documentation were categorised as primary artefact (Wartofsky, 1979). In many of these, it emerged that the teachers perceived the situations as playful environments which they connected to mathematical learning situations. In other documentation categorised as primary artefacts, the teachers described the situation as a representation of Playing (Bishop, 1988), similar to sorting the teddy bears, but which contained no explanation or reflection. The rest of the collected data was analysed as secondary and tertiary artefacts.

During the two meetings before the reflection meeting, when Playing (Bishop, 1988a) was discussed in different ways, the teachers expressed that they had difficulties to seeing the children engaged in modelling and the abstraction. The facilitators therefore chose to focus the meetings on these two parts, by showing many different representations of modelling and abstraction. However, in the results it is hypothetical thinking that many educators had difficulties with seeing. Consequently many of their sets of documentation could not be classified as indicating a tertiary artefact, because this lack of awareness hindered the teachers from changing their understanding about their practices.

Many of the teachers found that it was in the collegial learning, when they discussed their documentation of their own activity that contributed to opening up their view of Playing as a mathematical activity. In addition, the teachers identified the importance of the facilitators being involved in the discussion of their documentations in the reflection meeting in order for them to see Playing as a mathematical activity.

CONCLUSION

Analysing how teachers in preschool and preschool class were able to visualize Playing as a mathematical activity is very complex. By using Wartofsky's (1979) three levels of artefacts primary, secondary and tertiary it became possible to detect how preschool teachers developed their understanding of Playing as a mathematical activity. Helenius and colleagues (2014a) showed that teachers struggled to catch the sight of the mathematical activity Playing in their practice. The same phenomenon appeared in the documentation from this professional development. This suggests that teachers' conceptions of play were connected to the curriculum understanding that learning occurs through play or that mathematics maybe is only about counting and measuring. Wartofsky's (1979) three levels of artefacts could inform analysis of preschool teachers developing understanding of play as a mathematical activity. More research in this area is needed on how the mathematical activity Playing (Bishop, 1988b) is made visible and teachers understanding of the activity to enhancing playful learning in early childhood education for prepare professionals in the scientific, mathematical and engineering fields.

Unsolvable mathematical problems in kindergarten: Are they appropriate?

Dina Tirosh, Pessia Tsamir, Esther Levenson, Michal Tabach and Ruthi Barkai

Tel Aviv University, Tel Aviv, Israel, levenso@post.tau.ac.il

Not all mathematical problems have a solution. This paper describes a decomposition problem, set in a real-life context, for which no mathematical solution exists. It describes the strategies children use and how the rea-life context impacted on children's solutions. Results indicated that young children accept the possibility that a problem may not have a solution and that some turn to the context in order to find a practical solution instead.

Keywords: Unsolvable problems, kindergarten, real-life context.

Problem solving is an inherent part of learning mathematics at every age. In the U.S., the Curriculum Focal Points suggests that the content and concepts learned in kindergarten should be addressed in a context that promotes problem solving, reasoning and critical thinking (NCTM, 2006). In England, the Statuary Framework for the Early Years Foundation Stage (DCSF, 2008) states that "Children must be supported in developing their understanding of problem solving, reasoning, and numeracy in a broad range of contexts…" (p. 14). In Israel, the preschool mathematics curriculum stresses that problem solving should be interweaved throughout all of the main content strands (INMPC, 2008). Some major, related questions are: What types of problems should we present to young children? Should we only present problems that have a solution? Are young children capable of handling mathematical problems that have no solution? The INMPC (2008) suggests that problems, especially for young children, be set in a real-life context. How might such a context impact on the way young children approach a mathematical problem that has no solution?

One of the major content strands of preschool mathematics education is to promote number conceptualization and skills, including number composition and decomposition. The INMPC (2008) states that between the ages of 4 and 6 years, children should learn that a given amount of objects may be divided into two or more groups and that those groups may or may not have equal amounts of objects. Being able to flexibly compose and decompose numbers allows children to apply various strategies when solving number problems in various contexts and assists in the development of number sense (Baroody, 2004). This study describes kindergarten children's engagement with a number decomposition problem set in a real-life context that has no mathematical solution. Specifically, it investigates: What strategies do children employ when faced with a composition and decomposition problem? Do young children recognize when a problem has no mathematical solution? How might the context of a problem impact on the way children approach the absence of a solution?

NUMBER DECOMPOSITION AND PROBLEM SOLVING

Children's ability to compose and decompose numbers is at the heart of this study. Two prerequisite skills for composing and decomposing numbers are verbal counting and object counting. Both of these skills are almost always mastered by age five (Baroody, 2004). Related to quantification, but distinct from counting, is the process of subitizing (Baroody, Lai, & Mix, 2006). Subitizing refers to the immediate recognition of the number of items in a collection without counting the objects. It involves recognizing that three dots in a row has the same number of dots as three dots set up in a triangular array and that both of these sets have exactly three dots. As the child develops, these conceptions may be mentally operated on, such as mentally decomposing a pattern of five into two and three and combining them back together.

In addition to subitizing, children develop and use various counting strategies when solving arithmetic problems. Initially, when children are requested to add two numbers or to combine sets of objects, they use a "counting-all" strategy. For example, when combining three items with four items, children will count 1, 2, 3 and then 1, 2, 3, 4 and then finally, 1, 2, 3, 4, 5, 6, 7. This strategy develops into several more sophisticated strategies such as "counting-on-from-first" and "counting-on-from-larger". Eventually, procedural counting knowledge develops into declarative knowledge in the form of number-facts, which are remembered and retrieved (Baroody, 2004). Children take advantage of number facts, along with their knowledge of decomposing numbers, to count in a more efficient manner. In the above example, children may decompose the four into three and one, use a known fact such as "three and three makes six", and then add the leftover one, to make seven (Verschaffel, Greer, & deCorte, 2007).

Not all arithmetic problems present the same cognitive challenge. The easiest problems to solve are those that the child can use and manipulate physical items in a step-by-step procedure set out by the story problem (Sarama & Clements, 2009). For example, if the child is requested to find out how many candies Danny has if he received three candies from his grandma and four candies from his grandpa, the child can physically act out this story using substitute items, in order to figure out how many candies Danny now has.

Setting mathematical problems in real-life contexts is another issue discussed by mathematics educators. The realistic mathematics education (RME) approach, emphasizes that context problems must be imaginable to the students (e.g., Streefland, 1990). Such problems can serve as an introduction to a mathematical topic as opposed to merely demonstrating the applications of a mathematical topic at the end of a learning sequence. Students, however, do not always take into account the real-life context of the problem. When posed with the following problem:

> 450 soldiers must be bussed to their training site. Each army bus can hold 36 soldiers. How many buses are needed?

a considerable amount of students wrote that 12.5 buses would be needed (Verschaffel, De Corte, & Lasure, 1994).

While the bus problem is solvable (e.g., hire 13 buses), not all problems have a solution. For example, De Corte and Verschaffel (1985) posed the following problem to first graders: Pete had some apples; he gave 4 apples to Ann; how many apples does Pete have now?" (p. 11). More than half of the children did not recognize that the problem was unsolvable. In other studies with similar unsolvable situations, students gave answers which were irrelevant (Reusser & Stebler, 1997). It was as if students felt that if a problem is posed, a solution must exist. When does this belief develop? Does it exist already in kindergarten? In this study, we pose a problem which has no solution and investigate children's strategies when attempting to solve this problem.

METHODOLOGY

The participants in this study were 19 kindergarten children, ages 5–6 years old, attending three different kindergarten classes. All three kindergartens were located in the same middle-low socio-economic neighbourhood. Their teachers had participated for two years in one of our professional development programmes (Tirosh, Tsamir, & Levenson, 2011). The children were scheduled to enter first grade the following term. The study was conducted in March, the second half of the school year.

Birthday parties are part of children's reality. Every child experiences birthday parties in the kindergarten class. For this task, four empty party plates were placed on the table. In addition, eight cards were placed on the table, with different amounts of candies on each card. One of the eight cards was left blank (See Figure 1). The child was told, "Four children are coming to your party and you want to give each child seven candies on their plate. Can you arrange it so that there are seven candies on each plate? You can arrange the candies however you wish, but there have to be seven candies on each plate." At this point, the interviewer let the child work out the problem, adding comments as needed, such as letting the child know that it was permissible to place more than one card on a plate. When it seemed that the child had finished, the interviewer asked, "Are you finished?" When the child acknowledged that he or she was finished, the interviewer asked, "So, does every child get seven candies?" The problem has no solution; twenty-seven is not divisible by four; seven candies cannot be placed on each of the four plates.

Figure 1: The *Birthday Party* task cards

Analysis of the results began by considering correctness. First, we noted if a child who claimed to have placed seven candies on a plate, did indeed place seven candies on that plate. Second, when the child completed the task, did he or she recognize that not all plates had seven candies or did the child claim that each plate had seven candies? Third, we noted what strategies were used when composing seven. Did the child use a counting strategy or were number facts recalled? Finally, we were interested in investigating how the context of the birthday party might influence the children's solutions, and how the children would deal with a problem that had no acceptable mathematical solution.

FINDINGS

This section begins by summarizing the final arrangements of the cards on each plate, highlighting the issue of the blank card. It then describes one child's strategies when engaging with the problem. Finally, we describe how children dealt with the fact that this problem had no mathematical solution.

Table 1 summarizes the frequency of the final arrangements of candy cards on individual plates. The order in which the plates were filled was not recorded as children went back and forth moving cards from one plate to another. From the results we see that most children (11 out of 19) attempted to place seven candies on as many plates as possible, leaving only one plate with six candies.

An interesting aspect of this problem is the blank card. The blank card was meant to represent zero candies. In an abstract context, seven may be decomposed into seven and zero. However, in the birthday party context, there is no added value to placing the blank card on any of the plates. After all, if we place the card with seven candies on one of the plates, then that plate now has seven candies. Why add the blank card? And yet, eight children added the blank card to one of the plates. It could be that for these children, there was

Plate	Plate	Plate	Plate	Final Status	Frequency (claims not every plate has 7 candies)
7+0	6+1	5+1	4+3	7, 7, 7, 6	5(-)
7	6+1	5+1	4+3	7, 7, 7, 6	4(4)
7	6	5+1+1	4+3	7, 7, 7, 6	2(1)
7+1	6+1	5	4+3	8, 7, 7, 5	2(1)
7	6+1	5+3+0	4+1	8, 7, 7, 5	1(1)
7	5+1+1	-	-	7, 7, -, -	1*(1)
7	6	5	4	7, 6, 5, 4	1(-)
7	6	5	3	7, 6, 5, 3	1(-)
7+1	6+0	5+4	3+1	9, 8, 6, 4	1(-)
7+1	6+5	4+1	3+0	11, 8, 5, 3	1(-)

* This child stopped in the middle realizing that the problem was unsolvable.

Table 1: Frequency of arrangements of candy cards per plate (acknowledged that there were not 7 candies on every plate)

an implicit understanding that all of the cards had to be used, even if it did not make sense according to the story. If that was the case, then the blank card could have essentially been added to any of the plates. Yet, of the eight children, five placed it on the plate with the card with seven candies, representing the decomposition of seven into seven and zero. Perhaps they were trying to place two cards on each plate.

Regarding strategies for solving the problem, it was sometimes difficult to tell which strategy a child was employing. Counting was the most obvious, as children usually counted aloud or at least pointed and touched each candy, probably counting silently in their heads. Estimation and subitizing were more difficult to discern, although we gathered that many children used this strategy, especially those who placed seven candies on the first plate and six on the second, without counting the candies on either plate. Recalling number facts was most apparent for the decomposition of seven into four and three. For example, one girl looked at all the cards, chose the card with four candies on it and placed it on the first plate. Then she carefully looked over the rest of the cards and deliberately chose the card with three candies on it, placing it on the same plate as the four candies. She did not say anything. Because of the difficulty in accurately identifying which strategy was used, we do not quantify and summarize the number of times each strategy was used but instead illustrate in the following example how one child employed several different strategies when solving this problem and how the birthday party context impacted on her final answer.

Shula begins by counting the candies on the cards (lines 1, 3, and 4) and choosing which to place on plates. However, after she counts four candies (line 4) she adds a single candy without counting the total.

1 Shula: (Shula uses her finger to count the candies on the card:  .) 1, 2, 3, 4, 5.

2 Interviewer: You can place more than one card on the plate.

3 Shula: (Shula counts the seven candies on the card ) 1, 2, 3, 4, 5, 6, 7 (and places the card on the first plate).

4 Shula: (Shula counts the four candies on the card ) 1, 2, 3, 4 (and places it on the second plate. She then places the card with  on the same plate.)

She then seems to randomly place cards on the other plates (lines 5 and 6), without counting, perhaps just to fill up the plates with something. Later (line 10), when she does count them, we learn that perhaps she thought she was placing seven candies on each plate, possibly by estimating the amounts.

5 Shula: (Shula places  and  on the third plate.)

6 Shula: (Shula takes the three cards that are left:  , ,  and puts them on the fourth plate.

Shula realizes that not every plate has seven candies (lines 8 and 12), but claims that it does not matter.

7 Interviewer: So, does each friend have seven candies?

8 Shula: Here (pointing to the second plate with four and one) there are 1, 2, 3, 4, 5. It's not important.

9 Interviewer: It's not important?

10 Shula: (Shula counts the candies on the other plates, miscounting the 5 and 3 and concluding that there are seven candies on that plate.)

11 Interviewer: So, does everyone have seven?

12 Shula: No.

13 Interviewer: Who doesn't have seven?

14 Shula: (Shula points to the second plate with 5 candies.)

15 Interviewer: So, what should we do?

16 Shula: Leave it.

Shula uses a combination of strategies to solve the problem. She counts, sometimes correctly and sometimes incorrectly. She may also have used estimation, placing the card with a lot of candies (six candies) on the same plate as the card with only one candy. Only when asked if each plate has seven candies, does she go back and count the candies on that plate. It is interesting to note that after Shula acknowledges that not all plates have the required seven candies, she does not try to rearrange the cards and work it out. Nor does she complain that there are missing candies. Instead, she says that it is not important and we should leave it.

In real life, 27 hard candies cannot be distributed equally among four plates. Of the 19 children who participated in this study, eight children answered correctly at the end that not all plates had seven candies. Four of those children, like Shula in the vignette above, acknowledged this fact without further comment. They did not seem bothered by not having seven candies on each plate; they made no comments or gestures that might be interpreted as frustration or exasperation; nor did they intimate that the problem was unsolvable. They seemed satisfied that the task was completed. One of those children placed the card with seven candies on the first plate, the card with five candies and the cards with one candy each on the second plate (i.e., 5+1+1), and then sat back and said, "There aren't enough." When the interviewer asked her how come, she pointed and replied, "Because here this is zero and six and here four and three." This child did not count and instead seemed to use a combination of subitizing (she recognizes without counting that there are three candies on the one card and four on the other) and number facts (e.g., 3+4=7). When the interviewer asks, "so only two friends will get candies?", she does not respond further and at her own initiative, she stops the activity, leaving the other two plates empty.

Of the four other children, three made it clear that one candy was missing. One child, trying over and over to solve the problem said, "Something is not right," before explicitly stating that one candy was missing. Another child turned over the blank card to make sure that there wasn't a picture on the other side. When asked what he was looking for, he pointed to the card with one candy on it as if to say that he was missing one candy. The third child said that a card was missing and stated "like that one" pointing to the card with one candy on it. The interviewer responded, "You are right, so, what do you say we go to the store and buy candies?" The boy nodded his head in agreement and laughed. The fourth child suggested removing the plate that had less than seven candies, leaving the remaining three plates with exactly seven candies.

Of the 11 children who incorrectly claimed that each plate had seven candies, many simply did not count the candies as they distributed the candy cards. Some seem to have relied on the strategy of estimation. That is, the card with seven candies and the card with six candies both looked like a lot of candies and thus, they did not feel the necessity for counting. One boy began by placing the card with seven candies on one plate, the card with six candies on the next, and the card with five candies on the third. Only at that point did he stop and realize that the five candies were not enough. After he thought about it and added two extra cards, with one candy on each to that plate, he placed the card with four candies and the card with three candies on the fourth plate, counting the candies on that plate to make sure. He did not go back and check the cards on the first two plates (the second plate had six candies) and so claimed that each plate had seven candies. Other children counted incorrectly. Incorrect counting most often occurred for the cards with seven and five candies, possibly because the candies were not pictured in a row, making it more difficult to keep track of the counted candies. In general, children engaged enthusiastically with this problem, used various strategies to solve it, and displayed various levels of competency when it came to counting.

DISCUSSION

The mathematical context of the problem posed to children in this study was the decomposition of seven. As described above, many children did not recognize that the problem was unsolvable, possibly because they estimated and did not count or because they miscounted. One factor which contributed to the difficulty of counting was the physical setup of the task. If children had been given actual candies and could physically move the items, they might have found it easier to count (Sarama & Celements, 2009). However, if they had been given candies, the problem would have lost the focus on decomposing seven. Furthermore, with physical candies, children might have distributed the candies by placing one candy at a time on each plate until all the candies were used up. It would then be quite obvious that one candy was missing and thus the impact of having an unsolvable problem might have been lost.

When children did recognize that every plate could not be filled with exactly seven candies, they did not seem very disturbed by the insolvability of the problem. None claimed that every problem must have a solution. Only one child tried over and over to move the cards around and solve the problem. In addition, unlike the students in the studies reviewed in the background (e.g., De Corte & Verschaffel, 1985), none of the children in this study gave a non-relevant solution.

In analyzing the reasons behind the results, we offer a few possibilities. First, it could simply be that this problem was not abstract and children were able to actually see the pictures of the candies and see that there were not enough. However, in a previous study of students' handling of unsolvable problems, Reusser and Stebler (1997) found that when students were told to explicitly make a sketch of a real life problem, the results hardly improved. What did improve the results were students' past experiences with other unsolvable problems. Reusser and Stebler (1997) surmised that when students are made to solve "so-called" real- life problems that are essentially routine mathematical exercises disguised as word problems, they become immune to the actual contextual limitations of the problem. The students in that study were fourth and fifth graders, old enough to have absorbed implicit norms which indicate that every mathematical problem given in school, must have a solution. The children in our study were quite young, not yet enculturated to school mathematics problems. They were most likely young enough to rely on their natural problem solving sensibilities, sensibilities we wish to preserve and strengthen. We suggest that engaging young children with unsolvable mathematics problems is one way to provide experiences which children may reference in the future.

However, not every unsolvable problem may encourage children's insight into or acceptance of the insolvability of that problem. The context, and how close it is to the child's real world, may also impact on the child's ability to see that a specific problem is unsolvable. The solution to is not a whole number. The problem presented in this study cannot be solved. However, there are also cultural norms related to the practice of birthday parties in kindergarten. Four children accepted the final status of the plates without further comment. For them, it could be that as long as everyone received some candies, the problem had a satisfactory ending. Or perhaps they felt that the child with fewer candies might get an additional piece of cake. One child stated that one plate should be removed. Perhaps for that child, equal sharing is more important than filling up all the plates. Perhaps, from that child's perspective, it would be better to invite only three friends than have four friends who cannot get an equal amount of candies. Three children stated that one candy was missing; one of those three playfully agreed to go with the interviewer to buy more candies. That is a solution which is quite realistic. In answer to the the title of this paper, kindergarten children can engage with unsolvable mathematics problems.

"If she had rolled five, she'd have two more": Children focusing on differences between numbers in the context of a playing environment

Dorothea Tubach

TU Dortmund University, Institute for Development and Research in Mathematics Education (IEEM), Dortmund, Germany, dorothea.tubach@tu-dortmund.de

Mathematically rich games can offer children important informal learning contexts for playful mathematical activities in kindergarten. At the same time, these activities can be used as starting points for formal learning in primary school. In the reported qualitative study, 20 children were observed dealing with three developed playing and learning environments in the last year of kindergarten and the first year of school. This paper concentrates on children's mathematical activities and insights while dealing with a playing environment in kindergarten. On the one hand, the focus is on how children interpret relationships between numbers. On the other hand, two different types of play in the game are outlined. The results will be discussed regarding connecting points for learning processes in primary school.

Keywords: Kindergarten, playing, games, dice, relational understanding.

PLAYING GAMES AND LEARNING MATHEMATICS BEFORE FORMAL SCHOOLING

In recent years, empirical studies have provided evidence that playing mathematically rich games can have a positive impact on children's mathematical learning, including in kindergarten (e.g., Stebler, Vogt, Wolf, Hauser, & Rechsteiner, 2013). Characteristics of mathematical learning situations in games have been worked out and conditions for their development have been investigated, whereby mathematically rich games can provide a meaningful context for mathematical activities and are open for different individual strategies (Stebler et al., 2013). An adaptive guidance through adults can help to unfold the mathematical potential of the game as a learning situation for the child (Schuler, 2011). At the same time, mathematical activities can themselves – independent from a game – be considered as play. This is the case if the mathematical activity has characteristics of play, e.g. it moves between the poles of rules and freedom (van Oers, 2014).

While current studies emphasize the importance of playing games for mathematics learning in kindergarten, playing as a mathematical activity, as described by van Oers, can be important for both learning locations: kindergarten and primary school [1]. However, there are fewer findings on how to use the idea of 'mathematical play' as a bridge between kindergarten and primary school at present, as well as *how* mathematical learning in kindergarten is effected in the context of a game (van Oers, 2014). The purpose of this paper is to ascertain the children's mathematical interpretations and characterize the playing activity in the context of a playing environment to outline opportunities for connected learning processes in primary school.

Playing and mathematics learning

As mentioned above, playing games seems to provide an important mathematical learning opportunity. But how can play or playing be characterized? Following van Oers (2014), play is understood in this paper as an activity that is characterized by *high involvement* of the actors, oriented on *rules* and allowing *some degree of freedom*. Accordingly, a characteristic feature of playing activities is that players voluntary adhere to rules and adopt a specific role, e.g. in a game, they engage themselves in a fictitious competition. The rules of the game can be explicit or implicit, predefined or negotiated in the process of playing. Van Oers (2014) differentiates between four different functions of rules: (1) social rules, namely how to interact and deal in play; (2) technical rules, concerning how to use play objects properly; (3) conceptual rules, regarding how to act based upon specific concepts; and (4) strategic rules, in terms of how to improve the playing process. Van Oers (2014, p. 62) defines the degree of freedom in a positive way, “as the freedom *to* change, to resist, to produce extravagant ideas and so on” [original emphasis].

Ginsburg (2006) distinguishes the observable mathematical play of children according to different types: “Mathematics Embedded in Play” and “Play Centering on Mathematics”. The former type can arise by playing mathematically rich games. In particular, a game can imply mathematical aspects, although the core is the competition among the players. In contrast, “Play Centering on Mathematics” occurs in operative discovering, exploring and inventing patterns and structures. Children play with mathematical objects by varying them and, thus gaining insights into mathematical relations: They discover the impact of a change of objects and how to react accordingly with another specific change (Steinweg, 2001). Both types of play can offer children a context to verbalize their strategies and interpretations, as well as negotiating mathematical meanings. The playing environment “Who has more?”, which is addressed in this paper, links both types of play according to Ginsburg (2006): it enables “Mathematics Embedded in Play” as a game with mathematical aspects. While the choice of structured game materials it is designed to allow play with mathematical objects. Therefore, “Play Centering on Mathematics” can be realized. Here the question is how can the playing activities of the children in the context of the playing environment “Who has more?” be characterized?

Mathematical play and relational understanding

The pivotal activity of mathematically-centered play involves establishing relations between mathematical objects of play. Wittmann and Müller (2009) highlight the ability to identify and use relations between single numbers by counting and calculating as a central objective for learning processes in kindergarten. The epistemological perspective broadens the view for the principally relational nature of numbers. Numbers and relations between numbers are not concrete objects, but rather can only be represented by symbolic or concrete objects. Only by dealing with the concrete and abstract objects and construing differences between them can children acquire the concept of numbers and their relations (Steinbring, 2005).

Due to the relevance of relational understanding, the playing environment “Who has more?” is focused on relations of differences. It is intended to give children the opportunity to identify and use relations of differences in the interactive context of a game and based upon the game material. The main questions addressed in this paper are as follows:

1) How do children in kindergarten interpret relations of differences in the interactive context of the playing environment?

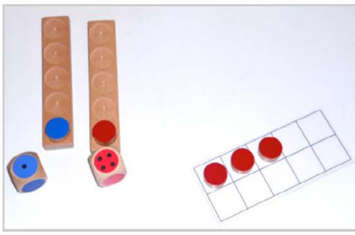
2) How can the children’s ‘mathematical play’ in the context of the playing environment be characterized?

METHODS

The research method is oriented by Cobb and colleagues’ method of “design experiments” (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). Accordingly, three complementary playing and learning environments for kindergarten and primary school were designed, focusing on the exploration of relations between numbers. In spring and summer, children in the last year of kindergarten were involved in playing environments. At the beginning of the first school year (in autumn and winter), they were involved again, albeit now in the context of learning environments. Overall, about 20 children were observed by video over two cycles dealing with the playing and learning environments in kindergarten and primary school. The sequences presented in this paper are from observation in kindergarten. To reconstruct interactive processes of understanding, a qualitative approach is chosen, oriented in the interpretative classroom research (Krummheuer, 2000). Essential for the mathematical analyses is the epistemological triangle, as described by Steinbring (2005), which enables identifying specific reference contexts that children use by interpreting differences. The epistemological analysis particularly focuses on the reconstructions of the interactive process of constructing knowledge based upon actions and interactions.

According to the rolled number, counters are put in the block of 5

Comparison: There are three red counters more.



The red player is allowed to take the three counters and put them onhis or her ten-frame.

Figure 1: Rolling and comparing

Construction of the playing environment "Who has more?"

In the following, one of three designed playing environments is exemplified: "Who has more?" The learning environment building on this playing environment is not considered here (for further details, see Tubach & Nührenbörger, 2014). "Who has more?" (WHM) is a game for two children, whereby each child receives a wooden block of five, a ten-frame and a dice (with the numbers 0 to 5) in the color blue or red. The game material is completed by small round gaming pieces, called counters (with a red and an alternate blue side).

Rule of the game: Both players roll their dice and put the appropriate number of counters in their respective blocks of five, according to the number rolled. The player with the higher number of counters is allowed to take the difference of counters (the ones that he or she has more) and puts them on the ten-frame (see Figure 1). Afterwards, the blocks are cleared and the dice are rolled again. The first player to fully fill the ten-frame wins the game.

At the heart of the playing environment is the comparison of two numbers and the determination of their difference. Children have the opportunity to gain insights into relations of differences. Meanwhile, children collect, structure and determine the number of counters on their ten-frame and gain experiences in composing and decomposing of numbers.

UNDERSTANDING OF MATHEMATICAL RELATIONS BY PLAYING "WHO HAS MORE?"

Maya (5,7) and Leon (6,4) play the game WHM with their guiding adult in kindergarten, a few months before entering primary school. Maya is already acquainted with WHM from previous game experience, whereas Leon is playing for the first time. From this game, two sequences are selected in which the children are engaged with the comparison of two numbers. One focus of the following analysis is on the children's interpretation of differences. The leading questions are: How do children interpret differences based upon the game material? Which reference contexts do the children use for the interpretation of differences in the gaming process? The second focus is on the characterization of the playing activities in these sequences. This will help to gain deeper insights into the mathematics activity in the gaming process, as well as understanding and clarifying the role of this game for mathematical and playing activities.

Focus 1: Interpretation of differences – Comparison of 3 and 2

Maya (M) and Leon (L) start the game WHM. Maya has chosen the red color and rolls number 3, while Leon rolls number 2 with the blue dice. Both children put the corresponding number of counters in their blocks of five (see Figure 2). They agree that Maya has one counter more. The following scene begins as the guiding adult (GA) asks once more.

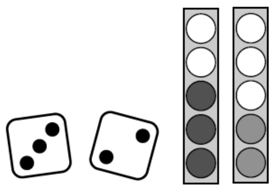


Figure 2: Initial situation

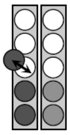
1 GA Ok. But how do you see that it's <u>one</u> more?

2 Maya 'Cause, 'cause <u>three</u> (*takes her dice with the rolled number 3 and covers one dot with her finger*)

3 GA Why aren't there <u>two</u> more?

4 Maya If, if you (.) because I didn't roll two. Leon rolled two and I have three <u>one</u> more (*lifting her third red counter and putting it back again*)



5 Leon # If she had rolled five, she'd have two more.

6 Maya # then I can take it (*takes the counter and puts it on her ten-frame*) [...]

7 Leon Ah I know, I know (*points at the blocks*) Look here, one, two (*tipping the blue counters*) and if it was there (*tipping the third now empty field of M's block*), it's <u>always</u> the one <u>above</u>, which is one more. And if she had five and I had two, then would be one, two, three, four, <u>five</u> (*tipping the fields from bottom up in M's block*) So one, two, <u>three</u> (*tipping the empty fields of M's block*) more. Three (.) more. Three pieces more (.) If she had rolled five.

In reply to the GA's question (l. 1), Maya turns to her dice and covers one dot. Therefore, instead of three, there are only two dots visible. By showing with the dice pattern how to change the number 3 to achieve 2, Maya relates the two rolled numbers 3 and 2: if you cover one dot of three, both dice show the same number of dots (l. 2). As the GA asks once more why there were not two more, Maya emphasizes that she rolled another number than Leon: she demonstrates the difference between the rolled numbers with the help of the blocks of five and lifts her third counter. Hence, she creates an *equality* of the red and blue numbers of counters. She emphasizes the difference 'one' by putting her counter back on the block (l. 3). Therefore, she interprets the difference as the change needed to establish an equality of two numbers; in this case, by removing or covering the difference. Leon, however, constructs an example of a number pair (5 and 2, l. 7), which he regards will have the difference 'two' (l. 4): if Maya had rolled number 5, she would have had two more. Accordingly, Leon increases the minuend to achieve a greater difference. In the following, he gains a new insight into how to compare two numbers ("I know"): he divides the counters in the blocks into 'lower' and 'upper', stating that the counters above are the additional ones (l. 7). Consequently, he matches the equal number of red and blue counters and highlights that only those counters that cannot be matched have to be considered. These counters can subsequently be counted one-by-one. By separating the numbers of counters into 'lower' and 'upper' and focusing on the 'upper', Leon creates a new initial situation for comparing: instead of 3 and 2, he compares 1 and 0. Here, he unconsciously uses the mathematical relation that the difference remains the same if minuend and subtrahend are increased or decreased by the same amount. He illustrates this insight with an own number pair of 5 and 2 and, thus, probably picks up on his assumption in line 5 to check it. He determines the difference by first identifying the fields where red counters would be located. The counting procedure of the fields seems to represent or replace the concrete action of putting counters in the block. He then counts the upper three empty fields in Maya's block where counters would be located, thus concluding that the difference is three. He succeeds in matching the equal number of blue and red counters, which are no longer important for determining the difference, whereby he can compare 3 and 0 rather than 5 and 2.

Conclusion: The children's interpretation can be characterized by their different reference contexts. Maya's actions indicate that she uses a reference context for interpreting the difference, which can be called "equalizing". She answers the question of how many counters have to be removed to establish an equality between the two numbers of counters. Expressed algebraic: $a\text{-}d\text{=}b;\ b\text{+}d\text{=}a$. She represents this change dynamically in the material. In contrast, Leon interprets the difference in a spatial-static way, which can be described as "matching", whereby he matches the same number of red and blue counters and determines as difference the number of counters that cannot be matched. Accordingly, he changes minuend and subtrahend by the same number to create a 'to zero' comparison: $a\text{-}b\text{=}(a\text{-}c)\text{-}(b\text{-}c)\text{=}d\text{-}0$, with $c\text{=}b$. By interpreting the arrangement of counters, however,

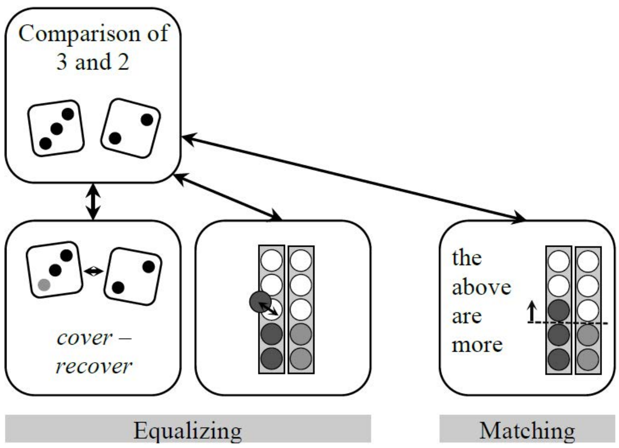


Figure 3: Epistemological triangle: 3 and 2

it is not necessary to identify the specific number of the equal change as subtrahend ($c=b$); rather, it is sufficient to remove or separate two unspecific yet equal amounts. This view on the arrangement of counters in the blocks of five helps Leon to determine the difference of his own example of a number pair.

The interpretation of "matching" builds upon the equality of two numbers to focus on the 'inequal'. "Equalizing", however, concentrates on inequality to determine the necessary change to establish equality between the two sets of counters. For both interpretations, it is not necessary to quantify the number of the equal counters; rather, a qualitative estimation 'equal' is sufficient.

Comparison of 5 and 2: What does Maya have to roll?

In the following, Maya and Leon win further counters. Now Maya has nine and Leon has seven counters collected on the ten-frame (see Figure 4). Leon rolls number 5 and is happy. Maya protests that number 5 would not be possible, since Leon would win too many counters. Hence, the question arises of what Maya has to roll for Leon to win.

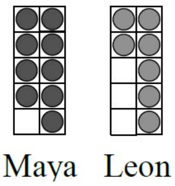

Figure 4

8 GA What does Maya have to roll so that you've won <u>immediately</u>?
9 Leon Mhh, one or zero or two.
10 GA Then you could win?
11 Leon 'Cause, 'cause wait (*takes his dice with the rolled number five and covers two dots with two fingers*), she's got to roll two.

12 GA # Why?
13 Maya # Heh?
14 Leon Because then I have three more (*shows his dice with the two covered dots*)

Leon answers the GA's question by giving three number pairs (5,1; 5,0; 5,2) with a difference greater than or equal to three (l. 9). Apparently, he assumes that he can win with every difference that is not less than three. In response to the question of whether he would win then (l. 10), Leon takes his dice with the rolled number 5 and covers two dots with two fingers so that only three dots are visible (l. 11). He concludes that Maya has to roll number 2 and then he would have three more. This approach leads to the following interpretation: Leon covers as many dots from the dice pattern of 5 so that three dots are left. The number of covered dots represent the number that Maya has to roll. In opposite to Maya, who covered the difference, Leon covers the subtrahend and the three dots left represent the difference.

It is remarkable that, on the one hand, Leon uses the dice pattern of 5 to *construe the difference* of 5 and 2. On the other hand, he uses it to *construct differences* due to the context of the game required to find a number pair with 5 for the given difference 3.

Conclusion: Leon's interpretation of the difference shows an expansion of his previous idea, whereby he decomposes the minuend 5 in two parts: 2 and 3. This enables both the statement that Maya has to roll number 2 to win three counters and the determination of the difference 3, if Maya had rolled number 2. Therefore, he compares 5 and 2 by "subtracting" 2 from 5. Expressed algebraic: a-b=d. Here, the activity of covering dots of the dice pattern has a double function: the construction of differences and the construing of differences.

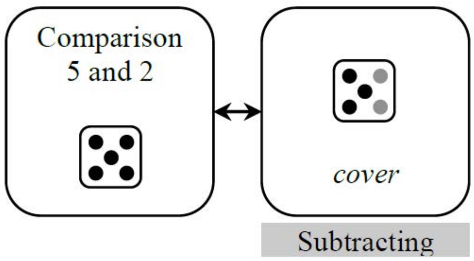

Figure 5: Comparing 5 and 2

Focus 2: The playing activity – Mathematically-centered play while playing a game

The playing activity of Maya and Leon in the context of "Who has more?" can primarily be described as "Mathematics Embedded in Play" (Ginsburg, 2006). Mathematical aspects are relevant, although the main issue is to win counters to fill the ten-frame the first. In addition and more surprisingly, "Play Centering on Mathematics" (ibid.) can be identified as a mathematical activity focusing on differences (see Figure 6). In this section, both mathematical playing activities are analyzed by the following characteristics: *involvement*, *rules* and *degree of freedom* (van Oers, 2014).

Children seem to be highly *involved* by playing WHM. They engage themselves in the fictitious competition and are pleased with a 'good' rolled number, for ex-

"Mathematics Embedded in Play" in the game	⇄	"Play Centering on Mathematics" esp. Differences
Put counters in blocks of five, according to the rolled number, determine the difference and fill the ten-frame.		a) Vary the use of materials b) Vary numbers c) Vary the interpretation of differences

Figure 6: Mathematically-centered play in the context of playing a game

ample. The game is framed by different explicit technical and conceptual *rules*, while further rules are negotiated in the gaming process (e.g. that the ten-frame has to be filled exactly). The children are *free* to choose whereupon they put their attention: social or mathematical aspects. Another analysis of WHM (Tubach & Nührenbörger, 2014) showed exemplarily that children keep the rule that 'the ten-frame has to be filled', aside from which they try to interpret the rules in their favor, e.g. manipulate the dice to get a full ten-frame quicker. Therefore, playing the game WHM embeds mathematics.

Nevertheless, this deviation from the intended playing course allows another type of play, namely "Play Centering on Mathematics". This playing activity can be recognized in the variation of using the game material, the variation of numbers and the interpretation of differences in the game material. In the following, these characteristics of mathematically-centered play are illustrated based upon the two sequences:

Variation of using materials: The reinterpretation of the game material is the key aspect for mathematically-centered play: Maya uses the dice pattern, which originally randomly determines the number of counters to put in the block of five, to represent the difference. In the second sequence, Leon also uses the rolled number as a representation to construct a number pair for a given difference. Furthermore, Leon regards the blocks of five 'as if' counters would lie there. Therefore, it is possible for him to cope with fictitious number pairs, not only to determine differences but also to test assumptions (5 and 2 have the difference 2).

Variation of numbers: Maya decreases the rolled number 3 by one and establishes a relationship to Leon's rolled number 2. Leon tries to increase the difference and increases the minuend of a number pair (5 and 2 instead of 3 and 2).

Variation of interpretations of numbers and differences: The analyzed different reference contexts show that children vary their interpretation of differences and also shorten the process of comparing two numbers in their blocks of five.

Children are obviously *involved* in these varying activities, as they are based upon their own ideas. They play together rather than against each other and inspire themselves towards new ideas, pick them up and develop them further. The *rules* are not explicit and predefined, but rather implicit and arise in the interaction in the playing process. In the context of the mathematically-centered play, transparency in own ideas seems important (social rule). At the same time, the children's ideas and interpretations are oriented on the properties and functions of the game material, e.g. they choose realistic numbers (technical rules). Their mathematical considerations are oriented on the game, which means that the game builds the conceptual framework for the mathematical activity (conceptual rule). The *degree of freedom* is apparent in the conceivable variations of how children (re-)interpret materials and their view on differences, as well as how they change numbers.

By means of the selected scenes, two types of play can be reconstructed, namely playing the game WHM and therein realizing mathematically-centered play with numbers, materials and interpretations.

CONCLUSION

The selected sequences of Maya and Leon indicate that the playing environment "Who has more?" offers rich possibilities to discuss interpretations of relations of differences. The epistemological analysis shows that children use individual reference contexts to compare two structured numbers of counters. However, these reference contexts are not used constantly, but rather are varied and become more sophisticated. This is reflected by the representations used and the ways of interpreting differences. As representation for differences, children use:

a) dice patterns, covering dots to represent a second or third number

b) blocks of five, to compare two linear structured (real or imagined) numbers

In addition, three different interpretations of differences could be worked out:

a) Equalizing: The difference (d) is the change needed to achieve equal numbers of counters: $b=a-d$ or $a=b+d$.

b) Matching: Equal amounts are matched to determine the number of counters that cannot be matched.

c) Subtracting: The two amounts are related so that the smaller number is interpreted as a part of the minuend, which can be removed: $a-b=d$.

It becomes clear that the recurring new situations for comparing and discussing in the game provide occasions to use not only individual different strategies but also make situational different and new interpretations, which become more differentiated (Nührenbörger & Steinbring, 2009; Stebler et al., 2013).

The analysis of the playing activities in the game also provided evidence that "Who has more?" not only enables "Mathematics Embedded in Play" but also allows "Play Centering on Mathematics", even while playing the game (Ginsburg, 2006). This mathematically-centered play can be distinguished from the social play where mathematics is embedded, in that it involves another intention (instead of winning, the focus is on varying numbers, materials and interpretation), it follows other rules and children are involved in other roles (explorer instead of competitor) (van Oers, 2014). Essential for mathematical play is the reinterpretation of the game materials as representations of mathematical relationships. Mathematically-centered play gains space in the process of playing the game. Thus, the space for mathematically-centered play is always limited by the game. To maintain the game process, there are only short periods for mathematically-centered play; for example, a new rolling of the dice interrupts the play with mathematical objects. If children's play stays focused on mathematical relations, e.g. they try to find further number pairs with a given difference, the game fades into the background or disappears.

Hence, connecting points for the arrangement of learning processes in primary school can be deduced: here, the mathematically-centered play can achieve more space in the context of a learning environment in primary school. Accordingly, children's experiences to construe and construct differences can be picked up, to play with the same material but independent from game, to construct differences, namely finding number pairs with a given difference.

From speaking to learning of parallelism and perpendicularity relations

Paola Vighi

University of Parma, Mathematics and Computer Science Department, Parma, Italy, paola.vighi@unipr.it

This paper studies the interaction between language and mathematical learning, with the aim of investigating whether the spontaneous language of younger pupils and class communication may improve understanding and learning. Simple artefacts, based on 'parallelism' and 'perpendicularity' of segments, were prepared and presented to two first grade classes in a primary school, through a narrative. Two different linguistic approaches were adopted: traditional mathematical nomenclature presented by the researcher in one class, spontaneous language suggested by the pupils in another class. Starting from this idea, similar didactical itineraries were realised in both classes. The results of the experiments are analysed and compared.

Keywords: 1st grade, spontaneous language, traditional language, parallelism, perpendicularity.

INTRODUCTION

Much research deals with the problem of the relationships between language and thinking. As is known, Piaget (1983) and Vygotsky (1987) have very different and divergent positions on this. From an epistemological point of view, the problem is in term of a priority among experience, language and mathematical knowledge. For Wittgenstein (1978), the language is necessary to communicate, but the word used to describe an object do not convey immediately its meaning, which must be constructed. Lakoff and Nunez (2000) see the linguistic activity as an effect of the cognitive activity and strictly dependent on it. Moreover, Sfard (2001) confers a big importance to the communication in mathematics; specifically, she deals with this topic in term of "metaphors".

In particular, in matter of the role of the language in learning processes, research underlines two fundamental and apparently opposing aspects: the specificity of mathematical language and the role of natural language in mathematical communication. In the present paper, I want investigate whether (and how much) the spontaneous language used to describe some geometrical configurations can improve the understanding and learning of some geometrical concepts. The main hypothesis is that the transition from the observation of geometrical configurations to the use of a spontaneous language to describe them can improve the learning of mathematical concepts. The choice of the mathematical topic "parallelism and perpendicularity" is motivated from the following reasons: these relations are uncommon in the 1st grade of Italian primary school, so it is possible to observe the role of spontaneous language without the influence of scholastic language. The geometrical context is suitable at this age, since it relies on visual mediators, objects and drawings. The history of humankind (Keller, 2004) shows drawings, made in Paleolithic, in which parallel and perpendicular segments are present (Lascaux caves). The training with parallel and perpendicular segments in 1st grade is encountered in writing some capital letters (E, F, H, T, ...). I found only a research on this geometrical topic (Meyer, 2010), but it was conducted in different manner and with students aged 9–10 years.

THEORETICAL FRAMEWORK

The present research compares the role of children's spontaneous language with that of traditional geometrical language in the acquisition of knowledge. The starting point is the following quotation:

> [...] *it is necessary to postpone the systematic use* [...] *of specific words*, i.e. the typical concepts of geometry (circle, square, sphere ...) [...]. Children must also *learn to speak about spatial events* with their own words (i.e. to describe a path, a fig-

> ure, a movement) (Speranza, Vighi, & Mazzoni Delfrate, 1988, p. 14)

In other words, at the beginning, pupils use their spontaneous language to describe geometrical situations and then the teacher promotes the passage to the specific language.

Starting from the idea that the origins of all languages are “rooted in the child’s first experiences”, Gawned (1990, p. 31) elaborated a theory based on four consecutives stages: the origins of the language of mathematics, as well of all languages, are rooted in the child’s first experiences (*real-word language*); the *classroom language* has an important formative effect on children’s mathematical understanding and learning, the teacher manages the *specific domain of the language of mathematics* as long as the *construction of meaning in mathematics* occurs. These four stages are not strictly sequential, but in practice, this model appears quite rigid.

Geometry allows one to work with concrete objects and their description by natural language. Therefore, I prepared some artefacts in the meaning of “theory of semiotic mediation” (Bartolini Bussi & Mariotti, 2008): an artefact is a “tool of semiotic mediation” when the teacher intentionally uses it to mediate a mathematical content:

> In particular, the teacher may guide the evolution towards what is recognizable as mathematics. In our view, that corresponds to the process of relating personal senses (Leont’ev, 1964/1976, p. 244 ff.) and mathematical meanings, or of relating spontaneous concepts and scientific concepts (Vygotsky, 1934/1990, pp. 286 ff.) (Bartolini Bussi & Mariotti, 2008, p. 754).

Duval (1993) introduced another important aspect, the ‘semiotic representation registers’ and their role in knowledge: he provides a rich theory on it, based on the assumption that ‘there is no knowledge without representation’. Following this theory, the introduction of artefacts promotes the transition from “visual semiotic register” to “verbal semiotic register”:

> We may distinguish three main groups of semiotic representations: material representation (in paper, card, wood, plaster, etc.), a drawing (made either with pencils on a sheet of paper, or on a computer screen, with use of a geometrical software, etc.), and a discursive representation (a description with words using a mixture of natural and formal languages). Each register bears its own internal functioning, with rules more or less explicit. Moreover, students have to move from one register to another, sometimes implicitly, sometimes back and forth (Dorier, Gutiérrez, & Strässer, 2004).

Following Nonaka and Tageuchi (1995, quoted in Lester & William, 2002, pp. 494–495) the dialogue is fundamental in moving from a tacit knowledge to an explicit one. Speech helps to build concepts; subsequently the word used is a symbol of the concept itself.

Sfard (2001, p. 26) integrates the previous considerations:

> The conceptualization of thinking as communication is an almost inescapable implication of the thesis on the inherently priority of social origins of all human activities. Anyone who believes, as Vygotsky did, in the developmental priority of communicational public speech (e.g. Vygotsky, 1987) must also admit that whether phylogeny or ontogenesis is considered, thinking arises as a modified private version of interpersonal communication.

Following these hints, the research chose to take advantage of the “need to find similarities” to lead pupils speak in their “real world language” about the relative position of segments.

The research questions

1) Is it possible to extend ideas of Speranza and colleagues (1988) to the descriptions of binary relations of parallelism and of perpendicularity? Could the use of personal words (or locutions) enhance a child’s understanding of the concepts of parallelism and perpendicularity? The transition from spontaneous language to geometric language could improve the learning?

2) Do very young pupils perceive the relations of ‘parallelism’ and ‘perpendicularity’ from a qualitative point of view?

THE EXPERIMENT AND ITS METHODOLOGY

The paper presents the results of a research performed in school year 2013/14 in different Primary Schools, which will continue into the following year. In particular, it reports only on an experiment that involved two 1st grade classes[1], class 1A (25 pupils) and class 1B (23 pupils), having the same mathematics teacher. All sessions of work were recorded using a video camera.

The researcher (the author of the present paper) prepared some artefacts, made of simple materials (cards, straws, buttons, glue, adhesive tape): eight square cards, with 23 cm. sides, each containing two straws in different positions. I used pleasant colours, red and green, for caterpillars, and a 'neutral' colour, light grey, for the background. Obviously, straws would be unsuitable for representing segments, since they are 3D objects, but the age of pupils (6–7 years old) allows this choice. Furthermore, the superimposition of the straws it is not possible, while this operation is permitted with segments in the plane. A small button (as the head of caterpillar) is glued at one end of each straw; in this way, another didactical variable, the orientation of the segment, is introduced. Children suggested this feature during a previous activity involving segments representing caterpillars (Vighi, 2008). The researcher produced some cards about parallelism (cards 2, 3, 6), other cards about perpendicularity (cards 5, 7, 8), and others (cards 1 and 4) with straws neither parallel nor perpendicular (Table 1).

The experimentation took place with the presence of both, the teacher and the researcher, in classroom. The activity starts by presenting a narrative regarding a green caterpillar, named Pelù [*P.*], and a red caterpillar, named Mangiamela [*M.*], who stroll together. It consisted of four (class1A) or five (class1B) *activities*:

1) <u>Presentation of the cards</u>. I adopted two completely different ways of working in class. In class 1A, the researcher presented the cards and she immediately introduced (and 'imposed') the corresponding traditional locutions: "*P.* and *M.* are parallel", "*P.* and *M.* are perpendicular" and "*P.* and *M.* are neither parallel nor perpendicular". In class1B, the researcher invited pupils to observe straws representing caterpillars placed on the cards and to describe them. Possible objections to the chosen methodology are: in class 1A the imposition of 'locutions' without explanation can create problems of understanding, in class 1B the choice of a 'name' for each card can obstruct the work by analogy and the recognition of common properties in same card's configurations. I was aware of this, but the aim was also to observe if and in which way pupils would overcome these problems.

2) <u>Choice of common linguistic expressions</u>. This activity, developed only in class1B, characterised the research. The children proposed many and different 'names' for each card and the teacher wrote all the linguistic expressions proposed on the blackboard; at the end, she asked for a vote to

1 Specifically, the experimentation took place in the Primary School of Vicofertile, a small town near to Parma (Italy). I acknowledge the teacher G. Barantani for kindly giving us the permission to perform in her classes and for her collaboration during the experiment.

Card 1	Card 2	Card 3	Card 4
			
Card 5	**Card 6**	**Card 7**	**Card 8**
			

Table 1: Cards

choose common locutions. Thus, the "language of classroom" (Gawned, 1990) was constructed gradually.

3) Drawing and writing in the notebook: the teacher placed each card in a very visible position and wrote the corresponding 'linguistic expression' on the blackboard. The task was to copy the card into the notebook and write its name, using a page for each caterpillar's position. In class 1A children wrote the 'locutions' imposed by the researcher (very long to write and difficult to read and to pronounce), in class 1B they wrote the 'names' obtained by vote.

4) Individual interviews: outside of the classroom, the researcher proposed two different tasks to each child. In the first the researcher presented the cards one by one to the pupil, asking him to remember to relative locutions and to say it out loud (transition from the representation to the language); when it was necessary, the child was allowed to bring her/his notebook to recall a forgotten linguistic expression. In the second part of the interview, the researcher gave two straws to the child, with the task of placing them following each locution previously introduced (transition from the language to the representation).

5) Activities in gymnasium: children worked two by two, reproducing the different mutual positions of caterpillars with their bodies, following the tasks suggested by the researcher.

The first four activities occurred of two-three weeks apart, the last at the end of school year.

RESULTS AND THEIR DISCUSSION

As expected, the *activity 1* had completely different effects in the two classes. In class 1A, the experiment confirms that the absence of a relationship between a word and its meaning created obstacles (sometimes insuperable): often, it compromised children's performances. I observed difficulties in remembering the word 'parallel' or 'perpendicular' and in pronouncing and writing them. Nevertheless, the methodology adopted allowed us to find possible relations among the cards described with the same locutions, without a specific request of recognition of common geometrical properties. In fact, it happened sometimes in the case of parallelism, rarely in case of perpendicularity: a possible explanation is that the visual perception of the first relation is 'stronger' than that of the second. In class 1B, the activity had a completely different development: each card suggested an image that evoked a common name or a linguistic expression and, in turn, each locution sent again to a mental image.

As regards the *activity 2*, children of the class 1B suggested many locutions, as shown in the following list of 'descriptions of each card' (DC):

- DC1: triangle, mountain, crocodile's mouth, their faces are far, they meet, they collide with each other, if you rotate it looks like an 'A'.
- DC2: pencil with rubber, they are horizontal, in a line, letter 'I', they are going to the same side, falling down the tree, looking like as one caterpillar, *M.* is going towards *P.*, *P.* works harder more since it ahead, letter 'I' rotated.
- DC 3: tree trunk, crocodile's closed mouth, horizontal stairs, pole, they are as a strip, they are horizontal, two lollipops, railway track, they do not meet since they are going straight, train, ladder with rungs.
- DC 4: beak, elephant's trunk, mouse's snout, mouse's whiskers, one straight and the other slanting, railway track, crocodile's closed mouth, railway, they do not meet since they are going straight, a boat.
- DC 5: as a 'T', *M.* helps *P.* to bring an apple from the tree, *P.* climbs up *M.*, turning it in another way it looks like a 'T', each one goes home, one goes up another one goes right, competing in a race.
- DC 6: slanting giraffe's neck, slanting vertical line; curve; escalator in a supermarket, slope, steps, competing in a race, slanting railway track, slanting vertical line, rows.
- DC 7: slanting; letter 'Y', *M.* is falling down, *P.* is standing up, a kind of 'L', turning it looks like a 'L', *P.* is below and *M.* is on it.
- DC 8: letter 'L', two attached lines, car seat, half rhombus, two colliding cars, *M.* sniffs the feet of *P.*, looks like a hut slightly tilted.

The locutions underlined represent the results obtained by votes. Afterwards, each locution became the only linguistic expression used in reference to the corresponding card. This list of possible names for the cards is a very rich material to study the role of the language as a vehicle of pupil's perceptions. In a previous research paper (Vighi & Marchini, 2014), they were analysed in terms of "intrafigural, interfigural or transfigural space", using the same adjectives introduced by Piaget and Garcia (1983) but with reference to the "stages of learning". I also observed the presence of "independent space" as reported by Speranza (1994); in particular, I remarked that the majority of the poll choices reveal an idea of intrafigural space (Vighi & Marchini, 2014, p. 115). The previous list contains metaphors (Sfard, 1997), linguistic constructions describing a subject in terms of another unrelated object. There are also expressions referring to movements of caterpillars (they collide, they are going to the same side, etc.), maybe influenced from the narrative.

Drawings made during the *activity 3* gave other information: it was possible to observe if pupil's drawings respect parallelism, perpendicularity, distances between segments, their orientation and their length. At this age, the ability to draw is limited, so the final drawings very often were quite different from the cards configurations. In particular, some names influenced the drawing: for instance, the name "letter Y" induced to draw two segments with different lengths and not perpendicular, the name "letter L" suggested drawing segments parallel to the sides of the card by a rotation of the segments, etc.

The qualitative analysis of films produced during *activity 4* was very interesting. The individual interviews allowed us to verify not only the children's learning and understanding, but also to study their behaviour, abilities, difficulties and progress. Regarding of the first part of the interviews, 'cards names' recollection, as expected, in class 1A were observed more difficulties than in class 1B. Indicatively the percentage of positive answers was respectively 30% in class 1A and 80% in class 1B. In the first class, very often children said: "I don't remember", "I don't know". Moreover, after the revision of their notebooks, some of them were unable to deal with the task. Often pupils remembered only the name of two or three cards and they used the locution 'neither parallel nor perpendicular', systematically, in the other cases. Therefore, the lack of connection between a word and its meaning clearly emerged (Wittgenstein, 1978). Some pupils overcame the problem by proposing personal *locutions* very similar to those that emerged in the other class: for instance, "the beak of a bird" for card 4, "the equal symbol" for card 3 etc. In contrast, in class 1B children gave correct answers very often. Sometimes they firstly remembered their own locution and only in a second time chose the common name. The case of Benedetta, a little girl of class 1B, is significant: in front of card 5, firstly she said her own description "*M.* helps *P.* to bring an apple on the tree" and only in a second time she remembered the common locution "as letter T" associated to the card. The behaviour of the pupils in class 1B can be explained also in term of 'evoked concept image' (Tall & Vinner, 1981): for instance, when card 1 was shown, the child spoke the locution "crocodile's mouth" almost immediately, since the 'mental image' and 'name' were strictly related.

About the second part of the *activity 4*, the work with straws, pupils particularly appreciated the possibility of 'manipulating the caterpillars', putting them in different positions. In both classes, I observed the attempt to remember the straws arrangements in the cards and to place them in the same way, but with very different results: it was very difficult in 1A, not in class 1B. Often in the first class, children put straws randomly, without relationship to the words suggested by the researcher, some pupils remembered only one relation, more often parallelism, only children with a 'very good memory' could deal with this straws activity without problems. An important observation emerged about the task "put the straw neither parallel nor perpendicular": sometimes its meaning became 'a change of straws orientation with respect to the sides of the card'. In fact, another didactic variable is present in our artefacts, the 'form of the background'[2]. In class 1B, both the activities of 'writing with straws' and of 'reading straws arrangements' appeared easy to execute. A possible interpretation, as previous written, is that the 'locutions' chosen after the vote (those underlined in the list) became the 'proper names' of the cards and that these 'locutions' derive from the natural or scholastic language, in any case from lived experiences.

2 I decided to study its role preparing also eight round cards with straws glued 'in the same positions' of the straws placed on the squared cards. I presented the same activity based on round cards in another class and I compared the results.

Lastly, pupils appreciated the *activity 5*: they considered it as a play activity and the suggestion to act out the caterpillars with their own bodies stimulated their motivation to remember the different arrangements of the straws.

CONCLUSIONS

Next year, the activity will continue and the researcher will show some films produced in other classes[3] on the same subject to class 1B. The comparison of very different locutions, adopted to describe the cards of Table 1, will pose the problem of the use of different linguistic expressions for the same thing. For instance, the card 3 was named "railway track" in class 1B, but in other classes the names proposed were "equal" and "road": the question will be on the use of only one name well accepted and understandable for all children. In a second occasion, the teacher will organize a meeting between her classes 1A and 1B, with a comparison of the locutions. In this way, gradually, it is possible to stimulate the need of a common language and, later, to touch the topic of the 'role of the scientific language'.

The activity proposed offers the possibility of rich visual and linguistic experiences about parallelism and perpendicularity. Pupils remembered more their own locutions easily, while the 'imposed locutions' created a real situation of difficulty. In class 1A some pupils tried to overcome by finding common properties when the 'name of the card' was the same. Other children memorized all the 'names' or many of them. In particular, one child refused to memorise and he repeated this question: "What is the meaning of this words?"

The answer to the first research question is affirmative: the experimentation confirms that the use of personal locutions favours the concepts learning. For instance, in class 1B, in the case of cards 3 and 6 the votes gave, respectively, "railway track" and "slanting giraffe's neck": a possible interpretation of the use of these two different metaphors is that pupils are unaware of the likeness (i.e. parallelism) of the two cards. But, when a child of class 1B describes the card 6 as "slanting railway track", he shows to transfer the 'name of card 3', "railway track", to the card 6, making an adjustment by the use of an adjective: it documents the recognition of a common property of the straws arrangements in both cards. Similarly, the confusion between "railway track" and "slanting giraffe's neck" shows a grasp of the property of parallelism present in both the cards. Hence, an apparent mistake becomes a symptom of generalisation and of the recognition of an analogy between the caterpillar's positions in cards 3 and 6.

Referring to the second research question, in both classes I observed that only a part of children perceived the presence of invariants and, consequently, they distinguished parallelism, perpendicularity or the incidence of two segments. As regard parallelism, the constant distance between straws plays an important role: sometimes a child indicates this property with her/his hand, comparing it with the cases of cards 1 and 4 and highlighting the difference of the distances between the straws. As regard perpendicularity, I could observe the clear role of writing capital letters: the idea that cards 5 and 8 present arrangements of the straws similar to 'letter T' (even if in 'not canonical position') or to 'letter L' supports the pre-conception of perpendicularity. The case of letter 'Y' (card 7) is different: if a child makes it by attaching two straws with as much contact as possible, he obtains a right angle, but in fact, the shape of the letter Y, without a right angles, prevails. However, the observation "turning in that way it looks like an 'L'", referred to card 7, suggests the recognition of right angles. Sometimes the role of capital letters was negative: since different letters have different names, some pupils did not recognise the analogy among cards 5, 7 and 8.

In conclusion, our research gives concrete and meaningful situations that highlight the invariants in the concepts of parallelism and perpendicularity. The proposed activity appears suitable for young pupils. Usually the teaching of geometry in Italian schools starts in the third class (pupils 8–9 years old), when the parallelism is necessary to work with parallelograms and the perpendicularity is associated with right angles. However, as I reported above, these concepts are already present in writing capital letters, so they can brought forward without problems.

3 Classes 1A of Fognano (Parma) school and 2A of Vigatto (Parma) school. I thank the teachers Barbara Riccardi and Lucia Ferrarini for their collaboration.

Preschool class children's mathematical meetings

Sofie Arnell

Linköping University, Department of Behavioural Sciences and Learning, Linköping, Sweden, sofie.arnell@liu.se

This paper presents a minor part of an ongoing study about how young children meet mathematics. The purpose of this study is to investigate how and when children meet mathematics and engage in mathematical activities in preschool class and also to see how their meeting with school's more formal mathematics is arranged.

Keywords: Mathematical meetings, mathematical activities, preschool class children.

INTRODUCTION

Mathematical knowledge develops through mathematical activities, when shifting from act to thought and backwards. Bishop (1991) listed six fundamental activities that constitute the foundation of a culture's mathematical development [1]. At an early age, children are involved and engaged in informal mathematics connected to these, but in different degrees (Seo & Ginsburg, 2004).

In Sweden, almost every six year old goes to preschool class, a voluntary type of school between preschool and elementary school. Preschool classes are supposed to follow most parts of the public school curriculum, but not the section about subjects and syllabuses, since preschool classes do not arrange regular lessons and subject teaching (Skolverket, 2011). When children enter school and meet more formal mathematics, we can see a large variation in mathematical skills between the children (Fredriksson, 2009). But we know less about how this meeting is arranged. Therefore, it is important to investigate in what ways children actually meet and engage in (informal) mathematical activities in preschool and to see how they meet more formal mathematics in school.

METHOD

The data collection has an ethnographic design (Hammersley & Atkinson, 2007). It includes observations of and informal dialogs with 20 preschool class children in their everyday classroom. The study began in September 2014 and will last to October 2015, when the children have entered school. After the summer vacation the observations will especially concern lessons in mathematics, but also "non lessons" such as lunch breaks.

ANALYTICAL FRAMEWORK

Throughout the data collection and the analysis process a grounded theory (GT) approach (Glaser & Strauss, 1967) is used. The research question is relatively wide and the constant comparative method in GT helps to avoid making premature conclusions by staying close to the data. It also helps to systematically sort the data to find categories that later will build up the theoretical model, grounded in data.

RESULTS

Preliminary results show that preschool class children meet mathematics in several ways, in this study constituted by different categories. An inside and an outside perspective represent each of these, where the inside perspective includes mathematics children meet through own mathematical engagement and the outside perspective includes mathematics children meet trough encouragement and involvement from others, such as teachers and peers.

One category, of how preschool class children meet mathematics, is called *notices quantities*. In this category the inside perspective, entitled *own quantity engagement*, contains the subcategory *quantity indicating*. This includes situations when the child, on its own initiative, meets or engages in mathematics by showing interest for quantities, for example by telling or informing about how many, being curious about how many and then exploring it, and also by asking questions with a specific number in it. The outside perspective of this category, entitled *quantity invitations from others,* includes two subcategories, *quantity challenging* and *quantity clarifying*. Quantity challenging involves situations when someone else, a teacher or a peer, challenges the child to explore quantities, for example by letting the child answering questions about quantities, count something, add two quantities up or take away something from a quantity. These tasks can be given both on a concrete and on an abstract level. Quantity clarifying involves situations where someone else, usually the teacher, confirms, develops and clarifies the child's quantifying answers. This category also involves making quantities visible for the child, for example by keeping statistics on the whiteboard or explaining the mathematical content in an activity, both individually and for the entire group.

Pre-school child and natural number

Michaela Kaslová

Charles University in Prague, Faculty of Education, Prague, Czech Republic, michaela.kaslova@pedf.cuni.cz

This work represents a part of a longitudinal research project realised in Czech kindergartens during last 15 years. We analysed data obtained from 580 children 5 to 6 years of age, 6–7 months before they began primary school. The research was focused on the natural number in different roles and situations. The variability of children´s reactions is presented and a particular deficiency in the pre-school curriculum is described. The results can help elementary school and kindergarten teachers.

Keywords: Natural number, kindergarten, configuration, quantity.

INTRODUCTION

Pre-school children differ from primary school pupils in that they are in the stage of concrete reasoning and at a pre-operational level, their vocabulary is relatively rich but not yet stabilised because the development of notions is at its initial stage; their process of generalisation is limited by the characteristics of this evolutional stage including egocentrism (projection, identification, impossibility to differentiate their needs, desires from reality) and syncretic perception (the object as a whole); children's experience could be deformed by accompanying emotions. The philosophy of education in families has changed during last twenty years, as has the teachers' work at kindergartens. What is the situation in reality?

Natural number can play different roles; it depends on the context in which it is used. For example, it can be in the role of quantity (number of objects/of physical units) or without any mention of quantity. Research shows that the development of the concept of natural number is not yet independent of the character of counted objects (colour, position, distance, configuration, material, shape, weight, size, visibility, ...); see Piaget (2000) and Anderson (1987) cited in (Atkinsonová et al., 2003), Hejný, Kuřina (2001), Kaslová (2010) and others . This process of generalisation depends on different aspects. It is a relatively long process, not unified for six-year-old children. We assumed a certain starting level of the development of this notion. The pre-mathematical test (or PM-Test) is composed of 4 parts in which a natural number is in the role of: 1) a member of spoken series, the orientation in its order (a, b, c, d), 2) quantity – its independence of colour (a), shape (b), position (c), visibility (d) of counted objects or by mixture of these characteristics (m, n), 3) quantity in changing conditions (a, b); 4) quantity objects in the structure/ rhythm (a, b, c).

METHODOLOGY

The PM-test was realized in the form of a dialogue between a questioner and 1 or 2 children. The PM-T had 15 subtests and it was accompanied by common checking activities. Subtest (2c) focused on natural number in the role of quantity of spots. I observed the independence of their quantity on their mutual position. The PM-T supposes that the pre-school child is able to draw more than 6 different representations of natural number "six". The child had to observe a picture (6 spots on paper 10 cm x 10 cm); the configuration of spots corresponded to the configuration on the dice. The child received white paper of the same measures and had to draw the same number of spots but in a new position (using only one colour). We assumed that 90 % of children would be able to create a minimum of 6 "new draws" with a success and 50 % of children will use the strategy of modification (changing only one position of a spot).

SELECTED RESULTS

5 % of children were unable to discover a new configuration; 10 % worked well but at most they created only 5 different configurations; 4 % of children created more than 30 different configurations (max. 68); 11 % of children in 20 % of their pictures, at maximum, created a new configuration, dividing an old configuration in two parts and transferring one part to a new posi-

tion; 7 % of children created a configuration different from the model but in the majority of cases by making a quantitative mistake; 88 % worked with 0 – 3 mistakes at maximum. 22 % of children were able to use a good spontaneous self-check, corrections included at one correction, only 6 % of children self-corrected all their mistakes (complementation, cancellation) – half of this group created more than 30 configurations; 71 % children worked in a special rhythm: after 3 to 5 new configurations, they repeated one of the "old" configurations ("smaller or bigger" drawing). 94 % of children did not use the strategy of modification, in the majority of cases. This means that the configuration was made as a new picture – a new whole. This shows that the "whole perception" (syncretism) still predominates.

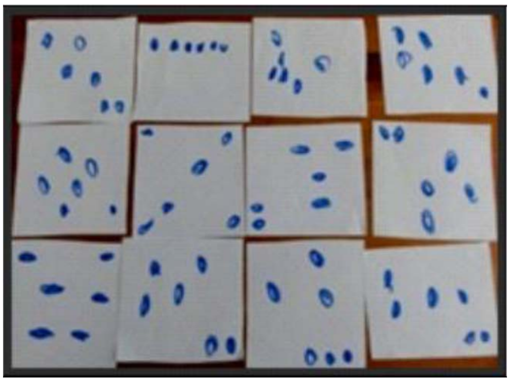

Figure 1: Example of children's work

The development of numerical thinking in children aged two to five

Irit Lavi

The University of Haifa and Oranim college, Haifa, Israel, iritla1@gmail.com

In this study, I will trace the development of young children's numerical discourse. I present a theoretical model constructed to reflect the hierarchical nature of primary numerical discourse. This model will be tested and refined in a longitudinal study among 2 to 5 year old children. Every child will participate in a series of number-related activities, to be performed either with the help of concrete objects like cubes, candies est. or as specially designed iPad tasks.

Keywords: Young children, numerical discourse, developmental model.

This research rest on the *communicational approach,* rooted in Vygotsky's socio-cultural theory, which emphasizes the social aspects of learning (Vygotsky, 1962), and puts communication at the heart of any learning (Sfard, 2008). In this framework, the term "numerical discourse" embraces both interpersonal communication on numbers, and the intrapersonal communication (child's thinking about numbers). This non-dualist vision implies that the object called number, rather than being a self-sustained, mind-independent entity, is a discursive construct, that is, emerges from discourse and is built through communication (Sfard, 2008, 2012, in press). Numerical discourse is using number words while telling stories about the world. As opposed to Piagetian approaches, in the communicational approach there is no ontological gap between the world of abstract mathematical objects and the mathematical discourse as such. Numbers are part and parcel of the talk about them. Hence, numbers are discursive constructs that emerge for a person through using number words while participating in a numerical discourse. Learning mathematics is the process of extending and modifying one's mathematical discourse. This process, called *individualization* happens while the student imitates the expert in the discourse, and results in the learner's autonomous participation in the discourse. It is through the process of individualization of numerical discourse as presented by others that the child will build new objects called numbers (Sfard, 2008).

This longitudinal study will follow 16 children with middle and upper class socio-economic backgrounds. Data collection will continue for two years, and the participants will be split into groups based on their age. The data will be collected from conversations of the researchers, the participants and their parents as they perform predetermined activities. Each activity will be completed twice, once with concrete visual mediators and once with a specially designed programme on a tablet. During each meeting, the children will be shown a task involving one-to-one correspondence, rote counting and comparison. Conversations with the participants will be recorded on video and will be precisely transcribed.

In presenting the poster I will provide a brief overview of the method of study, the individualization process of numerical discourse and the developmental model. In assembling the model we based on (1) our understanding of numerical discourse (2) the hierarchical nature of this discourse (3) historical data and (4) past findings about rudimentary numbers learning (Sfard & Lavie, 2005).The underlying assumption in this model is that the initial numerical discourse as I know it from observation and experience is built from two different discourses: (1) Quantity discourse, which contains comparison words such as, "bigger than", "smaller than", "a lot", "few", "equals" etc.; (2) numerical discourse, which is comprised of number words. I will argue that at some point, these two discourses join together. As a result of this amalgamation, two new discourses are produced: Numerical quantity discourse and Arithmetical discourse which deals with numbers and operations performed on them.

The challenge of this study is to develop and refine this current version of the model that describes the formation of the numerical discourse using the characterisation of mathematical discourse as consisting of vocabulary and syntax, visual mediators, routines and endorsed narratives (Sfard, 2008, 2012) and analysed the data by these characterizations. I hope that this unique analytic approach would shed new light on the vastly investigated subject – the numerical discourse. Another challenge of this research is to identify the individualization process as accrued through the use of iPad and material objects. These two alternating learning environments were chosen because these are the environments children play in nowadays, and in which they feel comfortable.

Visualisation of shapes and use of technology in kindergarten

Geir Olaf Pettersen[1], Monica Volden[1] and Elin Eriksen Ødegaard[2]

1 UiT The Arctic University of Norway, Faculty of Education, Tromsø, Norway, geir.olaf.pettersen@uit.no

2 Bergen University College, Faculty of Education, Bergen, Norway

In 2006, the Norwegian government added mathematics and technology as a subject in the national guidelines for kindergartens in Norway. The activity in this case is a visualisation task about the connection between 2D and 3D shapes. The activity starts with a short introduction from one of the researchers, where she together with children explored different 3D shapes with collapsible folding shapes. After a while, iPads were taken into the activity, using an application where they could see 3D shapes fold and unfold. The activity lasted for around 50 minutes where the children freely combined the work on the concrete folding shapes and the ones at the iPads. Preliminary findings indicate that the children were focused on the appearance more than the characteristics of the shapes. Further, technology gave some new opportunities, but also some limitations due to tactile feelings.

Keywords: Kindergarten, technology, geometrical shapes.

RESEARCH QUESTION

How do children utilise technology when exploring the transition between 2D and 3D shapes? Does technology add something to this activity?

The aim of the study is to develop knowledge about children's use of and explorations with interactive devices, like touch screens seen in relation to traditional play material for construction.

THEORY

The case study will be discussed in light of explorative and a playful approaches to mathematics (van Oers, 2010), where children experience different geometrical shapes. Van Hiele's model will work as a framework for the analyses of children's understanding (van Hiele, 1986). Clements and Sarama (2007) argue that use of different concrete models will help children develop spatial skills. The study reported here will support this by using an iPad application.

METHODS

The method is an explorative case study (Cohen, Morrison, & Manion, 2007) where the researchers together with kindergarten teachers designed and carried out the activity. The case study is explorative due to lack of research on kindergarten activities that combine virtual and concrete objects.

Figure 1

Two boys and two girls aged five were studied and the activity was recorded with two video cameras and transcribed. It was analyzed by the researchers and discussed with kindergarten teachers for validations.

EARLY FINDINGS

The children used the names of 2D shapes like circles, squares, rectangles and quadrilaterals, but not always in a very accurate way. For instance, a boy referred to a square as a long quadrilateral, although still pointing at a rectangle.

Figure 1 illustrates the activity. To the left, they compare the shapes included in the cylinder. Initially, they interpreted the group of shapes as a smiling face and pointed out the eyes and mouth. To the right, they compare concrete shapes with virtual shapes on an iPad. They used the color function to make the virtual shape look equal to the concrete shape. The children were focused on the appearance (e.g., color, proportions) more than the characteristics (e.g., angles, parallel sides) of shapes. Our findings indicate that the combination of technology and traditional collapsible folding shapes can give children richer experiences when they use the iPads to understand how to fold and unfold 3D shapes. We observed that this iPad application can help children investigate several shapes more effectively than with traditional solid shapes. Despite this, the tactile aspect must not be underestimated. Holding and touching the physical shapes is important for children´s investigation of shapes.

The role of the structure in early mathematics learning: Research with children aged four

This poster reports a broader project that aims to research the preschoolers' cognitive capacities in mathematics learning, and integrates two studies that were carried with four-year-old children aiming to understand: (i) the children´s ability to subitize, and (ii) how the process of emergence of algebraic thinking develops. The results show the importance of structure in early mathematics education.

Keywords: Structure, early mathematics learning, pattern.

SUMMARY

Mathematics has been an important subject area within the Portuguese curricula for preschool education. Moreover current research has shown that young children can generalize mathematical ideas much earlier than previously supposed (Mulligan, 2013). Structure has a key role in the process of generalization. With appropriate designed and implemented learning experiences, young children are able to develop forms of reasoning involving the process of generalizing (Papic, Mulligan, & Mitchelmore, 2011).

Conceptual subitizing plays an advanced-organizing role (Sarama & Clements, 2009). In spatial patterns, some arrangements lend themselves to grouping facilitating the sudden recognition of the number using consciously strategies of decomposition linked to numerical structure.

This poster will present the results of two studies integrated into a broader project which aims to research the preschoolers' cognitive capacities in mathematics learning. Both studies were carried with four-year-old children. One of them intended to understand the children´s ability to subitize and the other aimed to understand how the process of emergence of algebraic thinking develops.

Both studies were developed in private schools in Lisbon and adopted a qualitative research methodology under the interpretive paradigm, emphasizing meanings and processes. The researchers took the dual role of teacher-researcher: each one conducted the study with her own children's group and in her own natural environment. Participant observation and document analysis (audio and video recordings, images and documents produced by the children) were used as data collection methods.

The research data of Cordeiro's study showed that children can subitizing up until four and begin subitizing sets of five and six items with different spatial arrangements. Children do perceptive subitizing, but few children begin to show signs of doing conceptual subitizing which contributes to numerical structuring. Children are able to identify the number of dots in patterns, eventually become familiar with them and even start making mental relationships between numbers, composing and decomposing them, and developing their number sense. The most common spatial arrangement of sets in the cards (corresponding to the domino game) is the easiest to identify, followed by rectangular, and after by linear and circular arrangements. The structure marked by the use of two colors or by the use of two groups in the spatial arrangement of sets, in the cards, contributed to the emergence of conceptual subitizing, decomposing collections into smaller recognizable collections, and either using addition to determine the total.

The results of Serra's study indicate that children master the concept of repeating and growing patterns, and they are able to identify the unit of repeat, create and analyze patterns of various simple repeating and growing patterns, evolving from simpler forms to more complex forms, in the case of pictorial repeating patterns. Children are aware of the pattern's structure when they identify either the unit of repeat or the regularity of a pictorial growing pattern. In this last case, children used a correspondence analysis of change indexing the figure number with the changing aspect of the dependent variable.

These results offer possible implications for the existing research in the area stressing the role of structure in early mathematics education, namely in the field of mathematical relationships.

THE WAY OF PRESENTING

In the poster, we will illustrate the main results related with structure by exhibiting some of children's productions, communicating them in a pictorial format. Next to visual data there will be short sections: (1) Introduction; (2) Theoretical framework; (3) Methodology; (4) Results; (5) Final considerations; and (5) References.

Collaboration between scientists and teachers in the context of mathematics education of young children

Maria Sorokina

Warsaw University of Technology, Baltic Institute of Mathematics, Warsaw, Poland, mv40ina@gmail.com

Educators are always seeking alternative and effective approaches to education. The approaches, in the context of young (from 3 to 8 years old) children education, discussed in this poster are based on joint work between scientists and teachers involved in the process.

Keywords: Young children education, scientists, teachers, STEM.

AIM

Nearly from birth, young children develop everyday mathematics including informal ideas of more and less, taking away, shape, size, location, pattern and position. Mathematics helps children make sense of their world. All children can be successful with mathematics, provided that they have opportunities to explore mathematical ideas in ways that make personal sense to them and opportunities to develop mathematical concepts and understanding. Children need to know that teachers are interested in their thinking, respect their ideas, are sensitive to their feelings and value their contributions.

Young children have an endless supply of energy hence they can study till they have fun. It is very hard not to kill creativity and interest at that age. Apathy as a result of misunderstanding is a most common problem for the young children. No answer after another question "Why? What? etc." makes it happen. How we can solve that problem will be shown on the poster.

BACKGROUND

Mathematical education for young children is not new (Fuson, 2004; Denton & West, 2002; Vygotsky, 1986). In the 1850s, Froebel introduced a system of guided instruction focused on various "gifts." It included blocks that have been widely used ever since to help young children learn basic mathematics, especially geometry (Brosterman, 1997). In the early 1900s, Montessori, working in the slums of Rome, developed a structured series of mathematics activities to promote young children's mathematics learning. If children are capable of learning mathematics, and if we choose to help them learn it, what kind of mathematics should we teach and how should we teach it? The decisions stem from our educational values and goals, but should be informed by psychological research.

METHOD

The author of the poster proposes to seek for a solution as collaboration between science and education. For four years, the author has been involved in project Futurum2020. The project provides education for children. We use several method in the case of young children (3–8):

1) Scientists come to the classroom once a week. Topics, which children have mastered during that week, are discussed. A scientist shows some visualisations and gives some additional topics (graph theory, logic, etc) (For example, one can use Martin Gardner's ideas, 1970–1980)

2) A Math circle was organised for those children who enjoy math. Exciting topics that are normally outside the school curriculum were discussed. Some brilliant children get their first research problems. Simple ones, but real, with no known-in-advance solution.

3) STEM camps were organised 4 times a year. Time and space in the camp was filled with the atmo-

sphere of creativity. Solving problems took place both in classrooms and on the mountain paths thus allowing diving deeply into the amazing world of math.

Different generations of children and adults gathered at the same place but had their own educational programme. Scientists organised several lectures for teachers.

RESULTS

Organising camps in such a way helps to make transition between pre-primary and primary school "smooth" and unstressful. The results are amazing! During the first months of the programme, teams (a scientist and a teacher) found children with learning disabilities and helped them by co-working on finding different ways to approach math facts.

This way we showed that collaboration between a scientist and a teacher is very important and useful because it looks like a symbiosis in nature: teachers study mathematics, scientists study psychology. QED

THE WAY OF PRESENTING

The poster included the purpose, method and results, also examples of collaboration between scientists and teachers were discussed.

Preschool class – one year to count!

Helena Vennberg

Umeå University, Department of Science and Mathematics Education, Umeå, Sweden, helena.vennberg@umu.se

I will present results from a case study of teachers' experiences and opportunities to assess pupils' mathematical development and thereby identify pupils' mathematical difficulties during the preschoolclass year. The study is part of a development and cooperation project between NCM (National Center for Mathematics education) in Gothenburg and Umeå University.

Keywords: Preschool class, intervention, assessment, teachers.

BACKGROUND

The Swedish preschoolclass (age 6 years old) is often described as the link between preschool and school. Curriculum for preschool (age 1–5 years old) in Sweden has an ambitious mathematical content (Skolverket, 2010) that is in many ways linked to the compulsory school curriculum in mathematics (Skolverket, 2011). But for preschool-class there is no specific curriculum in mathematics. In preschool and school in Sweden there are different views on what develops pupils' knowledge and/or competencies. Knowing mathematics can be understood in two different types of knowledge (Wedege, 2010). Knowledge *developed* in everyday life (Type 1), with representatives as D'Ambrosio and Bishop, and knowledge *wanted* in everyday life (Type 2) were Kilpatrick and Niss are predominant. Preschool in Sweden are influenced by Type 1 whereas school are strongly influenced by Type 2. When it comes to developing mathematical knowledge, preschools assess their activities which is different from the school context were the pupils' knowledge are assessed. This circumstances lead to a lack of clear guidance for the mathematical work in preschool class. In view of the lack of clarity that surrounds goals in mathematics for preschool class, questions arise regarding on what grounds teachers meet and asses students' knowledge and when do teachers in preschool-class discover misunderstandings that may exist in mathematics?

AIM

The twofold aim of my study include to describe preschool-class teachers' perception of pupils' mathematical development and analyze if raised awareness of pupils' mathematical development changes the possibility of early identification of difficulties in pupils mathematical development and prevent creation of pupils with special educational needs in mathematics. For this purpose two questions are posed:

When and how will pupils' mathematical development become visible to preschool-class teachers? When and how will pupils' difficulties in their mathematical development become detectable to preschoolclass teachers?

METHODS

Data was generated by following 14 teachers in nine preschoolclasses with a total of 200 students from four different schools from November to June. Three of the classes and three teachers were part of a control group where I followed their regular activities. The remaining 11 teachers and six preschoolclasses were part of an intervention, designed to build structured activity in mathematics where pupils, meet, use, develop and reason with different representations of numbers (Sterner, 2014).

The study includes several data collecting elements. At four occasions the teachers were asked to assess their pupils. The assessment was based on a matrix, influenced by Kilpatrick's framework (2001) on mathematical proficiency and the similarities in curricula goals for preschool and primary school. All the pupils were interviewed and tested with the Van Luit's "Early Numeracy Test" (2005) – in November and in June. The scores are used mainly as control points in relation to the teachers' assessments in regards to number sense, as being one of the key factors in knowing mathematics.

Interviews were held with the teachers in November and at the end of the preschool class year, in June. Observations were conducted in the preschool-classes on several occasions.

RESULTS

The intervention group had more activities and communication between teachers and pupils and in-between teachers. Increased communication between teachers led to raised awareness regarding their own knowledge of mathematics and of pupils' mathematical development. Raised awareness of pupils' mathematical development enhances the teachers' possibility to assess pupils' and to detect and correct gaps in pupils' math skills. The teachers describe a feeling of security in their knowledge and assessment but at the same time they express a sense of greater difficulty in assessing, even when the assessment were more accurate.

TWG14

University mathematics education

Introduction to the papers of TWG14: University mathematics education

Elena Nardi[1], Irene Biza[1], Alejandro S. González-Martín[2], Ghislaine Gueudet[3], Paola Iannone[1], Olov Viirman[4] and Carl Winsløw[5]

1 University of East Anglia, Norwich, UK, e.nardi@uea.ac.uk
2 University of Montreal, Montréal, Canada
3 University of Brest, Brest, France
4 University of Agder, Kristiansand, Norway
5 University of Copenhagen, Copenhagen, Denmark

Research on university level mathematics education is a fast developing field as evident in the growth of the CERME *University Mathematics Education* (hereafter UME) Thematic Working Group. TWG14 was launched in CERME7 (Nardi, González-Martín, Gueudet, Iannone & Winsløw, 2011). After CERME8 (Nardi, Biza, González-Martín, Gueudet, & Winsløw, 2013), its leader team – in collaboration with TWG14 participants and others – worked towards a *Research in Mathematics Education* Special Issue on *Institutional, sociocultural and discursive approaches to research in university mathematics education* (Nardi, Biza, González-Martín, Gueudet & Winsløw, 2014) which focused on research that is conducted in the spirit of the following theoretical frameworks: *Anthropological Theory of the Didactic*, *Theory of Didactic Situations*, *Instrumental and Documentational Approaches*, *Communities of Practice and Inquiry* and *Theory of Commognition*.

The work of the group at CERME9 cemented and furthered this work but welcomed contributions from across the board of research approaches: the teaching and learning of advanced topics; mathematical reasoning and proof; transition issues "at the entrance" to university mathematics, or beyond; challenges for, and novel approaches to, teaching (including the teaching of students in non-mathematics degrees); the role of ICT tools (e.g. CAS) and other resources (e.g. textbooks, books and other materials); assessment; the preparation and education of university mathematics teachers; collaborative research between university mathematics teachers and researchers in mathematics education; and, theoretical approaches to UME research.

The critical – and growing – mass and quality of the work presented at TWG14 has led to the launch of an ERME Topic Conference, INDRUM2016, a conference of the newly launched *International Network for Didactic Research in University Mathematics* (France, Montpellier, March 31 – April 2). Its two broad themes are *teaching and learning of specific topics in university mathematics* and *teachers' and students' practices at university level*. In anticipation of INDRUM2016, in this report, we outline briefly the main focal points of the 45 papers (31 long and 14 short contributions) that comprise the set of CERME9 TWG14 papers published in these proceedings in accordance with these two broad themes. We note that several papers fit both themes and that we have opted to classify the papers according to what we see as their main research focus and contribution.

TEACHING AND LEARNING OF SPECIFIC TOPICS IN UNIVERSITY MATHEMATICS

The 16 papers classified under this theme (8 long and 8 short papers) address a range of mathematical *topics*, elaborate discussions of mathematical *reasoning, logic and proof* and introduce research into the teaching of mathematics to students in *other fields* (here: engineering and economics).

With regard to *mathematical topics*, contributions regarded topics in calculus and Complex Analysis. *Breen, Larson, O'Shea and Pettersson* analyse student data from Ireland and Sweden to discuss concept images of inverse functions, particularly in relation to the predominance of the models of "swapping x and y", reflection and reversal. *Ghedamsi* offers a *Theory of*

Didactic Situations (TDS)-based analysis of a teaching session on sequence convergence in order to examine the ways in which a university calculus teacher attends to students' prior knowledge in calculus and facilitates the transition from school to university mathematics. *Grønbæk and Winsløw* deploy an *Anthropological Theory of the Didactic* (ATD) lens to discuss the teaching of complex numbers using Maple sheets and demonstrate the institutional constraints – Maple sheets cannot create an appropriate media/milieu dialectic – which lead to the development of disconnected practices. The short papers also covered a range of topic-specific research: the transition from informal to formal understanding of the concept of order in abstract mathematics (*Akdemir, Narlı and Kaşıkçı*); improper integrals (*Cortés and Velasco*); differential geometry (*Dana-Picard and Zehavi*); differential equations (*Fardinpour*); linear independence of functions (*Wawro and Plaxco*); and, abstract algebra (*Mili and Ascah-Coallier*).

With regard to *mathematical reasoning, logic and proof, Hausberger* introduces the innovation of the *banquet*, a pocket-size algebraic structure aimed at helping students reflect on mathematical structures and the axiomatic method. *Bridoux and Durand-Guerrier*, through an a-priori and a-posteriori analysis of two tasks in an exam paper taken by students of a Computing Sciences module that aimed at improving students' proof production, find that the course did improve students' proof fluency, although they also observe that many difficulties remain. In their short paper concerning students' conceptions of logic, *Kazima, Eneya and Sawerengera* also highlight some of these difficulties, mainly focusing on issues of language.

With regard to research into the teaching of mathematics to students in *other fields*, a relatively novel strand, *Biehler and Kortemeier* analyse students' work with a typical electrical engineering task in relation to an expert solution and conclude that it is counterproductive to try to separate the mathematical and "real world" (engineering) parts of the problem. *Kürten and Greefrath* report aspects of a "bridging" course aiming to reduce engineering students' difficulties with mobilizing school mathematical skills. *Mkhatshwa and Doerr* investigate economics students' reasoning about marginal change (instantaneous rate of change) and in her short paper *Selinski* explores student noticing of exponential and power functions in university financial mathematics.

TEACHERS' AND STUDENTS' PRACTICES AT UNIVERSITY LEVEL

The 29 papers classified under this theme (23 long and 6 short papers) also address a range of teaching and learning issues: *curriculum and assessment; innovative course design in UME; student approaches to study; relating research mathematicians' practices to student practices; views and practices of mathematics lecturers;* and, *methodological and theoretical contributions to UME research.*

In the cluster of papers on *curriculum and assessment, González-Martín* deploys a combination of theoretical frameworks (ATD and the *documentational* approach) to investigate the use of textbooks by pre-university teachers (particular focus: the topic concept of series of real numbers) and to observe that the textbook is a central tool for the teachers, who align with its presentation and organisation. *Dibbs* describes the outcomes of the use of formative assessment in a calculus class and concludes that regular participation in formative assessment is the best predictor of achievement. *Raen* compares the assessment of student competencies through closed book examination and talk aloud interviews. She concludes that different methods reveal different competencies and that therefore a mixture of assessment methods is desirable. *Thoma and Iannone* use two different frameworks, the MATH framework based on Bloom's taxonomy, and a framework based on functional linguistics and Sfard's *commognitive* approach, to analyse tasks from an examination in abstract algebra. They find both frameworks useful in highlighting different, and often complementary, aspects of the tasks. In their short paper *Derouet, Henríquez, Menares and Panero* also deploy a priori analyses of examination tasks in order to compare final secondary assessments in different countries.

With regard to *innovative course design in UME, Biza and Vande Hey* deploy the *Communities of Practice* approach to study the process of – and the pedagogical benefits deriving from – involvement of two undergraduate students in a project of resource development for statistics. *Mesa and Cawley* report the 3-year implementation of Inquiry-Based Learning (IBL) in a range of courses. Drawing on data from teacher logs and a *Mathematical Knowledge for Teaching* (MKT) framework, they discuss challenges of the IBL approach. *Nardi and Barton* present a *commognitive* analysis of a "low lecture" episode (student-led inquiry oriented discussion on open-ended problems) to illustrate crucial steps of student enculturation into mathematical ways of acting and communicating, including a shift away from the lecturer's 'ultimate substantiator' role. *Rämö, Oinonen and Vikberg* take a similar approach to report the shifting of an introductory course on linear algebra from a "lecture based" format to a new "extreme apprenticeship" format.

In the growing area of *student approaches to study, Farah* investigates the role of students' personal work in mathematics and highlights the influence of institutional differences on student approach. *Gómez-Chacón, Griese, Roesken-Winter and Gónzalez-Guillén* report similarities in the learning strategies employed across two cohorts of engineering students, in Spain and Germany. *Liebendörfer and Hochmuth* identify different factors which support or hinder the autonomy of first year students and observe that student teachers are not convinced about the need of university mathematics for teaching at school. *Lehmann, Roesken-Winter and Schueler* reveal that mathematical competencies and beliefs about physics are substantial for engineering students' success in technical mechanics. In their short papers in this area, *Griese, Lehmann and Roesken-Winter* focus on what obstructs or facilitates examination success in first year engineering and *Švecová, Kohanová and Drábeková* explore issues concerning the mathematical literacy of first year students.

Three papers documented the *interplay between research mathematicians' pedagogical and mathematical practices and the influence of these on learner practices. Cooper* proposes a commognitive configuration of MKT (MDT, *Mathematical Discourse for Teaching*) as a tool to identify – and make optimal pedagogical use of – differences in the student teachers' and a mathematician's discourses. *Ouvrier-Buffet* presents a model of how research mathematicians practise the construction of formal mathematical definitions and highlights the pedagogical potency of epistemological analyses of mathematicians' practices. *Kondratieva* also favours epistemological analyses and discusses the pedagogical potential of exposing students to mathematical problems with different, more or less advanced, solutions to problems as opportunities for building mathematical connections.

In the populated area of studies on the *views and practices of mathematics lecturers* (6 long and 3 short papers), *Bergsten and Jablonka* investigate the views of mathematics lecturers on the transition problem for engineering students and observe that, despite the engineering context, lecturers see this transition as apprenticeship into becoming a mathematician, namely able to produce mathematics. *Hernandes Gomes and González-Martín* highlight differences in how teachers in engineering and in mathematics address rigor, approximation and modelling differently and how these views influence their teaching. *Gueudet* deploys the *documentational* approach to study teacher preparation and communication practices. She traces the interaction of teachers with resources in a goal-oriented activity that produces *documentation systems* (structured set of all the documents they develop) and identifies features of these systems. *Mali* studies how teachers with different disciplinary backgrounds use examples and representations in their teaching. *Petropoulou, Jaworski, Potari and Zachariades* deploy the *Teaching Triad* construct to investigate lecturer practices and rationales. They illustrate a case of a lecturer who shows sensitivity to students' needs and draws students into mathematical culture through mathematical challenge. *Viirman* offers *commognitive* analyses of how lecturers' epistemological and ontological positions on mathematics are articulated in their teaching discourse. The three short papers in this area touch on ways to enable student meaning making (*Didis and Jaworski*), UME conceptualisations of pedagogical content knowledge (*Khakbaz*) and tackling the difficulties of the transition from school to university mathematics (*Kouvela, Biza and Zachariades*).

Finally, *Kaspersen, Pepin and Sikko* propose a *methodological advance* in the study of the transition from higher education to the world of work through proposing an approach to purposeful sample selection for measuring student teachers' beliefs and practices. An advance of a *methodological as well as theoretical* character is put forward by *Tabach, Rasmussen, Hershkowitz and Dreyfus* who use a transcript of an excerpt of four undergraduate students' interaction while working on a specific initial value problem, to demonstrate a local integration of two theoretical and methodological perspectives on knowledge construction, namely *Abstraction in Context* (focusing on individuals) and *Documenting Collective Activity*.

IN CLOSING

While our presentation of CERME7 and CERME8 papers was in accordance with slightly different themes – for example in CERME8: *transitions*, *affect*, *teacher practices* and *mathematical topics* – some comparative observations across the three sets of papers are apt. As we noted in the Editorial of the RME Special Issue (Nardi et al., 2014), there is a clear surge of sociocultural and discursive approaches – and the number of papers using ATD and TDS is also remarkable. An emerging focus seems to be also on systematic investigations of innovative course design and implementation and there is certainly a rise in the number of studies that examine the teaching and learning of mathematics in the context of disciplines other than mathematics, such as engineering and economics. Furthermore, this time we welcomed more colleagues from outside Europe and also noted the rise in the number of papers on assessment and examination. We also observed the further strengthing, maturity and increasingly more robust theorizing of studies into teaching practices. Finally, we noticed in several papers the establishing of promising liaisons across different theoretical perspectives. We now look forward to cementing these developments further in future CERME conferences, in the rich presence of UME at the upcoming ICME13 and EMF2015 conferences – and of course INDRUM2016!

Research papers

The construction of the 'transition problem' by a group of mathematics lecturers

Christer Bergsten[1] and Eva Jablonka[2]

1 Linköping University, Linköping, Sweden, christer.bergsten@liu.se
2 King's College London, London, UK

This paper presents views of university staff about what has become called the 'transition problem' when students start studying mathematics at university. The data are from a focus group interview with eight experienced university lecturers at a Swedish university department that offers mathematics courses for engineering students. We use the portrayal of the problem in the literature as an axis for the discussion.

Keywords: Undergraduate mathematics, lecturers, transition problem, focus group.

DIMENSIONS OF THE 'TRANSITION PROBLEM'

In some places mathematicians seem to have for a very long time bemoaned a lack of university entrants' knowledge (Thwaites, 1972); it clearly became an international concern in the 1990's (ICMI, 1997) as part of a *transition problem*. Based on our reading of the literature, we have grouped the issues mentioned in a range of Swedish and international studies into eight dimensions [1].

(1) Pass rates and participation: In Sweden pass rates in undergraduate mathematics courses were at 70% for engineering students at the beginning of the 21st century (HSV, 2005, p. 45). Relatively low pass rates were also reported from other countries (Dieter & Törner, 2010; EC, 2000; De Guzmán, Hodgson, Robert, & Villani, 1998). Further, there is a perceived need to increase participation in higher education of under-represented groups in terms of gender, ethnicity and social class (Pampaka, Williams, & Hutcheson, 2012).

(2) Alignment of curriculum: A couple of studies reveal discrepancies between the mathematics faculties' expectations and the actual school curriculum (e.g., Brandell, Hemmi, & Thunberg, 2008). These relate to factual knowledge or use of formularies and tables, routine skills or problem solving, and computational fluency or use of technology. Swedish students' perceptions of their pre-knowledge tend to be more positive than that of their teachers (HSV, 2005, p. 34). Mismatches are also described in other countries (EC, 2000; Hourigan & O'Donoghue, 2007; Hoyles, Newman, & Noss, 2001; Kajander & Lovric, 2005).

(3) Changes in level of formalisation and abstraction: Mathematics at university entails specialised technical language, which students perceive as more cumbersome than at school. As depicted in the Swedish report issued by HSV (2005), 75% of the students find mathematics courses difficult, and for 85% the university creates new challenges. In a study in France, Spain and Canada, the tasks were perceived as more "abstract" (De Guzmán et al., 1998). The authors also point out that tertiary mathematics includes "unifying and generalising concepts" (pp. 752–753), often described as a switch from intuitive to formal mathematical thinking or from informal argumentation to mathematical proof (e.g., Brandell et al., 2008).

(4) Unclear role of mathematics for the students' career paths: HSV (2005) reports that only 40% of students in the second semester thought they have made much use of their mathematical knowledge in other subjects. Rather than 'directly' useful, students in another Swedish study described mathematics as generic problem solving technology (Bergsten & Jablonka, 2013). De Guzmán and colleagues (1998) see an underestimation of the role of mathematics in a range of subjects in the French, Spanish and Canadian context. A 'utilitarian trend', noticed in the UK (Hoyles et al., 2001), can cause conflicting messages as to the purpose of studying 'pure' mathematics.

(5) Differences in teaching and classroom organisation: In Swedish classrooms one finds a dominance of lessons devoted to individual work scaffolded by the teacher (Skolinspektionen, 2010), providing little experience with the lecture format common at universities where many students point at the increased pace as a characteristic difference to school (HSV, 2005). Similar views are reported by De Guzmán and colleagues (1998, p. 750). Also the character and function of assessment differ (Gueudet, 2008).

(6) Change in expected learning habits and study organisation: To study at university requires a higher degree of autonomy than in secondary school (Wingate, 2007; cf. De Guzman et al., 1998). This is also acknowledged by many of the engineering students in Sweden (HSV, 2005). When students' expectations do not match the reality they meet, including a change of the didactic contract (Gueudet, 2008), students can experience stress (Jackson, Pancer, Pratt, & Hunsberger, 2000).

(7) Differences in atmosphere and sense of belonging: A university setting with large group lectures increases the social distance between teachers and students, an issue also expressed by Swedish students (HSV, 2005). The anonymity at a large university can be 'quite a frightful experience' (De Guzmán et al., 1998, p. 755). As students often change groups, a sense of belonging cannot be developed as easily as at school.

(8) Differences in pedagogical awareness and education of teachers: The image of the university mathematics teachers held by Swedish engineering students is rather positive; while some complaints were raised, a large majority appreciated the engagement as well as the knowledge of their teachers (HSV, 2005). Similar perceptions were revealed in the study by De Guzmán and colleagues (1998). Nardi, Jaworski and Hegedus (2005) describe a spectrum of *pedagogical awareness* among undergraduate mathematics teachers, including four levels labelled as naive and dismissive, intuitive and questioning, reflective and analytic, and confident and articulate (p. 293).

From these studies it is evident that the shifts between the two institutional cultures concern the curricular content, forms of pedagogy as well as the identity of the students as learners of mathematics and as beginning university students. The outcomes of the studies suggest that the shifts of criteria for what counts as mathematics as well as for the appropriate study habits that help the students to acquire this 'new' type of mathematics are often neither coherent nor explicit.

This paper draws on data from a focus group interview to investigate how lecturers who teach first year undergraduate mathematics courses talk about the transition problem, and how their views match the dimensions portrayed in the literature as outlined above. While most previous studies have been framed by curriculum discussions, exam results, or student responses, we hoped that an exploration of the views of experienced lecturers who teach first year mathematics courses at university, may open up dimensions of the transition problem hitherto hidden.

METHODOLOGY

As part of a larger project [2], where around 70 engineering students at two universities in Sweden were followed and interviewed during their first year of study, their lecturers of the mathematics courses at one of these universities were invited to a focus group interview, moderated by one of the authors, to discuss the transition problem. The eight university lecturers/professors of mathematics who volunteered to participate all work at a mathematics department. The audio-recorded session lasted for about 80 minutes and was organised by prompts concerning the beginning mathematics studies at university [3]. As participants knew each other as colleagues and were a homogenous group in terms of their extensive teaching experience and involvement with undergraduate students, we hoped the interaction between them can develop freely into a shared opinion of the group and would also expose issues of disagreements (Morgan, 1997). The participants (L1 to L8 below) were between 40 and 65 years old, one female and seven males. The purpose of the ongoing project and the focus group interview was known to them, and shortly reviewed at the outset.

We used the dimensions of the transition problem as outlined in the literature review as a thematic framework, and indexed parts of the conversation that related to these themes and re-narrated the lecturers' statements. This also helped to identify new dimensions and views that differed from how the transition problem is portrayed in literature. Thus, after discussing some general issues about the focus group interview, some subheadings in the presentation below of our analysis of the interview transcript relate directly to some of the dimensions from the literature review (indicated by dimension number), while some categorise other topics emphasised by the lecturers. We also looked for expressions of emotions, disagreement and take-up of topics by group members. We believe that there was some interactive synergy in the discussion, which justifies our choice of conducting a focus group.

Our analysis draws on some analytical frameworks that have been used for analysing knowledge in education. Bernstein (1971) sees identity as the subjective, interiorised consequence of a discursive specialisation. This specialisation can for example be that of a pure mathematician, an engineer or an applied mathematician. In a more structuralist interpretation, pedagogic practices are an attempt to shape and distribute forms of consciousness, identity and desire (Bernstein, 2000, p. 203). For the purpose of the study, the concepts of classification and framing that describe the relations between discourses (and groups of actors) and how these are established by distinct pedagogic practices, are of relevance.

THE 'TRANSITION PROBLEM' IN THE EYES OF THE FOCUS GROUP

General framing of the problem

To the opening question about whether there exists a 'transition problem', the answer was unanimously, 'Yes'. Even though the opening prompt of the moderator was not phrased in a way that would essentialise the problem by talking about the 'so-called problem' and 'if there is such a thing', it might have been suggestive; but it did not suggest any specific way to talk about the problem, as, for example, in terms of their own experiences as teachers or in more general terms concerning the structuring of the university courses in relation to conceptions of the school curriculum. The group agreed that it was nothing new, 'This has existed all the time; one talked about this already when I started here as a doctoral student' (L8). Some shared their memories from the student point of view and one lecturer suspected that the problem might have increased in magnitude.

During the discussion the group consistently referred to experiences with their students. The curriculum was taken as a given, although some changes introduced earlier were mentioned. None of them referred to 'us' (as teachers or as an institution) having a problem. The participants did not phrase this as the students causing a problem for them. Instead they referred to their interpretations of students' knowledge and experiences and gave very specific examples. Only in one episode about marking criteria, the lecturers talked about themselves (in terms of an inclusive 'we'). When referring to students, the participants in most cases talked about 'students' and 'them' or 'one' (indefinite pronoun) as a homogeneous group and occasionally used passive voice (such as 'calculation rules have been forgotten'). In many of their statements, however, three of the lecturers did not generalise to all students, but said 'many students' and occasionally 'some students'. There was agreement in the group that there are many 'good students' who do not have problems with the transition.

A reading of the transcript with attention to individuals showed that none of them seemed to have changed their perception during the session. Also, there was not much evidence of argumentation amongst the group members. This does not entail that they held uniform views about of what dimensions the problem consisted, but that they mentioned different aspects and others agreed (often immediately with 'yes, yes') or provided additional examples. Some aspects brought to the discussion by L1 and L2 were picked up by the group and discussed in length. We looked for expressions of strong emotions, but felt there were no indications; most statements were to the point. The lecturers were engaged and eager to contribute and share their views.

Topics and themes

Most of the issues were discussed in contrasting them with what the lecturers knew or suspected about curriculum and pedagogy at school. In one prompt, they were explicitly asked about the differences, where some of the issues mentioned as being problematic were repeated. The problems raised were said to be very common, also among students who later 'show to be very capable' (L1).

Computational facility and problem solving strategies (#2 in the literature review)

Computation appeared as a key word in many statements by the lecturers. What they found lacking in students included general computational facility:

L6: minus signs brackets and such basic stuff can go wrong

L2: the probability that it goes wrong at least once is pretty high if you have to make several computational steps

When talking about computation, this was analysed as including both to calculate correctly and to have a strategy. In this context, they mentioned that many students appear not to have learned to think systematically, have no meta-strategies such as a habit to control results, do not know how to work through tasks that include more than one critical step and how to structure a solution when methods are not given:

L8: you get a problem and then you need to adapt .. restate and do things with it before you can get to a point where you can apply that old standard method ... at school this is more direct ... it works to shove that into it directly

The questions students ask in lectures were said to be mostly of the type, 'How did you do that?' that is, more about computational details than about conceptual issues.

Dependency on guidance and instruction (#5 and #6 in the literature review)

The lecturers said that at university students are asked to a much greater extent to approach new problem situations and find out how to use known methods rather than solving tasks by applying given methods, 'you must find out yourself what method to use' (L3). In relation to this requirement, they noticed that

L1: many students don't seem prepared that you may have a good idea and then we try it out and test it to see where it leads

L8: they just sit there if they don't see the whole way ahead they don't start but instead raise the hand and ask

The phenomenon illustrated by these statements had increased, according to the lecturers, and was given much attention in the discussion. Differences in the view of understanding were also raised: at school it means being able to follow the reasoning of others while at university one must do it oneself. One lecturer framed the inactivity of students in the face of more complex problems as a matter of 'maturity':

L5: it is also about being mature ... one can't require at upper secondary that people have the same maturity maybe one needs one semester to level it out

Organisation and academic study skills (#6 in the literature review)

Other aspects of an observed decrease in expected maturity of new students compared to earlier concerned generally more messy classes, students who do not bring things or return assignments in time, who take teaching for granted as a kind of service, and that as a teacher one must explicitly emphasise how many hours students are expected to work.

Formularies and electronic calculators (#2 in the literature review)

The group also mentioned that the common use of formularies at school creates problems at university where one must have some foundational knowledge available.

L2: we require that they should know some terms ... while at upper secondary it is required that they should know how to find [it in] a dictionary [...] you experience more and more difficulties to learn any ... rule and remember it

Another issue concerned the fact that at this department electronic calculators were not allowed at exams, while at upper secondary they were commonly used, 'that itself is a big step from upper secondary' (L2). This problem was linked to a lack of seeing meaning in mathematical objects that earlier had been available as buttons on a graphic calculator. Students, however, generally did not complain about the change.

L2: the elementary functions sooner or later must acquire some meaning they don't for many students when they come here [...] it's much more common that they complain that they were allowed to use them at upper secondary than that they're not allowed to use them here

Mathematical rigour (#3 in the literature review)

When asked about the differences between school and university mathematics, "rigour most of all" (L8) was mentioned, but when discussing the level of rigour the participants used in their lectures, it was agreed that such emphasis had decreased:

L1: much less than before
L3: you argue for your theorems by examples that make things likely

Nevertheless, how the examples were presented still supported a rigorous approach:

L2: the reasoning ... the examples they see in lectures there the solutions are as rigorous that they no doubt would pass as solutions [on exams]

The moderator also presented students' solutions to exam tasks, which the participants were asked to mark with the intention to initiate a discussion about the level of rigour they expected from the students. They could not reach full agreement on the accuracy of the presentation in a task they classified as a 'one-point task' (see below) and hence were not sure whether to give it a zero. While one lecturer compared the solution with one to another task and found it 'better', another qualified the discussion as 'nitpicking'. About one solution that contained calculations with approximate values for π and e, they found it unlikely that one of their students had produced it.

Incoherence in students' mathematical knowledge

An effect of the observations that 'a student can be very good at some things but [at the same time] maybe knows nothing at all about other things' (L3), implied that, in contrast to how it was earlier, 'it takes longer time to discover who are really strong' (L8). In the written exam results problems showed themselves through 'lots of simple mistakes' (L6), and that despite the adjustments of the level that had been made, results had generally decreased. However, in topics that were completely new to the students, this effect had not occurred:

L2: in linear algebra one is not so much disturbed by things one does not remember from upper secondary

Assessment and knowledge criteria (#3, #5 in the literature review)

There was a long discussion about the assessment practice for the written exams. Eventually the discussion revealed well-established practice. One aspect concerned the organisation of the tasks in written exam papers for summative assessment of the course. In most first and second year mathematics courses these included seven tasks to solve during a given time (commonly four or five hours) with full solutions to be handed in. Each task was marked with 0, 1, 2 or 3 points, where a solution obtaining 2 or 3 points was considered a pass on a task. A common criterion for a pass on the course was to obtain at least three 'pass tasks' and at least 8 points. However, the order of the tasks on the exam paper gave different 'weights' to the points given on each task. In this context, the intention of a task on behalf of the examiner was also critical, as was said after a long discussion about how to mark one specific task:

L1: if I had been the examiner on this task I would have considered beforehand what I want to test with this task, if I want to test the understanding of graphs yes then maybe this is a task for the upper part of the exam paper and then you can let a way of reasoning pass that we know or ... want to test a rigorous mathematical reasoning then it ends up further down and then there will be no points for the B task

The overall result for the specific student being assessed thus influenced the marking:

L2: actually we assess the exams the solutions differently if it is about a pass or a pass with distinction ... this we all do a little ... that we set up higher formal requirements for solutions if it is about a pass with distinction

This marking practice was termed 'holistic assessment', as explained by L7:

L7: if you make a holistic assessment of the whole exam paper and you look at this task in its context and compare to other tasks there are good things in it and pass or not is maybe not decided from this particular one but from a holistic evaluation of the whole paper

When asked whether students would be aware of this practice, one lecturer replied, 'I don't think so' (L2).

However, the holistic approach had been the practice at this department for a long time and several lectures acknowledged that it was somewhat hidden to the students: 'I think not many students know this practice' (L7).

How to overcome the problems

Typical for students who do well is that they work a lot with the course. The formulation that they 'get it' (i.e. the method, the theorem) was used here. It was emphasised, though, that also students with the highest school mark often have a very uneven knowledge base. However, when asked about what positive things they observe today, the group of lecturers agreed about a good 'spirit' in students and that most of them in the end overcome most of the problems pointed out.

L1: enthusiasm is actually something I think has become better the last years

L8: when they eventually get going and go through our courses then in the end they do pretty well … and I don't think we in any way produce worse engineers than we did some years ago …the end product I think is at least comparable … even if they maybe had to struggle more on the way

DISCUSSION

Much of what this group of lecturers discussed is implicated in the dimensions of the transition problem as portrayed in the literature. Not mentioned by the group as problematic was the lack of experience of students with the lecture format. As to the differences in teaching, the issue was only discussed in relation to the students' behaviour and not in terms of differences in teachers' pedagogical strategies. Change in expected learning habits and study organisation were touched upon, while differences in atmosphere and a sense of belonging were not discussed. The group focussed on differences in mathematical activities but did not talk about the role of mathematics for the engineering students' careers. Interviewing lecturers allowed for a differentiation of the transition problem and opened up some new dimensions.

The institution aims at introducing their students into a strongly classified (Bernstein, 1971) canon of traditional undergraduate mathematics. The lecturers expected, for example, avoiding inappropriate levels of approximation and not relying on arguments derived from graphs of functions. They also saw school mathematics as strongly classified (applications and modelling were not mentioned) but different in knowledge structure and pedagogic relation. In addition, they did not differentiate between different groups of students, such as from different engineering programmes.

The lecturers shortly talked about decreasing pass rates, but were not sure about any trend before a member with access to the data reported a decrease. In relation to the performance patterns in the assessments, they mentioned an increased 'incoherence' in the levels of individual students' knowledge. The discussion about the 'holistic assessment' is related to this observation about the increased unpredictability of the students' knowledge. The assessment practice is based on the assumption that there is only one dimension of mathematical competence that amounts to the students' performance. 'It takes longer time to discover who are really strong', reveals an assumption about an essential generic mathematical competence hidden behind a range of more or less virtuoso performances, a form of 'mathematicality'.

The 'pedagogic relation' (Bernstein, 2000) was by the lecturers depicted as one with students who depend on the expertise of their lecturers but even more so on their teachers at school level. In the eyes of the lecturers, the positions made available to the students change substantially: While at school they are constructed as dependant learners who learn how to use a range of techniques with the aid of calculators and formularies but with no authorship in producing some original piece of mathematics, at university they grant the students authorship to create some mathematics through combinations of techniques and mathematical argument as acceptable by academic mathematicians without calculation aids and formularies. This is an apprenticeship into becoming an academic mathematician. Despite the vast majority of the students being from engineering programmes, the lecturers do not conceptualise their teaching as apprenticeship into users of techniques for mathematical modelling in some of their students' future engineering fields.

The focus group came to the unexpected (with respect to the literature) conclusion that overcoming the transition problem is a matter of the students' own work and natural development as they become more mature and used to studying mathematics at university. They also maintained that the level of competency of the engineers who graduate from the institution has not in any significant sense dropped. As compared to earlier, however, today the students have to 'struggle more on the way'.

ENDNOTES

1. These only partly overlap with the 'groupings' in De Guzman and colleagues (1998) and Gueudet (2008).

2. The project is funded by the Swedish Research Council; see www.vr.se.

3. These prompts were: Is there a transition problem? How does it show? How common are these 'problems'? How does it show in exam results? How much emphasis is made, in lectures and exams, on the formal aspects of mathematics? How are students informed about the assessment criteria? What type of questions do students ask in lectures? What is typical for students who do well? How does (upper secondary) school mathematics differ from university mathematics? Differences in knowledge criteria? Other issues? What is positive today?

Conceptualizing and studying students' processes of solving typical problems in introductory engineering courses requiring mathematical competences

Rolf Biehler, Jörg Kortemeyer and Niclas Schaper

University of Paderborn, Paderborn, Germany

The project KoM@ING aims to investigate the mathematical skills which are required in technical subjects of engineering bachelor courses. Our subproject is especially interested in the first-year-course "foundations of electrical engineering". In order to do research on this subject we developed the concept of a "student-expert-solution" (SES) which was generated by analysing expert interviews. The SES is supplemented by the required resources and a didactical reconstruction, for example, typical mistakes, alternative solution approaches and learning goals. The SES of a basic engineering exercise will be presented. We find some discrepancies with the standard modelling cycle, as well as some surprising problem solving strategies.

INTRODUCTION

We are interested in the competence expectations that are implicit in these tasks, i.e., expectations that are set up by the instructors of engineering courses, often based on years of experience, but not on any explicit theory of engineering competence. Originally, we intended to focus on mathematical aspects only, but it turned out that a more holistic approach is more appropriate. Based on this, we are analysing how and how well students in first year standard university courses on electrical engineering solve tasks given to them in homework assignments and written examinations Our project is part of the KoM@ING-project, where the modelling and assessment of mathematical and engineering competences is the focus. Our subproject chose a qualitative approach. The tasks we are analysing require knowledge and cognitive resources from mathematics on the one hand and from electrical engineering on the other. The mathematical knowledge is partly based on school knowledge and on the mathematics that students learn in the separate courses on higher math in the first year parallel to the engineering courses. It is well known that there is a mismatch between the mathematics learned in the separate courses, the mathematics at school level and "the contextual mathematics" required in solving engineering tasks (see, e.g., Redish, 2005). The mathematical practices in engineering contexts look far different from those in purely mathematical contexts. The tasks given to the students cannot directly be regarded as mathematical modelling tasks in the sense as this is discussed in mathematics education.

We focus on five tasks from the final exam of the second part of the "foundations of electrical engineering"-course (called the "GET-B" exam), which electrical engineering students are to take after their first year. All of the students' written work was scanned. Moreover the same tasks were given to eighteen pairs of students and their work and communication was video-recorded. With nine of the student pairs we used stimulated recall for extending the base of our analysis. In order to analyse the problem solving processes and the written work of the students we need a didactically oriented task analysis and theoretical frameworks on which we can base this analysis, in other words a "normative solution" of our task.

THEORETICAL BACKGROUND

We consider the following three theoretical frameworks as relevant: The first approach is the modelling cycle by Blum and Leiß (2007), which divides the solving of a mathematical modelling exercise into seven steps: (1) understanding of the task and the underlying situation, construction of the so-called "situation model" (2) simplifying and structuring of the situation: construction of the so-called "real model", (3) translating into a mathematical problem (entering the "world of mathematics"), (4) mathematical work, (5) interpretation of the result in the real world, (6) validating and (7) presenting of the results. The cycle consists of two parts, the "rest of the world" with steps (1), (2), (6), (7) and the mathematics with step (4). The changes between the two worlds happen in step (3) and (5). This modelling cycle description is considered as an idealisation, probably only applicable in school contexts. Nevertheless, this approach is useful for us as a tool to show important features of our "modelling example", which differ even on an idealised level.

The second approach is problem solving by Polya (1949), who divides problem solving processes into four phases: understanding the problem, devising a plan, carrying out the plan and looking back. The third approach is the description of ways of mathematical argumentation and mathematical resources in physics by Bing (2008) and by Redish and Tuminaro (2007). They distinguish between four framings that describe how students justify their results to exercises: calculation (algorithms give exact results), physical mapping (math should represent physics correctly), invoking authority (using of results of the physics-course) and math consistency (similarities to other physics problems solved with math).

We consider the first two approaches as "draft" process models, which will have to be extended and adapted to the specific tasks we are analysing. The third approach discusses the role of mathematical resources and knowledge in solving problems from physics and we use this approach to identify and characterize resources needed by the students. In other words, we consider that the development of theoretical descriptions has to be based on empirical results as well. We ask the task designer and electrical engineering experts to solve the tasks from the perspective of students who well understood the contents of the electrical engineering course. Based on further consultation of subject matter and didactical experts, we (re-)construct what we call the "student-expert-solution" (SES). The SES is used as a basis for sharpening the theoretical description and analysis of the solving processes, resulting in what we call a "theoretically enhanced SES" (TESES). We use this as a tool for understanding first year engineering students' solving problems.

METHODOLOGY

In order to get a detailed solution for the exercises we conducted interviews with the task designer and electrical engineering experts from the institute at the University of Paderborn, which is responsible for the GET-B, using the Precursor-Action-Result-Interpretation (PARI) method, a task-based interview technique conducted with experts of the task (Means et al., 1995). The aim of these interviews is to identify the explicit and implicit expectations of competences. The half-structured PARI-interview consists of three phases: In the first phase, experts have to do the exercise without any interruptions, but they are told to think aloud while writing down solutions. In the second phase, the interviewer goes through the written solutions with the expert in order to reconstruct the reasons for the way the exercise was solved and identify the used resources. In this phase experts need to justify each step of their solutions and make explicit the knowledge they used. The last phase is a didactic reconstruction of the exercise, which consists of two parts. In the first part the experts' view on students' expected solutions is solicited. This part contains questions on alternative solutions to the exercise, typical mistakes of students after their first year and possibilities to validate the results. In the second part the interviewer asks for the reasons for assigning the exercise and possible variations for exercises on the topic, aimed at making explicit the implicit competence expectations.

The interview is the foundation of the student-expert-solution (SES), which is the best solution an electrical engineering student could achieve with the knowledge presented in electrical engineering and mathematics lectures prior to the exam (i.e., the knowledge after their first year of studies). In the next step the student-expert-solution is subdivided into categories, i.e., phases and cognitive resources in a deductive approach based on the three mentioned theoretic approaches. This document consists of a two-column table: the SES in first column and related theory-based comments in the second column; it is called the "theoretically enhanced" student expert solution (TESES). The TESES is used as theoretical instrument to analyse the transcribed solution processes of our pairs of students. The participating students attend degree-relevant courses in electrical engineering or industrial engineering, and they were at the end of their first year when the study was conducted. Nine pairs were filmed while they were working on the exercises and were talking about the way they solved them.

EXEMPLARY RESULT: A SES FOR ONE TYPICAL TASK

A sample exercise

For illustration, we present one of the exercises of the mentioned exam, which deals with magnetic circuits, and its theoretically enhanced student-expert-solution. This section gives the problem setting and a short overview of the solution. The exercise consists of six subtasks and starts with the following sketch of a magnetic circuit:

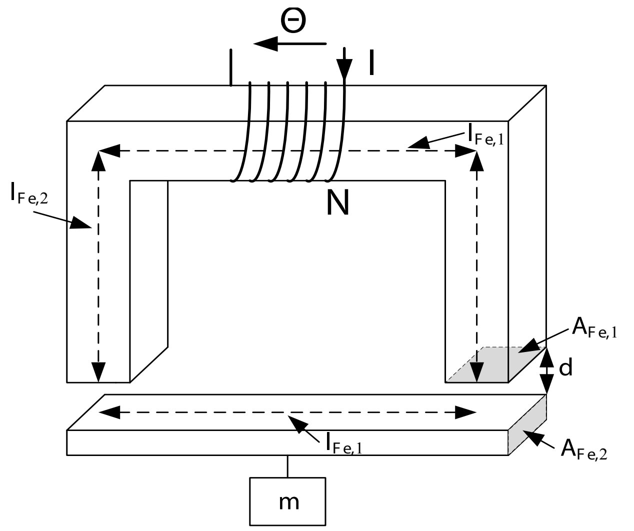

Figure 1: Sketch of a magnetic circuit consisting of two iron cores

The magnetic circuit consists of two iron cores with different cross section areas. The winding on the U-core has N=100 windings und is flown through by an electric current of I=10A. At the places of minimal distance between the two cores there should be a joint that behaves like an air gap. The exercise gives the following data for the iron cores: $l_{Fe,1}$=50 cm, $l_{Fe,2}$=30 cm, $A_{Fe,1}$=150 cm², $A_{Fe,2}$=60 cm², μ_r=1000.

Subtask 1: Sketch the equivalent electric circuit diagram of the magnetic circuit und simplify it as much as possible. Solution: The three parts of the U-core (the upper part and the left and right parts) and the lower iron core each give constant reluctances and can thus be summed up to one reluctance R_{Fe}. R_L, the reluctance in the air gap, is dependant on the width of the air gap d and has to be doubled, because there are two joints between the two parts.

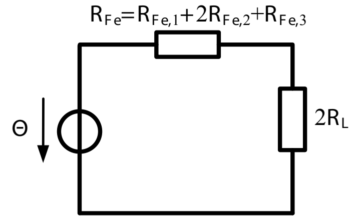

Figure 2: Equivalent circuit diagram

Subtask 2: Describe the total reluctance $R_M(d)$ as a function of the variable d. Solution: Because of subtask 1 the total reluctance can be written as the linear function of d: $R_M(d)=R_{Fe}+2R_L \cdot d$ using calculated values for R_{Fe} and R_L.

Subtask 3: Describe the inductance L of the setting as a function of d, the width of the air gap; assess the width of the air gap for which the inductance is maximal, and calculate the value of this maximum. Solution: The formula for L is $L(d)=N^2/R_M(d)$, i.e., the width of the air gap d is part of the denominator and the fraction becomes maximal, if $d=0$. We get the maximal value by insertion of $d=0$.

Subtask 4: Calculate the magnetic flux density b_L in the air gap.

Solution: We get the formula for the magnetic flux density by combining two formulas for magnetic fluxes.

Construction of the associated theoretically enhanced student-expert-solution

The first tool to analyse the exercise is the modelling cycle by Blum & Leiß (2007). We have developed several modifications of this cycle in order to better describe students' processes including identifying the resources required during the solving process. We summarize first and go into details later:

— Instead of constructing a real model as suggested in the modelling cycle students rather need strategies to understand conventionalized sketches and use them to mathematize the electrical engineering problem.

— Instead of entering the "world of mathematics," they enter into a "mathematics of physical quantities" with special resources: those resources are not solely based on pure mathematics learned in school or university mathematics courses.

— The authenticity of the problems offers strategies to validate the results.

We subdivided the solution process of subtask 1 and 2 into four phases. The two subtasks can be preliminary assigned to what is called (1) understanding of the task and the underlying situation, construction of the so-called "situation model" and (2) simplifying and structuring of the situation: construction of the so-called "real model". However, the competence requirements are quite different. The students do not do idealisations and simplification themselves, but they have to understand the given sketches as a "real model" whose idealisations will remain largely unconscious to them. The following idealisations, which were expressed in the interviews with the experts, are implicit: We only look at the magnetic behaviour of the test arrangement in an idealized static situation. The inductance of the windings, leakage fields and non-linear magnetic behaviour of the test arrangement are disregarded. Dynamic effects caused by the motions in the system are disregarded: Because of the changing of the distance between the two iron cores the energy changes and hence a non-linear ratio between power and force arises. The students are socialised into a world of certain real models. Idealisations often stay implicit and the students are often not aware, that there are idealisations. That is similar to physics students who use mass points without being aware of the idealisation, or geometry students that use dimensionless points. Students are to learn to "read" the sketch of Figure 1 and later find the fitting equations for this figure.

In contrast to saying that students should draw a picture or diagram of their own choice for understanding a situation (Polya, 1949; Blum & Leiß, 2007), the diagrams of Figure 1 and Figure 2 are very conventionalized in electrical engineering and constitute a specific "notational system", which is part of the tools of the discipline. Students who have not understood this might have difficulties if they approach the tasks and try to develop their own idealizations based on general physical knowledge – they could try to understand all the physical mechanisms and then be overwhelmed by the real situation. A further requirement is that students are familiar with the technical terminology (concepts) of electrical engineering in order to understand terms like the "magnetic flux" or "reluctance". Subtask 1 of the exercise requires using the "method of the equivalent electric circuit diagram", which helps to eventually mathematize the situation. The sketch of the test arrangement (Figure 1) has to be translated into an equivalent circuit diagram (e.g., Figure 2) using special rules for translation, which were expressed in the previous section. Equivalent electric circuit diagrams form a second notational system in electrical engineering. They are part of the acquisition of a domain-specific "graphical language" (similar to free-body force diagrams in mechanics or Feynman diagrams in quantum mechanics).

The third phase consists of setting up the equation for calculating the total reluctance with the help of the equivalent circuit diagram, which was generated in the first subtask. Once again, this is a translation task into which students have been socialized – idealized electrical or magnetic circuit diagrams are translated into sets of equations using the so-called Kirchhoff rules, just like free-body force diagrams are translated into vector equations using Newton's Laws, and Feynman diagrams are translated into path integrals using Feynman rules. The modelling of physical situations as idealized graphical diagrams and subsequent "mathematization" using sets of algorithmic translation rules is a common theme among the most powerful theories in physics and engineering. As mentioned above the reluctances in the iron and the air gap have to be added to execute this step, which requires forming of a set of equations between known and unknown physical quantities. There are also some differences to the modelling cycle in this step: A set of equations between physical quantities (numbers with units instead of just numbers) has to be set up. The student does not enter the "world of mathematics", but instead the "mathematics of physical quantities" with electrical engineering meaning. We are also convinced that many modelling problems at school level equally do not enter the "world of pure mathematics," but remain contextual mathematics with quantities.

In the next phase the total reluctance is calculated using the previous derived formula. As an example, in Figure 3 we reproduce the calculation of the constant part of the total reluctance (i.e., the reluctance of the iron core). The shorthand $\mu=\mu_r\mu_0=1000\mu_0=1000\cdot 4\pi\cdot 10^{-7}$ Vs/(Am) is used for the

$$\begin{aligned}
R_{Fe} &= R_{top} + 2 \cdot R_{left} + R_{bottom} \\
&= \frac{1}{\mu}\frac{l_{Fe,1}}{A_{Fe,1}} + \frac{2}{\mu}\frac{l_{Fe,2}}{A_{Fe,1}} + \frac{1}{\mu}\frac{l_{Fe,1}}{A_{Fe,2}} \\
&= \frac{1}{4\,\pi \cdot 10^{-4}\frac{\mathrm{V\cdot s}}{\mathrm{A\cdot m}}}\frac{0.5\mathrm{m}}{0.015\mathrm{m}^2} + \frac{1}{4\,\pi \cdot 10^{-4}\frac{\mathrm{V\cdot s}}{\mathrm{A\cdot m}}}\frac{0.3\mathrm{m}}{0.015\mathrm{m}^2} + \frac{1}{4\,\pi \cdot 10^{-4}\frac{\mathrm{V\cdot s}}{\mathrm{A\cdot m}}}\frac{0.5\mathrm{m}}{0.006\mathrm{m}^2} \\
&= 26.526\frac{10^3\mathrm{A}}{\mathrm{Vs}} + 2 \cdot 15.916\frac{10^3\mathrm{A}}{\mathrm{Vs}} + 66.315\frac{10^3\mathrm{A}}{\mathrm{Vs}} \\
&= 124.673\frac{\mathrm{kA}}{\mathrm{Vs}}
\end{aligned}$$

Figure 3: Calculation of the total reluctance

permeability of the metal, where μ_0 is the vacuum permeability and μ_r is the given relative permeability.

In the fourth phase, the resources of "mathematics of physical quantities" are needed, i.e., the management of units as well as techniques and strategies for the transformation of fractions containing physical quantities. Often these have neither been part of school nor university mathematics, and students tend to make many mistakes when attempting to apply these resources. One central resource is the "management of units", which includes the "handling of powers of ten". Those resources are typically required in physics and physics-related subjects if tasks require to calculate numerical values of physical quantities.

We define the "management of units" as the manipulation of base and derived physical units. All physical units in this exercise can be expressed in the base-units meter (m, for lengths), kilograms (kg, for masses), seconds (s, for time), and Ampere (A, for electrical current). E.g., the unit Volt (for electric potential) can be expressed as $(m^2kg)/(s^2A)$ using base units. The handling of powers of ten, which are expressed by letters in front of units, is also part of the management of units. The students have to translate the letters like k or m (for milli) to powers of ten, in this case 10^3 and 10^{-3}, respectively. The powers of ten then have to be multiplied, divided and potentiated using the rules for potentiation. For example, they need to realize that $6cm^2$ is equal to $6{\cdot}(10^{-2}m)^2=6{\cdot}10^{-4}m^2$, instead ignoring that the power of ten is squared alongside the unit and arriving at $6{\cdot}10^{-2}\,m^2$. In the last step the base units have to be translated in a summarising unit and the powers of ten into the right letter in front of the units.

The techniques and strategies for the transformation of fractions containing physical quantities include handling of algebraic and arithmetic terms with fractions. As seen in Figure 3, there are also compound fractions (especially due to units), and fractions have to be transformed in order to be able to add them.

Also resources of electrical engineering in a narrower sense are needed to solve the second subtask: students must know the formula for the reluctance, which is $R=1/\mu{\cdot}l/A$, where μ is the permeability, l is the length, and A is the cross-sectional area of the conductor. They have to insert the right values for each part of the iron core as well as for the two air gaps in order to apply the formula to the situation.

For the third subtask, students need to recall the formula for the inductance. Initially, students have to find a formula, which only contains known parameters from the problem setting, in this case the formula $L(d)=N^2/R_M(d)$. The maximum value can be determined using knowledge presented in the GET-B-lecture, namely, that the value for the inductance decreases the farther the two iron cores are moved away from each other. So the inductance is maximized if there is no air gap, i.e., the width of the air gap is zero. Alternatively $L(d)$ can be interpreted as a function of d, where the students can use techniques from mathematics to find the maximum (minimising the denominator). These two different types of reasoning for finding a solution are often applicable, i.e., reasoning by either calculation or physical mapping, see Bing (2008).

In the fourth part, students need to recall the formula for the magnetic flux density b_L, which is $\Phi=b_L{\cdot}A_{Fe,1}$, i.e., the product of the magnetic flux density and the relevant area. In this formula only $A_{Fe,1}$ is known, but there is another formula to calculate Φ, namely $\Phi=(N{\cdot}I)/R_M$, i.e., the product of the number of windings and the electric current divided by the total reluctance. In the second formula all physical quantities are known, and by combining the two formulas students can calculate the value for b_L. They get $b_L \cdot A_{Fe,I}=(N \cdot I)/R_M$ and with the help of this, $b_L=(N \cdot I)/(R_M \cdot A_{Fe,I})$.

This example shows the typical characteristics of "equation management". Initially students recall the relevant formulas containing known and unknown physical quantities. Then they start to transform these equations in order to get unknown quantities with the help of known quantities. This can either be done systematically by writing down all possibly relevant formulas at the beginning of the solution process, or step-by-step by starting with one formula and in each step trying to replace unknowns with the help of known physical quantities. This task is not rule based like solving systems of linear equations. It is not necessary to derive all the equations from general formulas in electric field theory presented in the lecture. This is a didactic reduction compared to the lecture, which was communicated in the exercise classes accompanying the lectures.

After finishing the calculations experts and students used various metacognitive strategies to validate their results:

— Validating of the result with the help of its unit in dimensional analysis: As the units of all physical quantities are known, one can check, if the units on the one side of each equation are the same as the units on the other side.

— Validating of the result with the help of its magnitude: In many cases the lectures, the problems in the exercise classes or previously done experiments show the order of magnitude of the resulting value.

— Check whether all information was used: it is a tacit agreement in the GET-B-course that all information that is mentioned in a problem is needed to solve it.

In contrast to the modelling cycle the implicit assumptions of the model are not questioned after finishing the exercise. On a positive note, in contrast to many school students' behaviour, validation takes place in a limited efficient manner, because the students expect tasks and results to be realistic, whereas in school mathematics often unrealistic, unauthentic assumptions and questions are prevalent.

PRELIMINARY RESULTS OF ANALYSING STUDENTS' SOLUTIONS

As we have not yet completed the analysis of students' work, we like just to point out two surprising results, where students employed special strategies that we did not anticipate. In the third subtask of the problem, the maximization of the inductance, all student pairs at first took the detour that when they read the word "maximum," they thought they needed to differentiate the term and find the roots of the first derivative. This does not lead to a solution, because the maximum is at the boundary of the interval; and since the differentiation itself is not easy, this approach could lead to further mistakes. This may be considered as a didactic obstacle in the sense of Brousseau having origin in school mathematics. In the fourth subtask, some pairs described the physical processes with the help of differentials like dA or dV, i. e., by application of university mathematics. Such argumentations are often used in exercises from field theory, which contain applications of Stokes' and Gauss' theorems for integral vector calculus. The magnetic flux through an infinitesimal area was expressed as $d\Phi=b_L \cdot dA$, where b_L is a function of the position. Students then used $b_L \cdot dA$ to mathematize the problem by seeing that the total flux can be computed using a surface integral. We observe a typical use of "differentials" in modelling physical problems that is not legitimated by mathematical theory. Since b_L is constant here, the integral method leads to the same simple formula as above, but in more general situations, the integral is mandatory. The phase of equation management was successfully preceded by a phase of deriving equations from more general principles. While unnecessary in this case, the approach was welcome as it shows further competencies. It depends on the course whether these are part of the expected range of competencies or whether students are just trained in "equation management."

FIRST CONCLUSIONS AND OUTLOOK

In summary we can state that our analysis shows that it is helpful to modify the modelling cycle as a theoretical tool for describing solution processes of students in engineering contexts:

— The component "cognitive resources" has to be added to the modelling cycle.

- One cannot distinguish between mathematics and the "rest of the world".
- Electrical engineering "does not exist" without mathematics.
- The setting up of equations is inseparably interwoven with the process of getting mathematical results. A division into two separate phases (setting up the model, mathematical solution) as in the modelling cycle is not adequate.

Furthermore, we have just started to use the TESES we described for analysing students' work. We will validate and extend our research results by developing additional student-expert-solutions for the remaining exercises of the GET-B exam, which require the higher mathematics taught at university level to a much greater extent than our above example. The content of these exercises includes for example ordinary differential equations of first and second order (in a task on oscillating circuits) or complex numbers (in a task on alternating current), which are the result of applying Kirchhoff rules to electrical circuits with time-varying currents through resistors, capacitors and inductances.

We will moreover analyse task solutions from written examinations to the GET-B-course in order to confirm, refine and enhance the results from the analysis using the SES and the video studies with the students. We also plan to interview teaching assistants from other universities. Although the content of the lectures is nearly identical between different German universities, there seem to be many differences in the expectations of competences, which can be made explicit by these interviews.

ACKNOWLEDGEMENT

Project funded by the German Federal Ministry of Education and Research (BMBF) under contract FKZ 01PK11021B. We would like to thank the reviewers for their thoughtful feedback.

“No longer a divide between students and staff”: Learning through participation in statistics resource development

Irene Biza[1] and Eugenie Vande Hey[2]

1 University of East Anglia, Norwich, UK, i.biza@uea.ac.uk;

2 Loughborough University, Loughborough, UK

In this paper, we analyse the diaries of two intern mathematics undergraduate students who were involved in a project on statistics resource development. Our purpose is to use the theoretical perspective of communities of practice (Wenger, 1998) to investigate how internship functions as a learning environment for these students. The results indicate how the two students shaped their own practice within the internship by establishing a mutual engagement and a shared repertoire and by integrating the joint enterprise of the task to their own work. The overall social environment of the internship, consisting of other students and staff, shaped the practice of the two students and became a learning environment for them.

Keywords: Communities of practice, participation, statistics education, undergraduate mathematics education, learning resource development.

INTRODUCTION

In the last fifteen years higher education has started addressing the demand for statistics professionals in business, economics and research with curricular changes that improve the quality of undergraduate statistics education (Bryce, 2002). These changes demand further development of learning and teaching resources that will cover not only the statistical content but also the contextual needs of a range of disciplines in which statistics is applied (e.g., in engineering, psychology, finance, etc.). In this spirit a team of staff members and students in a UK university has been working since 2012 on the development of resources that can be used in statistical teaching and research with the second author of this paper as a co-ordinator. The students are mathematics undergraduates involved in the resource development either in summer internships or in the context of their final year dissertation project. Although there is little research on student involvement in curricular development in undergraduate mathematics education (Croft, Duah, & Loch, 2013), it appears that there is potential benefit of this involvement to students' learning and to resource development practice (Croft et al., 2013; Biza & Vande Hey, 2014). The study presented in this paper aims to contribute to this area of research by using the theoretical perspective of *communities of practice* (Wenger, 1998) to identify how the internship functions as a learning environment for the involved students. Specifically, we take a case study approach by concentrating on the *Excel Data Generators* (EDGE) project, which is a section of the overall resource development activity we described above, and on two intern students (Beth and Pauline). To this aim we analyse the diaries Beth and Pauline kept across the internship to investigate the following research questions: (a) How do students shape their own practice across the internship? (b) How is this practice related to the overall social environment in which it takes place? (c) How does this practice contribute to students' learning?

THEORETICAL PERSPECTIVE – ELEMENTS FROM THE LITERATURE

In this paper, we see students' learning occurring in the social context of their interaction with staff and other students and we draw on the theoretical perspective of *communities of practice* suggested by Wenger (1998). Communities of practice are formed by people who engage in a process of collective learning in a shared domain of human endeavour. In order to form a *community*, people need to be involved in activities with the same objectives, share a concern or a passion for these and learn how to achieve them better as they interact regularly. The *practice* is the source of coherence for the community, and defines the community through three dimensions: *mutual engagement, joint enterprise* and *shared repertoire*. Mutual engagement gives substance to the practice that "exists because people are engaged in actions whose meanings they negotiate with one another" (p. 73).The joint enterprise "is the result of a collective process" (p. 77) towards a common understanding of what the aim of the mutual engagement is. Shared repertoire includes resources created and used in a community of practice including "routines, words, tools of doing things, stories, gestures, symbols, genres, actions" (p. 83). Research discusses several communities of practice related to the teaching and learning of mathematics, especially at university level: undergraduate students, mathematicians and mathematics education researchers (e.g., Biza, Jaworski, & Hemmi, 2014). Usually, in this research lecturers reflect on their teaching or/and students participate and potentially shape a learning environment without being involved in its design. In our study students join the resource developers' community of practice: they work closely with members of staff and other students in resource development (e.g., data generator spreadsheets, problem/lab sheets guidance, video demonstrations, etc.) and engage in activities that are not included in their usual university practices. In this sense, students who usually are users of learning resources find themselves on the other side as developers of these resources.

Recently there is a growing interest in students' engagement as partners in course design and its contribution to students' learning. Croft and colleagues (2013), for example, identified several students' benefits from their involvement in producing screencasts for other students: "increased and deeper understanding of mathematical topics, improved technological skills, improved study habits, improved personal and organizational skills, and enhanced communication skills" (p. 1053). On the other hand, although lecturers saw opportunities in this collaboration for their professional development, they expressed reservations regarding students' lack of mathematical maturity and concerns over the mathematical integrity of the produced content. However, the study concluded that collaboration between students and lecturers during the resource design and production "may help lecturers overcome reservations, whilst preserving the benefits for students" (p. 1045). Solomon, Croft, Duah and Lawson (2014) see undergraduate students' internships as a pathway for improving dialogue between students and staff that challenges traditional hierarchical roles and relationships. They claim that projects that support these internships establish a *boundary-crossing setting* in which there is a "potential for expansive learning to take place" for the students and challenges for "staff perceptions about pedagogy" (p. 332). Similarly, in our evaluation of students' learning through their involvement in resource development projects we have considered not only the learning per-se, but also how and in what extent this learning is a result of students' participation (Biza & Vande Hey, 2014). This evaluation revealed that students explicitly linked their participation to the solidification and organization of their knowledge in terms of statistical thinking and reasoning. Also, this participation contributed to their learning about how statistics is taught and learnt. Students contributed to the whole process by introducing new practices and bringing in 'student' perspective. We also found out how students merged, or sometimes experienced the conflict of, multiple perspectives such as student vs developer and mathematician vs non-mathematician (ibid). In this paper, we pursue this investigation further: we consider the internship as an apprenticeship to the resource developers' community of practice, consisted usually by tutors, and we use the communities of practice theoretical perspective to investigate how this internship functions as a learning environment for the involved students.

THE CASE OF THE STUDY: THE EDGE PROJECT-BETH AND PAULINE

The Excel Data Generators (EDGE) project is the development of an Excel based tool (called the EDGE tool) and materials that support its use in research or teaching and learning (e.g. guidance, online resources, video demonstrations, lab sheets, etc.). The EDGE tool can generate data according to statistical models whose parameters can be set by the user, and perform statistical tests. It can be used for teaching/learning resource development, such as generation of datasets with specific characteristics for problem sheets or assessment; creation of individualised tasks with similar datasets, demonstration of statistical methods with a range of datasets; experimentation with variation and randomness; etc. The instructor can design the context of the problem and use the tool to generate relevant data. The full EDGE tool includes 19 Excel spread sheets for data generation and statistical tests including: one sample t-test; two sample t-test; chi-square test; tables of t-distribution and chi-square distribution critical values; simple linear regression; one-way ANOVA; etc..

Beth and Pauline are the two intern students involved in the EDGE project. Beth had completed her mathematics degree (BSc with first class honours) just before the internship. Additionally, she was one of the final year students who worked on the development of learning resources for a module on Statistical Modelling in the context of her final year dissertation the preceding academic year. This module was aimed at second-year students in mathematics and Beth produced a lab sheet and three videos on multiple linear regression in R (free software environment for statistical computing and graphics, http://www.r-project.org/index.html), together with an assessment tool to evaluate the effectiveness of these resources (Biza & Vande Hey, 2014). With this background Beth entered her internship with prior experience on working with staff on resource development and with skills on R and video creation. Pauline had just completed the second year of undergraduate studies in mathematics and she had attended a module on Introductory Probability and Statistics in her first year and a module on Statistical Modelling in her second year. She did not have any experience on resource development at the time she started the internship, but in her personal statement attached to her internship application she expressed strong interest in Statistics as a subject she wanted to take further.

The internship lasted five weeks during the summer break. Beth and Pauline were mainly working in a study area in which computers, learning resources (books, leaflets, etc.) and specialised software (such as LaTex, R, Excel, and Camtasia) were available. Elizabeth, the lecturer who coordinated the resource development, visited the study area almost every day and spent some time with Beth and Pauline on their project. Elizabeth, both students and Alicia (researcher in mathematics education with statistical teaching experience) had weekly working meetings (lasting approximately an hour on average) in which the produced materials were discussed. In the same area other intern students (up to 6 in total) were working on statistical and mathematical resource development. Each afternoon the whole group of interns, Elizabeth, Alicia and other members of staff and PhD students had informal coffee/tea breaks of approximately 45 minutes in which they discussed the progress of their work as well as other topics. This provided an informal context of discussion between students and staff on topics that were very often outside the strict boundaries of the projects. The resources produced by Beth and Pauline included: a fully developed set of Excel spread sheets; four video demonstrations of the use of the EDGE tool made with Camtasia software; and, two lab activities on one-sample and two-sample t-test with their accompanying handouts and EDGE (excel) files.

METHODS

In parallel to the resource development, data were collected for research purposes and towards the evaluation of students' experiences. These data included students' weekly diaries and audiotape of the regular working meetings. Due to space limitations, in this paper, we report outcomes only from Beth's and Pauline's weekly diaries. In these diaries, produced by the end of each week, interns were asked by the first author to include: the activities of the week with some outcomes, if they existed; items that they have learnt or they want to improve (e.g., a statistical concept or method, creation of spreadsheets or videos, use of statistical language, time-management etc.); what went well and what didn't go so well and why; examples in which working together or individually helped them to understand statistics better; contradictions in the collaboration (e.g., cases in which the collaboration didn't work very well) and what they did to overcome them, if they did anything, or why they didn't take any action; and, any other item they want to write down and reflect on it. These diaries, which were each around one A4 page long, were analysed according to how the students collaborated with each other (including the organisation of their work), with other students and with staff; and, how this participation affected their learning.

RESULTS

Beth's and Pauline's collaboration

Beth and Pauline mentioned in their diaries how they organised the work between the two of them as a team and how also they interacted with the other students in the same study area and with the staff members. In terms of the teamwork, early on they decided to work individually in some parts and together in others but try to be consistent all the time, especially in terms of formatting and symbolisation. As Beth described in her first week's diary:

> This week myself and [Pauline] started working on the EDGE generator spread sheet. We focused on the first four sheets (one sample t-test, two sample t-test, simple linear regression and two-way chi-square test) and divided up responsibility for them. [Pauline] worked on the one-sample t-test and I worked on the two-sample t-test sheet. We talked a lot together about how they worked in order to fully understand what we were doing and also to keep each other involved with what the other one was doing. [Beth, W1]

In the above excerpt Beth, who is more experienced, described how they "divided responsibilities" (who was accountable for what) by building a shared understanding of what they "were doing" and what the "other one was doing" (mutual engagement). In other occasions they worked together and helped each other:

> After this, we worked together on developing the simple linear regression sheet and the Chi-square sheet. I think we worked very well together on these and both welcomed suggestions from one another. [Beth, W1]

So, from the first week, they both engaged with the resource development and they established the rules of this mutual engagement. They were working individually and together – and at the same time they maintained a consistency in the outputs of their work by using the same formatting and terminology (shared repertoire):

> Now, we are creating two lab sheets, one for the one-sample t-test and one for the two-sample t-test. [Pauline] focused on the first lab and I focused on the second lab. [...] We did make sure that the formatting was exactly the same and conferred with each other on specific terminology so that the lab sheets were consistent. [Beth, W1]

This was evident in Pauline's diary as well:

> Although we wrote the lab sheets separately, checking with each other periodically has been important to ensure the layout and terminology within the labs is consistent. [Pauline, W1]

This pattern of work was followed across the internship, as Beth mentions:

> We worked separately on these spread sheets, each picking a different one, so that we would not overlap with editing. We still discussed what we were doing with each other and would ask each other questions if we were stuck in order for both of us to understand how each spread sheet works. [Beth, W4]

It seems that this work distribution worked for them as Pauline acknowledged:

> I feel we both worked really well together in deciding who would work on which part of the project and ensuring that we both knew exactly where we were at and what needed to be completed in the timeframe. [Pauline, W5]

Beth's and Pauline's collaboration with staff

The role of both Elizabeth and Alicia was to offer feedback and assess students' work. But Elizabeth's role also included the co-ordination and the management of the overall project, its objectives and enterprises. Both Beth and Pauline knew from the very beginning what was the overall aim of this project. However the aim of their task became more evident when Elizabeth informed them that she would use these resources in her module the following year:

> [Elizabeth] informed us that she plans to use this lab sheet for her second year statistics students. Even though the lab sheet will be available to other staff throughout the University to use, having a clear audience for the resource made it a lot easier when returning to the lab sheet after the meeting. [Pauline, W2]

Elizabeth was accountable for the establishment of this enterprise and both Beth and Pauline had to align to her plan. It was difficult to them to proceed without a confirmation from her that everything was on the right track. When Elizabeth was busy with other tasks and not available to confirm that everything was alright they "both felt that [they] were lacking a bit of direction" [Beth, W2] and that "[i]t was difficult to know if [they] were covering what she wanted"

[Pauline, W2]. We were interested to see how both students saw their relationship with staff at the end of the internship. Beth, who already had the experience of previous projects, wrote:

> The interaction between myself and members of staff has been very positive. I have always felt like I could approach both [Alicia] and [Elizabeth], and am not afraid to ask questions. Also, having lunch and tea breaks with both [Alicia] and [Elizabeth], as well as many other members of staff and PhD students, has made all of us interns feel very comfortable, and I no longer see a divide between students and staff. [Beth, W5].

Whereas, Pauline described how her relationship with staff had developed through the internship and how this can be beneficial for the following year of her studies:

> I also feel I have built a good relationship with [Elizabeth] and [Alicia] as this internship has progressed. To begin with it still felt as they were lecturers, and there was a boundary, but as we have been working so closely together I have become more confident in voicing my opinion and feel happy to ask questions whenever I have an issue within my work. This is a skill I aim to take with me into my third year at university and beyond and I believe it will have a positive effect on my module grades and hopefully my dissertation. [Pauline, W5]

Beth's and Pauline's collaboration with others

Throughout the internship Pauline and Beth had many opportunities to receive feedback from other interns and other staff members. Sometimes this was happening informally in the coffee/tea breaks or on purpose. In Week 4, for example, the whole group of interns and supervisors ran a presentation of their projects to three Human Biology lecturers who were interested in using these resources in their teaching. Beth and Pauline were very satisfied by their presentation on the EDGE project and also by the fact that it attracted "some interest from other departments" [Pauline, W4]. This was the first time that they had some formal feedback from outside their team and their department and this was a strong motivation for them.

Additionally, the interns working in the same study area organised between themselves a practice of resource exchange and getting feedback that increased gradually towards the end of the internship. In Week 3, for example, Beth and Pauline shared the resources created by that time with the others. This helped them to make the content user-friendlier. Also, the appreciation of other interns on their work, especially Andy, a very experienced Masters student, encouraged Pauline:

> After [Andy] letting us know how impressed he was with the EDGE tool (which uplifted my spirits a lot as it seems to have taken a long time to complete this!) he gave us comments on the lab sheet and ideas for further improvement. [Pauline, W3]

Both students claimed that the overall social interaction in the study area was very positive. In Week 3 the whole team of interns was already getting along and they had started socialising, as Beth mentioned: "We're all getting on very well and were successful in winning a pub quiz last night!" [Beth, W3]. At the end of the internship, Beth acknowledged: "All of the interns have got along very well, and it's much nicer to work in an environment where everyone is happy and having a laugh." [Beth, W5]. Whereas, Pauline concluded:

> Overall I have really enjoyed this internship [...] It is definitely interesting how close you can become with a group of people when you are in a fairly small space with them for 40 hours a week! [...]. [Pauline, W5]

Contribution to learning

Both Beth and Pauline found their involvement in the project beneficial to their learning of statistics and other general skills. At the beginning Beth with her experience and her familiarity with this type of projects, worked as a bridge between Pauline and the lecturer (Elizabeth). As Pauline had not attended the module offered by Elizabeth the previous year, she had difficulty putting together the terminology she knew already with this used by Elizabeth. But Beth who had the experience from both modules was able to help Pauline to make the link:

> I found [Elizabeth] uses some different terminology to what I am used to in statistical modelling,

> however [Beth] has explained the differences to me which has made this clearer [Pauline, W1]

Beth helped Pauline to establish statistical knowledge that was familiar to her:

> Although simple linear regression is something I am familiar with, I found working together was the best way to tackle this as I found myself struggling with getting my head around some parts of this process and being able to collaborate with [Beth] helped my understanding. [Pauline, W1]

Or, to expand her knowledge in new items:

> I was unfamiliar with the code before doing this, so I am glad we both had a part in the completion of this sheet. It has expanded my knowledge of the different commands available in Excel and I have a good understanding of the calculations carried out throughout this sheet [Pauline, W1]

Pauline was keen on grasping the opportunity to learn new things although there were more experts than her to undertake the tasks. Whereas Beth found that explaining to Pauline (and other students) improved to her own knowledge.

> We [Beth and Pauline] have decided to work together on the videos as [Pauline] is very keen to learn how to create them and I have made them before. I think this will be good as I can help [Pauline] if she gets stuck and she may notice new things for us to do when making the videos. Next week I am going to help teach [Pauline] and [other intern] how to make Camtasia videos, which will improve my knowledge and usability with this software even further. [Beth W2]

Both Beth and Pauline acknowledged that their knowledge of statistics improved throughout the internship:

> Beth: Throughout this internship I would say my knowledge of statistics as a whole has improved, and through the creation of the EDGE tool, I have become a lot more comfortable with various tests. My understanding of significance and power has increased as we spent a long time creating and editing the lab sheets which involved a lot of interpreting p-values and manipulating various values to see the effect on significance and power. I have also acquired some knowledge of survival analysis [...] [Beth, W5]

> Pauline: [...] I feel as if I have taken a lot of knowledge away from this project. I have basically covered the bulk of [Elizabeth's] Statistical Methods module, learning about multiple statistical tests that I hadn't come across before. [Pauline, W5]

Also, they mentioned how their presentational skills improved alongside other skills:

> Beth: This has reassured me that I am capable to present to groups of people, and that I don't need to be nervous about presenting or having an interview. [...] My ability with Excel has naturally improved a lot and I feel these skills will help me in the future. Also, creating the videos has reinforced my understanding of this software [Beth, W5].

> Pauline: I really enjoyed learning how to use Camtasia to produce the tutorial videos. [...] It is a skill that I hope will come to use in my final year here [...] I also increased my confidence in using Latex and came across new programs such as GeoGebra. I am able to come away from this internship with a lot more confidence not only in myself, but in my ability to research new areas. [Pauline, W5]

CONCLUSION

In this paper, we analysed the diaries of two intern students who were involved in a project on statistics resource development to our aim to investigate how the internship, in this case, and students' involvement in curricular development, more generally, functions as learning environments. In this study we considered these students entering a resource developers' community of practice and we obtained some insight into how students form their own practice across the internship (research question (a)). Specifically, from early on, both students established a *mutual* engagement: they established a shared understanding and distribution of responsibilities; they shared their practice with other students and staff; they negotiated the meaning of their work with others and they valued this negotiation. At the same time they established a *shared repertoire* that they maintained later by bringing together different terminologies and being consistent in formatting and symbolisation. Finally, the *joint enterprise*, although among staff's responsibilities, became gradually part of their work. Also, we identified how this practice is related to the overall social environment in which takes place (research question (b)) through the students' regular interaction with each other and with other students and staff. Finally, we have evidence that, according to those students, the working environment of the internship became an environment of learning (research question (c)) through participation and communication. If we draw on the more recent work of Wenger, McDermott and Snyder (2002) on *cultivating communities of practice* – in our case the resource development community of practice Elizabeth aimed to establish – we identified different levels of participation: *core* members were Elizabeth and Alicia who knew the aims of the project and co-ordinated the actions; Beth was an *active* member, who was familiar with this type of work and understood the rules; Pauline started as a *peripheral* member but very keen on drifting to the centre and becoming *active* with Beth's and others' support; other students or staff acted *outside* the community but involved occasionally when the community shifted to their area of interest and expertise and asked for feedback. According to Wenger and colleagues (2002) the quality of a community is established when all its members regardless their level of participation feel *full members*. From Beth's and Pauline's self-reports in their diaries we have evidence of them experiencing this sense of membership. However, we cannot claim that the participation to the project did not have some drawbacks. Students' frustration, for example when Elizabeth was not available to assist them was an indication that the teamwork was not always efficient. From the lecturer's perspective on the other hand several downsides challenge the success of this experiment (see also Croft et al., 2013, about lecturers' resistance), such as disproportionate time investment; integrity of resources; limited contribution to lecturer's professional development; and lack of institutional value on projects like this. The evaluation of the overall experience will be more comprehensive when we combine the students' perspectives with staff views as well and this is the next step of our analysis.

ACKNOWLEDGEMENT

We would like to thank the Teaching Innovation Award-2013 scheme for its support to the EDGE project and all the intern students and staff members who participated in the EDGE project since its launch in 2012.

Contributions and limits of a specific course on manipulation of formal statements for fresh university students

Stéphanie Bridoux[1] and Viviane Durand-Guerrier[2]

1 Université de Mons, Mons, Belgium, stephanie.bridoux@umons.ac.be

2 Université de Montpellier, Montpellier, France

In this paper, we present preliminary results from an on-going project about an innovative course for first year students in Computer Sciences aiming to improve students' abilities in manipulation of formal statements and writing proofs. The data analysed show that although the course seems to improve syntactic abilities, the semantic control of formal statements remains problematic for most students.

Keywords: Didactics of mathematics at university level, logical analysis, proof, syntax, semantics.

INTRODUCTION

It is well known that the manipulation of formal statements is a main difficulty for many students starting university. In particular the widespread use of symbolic register to characterize the notions minimizes the use of natural language and faces students with the obstacle of formalism (Dorier, 1995). As a consequence, an important question is to find mathematical organisations [1] that allow students to both grasp the meaning of these notions and become familiar enough with formalism in order to be able to engage in proof and proving (Durand-Guerrier et al., 2012). In this paper, we describe such an attempt carried out at the University of Mons (Belgium), and we present elements of an explorative research aiming to investigate the effectiveness of such an innovation.

BACKGROUND

In the teaching of mathematics at university, definitions play a crucial role, in particular in the dialectic between proof and definition. From an axiomatic perspective, the role of definitions is to introduce new concepts relying on concepts already known, and avoiding contradiction. Ouvrier-Buffet (2006) showed the relevance of the activity of construction of definition for the process of mathematical conceptualization. However, in university courses, in France as in Belgium and in many other countries, the most common method of teaching is the axiomatic one (definitions, examples, theorems, proofs) in particular regarding formalising, unifying and generalizing (FUG) concepts such as the concept of vector space (Dorier, 1995). FUG concepts unify and generalize objects, tools or methods that exists previously in the students' background in various forms by using a new formalism. These concepts are difficult to introduce because the distance between previous and new knowledge is very big. Bridoux (2011) highlighted the nature of formalising, unifying and generalizing of the main notions of Topology, whose definitions require an intensive use of mathematical and logical formalism.

Durand-Guerrier (2013) stresses the importance of taking into account the logical complexity of the statement at stake in the tasks given to students in order to allow students to recognize the productiveness of operational formalism (the syntax) and to articulate it with the meaning of the mathematical objects involved in the tasks (the semantics). At the University of Mons (Belgium), in order to take into account this perspective, an innovative course was implemented in 2012 to replace the traditional mathematical courses for students in Computer Sciences.

Although these students are *a priori* well educated in mathematics, we hypothesize that they will face the classical difficulties identified in the literature when using mathematical language and notations, producing examples or engaging in proofs (e.g., Thomas et al., 2012). In this paper, we present the first stage of a project aiming to explore the following research question: How students involved in the innovative course deal with formal statements, in particular how do they take in consideration the relationship between syntactic and semantic aspects?

METHODOLOGY

The data was collected during a written examination. Due to the limited place, we choose two items for which the manipulation of formal statements was the key. The methodology that we use is a qualitative one relying on the consideration of the distance between *a priori* analysis, including a mathematical and a logical analysis of the tasks, and *a posteriori* analysis. The *a priori* analysis opens the possible answers that could be expected from students and the foreseeable difficulties. This *a priori* analysis has been done afterwards, for the purpose of the research, and reveals an underestimated logical complexity of the statements and the tasks considered. We first describe the main characteristics of the innovative course, and then present the data and the participants. In the next section, we provide the *a priori* analysis of the two items chosen for this paper, on which *our a posteriori analysis* relies. The last section of this paper is devoted to our conclusion.

DESCRIPTION OF THE DIDACTICAL INNOVATION INTRODUCED IN MONS UNIVERSITY

The teachers of the department of mathematics at UMONS took the opportunity of the introduction of the LMD [2] reform in Belgium to reconsider the content to be taught to first year students, and also the mathematical abilities that students should have developed at the end of their studies. The general objective for the first year at university is the deepening of concepts studied in upper secondary school in classical domains such as: Calculus, Algebra and Linear Algebra (e.g., Convergence of numerical sequences – Groups – Linear mapping – etc.) and at the same time helping students to master the following points: giving meaning to concepts, without neglecting technical and operational aspects; being able to use relevant knowledge even when they are not explicitly required; developing flexibility between the various representations, frames and registers of mathematical objects as suggested by Douady (1987); making explicit reasoning and providing justifications. All these aspects involve the manipulation of formal definitions and the properties studied during the courses. According to these aims, there are many tasks devoted to the manipulation of definitions during the tutorial classes and the assessment of students.

The course named « Mathématiques pour l'informatique 1 » takes place in the first semester. It comprises 20 hours of lectures and 40 hours of tutorials and deals with logic, set theory, methods for proof and proving (mathematical induction, proof by contradiction, proof by contraposition, etc.), and some topics in arithmetic. A characteristic of this course is to attempt working with students on the syntax and the semantics of quantified statements, involving more or less familiar or intuitive concepts. The quantified statements we work with involve simple inequalities, classical functions or classical sets and subsets such as intervals. At this stage, convergence of numerical sequences or infinite sequences of sets had not been introduced [3]. Here is an example of tasks proposed to students in this course.

Let X and Y be subsets of $\mathbb{R}$ and $f: X \to Y$ be a function.

a) *Define « f is injective ».*

b) *Define « f is surjective ».*

c) *Is the function $g: \mathbb{R} \to \mathbb{R}$ defined by $g(x) = x^4 + x^2$ injective ? Surjective? Justify your answer using the definitions provided in the previous points.*

This kind of task is generally not given in secondary school. As a consequence, the teacher has to use didactical means such as explanations on the methods, orally as well as in writing. During the tutorial classes, the students are asked to present their work to their peers in order to facilitate exchanges between students and to allow collective discussions on reasoning and other difficulties.

PRESENTATION OF THE DATA AND OF THE PARTICIPANTS

In accordance with the aim of the course, exercises involving reasoning and manipulation of definitions were included in the assessment. We present below two items, the first one requires to prove by contraposition the statement that characterises non positive real numbers; the second one requires the definitions of injective and surjective function and their use for studying two given functions. In the first exercise, we will mainly observe the mastery of the syntax, while in the second one, we will focus more on the articulation between syntax and semantics (Weber & Alcock, 2004, Durand-Guerrier, 2011).

52 students were assessed in January 2014 and the assessment lasted 4 hours. Around 80% of the participants attended the whole course. Our data consists in the assessment papers submitted by the students. The seven questions given to students challenged them to manipulate quantified statements. It is not possible to say how much time the students spent on these two particular questions. The assessment was a closed book exam.

A PRIORI ANALYSIS OF THE TWO EXERCISES

In this paragraph, we present the *a priori* analysis of the two chosen exercises taking into account their logical structure.

First exercise: A proof by contraposition [4]

Let us consider the proposition: $\forall x \in \mathbb{R}, (\forall \varepsilon > 0\ x \leq \frac{\varepsilon}{2}) \Rightarrow$
$\Rightarrow x \leq 0$ *(1)*

The goal is to prove this statement by contraposition

- *Provide the proposition to prove in order to achieve this proof*
- *Write down the proof*

In the first item, it is required to provide the statement that will be proved, that is providing the contrapositive of statement (1). During the course, students were encouraged to perform this step prior to engage in the proof in order to avoid confusion between negation, proof by contraposition and proof by contradiction. The statement (1) is a universally quantified conditional statement whose antecedent is a universally quantified statement.

Global structure of the contrapositive

Let us denote $A(x)$: $(\forall \varepsilon > 0\ x \leq \frac{\varepsilon}{2})$ and $B(x)$: $x \leq 0$ respectively the antecedent and the consequent. Statement (1) can be formalized as: $\forall x[A(x) \Rightarrow B(x)]$. We hypothesize that students will recognize this structure. The global structure of the contrapositive is hence: $\forall x[\neg B(x) \Rightarrow \neg A(x)]$. It is possible that some students could apply incorrectly the following rule: *while negating a statement, change all the quantifiers* (this rule is valid only for quantifiers in prenex position) providing: $\exists x[\neg B(x) \Rightarrow \neg A(x)]$. Also some students may confuse negation and contraposition (or proof by contraposition and proof by contradiction) and propose: $\exists x[\neg B(x) \wedge \neg A(x)]$.

The next step is applying the negation to $A(x)$ and $B(x)$.

Negation of A(x) and B(x)

$B(x)$ is an atomic formula; taking its negation is elementary: $\neg B(x)$: $x > 0$.

$A(x)$ is a complex formula comprising a variable in the scope of a bounded universal quantifier: $(\forall \varepsilon > 0\ x \leq \frac{\varepsilon}{2})$. Taking the negation provides a statement $(\neg A(x))$ with a bounded existential quantifier: $(\exists \varepsilon > 0\ x > \frac{\varepsilon}{2})$.

Two rules are involved:

a) While negating a universally quantified statement, change the quantifier to the existential one.

b) Negating "$\leq$" provides "$>$" and vice-versa, that applies correctly to "$x \leq \frac{\varepsilon}{2}$", but not to "$\forall \varepsilon > 0$".

Although the treatment of bounded quantifiers had been discussed during the course, some students may apply this rule incorrectly, providing "$\exists \varepsilon \leq 0$,".

The method to prove the contrapositive consists of providing a number strictly superior to a given number. It had been widely discussed during the course, and the mathematical knowledge required is elementary. So in this exercise we aimed to test the reasoning structure and the consideration of the logical structure (mainly the manipulation of syntactic rules). Although this exercise might appear rather easy, this brief *a priori* analysis shows the complexity of the first item, whose understanding should help students to successfully write down the proof.

Second exercise: Manipulation of definitions

First, students are asked to provide the definition of an injective function and the definition of a surjective function. The formal definitions are expected, this should be clear for students due to the focus of the course. Indeed, during the course, the two classical definitions of an injective function were given, both in natural language and in formalized language:

$$\forall x \in D_f \forall y \in D_f (x \neq y \Rightarrow f(x) \neq f(y)) \text{ (1)}$$

$$\forall x \in D_f \forall y \in D_f (f(x) = f(y) \Rightarrow x = y) \text{ (2)}$$

Various examples of functions had been studied and the necessity of identifying the logical structure and the mathematical needed to prove that a given function is injective (surjective) or not had been considered. This is required in the two following items, for which the students should indicate if the given function is or not injective, resp. is or not surjective, and then prove their claims.

Type of proofs expected from students

It should be obvious that to prove that a given function is not injective it is enough to simply provide a counterexample. To prove that a given function is injective students need to provide a proof by generic element using definition (1) or (2). Likewise, to prove that a given function is not surjective, students need either to determine the set of all the images, or identify an element b with no antecedent. To prove that a given function is surjective, students have to consider a generic element b of the outputs set and find an antecedent. This leads to prove that for any b in codomain, the equation $f(x) = b$ has at least one solution.

In the course expectations, critical review of the reasoning produced by students is emphasised. A strong requirement of the course is also making explicit the logical structure of formal statement that should appear in the students' work. Another requirement concerns justifications: students have to explicitly indicate the results of the course.

Mathematical analysis

a) $g: \mathbb{R} \to \mathbb{R}: x \to g(x) = x^4 - 1$

Injection: Here $D_g = \mathbb{R}$. is an even function; hence it is not injective. It is also possible to prove this by providing a counterexample, i.e. an element satisfying the negation: any couple of element $(-a, a)$ with $a \neq 0$ is suitable. Note that attempting to prove that function g is injective leads to the class of counterexamples $(a, -a)$ with a in $\mathbb{R}^*$ (nevertheless, some students could provide an erroneous proof).

Surjection: As $Im\, g = [-1, +\infty[$, while the set of outputs is $\mathbb{R}$, function g is not surjective. It is also possible to prove directly that any given element of $]-\infty, -1[$ is not reached, i.e. that equation $x^4 - 1 = b$ with b an element of $]-\infty, -1[$ has no solution.

So in this question only elementary knowledge of functions, equations and real numbers previously studied at secondary school is involved. As indicated in the course description, similar functions had been studied during the course.

b) $h: 2^{\mathbb{N}} \times 2^{\mathbb{N}} \to 2^{\mathbb{N}}$
The function h associates to each couple of subsets of the set of natural integers the intersection of the two subsets. No similar function has been studied during the course, but the set theory knowledge that is necessary to prove the function is surjective had been studied, and numerous examples had been treated in the corresponding chapter, so that *a priori* the repertoire of students is sufficient to provide a counterexample for injection, in order to prove that function is not injective.

Injection: It is possible to find different couples of elements with the same image; example: $h(\{1\}, \{1\}) = h(\{1, 2\}, \{1\}) = \{1\}$. Hence, h is not injective.

Surjection: $\forall X \in 2^{\mathbb{N}}\ X = h(X, X)$; as a consequence h is a surjection.

Nevertheless, as considering couples of sets as inputs for a function is a rather abstract process, it is likely that many students will not be able to provide a correct proof. In particular, considering a pair of pairs of subsets in order to engage in a general proof of injection (in case non injection is not recognized) is difficult in terms of formal manipulation as well as conceptually. We hypothesize that such a proof will not appear in the students' work.

This brief *a priori* analysis of this second exercise emphasizes the fact that here both syntactic and semantic aspects of proof are closely and dialectically intertwined (Durand-Guerrier & Arsac, 2005). So although syntactic forms are clue aspects of mathematical reasoning, a semantic control on objects is needed in order to elaborate the expected proofs.

$\forall x \in \mathbb{R}, x > 0 \Rightarrow \exists \varepsilon > 0\, x > \frac{\varepsilon}{2}$	21	$\forall x \in \mathbb{R}, x > 0 \Rightarrow \exists \varepsilon \leq 0\, x > \frac{\varepsilon}{2}$	16
$\exists x \in \mathbb{R}, x \leq 0 \wedge \exists \varepsilon > 0\, x > \frac{\varepsilon}{2}$	2	$\exists x \in \mathbb{R}, x \leq 0 \vee \exists \varepsilon \leq 0\, x > \frac{\varepsilon}{2}$	2
$\exists x \in \mathbb{R}, x > 0 \Rightarrow \exists \varepsilon > 0\, x > \frac{\varepsilon}{2}$	2	$x > 0 \Rightarrow \exists \varepsilon > 0\, x > \frac{\varepsilon}{2}$	2
$\forall x \in \mathbb{R}, x > 0 \Rightarrow \forall \varepsilon \leq 0\, x > \frac{\varepsilon}{2}$	1	No answer	6

Table 1: Students' answers for the contrapositive

A POSTERIORI ANALYSIS OF THE TWO SELECTED QUESTIONS

First exercise: a proof by contraposition

Statements provided by the students are given in Table 1.

For this item, 42 students provide a conditional statement, among them 21 provide a correct answer; 6 change the universal quantifier in prenex position in an existential one, and 19 negate "$\forall \varepsilon > 0$" in "$\forall \varepsilon \leq 0$". Two students provide a conjunction, which is not the negation, and two students provide a disjunction not equivalent to the contrapositive.

We observed that the statement provided by students for the contrapositive had an impact on the way they shaped their proof, as in the following example, where the student fulfils the expectation of the teachers by writing down the proof in detail:

Given $x \in \mathbb{R}$. Let us consider $x > 0$. Let us show then: $\exists \varepsilon \leq 0, x > \frac{\varepsilon}{2}$. *Let us take $\varepsilon = -1$. Let us show $x > \frac{\varepsilon}{2}$, i.e. $x > -\frac{1}{2}$; true as x>0 by hypothesis.*

Table 2: An example of an incorrect proof in the first exercise

We interpret this as an indicator that this student remains in a syntactic point of view, neglecting the possible semantic control that could have lead him to come back to (and may be modify) the statement provided for the contrapositive. This example illustrates the importance of the relations between syntax and semantics in proof production, in line with consideration by Weber & Alcock (2004).

Second Exercise: manipulation of definitions

Providing the definition of an injective (resp. surjective) function

Most students (45 out of 52) were able to provide the definition of an injective function. Among them 38 choose the definition considering two distinct elements in the antecedent of the implicative statement. For the definition of a surjective function, we have 38 correct answers; all students, except one who used the image set, provided the definition with quantifiers. Wrong answers are either incorrect statements in natural language like "f is surjective if every real number has at least one image" or incorrect quantified statements like "f is injective if $\forall x_1 \in C\, \forall x_2 \in D\, x_1 \neq x_2 \Rightarrow f(x_1) \neq f(x_2)$".

Manipulation of definitions

a) The first function considered in the *a priori* analysis is $g(x) = x^4 - 1$.

As already said this function is not injective. 36 students gave the correct answer, first writing down the negation of the statement (which is a teacher's expectation) and then giving a counterexample taking two opposite numbers. 5 students did not write down the negation, but provided a counterexample. This confirms that the rule "to prove that a universal statement is false, provide a counterexample" is available at that level for most students. What is often problematic is the relationship to the negation of a given statement (Njomgang & Durand-Guerrier, 2011) – here it is difficult to know if those who provide the negation make the links, or just fulfil the teacher's expectation.

Function g is not surjective. We obtained 27 out of 52 correct answers. Half of these 27 students began to write down the negation of the definition with a correct logical structure. Then, they provided a counterexample: mainly saying that −2 has no antecedent, sometimes without mathematical justification; 3 students provided *Im g* without mathematical justification. These students seem to master the mathematical knowledge involved. It is not the case with the 8 students who assumed the function is surjective, providing an antecedent for each given real number, without controlling its effective existence. In the following example, the student does not take in account the fact that $\sqrt[4]{y+1}$ is defined only on the interval $[-1, +\infty[$.

Function g is surjective, i.e. $\forall y \in \mathbb{R}, \exists x \in \mathbb{R}, g(x)=y$. *Given* $y \in \mathbb{R}$. *Let us take* $x = \sqrt[4]{y+1}$. *Let us show* $g(x) = y$ *i.e.* $x^4 - 1 = y$. $(\sqrt[4]{y+1})^4 - 1 = y$, *i.e.* $(\sqrt[4]{y+1})^{\frac{4}{4}} - 1 = y$, $y + 1 - 1 = y$, $y = y$.

Table 3: An example of an incorrect proof of the false claim that *g* is surjective

The second function considered in the *a priori* analysis is h: $2^{\mathbb{N}} \times 2^{\mathbb{N}} \rightarrow 2^{\mathbb{N}}$ that associates to each couple of subset of the set of natural integers, the intersection of the two subsets. Function h is not injective. We obtained 20 correct answers; 18 students did not answer this question. As in the previous exercise, most of the students began to write the negation of the definition. It appears that those who were able to identify that the elements of the inputs set were couple of subsets succeeded in providing the proof. Recognizing the nature of these elements was a difficulty for many students: some identified them as a subset of $\mathbb{N}$, or as a pair of numbers. In the following example, the logical structure of the proof is more or less adequate [5], but the proof is invalid due to the involvement of inappropriate objects.

h is not injective, thus $\exists x_1, x_2 \in 2^{\mathbb{N}}, f(x_1) = f(x_2) \Rightarrow x_1 = x_2$. *Let us take* $x_1 = (0,1)(1,2)$ *and* $x_2 = (1,2)(0,1)$. $f(x_1) = f(x_2) = 1$.

Table 4: An example of incorrect proof

Function h is surjective. We obtained 13 correct answers; 20 students did not provide an answer. Here the nature of the mathematical objects at stake is problematic for many students.

Concerning the results for both questions, we are able to say that students successful in the first question are, except one, successful in the second one. One perspective is to study whether the difficulties are the same in each question, for example for the sense given to the objects or for the manipulation of formal statements.

CONCLUSION

In this paper, we have focused on the elaboration of an innovative course for students attending the first year university in Computer Sciences in Belgium (Mons University). The aim of this course is to work with students on formal statements and proof and proving in mathematics. A main issue of this course is to emphasise some logical aspects that are often not elaborated upon by teachers, such as explicitly teaching and insist on *how to negate* or *how to take the contrapositive of* a conditional statement. In addition, specific attention is paid to the production of examples and counterexamples.

As a first exploration of the impact of this course on the students' logical and proving abilities, we have analysed two of the exercises focusing on manipulation of formal statements including definitions that were given in the assessment at the end of the course. A first result is that a rather large number of students attending the course were able to provide the required definitions, to recognize the logical structure of statements and to correctly negate a statement involving quantifiers. Referring to the existing literature that attest of strong difficulties with negation for university students (e.g., Njomgang Ngansop & Durand-Guerrier, 2011), we hypothesize that this could be a benefit of the course. Nevertheless, difficulties remain: we have observed that for some students, the manipulation of formal statements remains at a syntactic level. They seem to use routines without any semantic controls. In the case where familiar mathematical objects (such as real numbers) are involved, the related difficulties are limited, while these difficulties seriously increased when knowledge of less familiar objects is required. A second result concerns the logical complexity of the tasks that the students had to achieve, complexity that had been partly underestimated when designing the assessment. We mention in particular those difficulties related to the negation of statements involving bounded quantifiers, so that difficulties related with the dialectic between syntax and semantics, in particular in cases unfamiliar mathematical objects are being considered. The next step of this on-going study is to conduct interviews in order to better understand the way students deal with this type of tasks, for which mathematical and logical aspects are closely intertwined.

ENDNOTES

1. A mathematical organisation of a subject to be taught consists of teachers' or institutionnal's choices among « a set of mathematical elements » (types of problems, techniques, notions, properties, results, etc.) (for developments in English see, for example, Barbé et al. 2005).

2. LMD is the acronym for the three degrees of Higher Education in the Francophone area: Licence (Bachelor's degree), Master (Master's degree), Doctorat (Doctorate).

3. These concepts are taught in the course named « Mathématiques pour l'informatique 2 », organised during semester 2.

4. In the course, the coma is used to indicate that the scope of the universal quantifier is the conditional statement, so that the statement at stake is closed. In predicate calculus, we would write: $\forall x \in \mathbb{R}\ [(\forall \varepsilon > 0\ x \leq \frac{\varepsilon}{2}) \Rightarrow x \leq 0]$.

5. We notice an incorrect use of *thus* (in French *donc*), while what is expected here is *That is to say* (*c'est-à-dire* in French). Moreover, the statement provided by this students to formalise « *f* is not injective » is not correct.

Growth of mathematical knowledge for teaching – the case of long division

Jason Cooper

Weizmann Institute of Science, Rehovot, Israel, ntjason@weizmann.ac.il

When university mathematicians teach mathematics courses for non-mathematicians, there may be a discrepancy between the mathematics they aim to teach and the mathematics their students aim to learn. In this paper, I analyze a lesson on long division taught by a mathematics Ph.D. student, where the learners were in-service elementary school teachers. Taking a Commognitive approach, I describe some crucial differences in the teachers' and the mathematician's discourse on mathematics and on teaching, which created opportunities for mutual learning. Uncovering the affordances and limitations of this teaching/learning situation is expected to help mathematicians become more effective teachers of non-mathematicians in general, and of pre-service and in-service teachers in particular.

Keywords: Elementary school mathematics, university mathematics, professional development, Commognition.

INTRODUCTION

Researchers such as Nardi and colleagues (2014) are coming to view university mathematics as a discourse, conceived as accepted modes of communication in mathematics departments. However, other communities engage in their own mathematical discourses (physicists, chemists, mathematics teachers), which may be quite different from the discourse of mathematicians. What happens when mathematicians teach courses for non-mathematicians? What is the nature of productive learning in such situations? These are the questions that guide my investigation of an extreme case – a mathematics Ph.D. student teaching in-service elementary-school teachers a lesson on the long division algorithm (LDA). This mathematician may be an expert on abstract algebra, but what can he possibly know about division in elementary school, how it's taught, or what kind of difficulties students typically encounter? I show how the differences in mathematical discourses of the two parties created opportunities for mutual learning, and how this meeting of two communities of mathematics educators brought a rich perspective to the teaching of LDA, where pedagogical considerations of teaching and learning interacted with mathematical considerations. Understanding how this came about may guide mathematicians in teaching pre-university mathematics to non-mathematicians, particularly in the teaching of school teachers.

SETTING

The professional development (PD) under investigation was the initiative of a university professor of mathematics, and was taught by mathematics graduate students. Its declared goal was to broaden and deepen the teachers' understanding of the mathematics they teach. Approximately 90 teachers enrolled in the 2011–12 program, which consisted of ten 3-hour sessions taught in six groups. The data collected in this research project consists of audio recordings of all the sessions, interviews with the instructors, and teacher questionnaires – expectations at the outset and feedback after each session. In this paper, I analyze a lesson on LDA in which 15 grade 3–6 teachers participated. The instructor was a mathematics doctoral candidate.

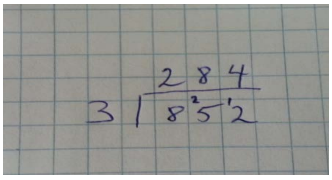
Here are some features of LDA that the instructor decided to attend to in this lesson:

- LDA is opaque – the underlying mathematical ideas of number decomposition, distributive rule, place value and regrouping are not salient.
- Treating the dividend as a sequence of digits discourages estimation.

— Answering "how many times does the divisor go into…" is difficult, since there is no margin for error – we must find the *greatest* multiple that "goes in".

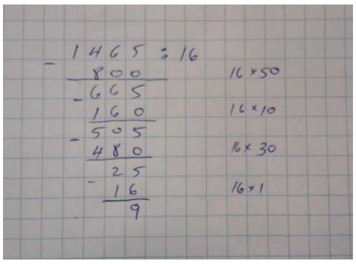
The lesson proceeded as follows in Table 1.

The Short Division Algorithm (SDA) discussed in lesson segment B is a variant of LDA for cases where the divisor has a single digit. Remainders are calculated mentally and written between the digits of the dividend (Figure 1). The sequence of LD problems (segment C) focused first on place-value decomposition: , then on decomposition induced by LDA: , connected with regrouping and the distributive property. Two alternative division algorithms were presented (segment D), neither of which requires the performance of division operations: Division by approximation: choose an *easy* multiple of the divisor, subtract it from the dividend, and repeat. This algorithm does not have a single correct implementation; you are free to choose any multiple of the divisor you are comfortable with (Figure 2). Division in parts: pre-calculate the divisor multiplied by 1, 2, 4 and 8 by repeatedly multiplying by 2, and use these multiples (possibly with added zeros) to *divide by approximation* as described above. This algorithm, unlike division by approximation, has a single correct implementation. You are not free to choose any multiple of the divisor, you should always subtract the largest one from the pre-calculated multiples (Figure 3).



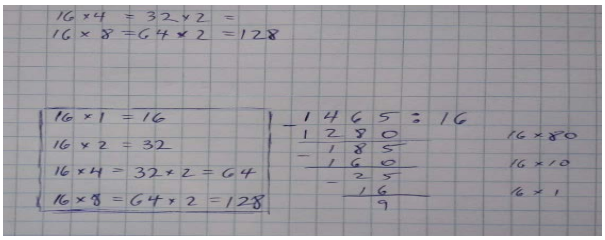
3 goes into 8 2 times. The remainder (2) is calculated mentally and written to the left of the 5, which is now read as 25. 3 goes into 25 8 times. The remainder is written to the left of the 2. Finally 3 goes into 12 4 times.

Figure 1: Short Division Algorithm (SDA)



"16×50=800 is easy for me. I subtract from 1465 to get 665. Subtracting 16×10 is convenient, leaving 505. I know 16×30=480. Subtracting leaves 25. Subtracting 16×1 leaves 9. 50+10+30+1=91. The solution is 91 (9)".

Figure 2: Division by approximation



Four multiples of 16 are pre-calculated. The algorithm proceeds as in Division by Approximation, except that each stage is determined – we must use the *greatest* multiple from the table, adding zeros where appropriate.

Figure 3: Division by parts

	Utterances	Duration	What was going on
A	88–195	11 min.	Introducing the lesson's topic and motivation
B	196–389	13 min.	LDA and SDA exemplified and compared
C	390–862	30 min.	Sequence of LD problems that focus on mathematical ideas one at a time.
D	863–1308	23 min.	Two alternate division algorithms

Table 1: Overview of transcript data

THEORETICAL FRAMEWORK AND RESEARCH QUESTIONS

The framework of Mathematical Discourse for Teaching (MDT) (Cooper, 2014) takes inspiration from Mathematical Knowledge for Teaching (MKT) (Ball, Thames, & Phelps, 2008) – in viewing mathematics *for teaching* as special and different from mathematics for other purposes. Epistemologically, MDT endorses tenets of the commognitive framework (Sfard, 2008), seeing fields of human knowledge, such as mathematical knowledge for teaching, as well defined forms of communication, and thus communication and cognition as aspects of a single entity termed discourse. Hence, MKT's distinction between Subject Matter Content Knowledge and Pedagogical Content Knowledge is mirrored as a distinction between Subject Matter Content *Discourse* (SMCD) and Pedagogical Content *Discourse* (PCD). Similarly, each of the six subcategories of MKT has its discursive counterpart. Discourses are associated with communities, thus university mathematicians' MDT and elementary school teachers' MDT are expected to be different. In the Commognitive framework, learning is conceived as changes in one's discourse, which typically start out as discourse-for-others – imitation, possibly thoughtful, of a leader's discourse – but may evolve into discourse-for-oneself – the discourse with which one communicates with oneself in problem solving (i.e. thinking).

Research questions

1) In what ways are the significance and the role of long division different for the instructor (in his university MDT) and for the teachers (in their elementary school MDT)?

2) What opportunities for learning emerged from these differences?

   a) How did the meeting of two MDTs create opportunities for learning?

   b) What learning actually took place in this lesson, on the part of the teachers and the instructor?

METHOD AND DATA

This paper draws on the instructor's lesson plan, a 77 minute audio recording of the lesson – fully transcribed and selectively translated, and an unstructured interview with the instructor five days after the lesson.

Commognitive methods of analysis focus on four interrelated characteristic features of discourse: *keywords*, *visual mediators*, distinctive *routines*, and generally *endorsed narratives*. Differences in interlocutors' discourse (e.g. differences in the ways they use keywords, in their attitudes to visual mediators, in the routines they typically engage in, or in the narratives they endorse), may present opportunities for learning. *Crisis points* in communication – "signs indicating that something has gone wrong in the interaction" (Jorgensen & Phillips, 2002, p. 125) – are a natural place to look for differences in interlocutors' discourse, and for learning taking place.

LONG DIVISION IN SUBJECT MATTER CONTENT DISCOURSE (SMCD)

Understanding LDA as process, concept and visual mediator

The teachers and the instructor agreed that understanding LDA is important, but the keyword *understanding* is used differently in their respective MDTs. For the teachers, understanding is strongly linked to the algorithm process, as is evident in a teacher's comment after a detailed review of a LD problem: *Here there's awareness of the process, it's not automatic. <u>This</u> is your understanding*. For the instructor, understanding LDA has to do with making connections between the related mathematical ideas – decomposition, the distributive rule and place value: *using the distributive rule and convenient decompositions (of the dividend) can be done without the algorithm... is very helpful for understanding the algorithm... sharpens the understanding of the distributive property in the context of division... understanding something we already know how to do*. Here are some additional examples of the procedural nature of the teachers' MDT versus the instructor's more conceptual nature: The keyword DMSB (acronym for divide, multiply, subtract, bring down) is central in teachers' discourse. Where the teachers speak of *remainder* in LDA ("in the LDA for 693÷3 there's no *remainder*"), the instructor replies "you mean there's no *regrouping*". Both keywords refer to the LDA procedure, but *regrouping* is the conceptual counterpart of *bring down*.

Another difference in the MDT of the two parties is in the significance attributed to the visual mediation of processes. Comparing SDA to LDA, the instructor notes: *we perform exactly the same operations in the same order... the difference is... [in LDA] we write a lot, and we've agreed that it's a big mess*. This does not do justice to the visual aspects of the algorithms. There are rules regarding how LDA and SDA are arranged on the page (see Figure 1), and these rules interact with the process and with the conceptual underpinnings, as is evident in some teachers' comments: *The bringing down is difficult... especially without grid paper* (a difficulty that is avoided in SDA where digits are not brought down); *[in SD the kids] immediately notice the remainder ... [because] they need to write it*; There are other examples of the teachers attending to visual mediation where the instructor seems to see it as secondary to the underlying mathematics: as the instructor walks through an alternate procedure, a teacher asks for a visual mediator: *don't you write down the [interim] result?* His response – *I'm trying to tell you how I'm thinking about it, not how I'd explain it to students* – implies that he views visual mediation as a teaching tool, having little to do with cognition. However, issues of visual mediation may be closely related to mathematical concepts. For example, working through using the approximation algorithm, the instructor mediates his actions by writing . A teacher says she would have written . Other teachers justify the division notation in many ways: *it's easier*; *it's confusing otherwise*; *in a classroom with students struggling with division we need to get them accustomed to thinking division*. For this last teacher, the visual mediation is entwined with a mathematical issue concerning the relationship between division and multiplication. In university mathematics there is no independent division operation, instead there is multiplication by inverse. This attitude to division is particularly evident in the alternate division algorithms, where division problems are solved without performing any division operations, only multiplications and subtractions! According to the instructor, the benefit is in avoiding the most difficult aspect of LDA – finding the *greatest* multiple of the divisor that goes into the dividend with no margin for error, but it is conceivable that he was influenced by his university conception of division as an unprivileged operation.

LONG DIVISION IN PEDAGOGICAL CONTENT DISCOURSE (PCD)

Teaching and learning long division

The instructor's Pedagogical Content Discourse pertains both to teacher education and to elementary school pedagogy. For him they are connected; in his words he aimed to *give the angle that will connect [the PD] to what goes on in the classroom*. One such connection would be the teachers using PD activities in their classrooms, possibly with minor modifications. This is something the teachers also hoped for, based on questionnaires that explored their expectations. However, the teachers deemed much of the LD lesson unteachable. Regarding the alternate division algorithms responses included: *[Division by parts is] not a method you can teach a class*; *[it's] explanations for good students*. The instructor appealed to other modes of relevance, suggesting the method as an aid for struggling students, but this too was rejected by a chorus of teachers: *it would confuse them so badly; it's difficult; no way*. Finally the instructor suggested yet another role for these algorithms, as a means for independent checking of standard LDA results. The teachers were not explicit about why they rejected methods that the instructor considered useful, but I offer some speculations, supported by what I have shown regarding the MDT of the two parties:

In the teachers' MDT, an alternate algorithm is yet another procedure that would need to be mastered, i.e. memorized. For the instructor these algorithms make so much sense that they should not need to be memorized.

The instructor considers the flexibility of the approximation algorithm a strength: *By using approximations and working with multiples that we're comfortable with, we're converting the problem to an easier problem*. However teachers may be wondering how to teach an idiosyncratic algorithm, which each student may solve differently. And what about students who are not comfortable with *any* multiples of the divisor?

Visual mediation may also be an issue. The instructor's focus was on the mathematics involved in each of the algorithms, but a teacher commented that *[we] need to remember [the multiplier] at each stage*, apparently attending to the lack of well-defined rules for organizing the solution visually. This is backed by teacher comments throughout the activities such as:

I'd have organized [the decomposition] in a [place value] chart; why don't you do [by parts algorithm] in the table?

WHAT ARE THE PARTIES LEARNING?

In commognitive terms, the differences in the MDTs of the teachers and the instructor present opportunities for mutual learning. Although the goal of PD was for *teachers* to learn – primarily mathematical content – learning on the part of instructor is crucial for the design and implementation of activities that will be relevant for teachers. In this section I show some examples of both kinds of learning taking place.

The teachers, in their active engagement in the various division algorithms – LDA, SDA, by approximation and by parts – were exploring connections between mathematical objects such as division, multiplication, decomposition, place value, estimation. They had accepted the goal of understanding LD and its entailments, as is evident in this teacher's comment, which followed the decomposition activity: *When we eventually reach long division, everything we did in this activity [decompositions of the dividend], the understandings, they disappear… The question is how to achieve understanding [for our students].* I now analyze some transcript excerpts to show the kind of learning that was taking place.

Excerpt 1: Developing Specialized Content Discourse, decomposing 852÷3

574 I: What I think can help prepare for LDA is doing the division first without mentioning the algorithm. Let's write it as a word problem. What do we get from dividing 8 hundreds, 5 tens and 2 units into 3 equal groups?
578 I: First we divide what we can…six-hundred… I'm left with 2 hundreds… not 2.
585 T1: Which are in fact 20 tens
596 I: [We now have 25 tens.] How many tens can be divided?
597 T1: 240
598 I: 24 tens…
599 T2: You can do 240. Why 24?
601 I: Oh, here I wrote six-hundred…
610 T3: Why convert to hundreds? … 6 instead of six-hundred… in Hebrew six…
613 I: Exactly. When I said six hundreds, I automatically thought six-hundred

Perhaps the most salient aspect of this excerpt is that teachers engaged in explorative discourse around a division procedure which is not part of the curriculum. I would like to draw attention to what may appear to be a rather trivial slip on the part of the instructor, saying and writing *six-hundred* (600) instead of *six hundreds*. This is not at all trivial. Three related but very different division algorithms are being considered, each with its own language usage. In LDA the symbol 6 in the hundreds place represents 600, in the precursor algorithm under discussion in the excerpt 6 hundreds need to be divided equally (explicitly compared by the instructor to the problem of equally dividing 6 melons), and in the alternate algorithms (by approximation and in parts) the number six-hundred needs to be divided as a number, not a quantity. These subtle differences are at the heart of the instructor's design. The alternate algorithms, in referring to the number, support estimation strategies. LDA makes sophisticated but opaque use of the principle of place value. The procedure in the excerpt subtly bridges the two; procedurally it follows LDA (hundreds, tens, units) while keeping track of the dividend as a quantity and not just a sequence of symbols. T1 and T2 are not yet fully aware of these subtleties, but T3, in catching the instructor's slip, appears to be on the way to making these distinctions part of her own discourse.

Excerpt 2: Specialized Content Discourse – endorsing an algorithm

Please refer to Figure 3 to make sense of this excerpt. T3 makes a "mistake", subtracting 128 from 185, the instructor goes along with it, T4 catches the mistake.

1125 T1: I'd start with 128
1127 T2: 1280
1128 I: Alright? 128, but times 10 is 1280. 1465 less 1280 is … 185
1175 T3: Less 128
1177 I: 128
1178 T4: But why did you do 128? You can do 160… It's much easier
1180 T3: Yes, 160 is preferable
1189 I: It's in the table, I forgot. I have 160 here, you're right.
1190 T5: Because in your table, instead of 8 you can do 10… 10 times 16.

Here again a number of teachers are actively exploring a division algorithm, and again are correcting the instructor's authentic error. An important aspect of this algorithm is that it has a unique "correct" move at each stage. By contrast, division by approximation is idiosyncratic – looking for "convenient" multiples of the divisor and subtracting them from the dividend. In division by parts we look for the unique *greatest* multiple from the table, where the instructor, using a procedural discourse, stated that *obviously we can add zeros*. T5 did not adopt this procedural language, preferring the more conceptual *10 times*. Furthermore, T3 and T4 seem to have appropriated something from the approximation algorithm, since they do not consider the instructor's slip an error, rather 160 would have been *easier* or *preferable*. This is not a minor point. LDA has a single correct flow; procedures that can correctly proceed in different paths are from quite a different discourse.

Excerpt 3: Specialized Content Discourse – mediating division and multiplication

The instructor commented that *how many times does 3 go into 8* is an instance of the measurement model of division. But *times* suggests multiplication at least as much as it suggests division. With this in mind, consider the following exchange:

1000 I: I think about it this way: I want to know how many times 16 goes into 1220.
1001 T1: So, times...
1002 T2: times...
1003 T1: 50 times
1004 I: Yes. Ok, times. So we found 50 times 16. It sounds a bit strange doesn't it?
1009 T3: Because you're asking how many times 16 there are in...
1011 T4: goes into 1220? It goes in 50 times.

The instructor invested some effort in mapping out connections between division and multiplication prior to the lesson. The discussion evolved in ways he could not have anticipated or prepared for. The teachers' testimonies regarding students' strategies for answering *how many times it goes in* (skip counting and repeated subtraction) revealed some such connections, but in this excerpt we see something different – the parties are listening to each other carefully and jointly exploring the role of the word *times* in mediating meanings of division and multiplication. We have "how many times 16 *goes in*" (division), "50 times 16" (multiplication), and "how many times 16 *there are* in 1220", which can be seen as bridging the two preceding meanings. This is a case of a joint object-level learning in the realm of Specialized Content Discourse, with obvious implication for Discourse of Content and Teaching.

Excerpt 4: Discourse of Content and Teaching – is the algorithm teachable?

From the teachers' participation throughout the activities it is clear that by and large they mastered the suggested algorithms, yet they were convinced that their students would not, whereas the instructor believed that they would. This discrepancy is due to the rules by which the parties endorse narratives about students and teaching – the teachers based on their experience and the instructor based on an analysis of the mathematics. The teachers' experience is a valuable resource and should not be taken lightly, and indeed I have shown why the alternate division algorithms might be difficult to teach, however, the teachers' don't have any direct experience regarding what they have *not* taught. Four teachers came to realize this towards the end of the lesson, where there were a total of 9 utterances to this effect, for example:

1237 T1: Could be, I haven't tried it. Could be that if you do one or two lessons this way... they'd understand the meaning of decomposition.
1240 T2: Exactly.
1244 T1: Not necessarily after LDA. I'm saying this cautiously since I haven't tried...
1248 T3: Not in order to know *how* to do it, rather to understand the meaning
1264 T4: Theoretically. We should try it some time.

Even as these teachers entertained the thought of teaching this algorithm, the principle by which it will (or not) be endorsed remains reliant on teaching experience.

Specialized Content Discourse – appreciating the role of visual mediation

I have shown that there is less attention to visual mediation in the instructor's discourse than in the teachers', however, the instructor was attentive to the teachers' comments and suggestions. He accepted two suggestions: mediating division by approximation in terms of division instead of multiplication; and, keeping track of the stages of division by parts in a table. Furthermore, in the discussion about SDA he realized that writing the remainder between the dividend's digits addresses the common error of skipping digits in the *bring down* stage. He also noted that the alternate algorithms generate solutions that *look completely different* than the LDA solution, even though they make use of similar mathematics.

SUMMARY

I have shown that the teachers tended to see LDA as a procedure that needs to be mastered and understood, whereas the mathematician saw it as an opportunity for deepening understanding by connecting a number of different topics. This is just one of the many ways in which their MDTs differed. In the face of such differences, the lesson could have followed various different paths: The instructor could have insisted on his agenda, alienating the teachers, or he could have adopted the teachers' point of view, setting aside his own agenda. Neither of these is what actually took place. The instructor was true to his mathematical agenda, but made a genuine attempt to appropriate the teachers' discourse. This can be seen both in his preparation of the lesson and in the way it played out. Why did he present two similar algorithms – approximation and in parts? The underlying mathematical principle is the same – incrementally decomposing the dividend into multiples of the divisor. I suggest that the instructor was developing sensitivity to the teachers' Discourse of Content and Teaching, and, realizing how difficult it would be to teach an idiosyncratic algorithm, suggested the deterministic version as an alternative. Furthermore, the motivation he gave for these algorithms was from the teachers' Discourse of Content and Students – they avoid the aspect of LDA that he considers most difficult for children (division).

The lesson on LDA may be considered productive in the sense that both the teachers and the instructor were enriching their MDT. It is interesting to note that this learning, when it involved changes in the rules of the discourse, did not follow the pattern described by Ben Zvi & Sfard (2007); there was no agreement on the leading discourse, the roles of the interlocutors, or the course of discursive change. Expertise was shared by teachers and mathematicians, who were all in the position of learners.

My aim in this paper was to point out *opportunities* for learning in the meeting of two MDTs. I have claimed that, in some cases, learning was in fact taking place, in the sense that the parties – teachers and instructor – were not superficially adopting aspects of an unfamiliar discourse. Rather they were in the process of transforming this discourse into *discourse-for-oneself, that is, into the type of communication in which the person is likely to engage of her own accord, while trying to solve her own problems* (Sfard, 2008, p. 285). This was evident on the part of the teachers; the mathematical activities stretched their Specialized Content Discourse, yet all the while they were considering implications for their teaching. In this sense the teachers were *constructing* new knowledge not through experience (teaching) but rather through discursive interactions, transforming mathematical ideas into ideas for teaching. How these discursive shifts subsequently influenced their teaching (if at all) is an important question that will be addressed in future research.

The instructor extended his own SCD while unpacking LDA in preparation for the lesson. The lesson itself presented opportunities for learning, but it is difficult to make claims regarding the nature of the instructor's learning based on the lesson transcript. For example, when some teachers suggested 30÷3=10 instead of 3×10=30, he responded: *Ok, but I'll tell you why I did the multiplication.* If he is thoughtfully considering the teachers' discourse and is on the way to transforming it to discourse-for-himself, there are no indications of it in the transcript. Nonetheless, such learning is crucial for mathematicians to be relevant for the education of teachers. Based on an interview following the lesson, the instructor was thoughtfully exploring ways in which his teaching might be *relevant* for the teachers. It is not clear if the instructor's learning would have been as productive in the absence of a researcher. However I believe that exposing mathematicians to these research findings is a crucial step for supporting their sensitivity towards teachers and their learning in similar situations.

ACKNOWLEDGEMENT

This paper was supported by the Weizmann Institute of Science and the Israel Science Foundation (grant No. 615/13). The author is grateful to Abraham Arcavi and Ronnie Karsenty for many helpful comments.

Differential participation in formative assessment and achievement in introductory calculus

Rebecca-Anne Dibbs

Texas A&M University-Commerce, Commerce, USA

Prior formative assessment research has shown positive achievement gains when classes using formative assessment are compared to classes that do not. However, little is known about what, if any, benefits of formative assessment occur within a class. The purpose of this study was to investigate the achievement of the students in introductory calculus using formative assessment at the two different participation levels observed in class. Although there was no significant difference on any demographic variable other than gender and no significant difference in any achievement predictive variables between the groups of students at the different participation levels, regular participation in formative assessment was the most significant predictor of achievement in the hierarchical linear model.

Keywords: Approximation framework, calculus, formative assessment, hierarchical linear model, participation.

INTRODUCTION

Introductory calculus is one of the largest choke points for prospective undergraduates who wish to pursue STEM (Science, Technology, Engineering and Mathematics) careers. Students who leave STEM majors are very likely to do so during or immediately after the first semester of calculus (Ellis, Kelton, & Rasmussen, 2014; Rasmussen, Ellis, & Zazkis, 2014). There are several reasons why introductory calculus is a particularly difficult course. The majority of students enrolled in calculus are first-time freshmen, and mathematics and science classes are where students transitioning to higher education are most likely to struggle (Cabrera, Miner, & Milem, 2013; Waterson, Browne, & Carnegie, 2013). Furthermore, the students most likely to leave STEM majors after calculus are from groups that are underrepresented in STEM areas: women, first generation college students, English-language-learning students, and students from underfunded urban and rural high schools (Waterson, Browne, & Carnegie, 2013).

One study found that switchers were less likely to feel a sense of connection with their instructors (Ellis, Kelton, & Rasmussen, 2014), which suggests that the increased use of formative assessment, low stakes assignments for instructional planning purposes, may help to increase the number of prospective students in STEM majors past the first semester. The use of formative assessment with undergraduates appears to increase students' perception of a positive relationship with their instructor, make students more likely to seek help, and allows instructors to make data-based decisions on how much review instruction can/should be incorporated into a particular unit (Black & Wiliam, 2009; Dibbs, 2014). For the purposes of this study, formative assessments are defined to be written assignments graded on completion for the purposes of instructor planning.

Regardless of the content area or age of participants, the effect size on most quantitative formative assessment studies is around 0.5 (Karpinski & D'Agostino, 2013). These studies show that classes where formative assessment is used do better on average on common summative assessments than those classes where no formative assessment is used; however, even in classes where formative assessment is used, not all students will regularly complete the formative assignments. The purpose of this study was to investigate the influence of participation on students' growth trajectories on calculus labs designed to develop systematic understanding of limit concepts. Growth can be measured in either student achievement or increases in students' conceptual understanding. The analysis was delimited to the achievement definition of growth, though qualitative investigations of students' conceptual growth of the approximation framework also showed that regular participants appropriated nearly all limit concepts embedded in the approximation framework while the irregular participants showed little conceptual acquisition beyond procedural fluency (Dibbs, 2014). For this paper, I will distinguish between two different participation levels: regular and irregular. Students regularly participating in the formative assessments missed no more than two of 12 formative assessments during the semester. Although the regular participants earned significantly higher grades on the calculus limit labs, there were students that earned every possible final grade in each participation level.

METHODS

This study is part of a larger QUAL-quan mixed methods case study (Dibbs, 2014). Participants were recruited from two introductory calculus courses taught using the approximation framework at a midsized doctoral granting institution in the Rocky Mountain region. The students enrolled in introductory calculus are most commonly chemistry, science education, mathematics education, or mathematics major, and 35% of the students at the University are first generation college students. There were three sources of data collected: students' assignments, classroom observations, and interviews. The qualitative analysis consisted of daily classroom observations and student interviews. During classroom observations of labs, three of the eight groups in each class were closely observed for peer and instructor interaction: three groups of regular participants, two mixed groups, and one group of irregular participants. During non-lab class days, the instructor's interaction with the class and students' behavior was observed, with particular attention paid to the students observed during labs. After each lab, nine students (both of the mixed participation groups and one regular participation group) were interviewed about their lab write-ups using a cognitive think aloud technique. Students were given a clean copy of their lab and asked to explain each of their answers, who if anyone helped them figure out that particular portion of the lab, and if they would change their answer now; these qualitative data were analyzed to understand students' conceptual growth throughout the semester (Dibbs, 2014). The observations and interviews showed that there was some peer instruction during the labs, but most of the time, irregular participants only consistently understood the procedural computations portion of the lab. All assignments generated by each participant were collected for the quantitative analysis.

Introductory calculus is a four credit course that met Monday, Tuesday, Wednesday and Friday. The course begins with a brief pre-calculus review and ends with The Fundamental Theorem of Calculus and u-substitution. Students' final grade in the course was determined by online homework (10%), labs (20%), formative assessments (5%), three in-class exams (15% each), and a final exam (20%). Every week followed the same general schedule. On Monday, there was a new section of material introduced and students were given a prelab. Students were asked to complete the Unknown Value portion of the approximation framework (Figure 1) and identify a quantity with which to approximate the unknown value. Students were asked to complete the prelab before class on Tuesday; the prelab was graded on completion at the beginning of class. During class on Tuesday, students worked in groups of three or four on their assigned lab context. After class, students completed a postlab using the online course management software. Each postlab asked students to summarize what their groups did, evaluate how well they understood the material, perform a computation similar to the ones expected on the lab, and identify which portions of the lab they still needed help on. The post-lab was graded on completion, and instructors used students' answers to plan a 20 minute discussion about the lab to begin that class Wednesday.

Although the postlab completion grade was 5% of the students' final grades, the primary purpose of the assignment was to evaluate students' current understanding and plan the next class effectively; in that sense the postlab was primarily a formative assessment. Students were provided automated feedback through the CMS, and it took an average of 15 minutes/week to evaluate a classroom set of postlabs and plan the next class. The remainder of the week was spent on concepts from the textbook. For the derivatives and definite integral labs, the next week would be a repeat of the first; all of the other labs proceeded directly to the regrouping described next. On the third week, students would be placed in new groups, where they were responsible for teaching their context to their new group members; this type of presentation

Fluid traveling at a velocity v across a surface area A produces a flow rate of $F = vA$. Poiseuille's law says that in a pipe of radius R, the viscosity of a fluid causes the velocity to decrease from a maximum at the center ($r = 0$) to zero at the sides ($r = R$) according to the function $v = v_{\max}(1 - \frac{r^2}{R^2})$. In this activity you will approximate the rate that water flows in a 4-inch diameter pipe if $v_{\max} = 4.44$

is called a Jigsaw presentation because each student is responsible for one piece of a larger idea. After this Jigsaw presentation, students were expected to write up their individual answers to the 20 parts of the approximation framework; this assignment was the summative assessment of each lab. Each lab had one formative prelab and two or three postlabs associate with the summative lab writeup.

The approximation framework is built upon developing systematic reasoning about conceptually accessible approximations and error analyses but mirroring the rigorous structure of formal limit definitions and arguments (Oehrtman, 2008). Approximation is the most common of the seven informal understandings of the definition of a limit; by incorporating the approximation labs into the curriculum, all students are trained to conceptualize limits in the same manner; this makes the transition for formal calculus topics easier for both students and instructors (Oehrtman, 2008).

For each calculus concept, students are asked to identify the unknown value that cannot be solved with algebra, an algebraic technique for approximating the unknown, quantify the error, bound the error, and describe how an approximation can be computed to any desired accuracy. Although the context (and calculus context) changed with each lab, students were asked the same questions on each lab; hence, the labs may be considered repeated assessments on the approximation framework concepts since the process was identical on each lab once the appropriate approximation had been determined. Students were asked to represent these five components of the approximation framework contextually (words and pictures), graphically, algebraically, and numerically. Each lab had three or four different contexts; one of which was more challenging and intended for students that had seen calculus before. While there is a lab every week, this research was delimited to the approximation framework labs dealing with limits, derivatives, and definite integrals. These labs accounted for 10/14 lab sessions in the semester and contained topics common to all introductory calculus courses. The remaining labs dealt with practice on applications of derivatives: Taylor polynomials, optimization, and related rates. There was also a lab before limits on quantitative reasoning that was not considered due to its low reliability.

The courses were taught at the same time and on the same schedule by two equally experienced instructors. All of the lab questions were scored dichotomously so the inter-rater reliability of the lab write-ups was not a concern. The content validity of the assessments was checked by the course coordinator and an additional expert on the approximation framework. Since the labs were scored dichotomously, KR-20 was used to calculate reliability, and all assessments had reliabilities within acceptable levels (Gall, Gall, & Borg, 2007): the limit, derivative, and definite integral labs had KR-20 values of 0.83, 0.72, and 0.78 respectively.

In addition to participants' lab write-ups, grade predicative variables and demographic information were collected from each participant. There were no significant differences between the sporadic and non-participation groups on all but one of the demographic or grade predictive variables tested ($p > 0.25$) [1]. Female students were significantly more likely to be regular participants in formative assessment ($p = .03$). Since asynchronous formative assessment, like the ones used in this study, require a greater level of organization and engagement, these assignments tend to slightly favor female students (DiPrete, 2013). Despite the selection bias inherent in the participation levels, there was no significant difference on any measurement of prior knowledge taken at the beginning of the study. These measures of students' prior knowledge, which all indicated students that chose to participate or not participate in the formative assessments did not have significantly different levels of prior knowledge were not included in the model.

There were 66 students that consented to participate in the study; 13 of the students were removed from the sample because they had prior exposure to the labs that could confound the results. Of the 53 students that were new to the approximation framework labs, only seven had no prior exposure to limit concepts in a prior course, and 27 of the students had AP Calculus [2] in high school. Students needed to have completed at least 10/12 formative assessments to be classified as a regular participant. There were 30 students classified as irregular participants; the remaining 23 students participated regularly in the formative assessments. Only students that completed at least two of the four approximation labs were included in the analysis and are included in the table.

The initial analysis used Bonferroni corrected t-tests found that there were significant differences in the mean number of questions answered correctly by students in each participation level on the three labs, which suggested a hierarchical analysis was most appropriate for the data (Raudenbush, Bryk, Cheong, Congdon, & Toit, 2004). After the null model showed significant differences in the intercept and slope between the two participation classifications, the final model was:

$$SCORE_{ij} = \gamma_{00} + \gamma_{01}{*}REGULAR_j + \gamma_{10}{*}LAB_{ij} + \gamma_{11}{*}REGULAR_j{*}LAB_{ij} + u_{0j} + r_{ij}$$

The dependant variable is the number of questions a student answered correctly; regular and is a dummy coded variables at the student and time level. Gender, ACT Math score (a standardized exam students take their third year of high school in preparation for applying to college), ethnicity, year in school, native language, major, and the Calculus Readiness Test (a standardized exam administered to students on the second day of classes), did not explain significantly more variance when included, and were all discarded in order to retain the most parsimoniousness model.

RESULTS

There were students that earned every possible final grade in both participation levels, but on the labs, the students that regularly participated in the formative assessments that followed answered more items correctly on the lab write ups than the irregular participants. Table 1 summarizes the results of the t test assuming unequal variances. The *p*-values have all been multiplied by a factor of three to account for multiple hypothesis tests. Despite the correction, the regular participants in formative assessment have a significantly higher mean score than those not participating regularly. While these two groups were not significantly different on any of the grade-predictive measures available at the beginning of the semester, the students that were irregular participants in the formative postlabs actually had slightly higher average scores than the regular participants.

Given that there appeared to be differences in both the initial level of performance and the rate of change in

	Irregular Mean	Regular Mean	*p*-value
Limits	8.48	13	0.006
Derivatives (Final)	5.29	16.52	<0.001
Definite Integrals	5.51	17.34	<0.001

Table 1: *t*-test results for mean number of items answered correctly on each lab by participation level

Table 2: Null growth model results

score from lab to lab, an analysis that accounted for time was more appropriate to explore this phenomenon further. To confirm growth modelling was the appropriate choice of statistic, a null model [3] was run; this model was significant (Table 2), confirming that multilevel modelling was required; the unexplained variance was 0.504 [4].

The only measurement that resulted in a significant reduction of ICC was participation. When included as a Level-2 variable, the dummy code for regular participation reduced the unexplained variance to 0.363, a reduction of 0.141. The final variance component summary is given in Table 3.

The final estimation of the growth model fixed effects showed that students who regularly participated in the formative prelabs and postlabs were able to answer an average of 5.44 more questions correctly when compared to a student of similar ability who did not regularly participate in the formative assignments (Table 4). The maximum likelihood estimation of the number of significant parameters on the intercept was two, but it was not any of the measures collected as part of the set.

Regular participation in formative assessments also had a significant influence on the rate at which students improved on their lab writeups (Table 5). Given the pronounced ceiling effect of the regular participants' scores, it is not surprising that the slope is relatively small; the regular participants started with relatively high scores and had little room for improvement. However, the near-zero slope value for the non-regular participants does not imply that the irregular participants made no learning gains throughout the semester; rather by the end of the semester these students were able to answer the same questions correctly at the end of the semester on integration that they were able to answer correctly about removable discontinuities in the limits lab.

Although the score on the rewrite after accounting for initial score between the two participation groups was not significantly different (p=0.0501), the irregular participants' regression in the subsequent lab indicated that they were not able to apply all of the instructor's feedback in a new context. There is a marked ceiling effect on the final derivative lab and the integration lab for regular participants (Figure 2), which interview data (Dibbs, 2014) indicated was due to nearly complete conceptual acquisition of the limit concepts embedded in the labs.

DISCUSSION

The results of the study indicate that the students not participating in formative assessments were able to answer fewer questions on average than those students that did participate in the formative assessments, and improved at a slower rate throughout the semester. This is surprising because the students that did not complete any formative assessments attended class for the post-lab based instruction on the day after lab, and the students that did no formative assessments did not have significantly lower levels of prerequisites knowledge than those students participating in the formative prelabs and postlabs. Although this study has a relatively small sample size, this analysis showed that regular participation accounts for 28% of the interclass correlation.

While these results indicated that there were measurable achievement differences between the growth trajectory of those students who participated regularly in formative assessments and those that did not, the analysis also suggested that there were two significant student level factors in the data. Since there were no significant differences on any academic preparation measures for the participants in this study, this suggests that the missing factor in this model is not prerequisite mathematical knowledge. However, given that prerequisite mathematical knowledge is almost always an important factor, further research on the inclusion of this variable or the use of propensity scores in the model is warranted.

One possible explanation is calibration differences between regular and irregular participants in formative assessment. Calibration is considered to be a general metacognitive skill; it is the ability of a learner to accurately assess what they do and do not know (Hacker, Dunlosky, & Graesser, 1998). In this study, the opportunity for calibration occurred on the limits, first derivative lab, and the definite lab, and it is plausible that the regular participants in the formative assessments are better at identifying the areas in which they need additional help.

There is some support for this supposition in the data. In every lab there was a set of questions that no student asked about on their postlabs. Since none of the students asked for help on the post-lab for these items, an item was considered to be well-calibrated if the student produced the correct solution. In the labs, the statistical evidence for differences in calibration is not clear. The regular participants did answer significantly more of these items correctly, but there were no formal investigations of calibration during this study. Whether pattern of responses is because completing formative assessments on a regular basis helped students maintain a high calibration level or if the formative assessments helped students improve their calibration throughout the semester is an area for future research.

ENDNOTES

1. Age, race, native language, and year in school showed no significant difference on a Chi-Square test. GPA, Math GPA, ACT Math Score, Math GPA, the pre-calculus skills test administered the second day of class, and time elapsed since the previous mathematics course showed no significant differences using Mood's median test.

2. AP Calculus is a one year introductory calculus course generally taught in the last year of high school. The content of this course is the same as the content in the one semester introductory calculus course. Students may elect to take the AP exam at the end of the year. Passing the AP exam (a nationally administered standardized test) would allow students to earn college credit for introductory calculus. Students in introductory calculus who took AP Calculus in high school did not take/ did not pass this exam.

3. A Null Model assumes that the intercept and slope are both constant for all participants. Failure to reject this test indicates repeated measures ANOVA to be the appropriate test.

4. HLM reports unexplained variance rather than R^2. The unexplained variance is $1\text{-}R^2$.

Students' personal work in mathematics in French business school preparatory classes

Lynn Farah

Université Paris Diderot, Paris, France, lgf00@mail.aub.edu

This paper presents parts of a research study pertaining to students' personal work in the learning of mathematics at the undergraduate level. It focuses on the main results conveyed by data collected through a questionnaire completed by students enrolled in two different tracks of French business school preparatory classes, at the beginning and end of their first year of study. The approach adopted in the description and analysis of results in this paper focuses on the role of the institutional context and its impact on student work.

Keywords: Mathematics learning, student personal work, institution, CPGE.

CONTEXT

Students enrolled in preparatory classes in France (Classes Préparatoires aux Grandes Écoles referred to as CPGE) seem to achieve much better results in mathematics than those enrolled in regular universities (Castela, 2011), where student failure during the first years has long been a serious widespread problem. These specific French higher-education institutions prepare students over two academic years to enter the "Grandes Écoles", which are mainly business schools or engineering schools, by passing the "concours"[1]. In the French educational systems, the two preparatory years are equivalent to the first two years of undergraduate study at university. However, the CPGE differ from universities in many ways. They are known for their selectivity in recruiting good – if not the best – high school students who hold the French baccalaureate, as well as their supportive culture, which favours student collaboration and provides them with close follow-up by teachers, in a relatively rigid high-school-like system within stable moderate-sized classrooms. These institutions constitute a rich and interesting field of observation and study given both the resources they offer to students and the constraints they weigh on them.

Furthermore, research about student personal work is not very common in mathematics education, in France and elsewhere. There have been few studies in mathematics didactics that tackled this topic however mostly in a marginal manner. In addition, given the diversity of the situations in higher education in France, the number of studies relevant to each situation is very limited. Some studies in sociology and education have closely explored student personal work but without taking into account disciplinary specificities. Our work comes as a continuation of the research conducted by Castela (2004, 2009, 2011) who studied students' personal work in mathematics in high school (grade 11) and in higher education (comparing university and CPGE). Our study focuses on the personal work of students enrolled in two different tracks of business school preparatory classes, Scientific and Technological[2], during their first year of study. S track students hold a scientific baccalaureate and have a strong background in mathematics and sciences; whereas T students have had a teaching specialized in human resources, marketing, business and finance or information systems with little focus on mathematics[3]. Hence, our study adds to the existing research about CPGE by targeting an unprecedented population while emphasizing the diversity brought by the two tracks. Furthermore, our study explores specific aspects of the "enveloping" institutional func-

1 The "concours" are national competitive exams which students take by the end of the second preparatory year in order to enrol in the "Grandes Écoles". There are specific required written and oral exams for each type of school.

2 In what follows, we will designate the tracks by the letters S and T respectively.

3 The background difference is clearly reflected through the mathematics level of students in each track.

tioning of the CPGE analysed and evidenced through a sociological study (Darmon, 2013) from a transversal point of view, adding a disciplinary focus on mathematics, while examining the link between the personal organization and the institutional organization of study in CPGE. It also introduces methodological novelties to the existing studies about CPGE in terms of data collection, by combining quantitative methods with methods that give a closer access to students and teachers.

CONCEPTUAL FRAMEWORK

We borrow several constructs from French didactics of mathematics and sociology in order to build our conceptual framework. In what follows, we define the two main components of this framework which are addressed in this paper.

Firstly, the notion of institution is at the heart of this research. We use the definition of an institution given by Chevallard (2003) as our starting point. He describes an institution as a social system which allows and imposes on its subjects – that is people who occupy different positions within the institution – ways of doing and of thinking. In the broader sense of the term, we consider that the institution designates the CPGE. We adopt Darmon's perspective who describes the preparatory institution as an "enveloping" institution,

> ...powerful but not totalitarian, violent but concerned about the well-being of its members, it operates by individualizing to the extreme rather than homogenising, thus reinforcing its take over the individuals which are its members (2013, p. 28).
