term "continuity" between theories can refer only to those metonymic chains of signifiers that are of interest *to the recontextualising regard of the theory in question* – hence also the possibility of discontinuity. To claim otherwise, I argue, is counter to a fundamental socio-semantic principle: that sense is made locally in the context of an assembled practice not outside of it. There is, therefore, no possibility of "connection" in terms of similar "component parts". Such a claim would also involve an infinite regress: the notion of similarities or points of contact between theories begs the question of what is the theory that allows such similarity to be discerned. I formalise this as a *general argument* later in this paper.

INTRODUCING THE DOMAIN OF ACTION SCHEMA

The Public Domain

Radford's (2008, 2014) discussion of "*networking theories*" in mathematics education research recontextualises some aspects of Lotman's (2001) *semiotics* to introduce "the *semiosphere* as a theory networking space". Of particular interest is the resulting delimitation of theoretical work as "*bounded*" by the principles that grant its "*autonomy*". Radford (2008, p. 319) produces a description of the mathematics research semiosphere that is in "constant motion"; accelerating as information is transmitted and received with new technologies. Autonomy of a theory within the semiosphere is given by a *hierarchical* order of *principles, methodology* and *research questions* in which the *system* (Radford, 2008, p. 320) of principles is in regulative control. The potential for networking theories is then a question of their *closeness of principle*. Some theories are too far apart to work well together, others may have surprising affinities yet to be articulated. Generally, we may be experiencing a drifting apart: networking might stabilise this, at least for a time.

This paper is written in SAM: the selection of, and extracts from, Radford's paper are motivated by its common interest in the terms given emphasis in the paragraph above such as boundedness and system. But these are expressions not specialised in SAM; and neither is their content – see the axes of Figure 1 below. This schema relates expression to content but moves beyond semiotics by further taking into account whether this is specialised or unspecialised in the *institutionalisation* of the activity. My summary of Radford's position is in the *public domain* of SAM – involving unspecialised, weakly institutionalised (I-) expression and content (Dowling, 2009, p. 206) *from the regard of SAM*. Radford's language is a highly specialised one in its own terms; but these specialised terms – and the way in which they interlink – are not recruited in the institutionalisation (denoted I+) of SAM. Figure 1 expresses SAM's *self-reference*: as a research activity it articulates specialised expression and content in its *esoteric* domain, for example "domain of action".

The Esoteric Domain

A central concept in Radford's work is that of autonomy. I will retain this word but *recontextualise it* from SAM's regard in the *esoteric domain* of SAM. Figure 1 schematises this as a socio-semantics rather than a semiosphere – *institutionalisation* (recognisable regularity of practice) occurring as research *activity* where flows of strategic semiosis (gestures, images, words) are *assembled* in more or less stabilised emergent *alliances*. The principles of action in the esoteric domain regulate what can be recognised/realised in the public domain. Weakly institutionalised terms such as autonomy and semiosphere are alienated in favour of I+ terms such as those given emphasis in this section. This is a *deformance*: the "encounter" (Radford, 2008, p. 317) read through the principles of SAM. Yet the *expressive domain* ensures that self-reference need not become solipsism: the "identity" (Radford, 2008, p. 319) of the self-reference changes in its engagement with the other.

The Expressive Domain

The deformance involved in expressive domain action can be illustrated with respect to the expression "networking theories". *(a) Network*. Eco (1984, p. 81)

	Semiotic Mode	
Mode of Action	Discursive	Non-Discursive
Interpretative	*theorem/enunciation*	*template/graph*
Procedural	*procedure/protocol*	*operational matrix/operation*

Figure 2: Modalities of the Esoteric Domain Apparatus (Dowling, 2013, p. 333)

characterises the semiosphere (in his terms the *global semantic universe*) as a *labyrinthine rhizomatic net.*

> The main feature of a net is that every point can be connected with every other point, and where the connections are not yet designed, they are, however, conceivable and designable. A net is an unlimited territory [...] the abstract model of a net has neither a center nor an outside. (Eco, 1984, p. 81).

A network is not a net (fishing, internet, tuber or any other). The metaphoric expression nonetheless points to potentially productive specialised content. Perhaps its most significant aspect is that a network cannot be described as a whole or from a global point of view; because any attempt at such a description is immediately re-inscribed as new connectivity. The concept of connectivity here is semiotic: the deferred and anticipatory action of one signifier on another. This occurs *even if they are the same.* For example, the signifier <institutionalisation> in SAM points to the schematised content of Figure 1. The same signifier is part of ATD; but its sense there – forged in dialogue with Mary Douglas' *How Institutions Think* – is not organised as a relational space. No *literal* connection of this similar is then possible, only a transformative one. (*b*) *Theory.* At the nodes of the network, Radford has "theories". Radford is careful not to impart undue reliance on the discursive by putting emphasis on the composition of the "triplet" to include principles, methodology and the "template" of research questions. Yet from SAM's regard there is still some danger of the term being read as implying potential representational adequacy (the global all-seeing net). For this reason the phrase *research activity* or *approach* has been preferred to allow full room for the "practice turn" in theory.

ASSEMBLAGES OF MATHEMATICAL MODES

In its most recent development SAM has considered the esoteric domain of school mathematics to be constituted as an *assemblage* of strategies, a term recontextualised from Deleuze (Deleuze & Parnet, 2007 [1997], p. 69; Turnbull, 2000, p. 44). As a sociology, SAM is concerned with the distributional consequences of the ways alliances emerge through strategic action in the social: these indicate (never quite fix) the norms of who can say, think, or do what; here in school mathematics.

An assemblage is specified by SAM as a relational schema – Figure 2 – that can be contingently recruited in the (re)production of school mathematics. The dimension *semiotic mode* distinguishes discursive (explicitly articulated principles, methods and symbols, for example formulae) from non-discursive modes of mathematical engagement (diagrams, or equipment such as a pair of compasses). The dimension *mode of action* opposes interpretative and procedural activity: in the former case where there is work to be done in making sense of the semiotic mode (formulae, diagrams), in the latter case where there are rules or sequences to be followed (discursively ordered algorithms, non-discursive techniques for manipulating the compasses or computer software appropriately). This establishes four *general* strategies: *template, operational matrix, procedure and theorem.* Further, the second term of each strategy in the table denotes *local* rather than generalising action.

The schema suggests competence in that discipline (or anything else) is not *acquired as such* but is constituted by the development of a pragmatic ability to *contingently* deploy an effectively inter-linked mixture of strategies in local context – upon which action the assemblage and those whose alliances will be distributed by it will develop or change. SAM therefore has no "epistemological" concerns in contrast, for example, to ATD. Figure 2 is an introduction to the technology for generating empirical description in SAM – see the many further schemas in (Dowling, 2009). These pin down *modes of action.* This is not a speculative space: it arose from an empirical engagement with a number of mathematical settings (Dowling, 2013). For recent further work in SAM see (Burke, Jablonka, & Olley, 2014; Dowling, 2014; Dudley-Smith, 2015; Burke, 2015).

	Discursive Saturation	
Mode of Action	DS-	DS+
Operationalising	*technique* (τ)	*technology*(θ)
Orientation	*type of tasks* (*T*)	*theory* (Θ)
	skill	***discourse***

Figure 3: Praxeological Modes

A RECONTEXTUALISATION OF ATD

Dowling (2014, p. 528) has noted that Chevallard's work also makes use of a "complementary" concept of recontextualisation – didactic transposition – although with a primary focus on the contextualisation of *cultural* sense-making in pedagogic settings. The schema of the assemblage is potentially in dialogue with ATD's vision of schools as providers of *discoveries* along the way of *research and study paths* (Chevallard, 2015) contingent to the opening up of a body of questions found to be of interest as the research unfolds. In what follows the "amalgam" of *praxeologies* (Artigue et al., 2011, p. 2) is recontextualised by SAM in a *deformative re-ordering*.

Consider the praxeological components [T/τ/θ/Θ] of type of tasks, technique, technology and theory (Artigue, Bosch, & Gascon, 2011; Chevallard & Bosch, 2014). ATD notices a key relation between *praxis* and *logos*: one of both imbrication and tension. Yet empirical studies have shown that this is sometimes denied: thus, for example, in the university some action (Bosch, 2014) is seen to hive off [θ/Θ] from [T/τ]. This has proved a highly fruitful distinction: thus, for example, Job and Schneider (2014) use this framework to make a productive separation of the pragmatic praxeology of the development of calculus and the rather monumentalising deductive praxeology of analysis imposed on mathematics undergraduates – with school mathematics very much a hotchpotch of both. However, in ATD the amalgam [T/τ/θ/Θ] is conceived as containing "ingredients" (Artique et al., 2011, p. 3) – suggesting to a casual reader elements to be enumerated. From SAM's regard a prophylactic against such a misreading is to suggest that the idea of a praxeology can be schematised.

First, it is possible to distinguish what I will call *operationalising* and *orientation.* Orientation concerns what one is about in a specific context: practically as embodied in *type of tasks*, logo-centrically as informed by a *theory*. The former involves low discursive saturation (DS-) as it is embedded in the situated interests or (Maussian) habitus of context. The latter is discursively saturated (DS+), i.e., context free. Operationalising involves techniques – in SAM's terminology "DS- skills" or ways of doing – as well as DS+ "technological discourse" (Bosch & Gascón, 2014, p. 69).

In Figure 3 this produces four *strategies* rather than components. In SAM's research activity the development of schemas such as Figure 3 allows a *particular kind* of regulated engagement with the empirical (without exclusion of others such as ATD). One orienting strategic mode of this is given discursively by the *theory*-logos Θ; self-referentially in SAM's case, particularly the semiotics imbricated in the *raison d'être* of the operationalising *technology*-logos θ of its schemas. Yet much is tacitly acquired: the DS- orientation of SAM's emergent *type of tasks T* – a concern with emergent alliance, the strategies achieved that enable a stabilised commonality of action – is difficult to explain to novitiates outside a context of apprenticeship. Operationalising is also composed of strategies of practical *technique* τ. Certainly these can be aggregated in homology with ATD: the DS- modes identified by ATD as [T/τ] can be identified as *skill,* the DS+ strategies of [θ/Θ] as *discourse* (Dowling, 2009, p. 95); but the recontextualisation now sees each as a strategic mode rather than an element of an amalgam.

Once relationised in this way, SAM and ATD (from the deforming regard of SAM) have the same objective: to describe the empirical deployment of strategies in the assemblage of Figure 2 *and* in the praxeological modes of Figure 3. These common objectives are not *translatable* but they are *transformable.* Specifying the schema of Figure 3 allows a development *of SAM.* The insistence that this is a recontextualisation preserves the autonomy of ATD. Both may then point – in a dialogue of potential complementarity – to the principles for a resistance to the closed and syncretic esoteric domains typical of school disciplinary subjects precisely of the kind Job and Schneider (2014) identify. In learning it is then both *operationalising* and the *orientation* of the student to the regularities of practice *in both the DS- and DS+* that would establish apprenticeship

In ATD the theory of didactic transposition acknowledges that school is a specific context of pedagogic relations. In SAM this is expressed as a matter of recontextualising action conceived as a general socio-semantic process of structuration, i.e. in constituting the esoteric domain of a specialised social activity such as school mathematics as a cultural arbitrary. Both approaches put great emphasis on an interrogation of how mathematics is institutionalised differently according to circumstance. Thus in recent programmes for ATD (Chevallard & Bosch, 2014) the T of *the current milieu of the student* (in reference to its sociality outside the school) is given appropriate emphasis – this is so often tragically downplayed by policy makers. As Radford (2008, p. 322) observes, research questions derive from the principles that allow their articulation. The focus in ATD is on the provision of appropriate activity (and the elimination of the inappropriate) to open to the student the possibilities of what mathematics *might become* for the student in their specific context. To ATD the school may (and often does) block this possibility but this is incidental to the possibility. SAM also sees content as constituted through institutionalisation; within the research programme identified by Jablonka, Wagner and Walshaw (2013), the content of school mathematics is itself always-already recruited in processes of social reproduction – the *particular alliances* (and, of course, oppositions) formed in the schoolroom always *different* to those formed in research (for example, mathematics research).

GENERAL ARGUMENT

This paper has considered the way in which SAM might stand in productive relation to other theoretical frameworks and to itself. From the autonomous and self-referential regard of SAM this must be a matter of the principle of recontextualisation, as that is what organises its regard. The self-reference is fundamental; but it is not a solipsism unless foolishly demanding that its categories replace all others to totalise the net. Both development and renewal are possible via an openness to the empirical and to theoretical antecedents. The following *general argument* rejects the idea that there is a "landscape of strategies for connecting theoretical approaches" (Prediger, Bikner-Ahsbahs, & Arzarello, 2008, p. 170) in favour of the deformative determination of autonomous self-reference. To formalise the situation, let the operator → refer to the recontextualising regard of an approach, ABC, to mathematics education research. Further, let Δ refer to its development, ⇒ denote consequence and let ES_i be a particular empirical setting:

> If one has SAM → ES_i and, elsewhere, ABC → ES_i then recognition of commonality would require a *general unifying framework*, GUF, such that GUF → (SAM → ES_i, ABC → ES_i) to integrate an answer to "perspectives *of what?*". This would deny that ES_i is constituted as an artefact of SAM or of ABC (a refutation of this denial is the many (justified) observations in *Networking of Theories as a Research Practice in Mathematics Education* (Prediger & Bikner-Ahsbahs, 2014) that the data was not collected appropriately for the theoretical framework concerned). Rather networking occurs as SAM → (ABC → ES_i) ⇒ ΔSAM with possible *answerability* of the form ABC → (SAM → (ABC → ES_i)) ⇒ ΔABC *& etc*. In each case the recontextualisation is either misrecognised through literalised equivalence (including elements of "similarity") or constituted as a deformative chiasmus (Merleau-Ponty, 1968), that is, realised as (re)new(ed) embodied practice in response to the objectifying regard of the other. For obvious reasons SAM cannot totally catch its own tail: SAM → (SAM → ES_i) also ⇒ ΔSAM; hence the importance of the dialogic (even if with yourself), a potentially unlimited recursion (or freedom).

In terms of their key diagram (Prediger & Bikner-Ahsbahs, 2014, p. 119), there is no role here for understanding, comparison, synthesis or integration, no "relationships between parts of theoretical approaches" (ibid, 118). It is not a question of attempting to find "similarities and differences" (ibid, 119) but to be open to deformative encounters – allowing these to prompt further self-organisation. It is the possibility of *complementarity*, not commonalities, that defeats "isolation", and the principle of *recontextualisation* that annihilates "global unifiers" who put forward GUFs. In Lotman's (2001, p. 143) semiotics, as in SAM's social-semantics, the principle of *asymmetry* is paramount – information-enriching activity *deforms*.

CONCLUSION – SOME GENERAL THEMES

The main theme of the paper has been to provide a framework which allows a discussion of the continuities and discontinuities between SAM and ATD. It sets out an agenda for a commentary SAM → (ATD → ESi) in invitation of a counter-commentary from ATD. The framework claims *autonomy* in the regards of ATD and SAM, but also the possibility of dialogue as described in the *general argument*.

I have to this point left one consequence of this implicit. There is a need to *take mathematics out of the theoretical framework of mathematics education research*. From SAM's regard, mathematics (however institutionalised) is the *empirical setting* of research. Yet, contrary to both SAM and ATD, many research programmes seem to wish to make it part of their *theoretical framework* by including considerations from a (notional) *mathematics-itself*. For SAM, the separation is required because the truth claims of a particular practice (for example, the often rather strange modalities of school mathematics) have their *own specificity*. A further consequence arises from the relationality of SAM's approach. The coherence of a theoretical framework is not a matter of the signification of individual theoretical terms; as if these can be translated by single substitutes to stand on their own account – and thus be 'connected' *as such*, or be absorbed into another theory. A theory's coherence rests on the relationality of its content, not on a collection of atomised concepts. The *general argument* above suggests the importance of dialogue between the esoteric domains of autonomous research activities. The development takes place as a coherent deformance of the principles that enabled a particular position in argument. Above all, therefore, we should see theoretical frameworks as a space for the becoming of the subjectivity of the individuated researcher. As such they must *de-stabilise* existing identities in order to forge new ones. The development of a good research programme will offer the potential subject of research action an on-going deformance of their own certainties.

Secondary mathematics teacher candidates' pedagogical content knowledge and the challenges to measure it

F. Güneş Ertaş and Fatma Aslan-Tutak

Bogazici University, İstanbul, Turkey, gunesertas@gmail.com, fatma.tutak@boun.edu.tr

In this paper, the authors will discuss pedagogical content knowledge of secondary mathematics teacher candidates in Turkey. The discussion is based on comparisons between senior students from secondary mathematics education and mathematics departments in terms of their pedagogical content knowledge measured by Teacher Education and Development Study in Mathematics (TEDS-M) released items. In addition to comparison of two groups, there will be a discussion on the challenges to measure pedagogical content knowledge.

Keywords: Pedagogical content knowledge, TEDS-M, measuring PCK, secondary school, mathematics teacher candidates.

INTRODUCTION

Teacher knowledge and its components have been described and modelled in different ways by different researchers (Shulman, 1986; Ball, Thames, & Phelps, 2008; Franke & Fennema, 1992; Tatto et al., 2008). However, it can be said that many teacher knowledge approaches have been influenced by the Shulman's (1986) model of teacher knowledge. Shulman made an important contribution by categorizing teacher content knowledge as Subject Matter Knowledge (SMK) and Pedagogical Content Knowledge (PCK). As Petrou and Goulding (2011) stated, in the Shulman model, the most influential category was the new concept of PCK. Shulman (1986) described PCK as "special amalgam of content and pedagogy that is uniquely the province of teachers, their own special form of professional understanding" (p. 9). According to him as the requirement of PCK, teachers need to know using representations, illustrations, analogies, and demonstrations and also giving examples and explaining concepts in order to make them understandable.

Shulman's conceptualization of teacher knowledge provided a basis for research field of mathematics education. The knowledge that mathematics teachers need to acquire for teaching was described with the Mathematical Knowledge for Teaching (MKT) model, which is the refinement of Shulman's categorization (Ball et al., 2008). MKT model categorizes SMK and PCK into six subcomponents. Ball (2003) defined the subcomponents of PCK by reconsidering Shulman's categorization. The components are Knowledge of Content and Students, Knowledge of Content and Teaching and Knowledge of Curriculum.

Although the MKT model has been widely used, there is some criticism about it. This model was developed considering elementary and middle school mathematics teachers, but not secondary. Therefore, it is argued that the components of MKT do not meet the mathematical need for secondary mathematics teachers (Zazkis & Leikin, 2010). The claim is that "the higher the level taught, the more the teacher needs to know" (Usiskin, 2001, p. 86), so the nature of mathematics that secondary teachers need to know is at the much higher level than elementary teachers. According to Zazkis and Leikin (2010), Advanced Mathematical Knowledge (AMK), which is defined as knowledge of subject matter acquired during undergraduate studies at universities, is necessary knowledge for teaching mathematics at secondary level. It can then be said that, since generally SMK is prerequisite for PCK (Shulman, 1986) specifically at secondary level, AMK is also necessary for PCK. However, it is not sufficient because PCK includes the knowledge of content and teaching, the knowledge of content and students, and the knowledge of curriculum (Ball et al., 2008). Therefore, classroom experiences and practices are also important for the development of PCK. Researchers argue that there is an interaction between SMK, PCK, beliefs and practices (Franke & Fennema, 1992; Walshaw, 2012; Türnüklü, 2005). However, PCK has a special importance because it is influenced by all the others: SMK, practice and belief. It can be said that PCK has a multidimensional nature. Wilson (2007) claims that this complex nature makes it difficult to investigate PCK by using efficient measures. Even though developing scalable efficient measures for content knowledge for teaching is difficult (Wilson, 2007), researchers tried to develop rigorous, effective and valid instruments to measure mathematics teachers' knowledge (Hill, Schilling, & Ball, 2004; Krauss, Baumert, & Blum, 2008; Tatto et al., 2008).

One of the instruments to study mathematics teacher knowledge is the Teacher Education and Development Study in Mathematics (TEDS-M) measure. TEDS-M is a cross-national study in which 17 countries participated, even if Turkey was not involved. The characteristics that differentiate TEDS-M measure from others are to consider both primary and secondary levels and to be designed for international usage and national adaptations. Differences in students' achievement level in Trends in International Mathematics and Science Study (TIMSS) encouraged researchers to study on teacher education internationally in order to investigate how mathematics teaching quality differs across countries. Therefore, the TEDS-M measure was developed to examine the mathematical knowledge for teaching of future mathematics teachers, based on TIMSS 2007 framework of content areas and cognitive domains. By considering such characteristics of the measure, in this study, TEDS-M secondary released items were used for the investigation of the mathematical knowledge for teaching of secondary mathematics teacher candidates.

METHODS

Participants

In Turkey, both graduates of secondary mathematics teacher education departments and mathematics departments (after completing teaching certificate program) have chance to be mathematics teachers in secondary schools. Therefore, the participants of the study were senior students from secondary mathematics teacher education departments (n = 47) and senior student from mathematics departments (n = 48) of two universities in Istanbul. Totally, 32 females and 15 males senior secondary mathematics education students (the mean age is 24) and 35 females and 13 males students (the mean age is 22) from mathematics departments participated in this study. These two universities were ranked as first and second among the secondary mathematics education departments in the national university entrance exam. In the first ranked university, students enrol mathematics and secondary mathematics education programs by getting similar scores from university entrance exam. In the second university, the minimum score of secondary mathematics education department is a little higher than the one of the mathematics department.

These two programs have different curriculum in undergraduate education programs. The secondary mathematics education program includes 50 % of content knowledge and skills, 30 % of professional teaching knowledge and skills and 20 % of general knowledge courses (YÖK, 2007). However, the undergraduate program in a mathematics department consists of 70 % of content knowledge and 30 % of general knowledge. Moreover, participants of the study were asked to explain whether they had an informal teaching experience like tutoring or teaching in cram school. As they stated, 76 % of secondary mathematics education students and 70 % of mathematics students had informal teaching experiences.

Instrument

The instrument was designed by TEDS-M researchers considering the framework of Trends in International Mathematics and Science Study (TIMSS) 2007 (Tatto et al., 2008). MCK items comprised of four content areas: number, algebra, geometry and data, and three cognitive dimensions: knowing, applying and reasoning. Furthermore, MPCK items consist of two parts: knowledge of curricula planning, and interactive knowledge about how to enact mathematics for teaching and learning. These were aligned with the PCK domains in literature. Table 1 and Table 2 show the distributions of MCK and MPCK items according to their content, cognitive domains and PCK components. (In the appendix, Figures 1 and 2 are examples of MCK items and Figures 3 and 4 are examples of MPCK items.)

These items include 23 mathematics content knowledge (MCK) and 9 mathematics pedagogical content knowledge (MPCK) items with three different item

Cognitive Domain	Content Domain				
	Algebra	Geometry	Number	Data	Total
Knowing	-	2	4	-	6
Applying	5	4	-	1	10
Reasoning	2	1	4	-	7
Total	7	7	8	1	23

Table 1: MCK Secondary Items

	Content Domain				
	Algebra	Geometry	Number	Data	Total
Curriculum and Planning	4	-	-	-	4
Enacting	1	-	3	1	5
Total	5	0	3	1	9

Table 2:. MPCK Secondary Items

formats: multiple choice, complex multiple choice and open constructed response.

In order to compare MKT of participants who were studying in different departments, Turkish translated versions of TEDS-M secondary level released items were used. The method which was used while translating the instrument consists of three phases. Firstly, items were translated in Turkish by the researcher who is fluent in English. The translated items were reviewed by a mathematics educator who is an expert in the content area and fluent in English, a three-year experienced mathematics teacher who is fluent in English, and a professional translator. At the second phase, the original tests were administered to a group of pre-service mathematics teachers who are native in Turkish and fluent in English. The same group took the translated versions of the tests three weeks apart. At the last phase, the method of back translation was used to check the quality of translation and to investigate the linguistic or conceptual errors in translation. It was also used to consider particular attention to sensitive translation problems across cultural correspondence of the two versions.

Data collection and analysis

The data was collected from participants in a single point in different times. Instrument administered to senior students during the last two weeks of the spring semester of the 2012–2013 academic year just before they graduate.

After data collection, all items were scored according to the scoring guide of TEDS-M Secondary Items. Participants' scores acquired from 23 MCK items were calculated and called as MCK scores and scores obtained from 9 MPCK items were calculated and called as MPCK scores. Total scores of participants were also calculated by the summation of MCK and MPCK scores.

The scores of these two groups of participants were compared by using appropriate statistical methods. For total scores and MCK scores comparisons, an independent sample t-test was used since all the assumptions were met. For the comparison of MPCK scores, a non-parametric Mann-Whitney U test was used since the normality assumption was violated.

RESULTS

Participants' scores obtained from the 47 senior students from the mathematics teacher education department and the 48 senior students from the mathematics department were compared. Table 3 shows means and standard deviations of the two groups of participants.

		M	*SD*
Total	Math Teacher Education	26.83	3.96
	Math	23.63	4.42
MCK	Math Teacher Education	20.45	3.35
	Math	17.50	3.80
MPCK	Math Teacher Education	6.38	1.19
	Math	6.13	1.35

Table 3: Means and Standard Deviations

The results of the t-test indicate that the mean of the total score of mathematics teacher education students is significantly 3.2 points higher than those from mathematics department, $t\,(93) = 3.72$, $p < .001$ and Cohen's $d = .76$ with the marginal large effect size (Cohen, 1988). Furthermore, the independent sample t-test results show that students from the mathematics teacher education department have significantly higher MCK scores than those of mathematics departments: $t\,(93) = 4.00$, $p < .001$, and Cohen's $d = .82$ with the large effect size. Moreover, according to the non-parametric Mann-Whitney U test, there is no significant difference between them in relation to the MPCK scores: $Z = 1.00$, $p > .05$.

DISCUSSION AND CONCLUSION

The study aimed at comparing the mathematical knowledge for teaching of students who will graduate from a mathematics teacher education department and others who will graduate from a mathematics department. In Turkey, graduates of both departments have a chance to become mathematics teachers at secondary level, but graduates of the mathematics departments need to take a teaching certificate. However, the knowledge and skills that graduates are able to acquire through these programs are different from each other. For example, the contents of undergraduate education programs of these departments are notably different. The mathematics departments' program does not include any pedagogy or education course, but more advanced mathematics courses than the mathematics education departments' program does. Therefore, the result was unexpected: mathematics students, who were not required to take any teaching related courses, were not significantly different from students of the mathematics teacher education in terms of MPCK scores.

This unexpected result may be explained by discussing the nature of PCK for secondary level mathematics teaching. Even though teacher education programs are the most influential factors that affect PCK of teacher candidates, there are other factors when the nature of PCK is considered. PCK includes knowledge of "the ways of representing and formulating the subject that make it comprehensible to others" (Shulman, 1986, p. 9). It may be conceptualized as not only knowledge of students' thinking and conceptions, but also knowledge of explanations, representations and alternative definitions of mathematical concepts, and knowledge of multiple solutions to mathematical tasks (Shulman, 1986; Ball et al., 2008; Krauss, Baumert, & Blum, 2008). Therefore, teaching experiences play an important role in the development of teachers' PCK (Ball et al., 2008). Because of this, teacher education programs include many teaching experiences opportunities like field experience and practicum. Moreover, both groups of students who were studying mathematics teacher education in a mathematics department had informal teaching experiences like tutoring and teaching in cram school. Having this kind of teaching experience may explain the result. However, this may not be the only rationale. Measuring and assessing PCK is another issue that should be considered by focusing on its nature in order to explain the results of study.

Achieving the specialized knowledge for teaching mathematics at secondary level requires Advanced Mathematical Knowledge (AMK) which is defined as the knowledge of the subject matter acquired at the university (Zazkis & Leikin, 2010). Mathematics departments' students take many advanced mathematics courses and they develop AMK. It should be noted that AMK is a necessary but not sufficient condition for achieving the specialized knowledge for teaching at secondary level (Zazkis & Leikin, 2010).

Therefore, as it is seen, according to the PCK's multidimensional nature, deep mathematical knowledge plays an important role because it can provide teachers to use effective explanations, representations and alternative definitions. These components may contribute to make an explanation for the unexpected result of the study. For example, when MPCK items were examined according to required knowledge, and skills were needed to provide a correct answer, the need for AMK might be observed. For instance, one of the questions of the instrument (see Figure 3 in appendix) asks to determine what knowledge is needed to prove the quadratic formula. This question measures knowledge of content and teaching, but without knowing how to prove quadratic formula it is not possible to give a correct answer. Therefore, it is not easy to differentiate and measure this kind of knowledge and skills. Difficulty in measuring PCK may explain the unexpected result that there is no difference in MPCK scores between two groups of students.

Moreover, in this study, PCK was tried to be measured by few items (4 questions, 8 items). Therefore,

Questions (Items)	Content Domain	PCK Domain	Intended Ability
1 (b)	Algebra	Enacting	Analyse why one word problem is more difficult than the other.
6 (a, b, c)	Number	Enacting	Determine whether student's response is valid proof.
9 (a, b, c, d)	Algebra	Curriculum and Planning	Determine what knowledge is needed to prove the quadratic formula.
12 (b)	Data	Enacting	Explain student's thinking about histogram.

Table 4: TEDS-M Secondary PCK Items' Characteristics

only some domains of PCK and some abilities were able to be measured with these items. However, as Shulman (1986) and Ball and colleagues (2008) stated, PCK requires different kinds of knowledge, tasks and skills. This instrument can only address some of them. Table 2 shows the distribution of content and PCK domains of items, and Table 4 above shows the intended abilities for each of them.

The reactions of the two groups of participants to these PCK items are different. For example, item 9b (Figure 3 in the appendix) were answered correctly by 97 % of the mathematics department students and by 86 % of the students from the secondary mathematics education department. On the other hand, 72 % of the students from the secondary mathematics education department answered item 1b (Figure 4 in appendix) correctly, while only 52 % of the mathematics department student gave a correct response.

The epistemological dimension in didactics: Two problematic issues

Ignasi Florensa[1], Marianna Bosch[2] and Josep Gascón[3]

This paper presents some theoretical considerations concerning the relationships between epistemology and didactics. We distinguish two big issues that show the mutual enrichment of both fields. On the one hand, considering teaching and learning phenomena as part of the empirical basis of epistemology enables proposing new epistemological models of mathematical bodies of knowledge. On the other hand, these epistemological models provide guidelines for the design and analysis of new teaching proposals, which, in turn, show the constraints coming from the spontaneous epistemologies in school institutions. Some critical open questions derived from these issues draw up the guidelines for a future research programme.

Keywords: Epistemology, didactics, ATD, praxeologies.

PEDAGOGY, EPISTEMOLOGY AND DIDACTICS

What distinguishes didactics of mathematics (or of any other field of knowledge) from general education or pedagogy is the status given to the knowledge or "content" that is taught and learnt. Pedagogy considers the knowledge to be taught as a given, and focuses on the best, conditions or practices to teach and learn it: the knowledge is not problematic, the relationships of the students to it are (Chevallard, 2000). In contraposition, didactics locates the *epistemological problem* at the core of the analysis. A double assumption is meant by this. First, the phenomena underlying teaching and learning processes, at school as well as in other social institutions, are closely dependent on the content that is designed to be taught, actually taught and learnt, and also on how this content is considered by the participants of the teaching and learning process. Second, that the study of these phenomena is also strongly dependent on the way knowledge is considered and modelled by researchers in didactics. In fact, the main point of the paper is to describe a research programme that seeks to clarify the problem of how to teach (and learn) mathematics and its relationship with the problem of what is considered as mathematics.

The pedagogical dimension of teaching and learning phenomena refers to generic practices, discourses, strategies and regularities that can be described regardless of the content to be taught. The didactic dimension is reached when the concrete mathematical activities organised by the teacher and carried out by the students, as well as any other fact affecting the delimitation, construction, management, evolution and assessment of these activities are considered.

The need to integrate both the pedagogical and the epistemological dimensions was one of the main motivations for Guy Brousseau to promote the construction of a new field of knowledge called didactics of mathematics and which he contributed to with the first formulations of the theory of didactic situations during the decade 1970–1980 (Brousseau, 2002). We are here pointing out two main reasons for this integration that will later on be at the basis of the problematic issues we wish to raise. The first one is the dependence between the dominant *epistemologies of mathematics* (or of any other field of knowledge) at an educational institution and the way teaching is organised in this institution. In other words, the way mathematics and its specific bodies of knowledge are considered in a given institution, usually as implicit assumptions, affects the conditions established for its learning. In this sense, we can say, rephrasing Brousseau (2002), that *teaching organisations* are supported by *spontaneous epistemologies* appearing to the subjects of the school institution as the unquestionable and transparent way to conceive the content to be taught.

The second main reason, also put forward by Brousseau, is related to the implementation of research results wishing to improve teaching and learning. Whatever general strategies or conditions we may find at the pedagogical level, teachers will always have to specify them in terms of what ties them to the students: the knowledge-based learning activities. Of course, it is possible to delimit general pedagogical phenomena affecting any content to be taught and to propose general pedagogical actions in order to improve teaching and learning processes. However, eventually, these actions will need to be concretized and converted into didactic facts and strategies, that is, to specific ways of organizing mathematical contents and designing mathematical activities for the students.

Once the necessity to integrate the "epistemological problem" into the "teaching and learning problem" is assumed, there are different levels to take the epistemic dimension of the teaching and learning process into account. In some cases, the focus can be on a given piece of knowledge ("proportionality", "limits of functions", "linear equations"), or a whole area ("algebra", "calculus", "statistics"), thus considering specific models relying on a more or less explicit conception of what mathematics is and how it can be described. Therefore it can be said that the consideration of the *didactic problem* needs to include, in one way or another, a specific answer to the *epistemological problem*. To interpret the interrelation between epistemological and didactical problems, we now present a historical development of the object of study of each discipline and their respective empirical basis.

THE EVOLUTION OF EPISTEMOLOGICAL AND TEACHING PROBLEMS

In a previous study, Gascón (2001) describes a rational reconstruction of the evolution of the *epistemological problem* and, in parallel, the evolution of the *didactic problem* showing that a certain convergence exists between them. The evolution of the epistemological problem can be interpreted as a successive expansion of what is considered as the object of study and of the consequent empirical basis used to approach it. Briefly speaking, this work shows that the nature of the epistemological problem began as a purely logical problem (EP^1), became a historical problem (EP^2) and ended up being considered, at the end of the last century, as an essentially cognitive problem (EP^3). Its successive formulations together with its corresponding tentative answers can be outlined as follows:

> EP^1: How to stop infinite regress to get a logical justification of mathematical theories?
>
> EPA^1: Euclidean models: logicism (Russell), formalism (Hilbert) and intuitionism (Brouwer).
>
> EP^2: What is the logic of the development of mathematical discovery?
>
> EPA^2: Quasi-empirical models (Lakatos)
>
> EP^3: What are the tools and mechanisms found in history and psychogenesis of the development of mathematical discovery?
>
> EPA^3: Constructivist models (Piaget & García, 1982).

This evolution of the epistemological problem can be interpreted as a progressive detachment from logical procedures and an approximation to empirical sciences such as history and psychology. This expansion continues since the 70s, with the inclusion of sociological data. Indeed, sociologists such as Barry Barnes and David Bloor, and later others like Bruno Latour, heavily influenced by the ideas of Thomas Kuhn, tried to highlight the essential social nature of scientific research. Let us notice, however, that, apart from Kuhn's mention of the "textbooks epistemology" (Kuhn, 1971), none of these approaches seem to consider empirical phenomena related to the teaching, learning and disseminating of mathematics. The division between pedagogy and epistemology appears to be taken for granted in this research domain also.

All of the epistemological models above can be related to general teaching models, ranging from *theoricism* (organizing the teaching of mathematics following the logic construction of concepts) and *technicism* (exerciting the main techniques in a given domain without many theoretical tools), to *constructivism*, which aims to enable students to construct knowledge according to certain predetermined stages.

Gascón (1993) shows limitations of the empirical basis used by constructivism to address the epistemological problem. Taking into account personal psychogenesis data, in some sense completed with those provided by the history of science, it does not integrate *didactic facts* and, can thus hardly explain institutional-depending phenomena as the so-called "personal" construction of knowledge. In other words, and according to Chevallard (1991), the study of the *genesis and development* of knowledge (traditional object of epistemology) cannot be separated from the study of the *diffusion, use and transposition* of knowledge (object of study of didactics).

It is at this point where both problems, the epistemological and the didactic one, converge, with the consequently significant expansion of the object of study of both disciplines. Historically, this time corresponds to the first formulations of the theory of didactic situations (TDS) proposed by Guy Brousseau in the early 1970s (Brousseau, 2002). It is no coincidence that at this early stage of didactics of mathematics, Brousseau initially considered to name this new discipline "experimental epistemology". In particular, didactics of mathematics accepted the responsibility to elaborate and use epistemological models of mathematical bodies of knowledge as a new way to study didactic phenomena, thus turning the *pedagogical problem* into an *epistemological-didactic* one.

New questions arise from this perspective: What new general epistemological theories, based on which empirical data, may serve to support new teaching organizations in order to overcome the limitations of the current ones? To what extent and by what means can the dominant spontaneous epistemologies in a teaching institution be changed in solidarity with the teaching models based on them?

AN ANSWER TO THE EPISTEMOLOGICAL-DIDACTIC PROBLEM

The anthropological theory of the didactic (ATD), following the research programme initiated by the theory of didactic situations, considers a specific model of mathematical knowledge and its evolution formulated in terms of a dynamical sequence of *praxeologies*. Praxeologies are entities formed by the inseparable combination of a *praxis* or know-how made of types of tasks and techniques, and of a *logos* or knowledge consisting of a discourse aiming at describing, explaining and justifying the *praxis* (Chevallard, 2000). In didactics research, mathematical praxeologies are described using data from the different institutions participating in the didactic transposition process, thus including historical, semiotic and sociological research, assuming the institutionalized and socially articulated nature of praxeologies. Furthermore, a dialogue with the APOS theory shows how data interpreted as the different *levels of development of schemes* by psychogenetic developments, can be reformulated in ATD in terms of the *institutional evolution of praxeologies* (Trigueros, Bosch, & Gascón, 2011).

Reference epistemological models as sequences of praxeologies

To describe and analyse the specific contents that are at the core of teaching and learning processes, the general model in terms of praxeologies is structured in an articulated set of specific models of the different areas of the mathematical activity at stake called *reference epistemological models* (REM) (Barbé, Bosch, Gascón, & Espinoza, 2005; Bosch & Gascón, 2006). The Reference Epistemological Model of a body of knowledge is an alternative description of that body of knowledge elaborated by researchers in order to question and provide answers to didactic facts and problematic aspects taking place in a given institution. This REM prevent researchers to take for granted how this body of knowledge is conceived in the institution considered. For instance, Ruiz-Munzón (2010) and Ruíz-Munzon, Bosch and Gascón (2013) present a REM about elementary algebra which is used to analyse the status and role of this area of school mathematics in relation to arithmetic and functional modelling. The model takes into account the processes of didactic transposition to explain what is currently taught as algebra at school and provides a rationale to this area that does not coincide with the official and more limited one assigned by the educational system. Some of the difficulties in the teaching and learning of elementary algebra can then be referred to these limitations and new teaching proposals can be designed to overcome them (Ruiz-Munzón, 2010; Bosch, 2012).

In this REM, algebra is interpreted as a *tool for modelling* any type of (mathematical and extra-mathematical) systems and the process of *algebraization* is divided into three stages. The first one concerns the passage from the execution of computation programmes (sequences of arithmetic operations on numbers like the ones carried out when solving an arithmetic problem) to the written or rhetoric description of their structure; the second stage requires the symbolic manipulation of the global structure of written computation programmes (not only simplifying and developing, but also "cancelling", etc.); at the third stage, the whole manipulation of formulas is reached.

It is important to note that this REM is not a static description of a piece of mathematical knowledge, it also suggests a dynamical process to introduce elementary algebra: starting from the study of arithmetic computation programmes (CP) in order to motivate the entrance into the second stage of algebraization by the limitations of the rhetorical formulation of CPs in the first stage. Encountering problematic questions in this arithmetical work with CP may generate the need to build a written symbolic *formulation* of these CP to globally manipulate their structure, thus promoting the need to establish symbolic codes (hierarchy of operations and bracket rules).

In a similar way, different REM of other specific areas of mathematics have been proposed, all formulated in terms of sequences of related praxeologies: limits of functions (Barbé et al., 2005), proportionality (García, Gascón, Ruiz Higuera, & Bosch, 2006; Hersant, 2001), measure of quantities (Chambris, 2010), real numbers (Bergé, 2008; Rittaud & Vivier, 2013), among others. In general, the organisation of a teaching process based on the REM of a given mathematical content is called *research and study activities*.

From teaching of contents to enquiry processes: Study and research paths

These reference epistemological models correspond to previously established bodies of mathematical knowledge: algebra, limits, proportionality, etc. They provisionally assume the delimitations of mathematical knowledge provided by the school and the scholarly institutions, which are then often redefined. In order to also take into account enquiry processes that start with the consideration of problematic questions to be solved (instead of pre-established contents to be learnt), REM have been enriched with the proposal of the *Herbartian schema* (Chevallard, 2006; Chevallard, 2015). This scheme is a useful tool to observe, analyse and evaluate existing and potential didactic processes that start with the consideration of a generating question and evolve with the search of partially available answers ("contents" to be learnt) and the construction of new answers through the interaction with a milieu. The study of a specific *question* leads to a rooted-tree of derived questions and provisional answers, which outlines the generating power of the initial question and the possible paths to follow. We thus obtain new reference epistemological models assigned to problematic questions instead of pre-established praxeological contents. Winsløw, Matheron, and Mercier (2013) provide several examples of this kind of rooted-tree REM, such as the dynamics of a population or the trajectory of a three-point shot in basketball. The enquiry process of a particular generating question materializes in an open didactic organisation called a *study and research path* (SRP). During the development of SRP, the need for new knowledge to solve some of the derived questions found in the path usually leads to the activation of study and research *activities*.

Didactic praxeologies emerging from reference epistemological models

The previous section briefly outlined how the design, implementation and analysis of study and research paths and study and research activities call for the activation of specific didactic techniques and creates new types of didactic tasks. For instance, in the case of elementary algebra illustrated above, the didactic technique proposed by Ruiz-Munzon (2010) consists in introducing the study of "mathemagic" games of the sort "Think of a number, apply these calculations [...], you get 73" as generating questions. How do you explain the magician's trick?" These games generate the need to look for new pieces of answers, in the manipulation of the calculation programmes proposed or in their transformation and generalisation through algebraic symbolism. Questions based on "mathemagic" games allow producing an important number of computation programmes economically. They are presented to the students without much artificiality and their first contact with computation programmes is not problematic. Moreover, the limitations of the rhetorical and numerical formulations of computation programmes inevitably appear and they do so soon enough.

PROBLEMATIC ISSUES

The aim of this paper is to formulate some problematic issues at the crossroads of epistemology and didactics. We will initially explain them within the context of the ATD before extending the questioning to other didactic approaches. If we try to characterize a didactic approach by how "pedagogy" and "mathematics" are integrated, in the case of the ATD such integration can be formulated in terms of two movements. They appear in the design, management and evaluation of teaching and learning processes and can briefly be described as follows:

1) Starting from the analysis of teaching and learning processes at school and considering an empirical basis of study that is large enough to include the processes of didactic transposition, all this empirical work provides tools to design specific REMs for the main mathematical contents or areas that are designed as knowledge to be taught. We can define this movement as "using didactic facts and phenomena to produce epistemological models".

2) Conversely, the principles and criteria that have guided the construction of a REM for a specific area of school mathematical activity and, in particular, the contrast between the rationale assigned by the REM to this area and its official (explicit or tacit) role in school mathematics, all provide some mathematical and didactic tools to design, manage and evaluate teaching and learning processes based on study and research paths sustained by that REM. This movement can be defined as "using the epistemological model as the core of didactic tools".

This double movement raises different open issues which are at the starting point of the research programme we want to propose in this paper.

New didactic needs

We have seen how previously elaborated REM on mathematical contents or problematic questions (obviously complemented with other methodological design tools) can provide criteria for the design and implementation of teaching and learning processes that are considerably different from the existing ones. In principle, they aim at organising activities that should allow the students to carry out new mathematical tasks and techniques in a more autonomous, functional and justified way. The "mathemagic" games in the case of elementary algebra (Ruiz-Munzón, 2010) or the different enquiry processes described in Winsløw, Matheron and Mercier (2013) are good examples of this enrichment. Obviously, these new didactic organisations should be made available to the study community and their viability in different school institutions should be tested.

It is important to emphasize that all didactic approaches and theories are also based on general models of mathematical-didactic activities. These general models are a particular way to interpret the mathematical activity and to conceptualize the study process of mathematics (teaching, learning, diffusion and application). Even though these models are not always clearly spelled out, they remain an essential feature of theoretical approaches, as they strongly affect the type of research problems this approach can formulate. Two crucial questions arise:

1) In the case of ATD, how to transform the REM into possible didactic organisations that could live in current school institutions? How to take into account the interrelation between the REM and the didactic phenomena appearing in the implementation of these new didactic organisations? How to make this process available to the school institutions, especially to the profession of teachers?

2) How is this mutual enrichment between the epistemological and didactic proposals taken into account in other theoretical frameworks?

New epistemological needs

The empirical analysis of the study processes taking place in various institutions (for example, but not exclusively, in schools) clearly shows that the didactic praxeologies are closely related to the epistemological tools available in the institution to describe and manage the mathematical praxeologies. For example, in the institutions where the dominant model is Euclidean, teaching and learning processes are conceived and described in terms of didactic activities around "definitions", "concepts", "theorems", "proofs" and "applications". In addition, these didactic activities tend to be hierarchically structured according to the logical construction of mathematical concepts (real numbers before limits, limits before derivatives, etc.).

If, instead of analysing traditional teaching processes, we look at those based on didactic research, the situation is very similar: how didactic processes and the dynamics of mathematical praxeologies are designed, described and managed also depends on the tools provided by the epistemological model which upholds, more or less explicitly, the didactic approach considered. The further this research-based epistemological model is from the dominant epistemological model at schools and scholarly institutions, the more difficult it becomes for teachers to carry out innovative teaching proposals designed within this frame.

In all these cases, the most remarkable feature is the shortage and inadequacy of tools available in the teaching institution to describe, manage, and evaluate the dynamics of mathematical activity. This lack of tools could in the first place be attributed to the scarcity of spontaneous epistemological models and, in particular, to the shortage of the Euclidean epistemological model of mathematics whose supremacy is still present, to a greater or lesser extent, in most institutions.

Which new notions or tools are needed to describe and manage the dynamics of the mathematical activity that will take place in study processes? How to describe these tools depending on the role addressed (didactic researcher, teacher and students)? How to make them available in the teaching institution and to the participants of the didactic process?

The evolution of didactic-epistemological models

In order to establish an alternative and rich REM of a specific mathematical domain or questioning, it is necessary to take into account the didactic phenomena taking place in teaching institutions. This leads to an enrichment of the spontaneous epistemological model during the first design of the REM. However, it is important to keep the process running during the implementation and the evaluation of teaching proposals based on this REM. The consequent evolution of the REM is a clear example of the dynamic and provisional nature of the epistemological models elaborated by didactics, evolving from its initial proposals through the analysis of empirical facts. From a mathematical perspective, these continuous evolutions of the REMs can be seen as the incorporation of new notions and organisations into the field of knowledge. This phenomenon can be related to the transformation of some paramathematical notions into mathematical concepts, as happened with concepts (such as "set", "function", "continuity", "graphs", etc.), a transformation which takes place as long as researchers deal with new problems. For instance, in the case of elementary algebra, the notion of "computation programme" is a new and crucial element of the proposed REM. In the experiences described by Ruiz-Munzón (2010), this notion played a very ambiguous role in the management of the teaching and learning processes, given the fact that it did not belong to the official mathematics to be taught and the teacher did not feel at ease with it. A similar phenomenon happened when implementing SRP on population dynamics with notions such as "quantities", "model", "system", "mixed and separated generations", etc.

Another important and difficult question is the degree of explicitness that should be adopted with the new epistemological models necessary to design, implement and evaluate new teaching and learning processes depending on the participants of the study communities addressed (students, teachers, mathematicians, etc.). Also, what kind of similar experiences can be learnt from other approaches? Did they find similar difficulties? These open questions establish a new research programme where the results of previous investigations carried out within the ATD should be analysed together with analogous research from other perspectives. In all cases, the status given to the epistemological dimension in didactics analysis seems to appear as a crucial question to take into account.

Linking inquiry and transmission in teaching and learning mathematics

Juan D. Godino, Carmen Batanero, Gustavo R. Cañadas and José M. Contreras

University of Granada, Granada, Spain, jgodino@ugr.es

Different theories assume that learning mathematics should be based on constructivist methods where students inquire problem-situations and assign a facilitator role to the teacher. In a contrasting view other theories advocate for a more central role to the teacher, involving explicit transmission of knowledge and students' active reception. In this paper, we reason that mathematics learning optimization requires adopting an intermediate position between these two extremes models, in recognizing the complex dialectic between students' inquiry and teacher's transmission of mathematical knowledge. We base our position on a model with anthropological and semiotic assumptions about the nature of mathematical objects, as well as the structure of human cognition.

Keywords: Mathematical instruction, inquiry learning, knowledge transmission, onto-semiotic approach, mathematical knowledge.

INTRODUCTION

The debate between the models of a school that "conveys knowledge" and others in which "knowledge is constructed" currently seems to tend towards the latter. This preference can be seen in the curricular guidelines from different countries, which are based on constructivist and socio-constructive theoretical frameworks (NCTM, 2000):

> Students learn more and learn better when they can take control of their learning by defining their goals and monitoring their progress. When challenged with appropriately chosen tasks, students become confident in their ability to tackle difficult problems, eager to figure things out on their own, flexible in exploring mathematical ideas and trying alternative solution paths, and willing to persevere (p. 20).

In the case of mathematics education, problem solving and "mathematical investigations" are considered essential for both students' mathematical learning and teachers' professional development. Constructivist viewpoints of learning shift the focus towards the *processes* of the discipline, practical work, project implementation and problem solving, rather than prioritizing the study of facts, laws, principles and theories that constitute the body of disciplinary *knowledge*.

Nevertheless, this debate is hiding the fact that students differ in skills and knowledge, and most of them need a strong guidance to learn; even when some students with high skills and knowledge can learn advanced ideas with little or no help. The issue of the type of aid needed, depending on the nature of what is to be built or transmitted is also missed in this debate. Consequently of this situation, the question of the kind of help that a teacher should give to a usually heterogeneous class, when we want students acquire mathematical knowledge, understandings and skills, also arises.

The family of "Inquiry-Based Education" (IBE), "Inquiry-Based Learning" (IBL), and "Problem-Based Learning" (PBL) instructional theories, which postulate the inquiry-based learning with little guidance by the teacher, seem not to take into account the described reality, namely the students' heterogeneity and the variety of knowledge to be studied. These models may be suitable for gifted students, but possibly not for the majority, because the type of help that the teacher can provides could significantly influence the learning, even in talented students.

In this paper, we analyse the need to implement instructional models that articulate a mixture of construction/inquiry and transmission of knowledge to achieve a mathematical instruction that locally optimize learning. The basic assumption is that the moments in which transmission and construction of knowledge can take place are *everywhere dense* in the instructional process. Optimization of learning involves a complex dialectic between the roles of teacher as instructor (transmitter) and facilitator (manager), and student's roles as active constructor of knowledge and receivers of meaningful information. Hiebert and Grouws (2007) state that "because a range of goals might be included in a single lesson, and almost certainly in a multi-lesson unit, the best or most effective teaching method might be a mix of methods, with timely and nimble sifting among them" (p. 374).

We support this mixed model of mathematical instruction in cognitive (architecture of human cognition) and onto-semiotic (regulative nature of mathematical objects) reasons.

Below we first summarize the main features of instructional models based on inquiry and problem solving and secondly of models that attribute a key role to transmission of knowledge. We then present the case for a mixed model that combines dialectically inquiry and transmission, basing on the epistemological and didactical assumptions of the onto-semiotic approach to mathematical knowledge and instruction (Godino, Batanero, & Font, 2007). Finally we include some additional reflections and implications.

INQUIRY AND PROBLEM BASED LEARNING IN MATHEMATICS EDUCATION

As indicated above, the acronyms IBE, IBL, PBL designate instructional theoretical models developed from several disciplines, which have parallel versions for the teaching of experimental sciences (IBSE) and mathematics (IBME). They attributed a key role to solve "real" problems, under a constructivist approach. In some applications to mathematics education it is proposed that students construct knowledge following the lines of work of professional mathematicians themselves. The mathematician faces non-routine problems, explore, search for information, make conjectures, justify and communicate the results to the scientific community; mathematics learning should follows a similar pattern.

Using problem-situations (mathematics applications to everyday life or other fields of knowledge, or problems within the discipline itself) to enable students making sense of the mathematical conceptual structures is considered essential. These problems are the starting point of mathematical practice, so that problem solving activity, including formulation, communication and justification of solutions are keys to developing mathematical competence, i.e. the ability to cope with not routine problems. This is the main objective of the "problem solving" research tradition (Schoenfeld, 1992), whose focus is on the identification of heuristics and metacognitive strategies. It is also essential to other theoretical models such as the Theory of Didactical Situations (TDS) (Brousseau, 1997), and Realistic Mathematics Education (RME) (Freudenthal, 1973; 1991), whose main features are described below.

Theory of Didactical Situation (TDS)

In TDS, problem-situations should be selected in order to optimize the adaptive dimension of learning and students' autonomy. The intended mathematical knowledge should appear as the optimal solution to the problems; it is expected that, by interacting with an appropriate *milieu*, students progressively and collectively build knowledge rejecting or adapting their initial strategies if necessary. According to Brousseau (2002),

> The intellectual work of the student must at times be similar to this scientific activity. Knowing mathematics is not simply learning definitions and theorems in order to recognize when to use and apply them. We know very well that doing mathematics properly implies that one is dealing with problems. We do mathematics only when we are dealing with problems—but we forget at times that solving a problem is only a part of the work; finding good questions is just as important as finding their solutions. A faithful reproduction of a scientific activity by the student would require that she produce, formulate, prove, and construct models, languages, concepts and theories; that she exchange them with other people; that she recognize those which conform to the culture; that she borrow those which are useful to her; and so on. (p. 22).

To allow such activity, the teacher should conceive problem-situations in which they might be interested and ask the students to solve them. The notion of *devolution* is also related to the need for students to consider the problems as if they were their own and take responsibility for solving them. The TDS assumes a strong commitment with mathematical epistemology, as reflected in the meaning attributed to the notion of fundamental situation, which Artigue and Blomhøj (2013, p. 803) describe as "a situation which makes clear the raison d'être of the mathematical knowledge aimed at".

Another important feature of the TDS is the distinction made between different dialectics: action, formulation and validation, which reflect important specificities of mathematical knowledge.

Realistic Mathematics Education (RME)

In RME, principles that clearly correspond to IBME assumptions are assumed. Thus, according to the "activity principle", instead of being receivers of ready-made mathematics, the students, are treated as active participants in the educational process, in which they develop themselves all kinds of mathematical tools and insights. According to Freudenthal (1973), using scientifically structured curricula, in which students are confronted with ready-made mathematics, is an 'anti-didactic inversion.' It is based on the false assumption that the results of mathematical thinking, placed on a subject-matter framework, can be transferred directly to the students. (Van den Heuvel-Panhuizen, 2000).

The principle of reality is oriented in the same direction. As in most approaches to mathematics education, RME aims at enabling students to apply mathematics. The overall goal of mathematics education is making students able to use their mathematical understanding and tools to solve problems. Rather than beginning with specific abstractions or definitions to be applied later, one must start with rich contexts demanding mathematical organization or, in other words, contexts that can be mathematized. Thus, while working on context problems, the students can develop mathematical tools and understanding. The guidance principle stresses also the same ideas. One of Freudenthal's (1991) key principles for mathematics education is that it should give students a "guided" opportunity to "re-invent" mathematics. This implies that, in RME, both the teachers and the educational programs have a crucial role in how students acquire knowledge. According to Artigue and Blomhøj (2013, p. 804), "RME is thus a problem-solving approach to teaching and learning which offers important constructs and experience for conceptualizing IBME".

TRANSMISSION BASED LEARNING IN EDUCATION

We consider as models based on knowledge transmission various forms of educational intervention in which the direct and explicit instruction is highlighted. A characteristic feature of strongly guided instruction is the use of worked examples, while the discovery of the solution to a problem in an information-rich environment is similarly a compendium of discovery learning minimally guided.

For several decades these models were considered as inferior and undesirable regarding to different combinations of constructivist learning (learning with varying degrees of guidance, support or scaffolding), as shown in the initiatives taken in different international projects to promote the various IBSE and IBME modalities (Dorier & Garcia, 2013). Transmission of knowledge by presenting examples of solved problems and the conceptual structures of the discipline is ruled by didactical theories in mathematics education with strong predicament, as mentioned in the previous section.

The uncritical adoption of constructivist pedagogical models can be motivated by the observation of the large amount of knowledge and skills, in particular everyday life concepts, that individuals learn by discovery or immersion in a context However, Sweller, Kirschner and Clark (2007) state that

> There is no theoretical reason to suppose or empirical evidence to support the notion that constructivist teaching procedures based on the manner in which humans acquire biologically primary information will be effective in acquiring the biologically secondary information required by the citizens of an intellectually advanced society. That information requires direct, explicit instruction. (p. 121)

This position is consistent with the argument put forward by Vygotsky; scientific concepts do not develop in the same way that everyday concepts (Vygotsky, 1934). These authors believe that the design of appropriate learning tasks should include providing students an example of a completely solved problem or task, and information on the process used to reach the solution. As Sweller, Kirschner, and Clark (2007) observe, "we must learn domain-specific solutions to specific problems and the best way to acquire domain-specific problem-solving strategies is to be given the problem with its solution, leaving no role for IL [inquiry learning]" (p. 118). According to Sweller et al., empirical research of the last half century on this issue provides clear and overwhelming evidence that minimal guidance during instruction is significantly less effective and efficient than a guide specifically designed to support the cognitive process necessary for learning. According to (Kirschner, Sweller, & Clark, 2006):

> We are skilful in an area because our long-term memory contains huge amounts of information concerning the area. That information permits us to quickly recognize the characteristics of a situation and indicates to us, often unconsciously, what to do and when to do it. (p. 76).

STUDYING MATHEMATICS THROUGH AN INQUIRY AND TRANSMISSION BASED DIDACTICAL MODEL

In the two previous sections we described some basic features of two extreme models for organizing mathematics instruction: discovery learning versus learning based on the reception of knowledge (usually regarded as traditional whole-class expository instruction). In this section, we describe the characteristics of an instructional model in which these two models are combined: the students' investigation of problem-situations with explicit transmission of knowledge by the "teacher system" [1] at critical moments in the mathematical instruction process. We consider that it is necessary to recognize and address the complex dialectic between inquiry and knowledge transmission in learning mathematics. In this dialectic, *dialogue* and *cooperation* between the teacher and the students (and among the students themselves), regarding the situation-problem to solve and the mathematical content involved, can play a key role. In these phases of dialogue and cooperation, moments of transmitting knowledge necessarily happen.

The onto-semiotic complexity of mathematical knowledge and instruction

The semiotic, epistemological and cognitive assumptions of the Onto-semiotic approach to mathematical knowledge and instruction (OSA) (Godino, Batanero, & Font, 2007) are the basis for our instructional proposal, which recognizes a key role to both the inquiry and the transmission of knowledge in the teaching and learning of mathematics (and possibly other disciplines). This model takes into account the nature of mathematical objects involved in mathematical practices whose students' competent performance is intended.

The way a person learns something depends on what has to be learned. According to the OSA, students should appropriate (learn) the onto-semiotic institutional configurations involved in solving the proposed problem-situations. The paradigm of "questioning the world" proposed by the Anthropological Theory of Didactics (TAD) (Chevallard, 2015), and, in general, by IBE models is assumed, so that the starting point should be the selection and inquiry of "good problem-situations."

The key notion of the OSA for modelling knowledge is the *onto-semiotic configuration* (of mathematical practices, objects and processes) in its double version, institutional (epistemic) and (cognitive). In a training process, the student's performance of mathematical practices related to solving certain problems, brings into play a conglomerate of objects and processes whose nature, from the institutional point of view is essentially normative (regulative) (Font, Godino, & Gallardo, 2013) [2]. When the student makes no relevant practices, the teacher should guide him/her to those expected from the institutional point of view. Thus each object type (concepts, languages, propositions, procedures, argumentations) or process (definition, expression, generalization) requires a focus, a moment, in the study process. In particular regulative moments (institutionalization) are *everywhere dense* in the mathematical activity and in the process of study, as well as in the moments of formulation / communication and justification.

Performing mathematical practices involves the intervention of previously known objects to understand the demands of the problem-situation and implementing an initial strategy. Such objects, its rules and conditions of application, must be available in the subject's working memory. Although it is possible that the student him/herself could find such knowledge in the "workspace", there is not always enough time or the student could not succeed; so the teacher and peers can provide invaluable support to avoid frustration and abandonment. These are the moments of remembering and activation of prior knowledge, which are generally required throughout the study process. Remembering moments can be needed not only in the exploratory-investigative phase, but also in the formulation, communication, processing or calculation, and justification of results phases. These moments correspond to acts of knowledge transmission and may be crucial for optimizing learning.

Results of mathematical practices are new emerging objects whose definitions or statements have to be shared and approved within the community at the relevant time of institutionalization carried out by the teacher, which are also acts of knowledge transmission.

Inquiry and transmission didactical moments

Under the OSA framework other theoretical tools to describe and understand the dynamics of mathematics instruction processes have been developed. In particular, the notions of *didactical configuration* and *didactical suitability* (Godino, Contreras, & Font, 2006; Godino, 2011). A didactical configuration is any segment of didactical activity (teaching and learning) between the beginning and the end of solving a task or problem-situation. Figure 1 summarizes the components and the internal dynamics of a didactical configuration, including the students' and the teacher's actions, and the resources to face the joint study of the task.

The problem-situation that delimits a didactical configuration can be made of various subtasks, each of which can be considered as a sub-configuration. In every didactical configuration there is an epistemic configuration (system of institutional mathematical practices, objects and processes), an instructional configuration (system of teacher and learners roles and instructional media), and a cognitive configuration (system of personal mathematical practices, objects and processes) which describe learning. Figure 1 shows the relationships between teaching and learning, as well as with the key processes linked to the onto-semiotic modelling of mathematical knowledge (Font, Godino & Gallardo, 2013; Godino, Font, Wilhelmi, & Lurduy, 2011). Such modelling, together with the teachers and learners roles, and their interaction with technological tools, suggest the complexity of the relationships established within any didactical configuration, which cannot not be reduced to merely inquiry and transmission moments.

SYNTHESIS AND IMPLICATIONS

In this paper, we argued that instructional models based only on inquiry, or only on transmission are simplifications of an extraordinarily complex reality: the teaching and learning processes. As Hiebert and Grouws (2007) write, "classrooms are filled with complex dynamics, and many factors could be responsible

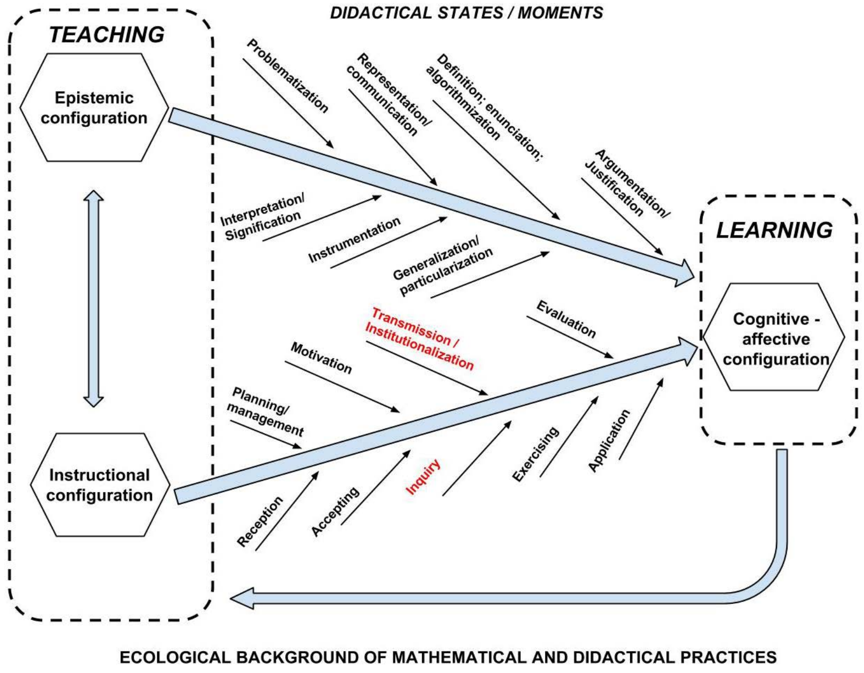

Figure 1: Components and internal dynamic of a didactical configuration

for increased student learning.... This is a very central and difficult question to answer" (p. 371).

Although we need to establish instructional designs based on the use of rich problem-situations, which guide the learning and decision-making at the global and intermediate level, local implementation of didactical systems also requires special attention to managing the students' background needed for solving the problems, and to the systematization of emerging knowledge. Decisions about the type of help needed essentially have a local component, and are mainly teacher's responsibility; he/she needs some guide in making these decisions to optimize the didactical suitability of the study process.

We also have supplemented the cognitive arguments of Kirschner, Sweller, and Clark (2006) in favour of models based on the transmission of knowledge in the case of mathematical learning, with reasons of onto-semiotic nature: What students need to learn are in a great deal, *mathematical rules*, the circumstances of its application and the required conditions for a proper application. The learners start from known rules (concepts, propositions, and procedures) and produce others rules that should be shared and compatible with those already established in the mathematical culture. Such rules (knowledge) must be stored in subject's long term memory and put to work at the right time in the short-term memory.

The scarce dissemination of IBE models in actual classrooms and the persistence of models based on the transmission and reception of knowledge can be explained not only by the teachers' inertia and lack of preparation, but by their perception or experience that the transmission models may be more appropriate to the specific circumstances of their classes. Faced with the dilemma that a majority of students learn nothing, get frustrated and disturb the classroom, it may be reasonable to diminish the learning expectations and prefer that most students learn something, even only routines and algorithms, and some examples to imitate. This may be a reason to support a mixed instructional model that articulates coherently, locally and dialectically inquiry and transmission [3].

ENDNOTES

1. This system can be an individual teacher, a virtual expert system, or the intervention of a "leader" student in a team working on a collaborative learning format.

2. This view of mathematical knowledge is consistent with that taken by Radford's objectification theory. Radford (2013) writes: "Knowledge, I just argued, is crystallized labor – culturally codified forms of doing, thinking and reflecting. Knowing is, I would like to suggest, the instantiation or actualization of knowledge" (p.16). He adds: "Objectification is the process of recognition of that which objects us – systems of ideas, cultural meanings, forms of thinking, etc." (p. 23). In our case, such crystallized forms of work are conceived as cultural "rules" fixing ways of doing, thinking and saying faced to problem-situations that demand an adaptive response.

3. The research reported in this paper was carried out as part of the research projects EDU2012-31869 and EDU2013-41141-P (Spanish Ministry of Economy and Competitiveness).

Mathematics communication within the frame of supplemental instruction – SOLO and ATD analysis

Annalena Holm and Susanne Pelger

Lund University, Faculty of science, Lund, Sweden, annalena.holm@varberg.se

Teaching at Swedish primary and secondary schools is often combined with collaborative exercises in a variety of subjects. One such method for learning together is Supplemental instruction (SI). Several studies have been made to evaluate SI in universities throughout the world, while at lower levels hardly any study has been made until now. This study aimed at identifying learning conditions in SI-sessions at two Swedish upper secondary schools. Within this study, a combination of ATD (Anthropological theory of the didactic) and the SOLO-taxonomy (Structure of the Observed Learning Outcome) was successfully tried as an analysis strategy.

Keywords: SOLO, ATD, networking, mathematics communication, SI.

INTRODUCTION

The teacher's choice of education methods has a high influence on what students learn (Hattie, 2009), and education research has shown to add to a better understanding of the prospects of successful teaching (Good & Grouws, 1979; Hattie, 2009). In spite of previous educational research, there is no clear answer to the question whether one method has advantages over the other, or if whole-class teaching is more successful than "dialogue-teaching".

To strengthen the findings, researchers have argued that there is a need for more sophisticated research methods (Jakobsson, Mäkitalo, & Säljö, 2009). There is also a need for more systematic connection between various education research theories – so-called networking (Prediger, Bikner-Ahsbahs, & Arzarello, 2008). According to (Prediger et al., 2008), the reasons that theories in mathematics education research have evolved differently are (1) mathematics education is a complex research environment, and (2) various research cultures prioritise different components of this complex field. Different theories and methods have different perspectives and can provide different kinds of knowledge. Thus, different theories and perspectives can connect in different ways.

An educational concept that needs to be explored, and systematically connected with various theories, is the so-called Supplemental instruction (SI). SI is a method where groups of students are provided peer collaborative learning exercises at meetings led by SI-leaders (Hurley, Jacobs, & Gilbert, 2006). The method is used worldwide both at the university level and lower levels. To strengthen students' knowledge in mathematics, a number of upper secondary schools in Sweden have introduced SI as a complement to regular teaching.

AIM

Within the present study, SI-sessions were analysed in upper secondary school. The purpose was gaining more insight into the conditions that may facilitate mathematics learning. For the analyses two frameworks were chosen and tested: (1) the Anthropological theory of the didactic (ATD) with focus on the development of mathematical activities defined in terms of praxeologies (Chevallard, 2015; Winsløw, 2010), and (2) Structure of the Observed Learning Outcome (SOLO), which instead focuses on students' learning outcome quality (Biggs & Collis, 1982). An aim of the study was to explore whether a combination of these two frameworks could contribute to deepen the analysis of the students' discussions. The research questions of this paper are, hence: *To what extent is a combination of SOLO and ATD a suitable strategy for analysing SI-sessions? Are these two frameworks compatible and complementary?*

THEORY AND CONNECTING FRAMEWORKS

Research needs theoretical frameworks. This was stated by (Lester, 2005), who argued that a theoretical framework provides a structure when designing research studies, and that a framework helps us to transcend common sense when analysing data. Below, the two frameworks that have been important for the study are discussed. First, the concept Supplemental instruction is presented. Then follows a section where SOLO-taxonomy and the ATD-praxeology are presented. Finally, possibilities and challenges with combining frameworks are discussed.

Supplemental instruction, or SI, is an educational method used at universities in many countries. Groups of students discuss and solve problems together, and SI is a complement to regular teaching. No teacher is present at the meetings (Malm, Bryngfors, & Mörner, 2012). The groups are instead guided by an older student, who is supposed to provide peer collaborative learning exercises (Hurley et al., 2006). SI has lately been introduced in some upper secondary schools in Sweden. First year students form the groups, while second and third year students serve as SI-leaders (Malm, Mörner, Bryngfors, Edman, & Gustafsson, 2012).

Biggs and Collis (1982) developed the *SOLO-taxonomy* for evaluating learning outcomes for students at tertiary level. SOLO names and distinguishes five levels according to the cognitive processes required to obtain them. The authors argued that SOLO is useful when categorising test results in closed situations with formulated expectations. They used five levels, SOLO-1 to SOLO-5, when categorising student responses (Biggs & Collis, 1982). Later Brabrand and Dahl (2009) used the SOLO-taxonomy for analysing (1) what curricula focus on and (2) what students actually learn. By using so-called active verbs (as shown hereafter), the authors state that it is possible to understand on which level of knowledge the learning outcome is:

SOLO 1 *(pre-structural):* student misses the point

SOLO 2 (*uni-structural*): define, count, name, recite, follow instructions, calculate

SOLO 3 (*multi-structural*): classify,describe, enumerate, list, do algorithm, apply method

SOLO 4 (*relational*): analyse, compare, explain causes, apply theory (to its domain)

SOLO 5 (*extended abstract*): theorize, generalize, hypothesize, predict, judge, reflect, transfer theory (to new domain)

Brabrand and Dahl (2009) conclude that SOLO can be used when analysing science curricula, but they question whether SOLO is a relevant tool when analysing mathematics curricula. They write:

> For mathematics it is usually not until the Ph.D. level that the students reach SOLO 5 and to some extent also SOLO 4. The main reason is that to be able to give a qualified critique of mathematics requires a counter proof or counter example as well as a large overview over mathematics which the students usually do not have before Ph.D. level. (Brabrand & Dahl, 2009, p. 543)

Other researchers, however, claim that SOLO is useful in various contexts. Pegg (2010) has described three studies where SOLO has been used to analyse primary and secondary students' learning mathematics. In addition, Pegg (2010) states that SOLO helps to describe observations of students' mathematics performance. Hattie and Brown (2004) also describe SOLO as a useful tool in mathematics education. They use a strategy where mathematics exercises are formulated by using SOLO, and they claim it is possible to use SOLO when analysing children's mathematics knowledge and when describing the processes involved in asking and answering a question on a scale of increasing difficulty or complexity.

The Anthropological theory of the didactic (ATD) is a research program for analysing and developing mathematics education, which offers a handful of tools (Chevallard, 2006; Winsløw, 2010). One of these is *the notion of praxeology,* and one of the overarching perspectives is *the paradigm of questioning the world*.

While *the paradigm of questioning the world* defines the perspective of the curriculum, the ATD-praxeology makes a helpful tool for analysing the content that is taught. A praxeology can be described as a four-tuple explaining the *components* of activities or knowledge that are taught. This four-tuple consists of: a *type of tasks* (T), a *technique* (τ), a *technology* (θ) and a *theory* (Θ) (Winsløw, 2010). These four constituents, if fully understood and used, can help to analyse what is done at school. The *type of tasks* and the *technique* form the *practice block* or the *know-how*. The *technology* and the *theory* constitute the *theory block* or the *know-why*. Hence, a technique is used to solve a task of a given type, while the technology justifies the technique, and the theory gives a broader understanding of the field. When used to describe bodies of knowledge, praxeologies can refer to "small" as well as "big" fields. Hence, a *point praxeology* is a single type of tasks that is solved by a technique; several point praxeologies can be combined into a local praxeology when they share the same technology and several local praxeologies sharing the same theory can be combined to form a regional praxeology (Winsløw, 2010).

The ATD-praxeology can be applied at various levels of education. Winsløw (2006), for example, discusses how to use the praxeology when studying advanced mathematics, while Barbé, Bosch, Espinoza, and Gascón (2005) suggest how to use ATD when studying classroom activities at upper secondary school. All together ATD is described as a theory which analyses what is taught and thus *showing the shortcomings* or even paradoxes of didactic practices. Winsløw (2010) also states that ATD is useful when proposing ambitious ways to *transform* education.

Different theories have different perspectives and can provide different kinds of knowledge. Looking at the same data from different perspectives can give deeper insights (Prediger et al., 2008). In this study, the ATD and SOLO frameworks were combined in order to study the conditions and outcomes of students' learning through SI. The purpose of combining two frameworks was to catch the advantages of each of them, and hence, to contribute to mathematics education research and networking.

METHOD

This study bases its statements on classroom observations. The phenomenon being studied was students' discussions of mathematics. The context was small groups in upper secondary school. We used a qualitative case study approach (Cohen et al., 2007) to provide an analysis of how the students in the groups dealt with the mathematical problems. (Cohen, Manion, & Morrison, 2007) describe the purpose of a case study to portray, analyse, and interpret situations through accessible accounts. As such, the case study method provided a systematic way of looking in depth, analysing and reporting how students discuss mathematical problems and how the discussions might facilitate learning.

Meetings at two upper secondary schools in south-western Sweden were observed with groups from the humanist, technology and natural science programs. The main criterion for choosing schools was their different experiences of support from the university. Another difference between the two schools was the implementation of SI. The criterion for choosing SI-groups to observe was availability. Not all groups wanted to be observed. Meetings were *videotaped* and the tapes were transcribed. The documents were coded by closed coding, i.e. a deductive *analysis* with codes from theoretical frameworks. During the whole study, the analysis strategy was developed and revised. Due to limited space not all observations can be presented here. For more comprehensive insight in the study see Holm (2014).

The first students to be observed were one group from the technology program and one group from the humanistic program. Both groups discussed the same exercise (see Table 1). The exercise was part of a former national test from the Swedish national agency for education, which in 2010 had been intended for all students in the first grade of Swedish upper secondary school. At these two particular group-sessions no SI-leaders were present as this was a first test of the frameworks. The observed sessions lasted 40 minutes at one school and 60 minutes at the other. The students were not told anything about the SOLO- and ATD-classification of the exercise.

The exercise was *pre-classified* by SOLO and the ATD-praxeology. The intention was (1) to test if it was possible to do this classification in advance before giving the exercise to the students, (2) to decide whether the two frameworks were a suitable choice when analysing student learning outcome, and finally, (3) if it was possible to correlate every SOLO-level to a specific dimension of the ATD-praxeology.

Three different ways of using the SOLO-taxonomy were found in the literature, and initially all three of them were used when classifying the exercise. One of the three was part of the original method defined by Biggs and Collis (1982), with instructions for how to analyse student achievements in elementary mathematics. The authors recommended that the children's solutions were to be analysed by deciding inter alia whether the child can handle several data at the same time and whether the child shows the ability to "hold off actual closures while decisions are made".

A second method was described by Hattie and Brown (2004). They grouped the exercises in advance, so that if a student answered a certain question the student was considered to reach a certain SOLO-level. Finally, Brabrand and Dahl (2009) used the SOLO-taxonomy by the active verbs once formulated by Biggs (2003) and compared university curricula with the table of verbs. Certain verbs were considered to point at certain "intended learning outcomes" in the curricula. Notice that the verb "calculate" and "do simple procedure" are added to SOLO 2. These verbs are mentioned in (Brabrand & Dahl, 2009) and in (Biggs & Tang, 2011). In the results section we explain why not all the three ways of using the SOLO-taxonomy were suitable for the present study.

Although the SOLO-taxonomy is widely used, in different ways, the work done by Biggs and Collis (1982) was based on closed situations, and not open situations, which are one of the main ideas of SI. Thus, it was decided that a complementary framework was needed for this study, specifically designed for mathematics education and also for open situations. Here, the ATD was found a suitable complement to SOLO.

The ATD is widely used, especially within the French, Spanish and Latin-American mathematics education research traditions (Bosch & Gascón, 2006; Chevallard, 2015). It is developed to fit education research in mathematics and other disciplines, and calls for more open situations and open questions at school in general and in school mathematics in particular (Chevallard, 2015). In this study, the analysis and development of open mathematics learning situations was, thus, done by using the ATD-praxeology, while the SOLO-taxonomy was used for the analysis of student learning outcomes.

RESULTS

The initial exercise about the volume of a cylinder was coded before it was given to the students (see Table 1). The SOLO-coding was based on the three methods described above. First, the "Hattie-Brown-method" was used, as it appeared to be near to practice.

Exercise: A roll of paper (statement)	SOLO	ATD praxeology
A rectangular sheet of paper can be rolled to make a tube (cylinder) as shown in the figure.		
Such a tube is made by rolling a square piece of paper with side length 10 cm. **The diameter of the tube will be about 3.2 cm. Find the volume of this tube (cylinder).*	2 /later chang-ed to 3	Technique $\tau 1$ (calculate the volume of a cylinder given its diameter and height)
*Show that the diameter of the tube will be about 3.2 cm if the side length of the sheet of paper used is 10 cm	2/3 /later 3	Technique $\tau 2$ (calculate the diameter of a circle given its perimeter)
If the length and width of the paper are different, you can make two different tubes (cylinders) depending on how you roll the paper. **Starting with rectangular sheets of paper with dimensions 10 cm × 20 cm, two different tubes are made. Find the volumes of the two tubes (cylinders).*	3	Combination of techniques $\tau 1$ & $\tau 2$ (first calculate diameter, then the volume)
*Compare these two volumes and calculate the ratio between them. **Investigate the ratio between the cylinder volumes using sheets of paper with other dimensions. What affects the volume ratio between the tall and the short cylinder?*	4 4	Technique $\tau 3$ (calculate the ratio of the volumes found) Technology (general statement about the ratio)
**Show that your conclusion is true for all rectangular papers.*	5	Technology (variation of $\tau 3$ using parameters, proof the general case)

Table 1: An exercise was pre-classified SOLO and the ATD-praxeology

It seemed to be easy to decide whether one or two aspects were involved in the question. However, when it came to higher SOLO-levels, it was more difficult to judge whether the aspects were "integrated". Here, the "Biggs-Brabrand-Dahl-method" was helpful as it offered additional verbs, alternative to "integrate", e.g., "compare" and "analyse", which could be used for the coding.

An example of the use of active verbs in the coding is the sub-task where students should first calculate two volumes and then compare these two volumes (Table 1):

> "Starting with rectangular sheets of paper with dimensions 10 cm × 20 cm, two different tubes are made. Find the volumes of the two tubes (cylinders)."

> "Compare these two volumes and calculate the ratio between them."

In both sub-exercises several aspects are involved. A volume is calculated by multiple parameters. But the active verbs separate the two sub-tasks, as the first requires only an algorithm: "find" (the volume), while the second requires that the student goes one step further and makes a comparison: "compare" (these two volumes). Finally, it was important to compare the coding with the "Biggs-Collis-method", as Biggs and Collis (1982) had formulated the original recommendations for how to use SOLO. In their book, however, the mathematics examples were fetched from elementary mathematics, and it was not obvious how to apply the method in the present study.

To conclude, the active verbs were found to be the most appropriate method when dealing with mathematics exercises. By using SOLO, a clear borderline could be drawn between the active verbs "do algorithm" (SOLO 3) and "explain causes" (SOLO 4), and the active verbs made it possible to identify these structural differences between exercises. The initial exercise about the volume of a cylinder was also coded using the ATD-praxeology (Table 1). This coding was based on the work done by Mortensen (2011), who has coded museum exhibition exercises – the so-called "intended praxeology". In the exercise about the cylinder, each sentence was coded. It was for example decided whether the students were supposed to deal with available "know-how" to solve a problem (the dimensions type of task & technique) or if they were supposed to deal with "know-why", i.e., a special way to justify the technique (the dimensions technology and theory).

At first, in the analysis of the described exercise (Table 1), SOLO and the ATD-praxeology were laid side by side. The exercise was coded both by SOLO and ATD. The strategy to try to correlate every SOLO-level to a specific dimension of ATD- praxeology caused problems. ATD and SOLO evaluate different dimensions. Thus, the strategy was abandoned at this early stage in the study. From now on, the two frameworks were used for different purposes: SOLO to analyse the quality of student learning outcomes, and the ATD-praxeology to analyse the didactic situations. In other words, they were considered answering different questions: *what qualities does the student outcome show?* and *which dimensions does the learning situation contain?* During the rest of the study it was discovered that the two frameworks often did not correlate.

The next step of the study was to code the group discussions about the cylinder. The sentences of the discussions were coded by the active verbs, and by the praxeological analysis. There were occasions when SOLO and ATD did correlate and there were other occasions when they did not. Table 2 shows part of one discussion and how the discussion can be analysed by SOLO and ATD. The students discussed the volume of the cylinder. They did not remember the formula and therefore they tried different strategies. Finally one student managed to solve the first exercise.

According to the analysis of the discussions of this first exercise, the SOLO-active verbs clarified the *learning outcome*. SOLO 4 for example told that students may have "explained" and/or "analysed". If an element of the situation was classified by ATD as "technology", it means that the student *dealt with a discussion concerning* "knowing why" a technique was being used. *Hence, it was possible to use the two frameworks within one study (compatible).* However, when entering into detail, the two approaches *lead to different characterisations* of students' mathematical activities (*complementary*).

— Students follow instructions "how": SOLO 2 & Technique

- Students use an algorithm: SOLO 3 & Technique
- A discussion about single tasks (point praxeologies) develops into a situation about knowing why (regional praxeologies), students may then explain why a method works: SOLO 4 & Technology
- A problem can develop into a situation that deals with knowing why, but students use the algorithm without discussing why: SOLO 3 & Technology
- The situation deals with knowing how to solve a problem by using an algorithm and students compare different solutions: SOLO 4 & Technique

Finally, it was concluded that the pre-classification did not hold. When the students did not remember the formula, they had to discuss the problem more thoroughly and thus reach other SOLO-levels and ATD-dimensions (Table 2).

DISCUSSION AND CONCLUSIONS

ATD and SOLO were combined to deepen the analysis of students' mathematics discussions. Such networking of frameworks is supported by Lester (2005) and Prediger and colleagues (2008), who argue that networking does not have to imply a total integration or unifying between frameworks. Lester (2005, p. 466) even advocates the adaptation of ideas from a range of theoretical sources to suit goals both for research and for developing practice in the classroom in a way that "practitioners care about".

The initial intention was to correlate specific SOLO-levels to specific ATD-praxeology dimensions. If this had been possible the conclusion would have been that one of the frameworks had been eliminated from this study. However, it was found that the two frameworks were both compatible and complementary. The present study thus succeeded in adapting theoretical models for analysing empirical material and in contributing to the development of strategies for analysing students' learning.

Re-conceptualising conceptual understanding in mathematics

Geoff Kent[1] and Colin Foster[2]

1 University College London, UCL Institute of Education, London, UK, G.Kent@ioe.ac.uk

2 University of Nottingham, Nottingham, UK

In this theoretical paper, we explore interrelationships between conceptual and procedural understanding of mathematics in the context of individuals and groups. We question the enterprise of attempting to assess learners' mathematical understanding by inviting them to perform a (perhaps unfamiliar) procedure or offer an explanation. Would it be appropriate to describe a learner in possession of an algorithm for responding satisfactorily to such prompts as displaying conceptual understanding? We relate the discussion to Searle's "Chinese Room" thought experiment and draw on Habermas' Theory of Communicative Action to develop potential implications for addressing the problem of interpreting learners' mathematical understanding.

Keywords: Conceptual, Habermas, procedural, Searle, understanding.

INTRODUCTION

The quest to help learners develop a deep and meaningful understanding of mathematics has become the holy grail for mathematics educators (Llewellyn, 2012), particularly since Skemp's (1976) seminal division of understanding into "instrumental" and "relational" categories. Relational (or conceptual) understanding is seen as more powerful, authentic and satisfying for the learner, representing true mathematical sense-making. But how can we know whether or not a learner has this relational understanding in any particular area of mathematics? The short, closed questions which dominate traditional paper-based assessments are unlikely to elicit this information. Hewitt (2009, p. 91) comments that "it is perfectly possible for a student to get right answers whilst not knowing about the mathematics within their work", and offers an example in which a learner aged 12–13 was finding the areas of triangles by multiplying the base by the height and dividing by 2, but admitted that he had no idea why he was multiplying or dividing by 2. This same example is used by Skemp (1976) to exemplify his distinction between instrumental and relational understanding of mathematics. Yet inviting learners to go further and explain their mathematics is also problematic. An invitation to "explain" an answer may be experienced as yet another request for "a performance": the "right" explanation that will satisfy a teacher or examiner may be memorised or produced algorithmically, just like the answer itself.

We might ask what it means for learners to have relational understanding of factorising a quadratic expression, for instance (Foster, 2014). If they can perform the procedure fluently (i.e., quickly, accurately, flexibly and confidently) then would we be satisfied (Foster, 2013)? We might argue that relational understanding involves adapting what is known to novel, non-straightforward problem-solving situations. Yet a robust enough algorithm will dispose of a very wide range of scenarios, including unanticipated ones, and a comprehensive enough set of algorithms might successfully deal with any situation likely to be encountered in any assessment (MacCormick, 2012). If the learner's performance continued to be faultless would we wish to probe their thinking further? To some extent mathematical fluency entails withdrawing attention from the details of why and how the procedure works so as to speed up the process and allow cognitive space for focusing on wider aspects of the problem (Hewitt, 1996; Foster, 2013). A mathematician does not want to have to differentiate $3x^2 - 2x + 4$ from first principles every time, although they are capable of doing so. Perhaps relational understanding involves an ability to deconstruct the procedure *if required* rather than an expectation that this is going on every time it is carried out? But deconstructing a procedure could *itself* be regarded as a procedure, and presumably one that can be prepared for – even memorised, just as proofs can be memorised. So is there something more to relational understanding than expert procedural fluency, and if so how might this be conceptualised? Is there a difference between being able to manipulate syntax and being able to understanding meaning?

PROCEDURAL AND CONCEPTUAL KNOWLEDGE

Skemp's (1976) famous distinction between instrumental and relational understanding characterises relational understanding as "knowing both what to do and why" (p. 20), whereas instrumental understanding is merely "rules without reasons" (p. 20). While acknowledging that "one can often get the right answer more quickly and reliably by instrumental thinking than relational" (p. 23), he nonetheless criticises instrumental learning as a proliferation of little rules to remember rather than fewer general principles with wider application. More recently, the terms procedural and conceptual learning have been widely adopted, and theoretical interpretations of these in mathematics education have increasingly highlighted their interweaving and iterative relationship (Star, 2005; Baroody, Feil, & Johnson, 2007; Star, 2007; Kieran, 2013; Star & Stylianides, 2013; Foster, 2014).

The most commonly-used definitions of procedural and conceptual knowledge in the context of mathematics are those due to Hiebert and Lefevre (1986). They see conceptual knowledge as knowledge that is rich in relationships, where the connections between facts are as important as the facts themselves, whereas procedural knowledge is rules for solving mathematical problems. This distinction parallels Skemp's (1976) conclusion that there are really two kinds of *mathematics* – instrumental and relational – dealing with different kinds of knowledge. More recently, Star (2005, 2007) distinguishes between *types* of knowledge (knowledge about procedures or knowledge about concepts) and *qualities* of knowledge (superficial or deep), and complains that these are frequently confounded. He highlights the way in which "procedural" is often equated with "superficial", and "conceptual" with "deep", and draws attention to the possibility of "deep procedural knowledge" and "superficial conceptual knowledge" as valid categories. Kieran (2013) goes further in declaring the dichotomy between conceptual understanding and procedural skills a fundamentally false one. Other researchers have also explored the interplay between procedural and conceptual knowledge (Sfard, 1991), with Gray and Tall (1994) integrating processes and concepts into what they term "procepts" (Tall, 2013). But there remains the question of what precisely it is that conceptual knowledge consists of beyond confident procedural knowledge.

THE CHINESE ROOM

Searle's (1980) famous thought experiment about a "Chinese Room" was an attack on the "strong" artificial intelligence claim that a computer is a mind, having cognitive states such as "understanding". Searle imagined a native English speaker who knew no Chinese locked in a room with a book of instructions for manipulating Chinese symbols. Messages in Chinese are posted through the door and the English speaker follows the instructions in the book to produce new messages in Chinese, which they post out of the room. Unknown to them, they are having a conversation in Chinese, a language which they do not speak a word of. Searle argued that syntax does not add up to semantics; behaving "as if" you understand is not the same as understanding. But it is very difficult to pinpoint exactly where the difference lies (Gavalas, 2007). Searle does acknowledge that "The rules are in English, and I understand these rules as well as any other native speaker of English" (1980, p. 418), but it remains mysterious exactly what test could distinguish a competently performing machine from a real mathematician. A learner performing a mathematical procedure may be making mathematical sense to an observing mathematician, such as a teacher, without apparently knowing much themselves about what they are doing.

The focus here has now changed from whether the computer (or the mind as a computer) understands mathematics to the question of whether some computer could be such that it is indistinguishable from a real mathematician. It may be that, whether or not you could tell them apart, they would perform the tasks of producing syntactically correct mathematics in importantly different manners. Thus the issue becomes the *sense* in which rules are being followed. If rules are followed in a meaningful sense and their semantic content is well defined and connected within constellations of schemas, then test item responses could be strong evidence of mathematical understanding. But this requires that those items are designed so that they engage procedural knowledge in a sophisticated manner which takes into account all of the aspects of the concept image that is the object of assessment. We could specify an additional requirement that the test be administered to a human being and not a computer. While this may seem flippant, it points to the heart of Searle's argument, which is that humans follow rules through semantic causality that is more or less part of the "hardware" of our brains; that there is no (or minimal) "software" layer (Searle, 1984). So does this imply that truly instrumental understanding is an impossibility for a human being?

MATHEMATICAL UNDERSTANDING

Searle's later articulation of social theory addresses how language can be used to create a social reality which is iterative and generative (Searle 1995, 2010). Further, Searle articulates an analysis of language that points towards strong connections between the structure of language and the structure of intentional states. In some ways this leads us back to the idea of the mathematician as performing *as though* merely in command of a complex constellation of algorithms that are triggered and brought to bear in a purely syntactical manner. In light of the argument put forth by Searle, we should rather say that the mathematician employs an array of mathematical understandings which have semantic content. While this seems unsatisfying, as though Searle is saying "it is semantic when humans do it", it bears strong connections with Sierpinska's articulation of procedural understanding and its relationship to conceptual understanding. Procedural understandings, according to Sierpinska (1994):

> are representations based on some sort of schema of actions, procedures. There must be a conceptual component in them – these procedures serve to manipulate abstract objects, symbols, and they are sufficiently general to be applied in a variety of cases. Without the conceptual component they would not become procedures. We may only say that the conceptual component is stronger or weaker. (p. 51)

Hence, it is reasonable for a mathematician to see many elements of their understanding as arrays of algorithms that allow them to address wide categories of mathematical problems. Yet this is fundamentally different from how a digital computer would operate in a purely syntactical approach.

Gordon, Achiman and Melman (1981, p. 2) define *rules* as "statements of the logical form 'In type-*Y* situations one does ... *X*'". For Wittgenstein (1953), it is not possible to *choose* to follow a rule: "When I obey a rule, I do not choose. I obey the rule *blindly*" (p. 85, original emphasis). Otherwise it is not a rule. It is in this sense that Searle raises a question fundamental to this discussion: Should understanding mathematics be understood as sophisticated algorithmic arrays which are akin to complex computer programs? Searle's (1984) critique of this and related ideas has several facets, the most pertinent of which is that there is an ambiguity in what is meant by rule following and that humans and computers do not follow rules in the same sense. In essence, Searle argues that humans follow rules in as much as they understand the *meaning* of the rules (which is thus semantic and about intentional states), whereas computers are purely syntactical in their rule following; they can be said to "*act in accord with formal procedures*" (ibid, p. 45, original emphasis).

Returning to the question of relational versus instrumental understanding, it seems that if we follow Searle's arguments we can say that mathematical understanding is probably not effective human understanding if it is primarily instrumental (in the sense of syntactical rule following). However, it is clear that procedural, syntactical and algorithmic practices and concepts form an important part of the background to meaningful mathematical understanding. Thus from a perspective of assessment we would expect it to be important to assess algorithmic fluency while also seeking to assess the strength of the conceptual content associated with the procedural performance.

So in contrast to the kinds of digital computers that Searle and Hiebert and Lefevre are talking about, algorithms exist within a semantic framework. Perhaps it is as though a digital computer (syntactical machine environment) is being modelled using a semantic machine environment (the brain). If so, the potential problem for mathematics education relating to instrumental learning in mathematics may be that the seeming simplicity of rule following is made vastly more complicated by its need to run in a sort of virtual syntactic machine running on essentially semantic hardware. On the other hand, the generation of correct syntactical content is a power of certain constellations of semantic knowledge (relational knowledge). It seems that the teaching of algorithms and procedures is crucial for the development of sophisticated mathematical understanding, but also that *how* they are taught is critical to supporting the development in learners of mathematical understanding that goes beyond procedural understandings with weak conceptual content (Foster, 2014).

Habermas' theory of communication, partly based in and complementary to Searle's theories, can point towards models of understanding and how to assess it. In communicative action, as defined by Habermas (1984), action is coordinated intersubjectively through achieving understanding. The theory of communicative action (TCA) analyses communication as having an inherent rationality focused on the goal of achieving understanding. Using speech act theory and argumentation theory, Habermas identifies categories of validity claims that are raised in any communicative interaction and also identifies implicit preconditions for successful communication. The former is referred to by Habermas as "discourse", but might better be termed "validity-discourse", in order to differentiate it from other uses of that term in social sciences. The preconditions for communicative action are referred to collectively as the "Ideal Speech Situation" by Habermas and constitute a set of counterfactual norms identified abductively as necessary for successful communication. These norms are focused on equitable conditions for participation in communication where the "unforced force of the better argument" has the opportunity to motivate agreement. This is a bit tricky, as Habermas claims that such conditions must be assumed by participants as in operation in order to communicate, despite representing more of an ideal horizon that never completely obtains. Society is power-laden, and all communication occurs within a social context. Thus the breakdown of communication is all too common, and intersubjective understanding is seen as a fleeting and fallible goal that is ever approached but seldom attained.

The claim that Habermas's TCA and Searle's speech act theory are complementary and can be productively networked is based on the specific arguments made by Habermas in the TCA, his use of speech act theory to develop his ideas of communicative action and also upon analysis of similarities and departures between the principles, methodologies and questions of each author:

> Analytical philosophy, with the theory of meaning at its core, does offer a promising point of departure for a theory of communicative action that places understanding in language, as the medium for coordinating action at the focal point of interest. (Habermas, 1984, p. 274)

While it might be possible to argue that Searle's theories depart somewhat from the kinds of analytic theories that Habermas wants to make use of, this is mistaken, since their focus is on incorporating theories of intentionality. Searle beings with the structure of linguistic expressions and then deals with intentionality, and importantly in his later work he introduces the idea of *collective* intentionality, which is focused on the coordination of speakers, and which is closely related to Habermas' ideas about the importance of intersubjectivity in communicative action:

> For a theory of communicative action only those analytic theories of meaning are instructive that start from the structure of linguistic expressions rather than from speakers' intentions. And the theory will need to keep in mind how the actions of several actors are linked to one another by means of the mechanism of reaching understanding. (Habermas, 1984, p. 275)

Searle's ideas add rigour and detail at the level of social ontology and may allow for a more sophisticated operationalising of concepts and constructs based in Habermas' TCA. These ideas could be used to further network critical theory, cognitive science, neuroscience and other approaches to the study of mathematics education so that they may inform one another without reducing one to the other. Thus the issue of theoretical incommensurability may be navigated without theoretical insights becoming "siloed" within various sub-cultures of theory which do not communicate with one another. A common theoretical language might allow researchers to disagree with greater clarity without running the risk of becoming an over-arching "grand theory". More broadly, Searle's ideas could serve as tools for building rigorous analysis of particular instances of theoretical networking, allowing productive discussion between theoretical perspectives.

These ideas can be operationalised to analyse small-group problem solving and in this manner interpret the mathematical understanding of participants (Kent, 2013), which could serve as the basis for the development of interactive assessment techniques, activities and protocols. Understanding from this perspective is about being able to identify what reasons, arguments and evidence could be legitimately raised to justify a claim. This emphasis on the identification of shared bases for validity can serve as a pragmatic approach to the analysis of human understanding in mathematics. Thus when we speak of assessing mathematical understanding we can begin to identify as a community of mathematicians and mathematics educators (with due consideration of developmental and disciplinary appropriateness) the claims and the appropriate reasons that justify these claims. We can consider how to engage participants in communicative actions around mathematical goals that require the articulation of arguments and justifications that show evidence that the participants can explain why certain mathematical claims are true.

Returning to the Chinese Room, this turn to the social does not suggest that there need be two people in the room, but rather that the person in the room must share requisite background knowledge or be able to develop it contextually with the Chinese speakers outside the room. The idea of communicative competence is key: sharing the contextual background knowledge that allows a language to have semantic meaning is the basis for "understanding". This is different from quickly and accurately manipulating the symbols in a language in a syntactic fashion: no *shared* understanding entails from such activity. Now it is possible that meaning could be attributed to rules or symbols by the person in the Chinese room, but, without the ability to test these against another person who has semantic understanding of the symbols, no interpersonal communication or shared understanding is achievable. The meaning so developed would be a private language that would not necessarily correspond to that of the interlocutor. Thus the person in the Chinese room might imagine that they were having a discussion about a family's vacation outing when in fact the interlocutor interpreted the exchange of symbols as being a mathematical discourse on the solution to an algebraic problem (or vice versa).

CONCLUSION

These ideas about the nature of the relationship between syntax and semantics, procedure and concept, and instrumental and relational understanding do not undermine the importance of procedural fluency. Pimm (1995) addresses the issue in depth and identifies some of the important features of fluency in mathematics education:

> For me, fluency is about ease of production and mastery of generation – it is used also in relation to a complex system. 'Fluent' may be related to efficient, or just no wasted effort. It is often about working with the *form*. Finally, it can be about not having to pay conscious attention. (ibid, p. 174, original emphasis)

Thus fluency, including syntactical fluency, can serve as partial evidence of understanding in a communicational context. Mathematical fluency, as in non-mathematical communication, is a sign of communicative competence, which is a prerequisite for interpersonal understanding according to the hermeneutic/communicational tradition (Habermas, 1984; Sierpinska, 1994). Thus when we say that a human being does not follow rules in the same sense as a computer, we mean that the symbolic rule following (or algorithmic manipulation of syntax) is done in the context of mathematical communication, and thus has semantic framing.

Habermas' articulation of rational behaviour in discursive practices has been identified as productive for the analysis of shared cognition in mathematics education (Boero et al., 2010). In communicative action participants achieve shared goals by coordinating action (including speech action) through the development of a shared understanding. Thus, establishing shared goals and coordinating action around an appropriately designed mathematical task could serve as an interpretive basis for the researcher (or other virtual participant) to make a judgement about the understanding of the participants in collaborative learning of mathematics (Kent, 2013).

We suggest that consideration of Searle's (1984) critique of cognitive science allows for ongoing productive insight into what mathematical thinking is and its relation to education. An important problem faced by the mathematics education community is how we can use ideas of relational understanding and instrumental understanding in a sophisticated manner to promote the learning of mathematics. Learners of mathematics should gain genuine experience of real mathematical sense-making rather than engage in a charade of imitating what they think such behavior should look like. The increasing focus on fluency in policy in the UK (DfE, 2013) suggests the need for tools and practices to be developed which coordinate ideas of cognition, mathematical understanding and educational practices of teaching and assessment. Our consideration of Searle's Chinese Room argument has sought to highlight the nuance involved in these issues and the kinds of practices and theoretical frameworks that could be leveraged to address the problem of interpreting learners' mathematical understanding.

The epistemological dimension revisited

Ivy Kidron

Jerusalem College of Technology, Jerusalem, Israel, ivy@jct.ac.il

Epistemology and networking was discussed in the last CERME working group on theory. This paper aims to continue the discussion. I reflect on epistemological analysis and the cultural dimension of knowing and present examples which demonstrate how the changes in the cultural context influence the epistemological analysis. Then, I reconsider the epistemological dimension and the networking of theories. In some cases, the epistemological dimension permits the networking. In other cases, we notice how by means of networking, strong epistemological concerns in one theory might be integrated in another theory in a way that reinforces the underlying assumptions of this other theory. I end the paper with an example of networking that demonstrates how the social dimension might influence the epistemological analysis.

Keywords: Cultural dimension, epistemological analysis, networking theories, social dimension.

EPISTEMOLOGY AND NETWORKING THEORIES IN THE PREVIOUS CERME WORKING GROUPS ON THEORIES

The present paper aims to continue the work done at the previous CERMEs in relation to the epistemological dimension in theories. At CERME8, the focus on networking and epistemology was stronger than in the previous working groups on theory. For example, the role of epistemology in the networking of theories was an explicit focus in the paper by Ruiz-Munzón, Bosch, and Gascón (2013). The idea of a "reference epistemological model" (REM) was introduced for networking Chevallard's Anthropological Theory of the Didactic (ATD) and Radford's Theory of Knowledge Objectification (TKO). The authors analyzed how each approach addresses the nature of algebraic thinking. The point of view of the ATD was presented with its own REM about elementary algebra as well as the kind of questions addressed by this approach, in relation to the TKO.

In their paper, presented at CERME8, Godino and colleagues (2013) analyzed two approaches to research in mathematics education: "Design-based research" (DBR) and "Didactic engineering" (DE), in order to study their possible networking. DE (closely linked to Brousseau's theory of didactical situations) focuses on epistemological questions; DBR does not adopt a specific theoretical framework, nor does it explicitly raise epistemological questions. In the working group (Kidron et al., 2013) interesting questions arose like the following one: "is the epistemological focus only a question of 'cultural and intellectual context' or is an epistemological reference necessary for each theoretical approach used in design based research in math education?"

Artigue (2002) wrote that the anthropological approach shares with the socio-cultural approaches the view that mathematical objects are not absolute objects, but are entities which arise from the practices of given institutions. These practices are described in terms of tasks in which the mathematical object is embedded, in terms of techniques used to solve these tasks and in terms of discourse which both explains and justifies the techniques. It is interesting to note that the nature of mathematical objects was a theme that appears at CERME4 in the context of the need to be aware of the underlying assumptions of each theory and that underlying assumptions also concern ontological or epistemological questions such as the nature of mathematical objects. This theme reappears in the next CERMEs especially at CERME7 while networking was needed in order to analyze the emergence and nature of mathematical objects. This was well demonstrated, for example, in the paper presented by Font and colleagues (2011). The authors asked "What is the nature of the mathematical objects?" They explored this question by the use of a synthesis between the onto-semiotic approach (OSA), APOS theory (with its four components, Action, Process, Object, and Schema) and the cognitive science of mathematics (CSM) as regards their use of the concept of "mathematical object". APOS theory and CSM highlight partial aspects of the complex process through which, according to OSA, mathematical objects emerge. OSA extends APOS theory by addressing the role of semiotic representations; it improves the genetic decomposition by incorporating ideas of semiotic complexity, networks of semiotic functions and semiotic conflicts; it offers a refined analysis due to the way in which it considers the nature of such objects and their emergence out of mathematical practices. Considering mathematical objects not as absolute objects, but as entities which arise from the practices of given institutions, leads us to analyze the role of both, the epistemological dimension and the socio cultural dimension, in theories.

EPISTEMOLOGICAL ANALYSIS AND SOCIO CULTURAL DIMENSION

The following question was asked by Luis Radford at the colloquium at Paris in honour of Artigue (2012): "How can epistemological analysis take into account the social and cultural dimension of knowing?" In the last decades the increasing influence of sociocultural approaches towards learning processes is well recognized. Therefore, the question is essentially *how* the social and cultural dimensions are taken into account in the epistemological analysis. In this section, I will consider this question in relation to the cultural dimension of knowing, I analyze the changes in the cultural context and their influences on the epistemological analysis. In the section about epistemological dimension and networking theories, I will reconsider Radford's question in relation to the social dimension of knowing.

Changes in the cultural context and their influences on the epistemological analysis

In the last decades we face the changes of our cultural environment as well as the changes of the context in which our theory emerged. I will give an example from my own research on students' conceptual understanding of central notions in calculus like the notion of limit in the definition of the derivative. In my previous research, using essentially theories that privilege epistemological and cognitive dimensions, I was aware of the cognitive difficulties relating to the understanding of the definition of the derivative as the "limit of the quotient $\Delta y/\Delta x$ as Δx approaches 0". In my epistemological analysis, my first thinking was that these cognitive difficulties are inherent to the epistemological nature of the mathematics domain. I realized that students viewed the limit concept as a potential infinite process and I understood that this was a possible source of difficulties. Moreover, previous researches (Tall, 1992) expressed students' belief that any property common to all terms of a sequence also holds of the limit. I therefore realized that this natural way in which the limit concept is viewed might be an obstacle to the conceptual understanding of the limit notion in the definition of the derivative function $f'(x)$ as $\lim_{\Delta x\to 0} \Delta y/\Delta x$. In particular, the derivative might be viewed as a potentially infinite process of $\Delta y/\Delta x$ approaching $f'(x)$ for decreasing Δx. As a result of the belief that any property common to all terms of a sequence also holds of the limit, the limit might be viewed as an element of the potentially infinite process. In other words, $\lim_{\Delta x\to 0} \Delta y/\Delta x$ might be conceived as $\Delta y/\Delta x$ for a small Δx. I therefore looked for a counterexample that demonstrates that one cannot replace the limit "$\lim_{\Delta x\to 0} \Delta y/\Delta x$" by $\Delta y/\Delta x$ for Δx very small. "Finding such a counterexample.... was crucial to my research focus. Such a counterexample demonstrates that the passage to the limit leads to a new *entity* and that therefore omitting the limit will change significantly the nature of the concept. It demonstrates that the limit could not be viewed as an element of the potentially infinite process" (Kidron, 2008, p. 202). In Kidron (2008), I explain that such counterexample exists in the field of dynamical systems which is considered as a new field in mathematics. In the counterexample (the logistic equation), the analytical solution obtained by means of continuous calculus is totally different from the numerical solution obtained by means of discrete numerical methods. The essential point is that using the analytical solution, the students use the concept of the derivative as a limit $\lim_{\Delta x\to 0} \Delta y/\Delta x$ but, using the discrete approximation by means of the numerical method, the students omit the limit and use $\Delta y/\Delta x$ for small Δx. Students reactions are analyzed in (Kidron, 2008), in particular how students reach the conclusion that passing to limits may change the nature of a problem significantly. The essential point is that the changes in the cultural context permit the new settings for the learning experience. More precisely, the changes in the cultural context permit modern results in research Mathematics which influenced my own research in mathematics education by means of changes in the didactical designs. The didactical design described in (Kidron, 2008) was possible by means of the epistemic status of the new artifacts used in the research study. The way the students interacted with the software demonstrates that the artifact used in this study should not be considered only as an aid for the students. It had a deep cognitive role while learners interacted with it. The artifact was conceived as co-extensive of thinking: the students act and think *with* and *through* the artifact as described by Radford (2008). In another study (Kidron & Dreyfus, 2010) we also notice this specific epistemic status of the artifact as co-extensive of thinking while the computer is considered as a dynamic partner. Kidron and Dreyfus consider the influence of a CAS (Computer Algebra System) context on a learner's process of constructing a justification for the bifurcations in a logistic dynamical process. The authors describe how instrumentation led to cognitive constructions and how the roles of the learner and the computer intertwined during the process of constructing the justification.

Another example describing how epistemological analysis takes into account the cultural dimension of knowing is described in Artigue (1995, p. 16) in which the author describes her mathematical research in differential equations and the way she notes the epistemological inadequacy of teaching in this area, for students in their first two years at university. By means of epistemological analysis, Artigue described how historically the differential equations field had developed in three settings: the algebraic, the numerical and the geometric settings. For many years, teaching was focused on the first setting due to epistemological and cognitive constraints. Reflecting on these constraints was a starting point towards building new teaching strategies which better respect the current fields' epistemology. By means of the epistemological analysis, Artigue could see the epistemological evolution of the field towards new approaches, the geometrical and numerical approaches. The essential point in this example is that the epistemological evolution is a consequence of the changes in the mathematical culture and the epistemological analysis highlights the crucial role of the cultural dimension.

THE EPISTEMOLOGICAL DIMENSION AND THE NETWORKING OF THEORIES

Epistemological sensitivity

A new view on the epistemological dimension is offered in Kidron and colleagues (2014) by means of the networking between three theories, TDS, the Theory of Didactic situations (Artigue, Haspekian, & Corblin-Lenfant, 2014), ATD, the Anthropological Theory of the Didactic (Bosch & Gascón, 2014), and AiC, the theory of Abstraction in Context (Hershkowitz et al., 2001; Schwarz et al., 2009; Dreyfus & Kidron, 2014). The foci of the three theoretical approaches are different. In particular, AiC focuses on the learner and his or her cognitive development, while TDS and ATD focus on didactical systems. The three theoretical approaches are sensitive to issues of context but, due to these differences in focus, context is not theorized and treated in the same way. The authors expected some complexity in the effort of creating a dialogue between the three theories in relation to constructs such as context, milieu, and media-milieus dialectic. However, they observed how the dialogue between the three theories appears as a progressive enlargement of the focus, showing the complementarity of the approaches and the reciprocal enrichment. A new term was introduced in this research study: *epistemological sensitivity*.

The authors explain the meanings of the terms context (for AiC), milieu (for TDS) and media-milieus dialectic (for ATD), each of them being a cornerstone for the theory while all of them try to theorize specific contextual elements. The three theories share the aim to understand the epistemological nature of the episode described in the paper but in each of the three theories different questions were asked. Questions for analyses in AiC stressed the epistemic process itself, whereas researchers in TDS and ATD asked how this process is made possible. Nevertheless, these questions indicated that the researchers were able to build on the other analyses in a complementary way. The dialogue between the different approaches was possible because a point of contact was found. In this case, we may talk about a common *epistemological sensitivity* of AiC, TDS, and ATD, which can be noticed in the a priori analyses provided by each frame. This initial proximity was essential for the dialogue to start and become productive, showing the complementarity of the approaches and the reciprocal enrichment, without losing what is specific to each one. The three concepts, context, milieu and media-milieus dialectic were accessed by different data or different foci on data in a complementary way sharing *epistemological sensitivity*, which facilitated establishing connections and reflecting on them.

Epistemological concerns as a consequence of networking

It is not by chance that the common *epistemological sensitivity* of AiC, TDS, and ATD, was noticed in the a priori analyses provided by each frame: the reason is that the a priori analyses take into account the mathematical epistemology of the given domain. In the last years, the AiC researchers decided to implement the idea of a priori analysis in an explicit way. This happened as a consequence of the networking experience with the TDS researchers. An example of such a networking experience is described in Kidron and colleagues (2008). Three theories were involved in this case of networking: TDS, AiC and IDS, the theory of Interest-Dense Situations (Bikner-Ahsbahs & Halverscheid, 2014). Kidron and colleagues (2008) focus on how each of these frameworks is taking into account social interactions in learning processes. The authors wrote that

> In a more general way, the different views the three theoretical approaches have in relation to social interactions force us to reconsider these approaches in all their details. The reason for this is that the social interactions, as seen by the different frameworks, intertwine with the other characteristics of the frameworks. (p. 253)

The authors identified not only connections and contrasts between the frameworks but also additional insights, which each of these frameworks can provide to each of the others. In this paper, we only focus on a specific kind of insights: the epistemological concerns which were highlighted as a consequence of the networking of theories. We first characterize the epistemological dimension in each of the three theories before the networking experience:

— TDS provides a frame for developing and investigating didactical situations in mathematics from an epistemological and systemic perspective. TDS combines epistemological, cognitive, and didactical perspectives. TDS focuses on the epistemological potential of didactical situations;

— IDS, the theory of interest-dense situations, is "a social constructivist theory that cannot say much about cognitive processes of individuals and does not provide tools for epistemological analyses" (Bikner-Ahsbahs & Halverscheid, 2014, p. 102);

— AiC analysis focuses on the students' reasoning; mathematical meaning resides in the verticality of the knowledge constructing process and the added depth of the resulting constructs. An epistemological stance is underlying this idea of vertical reorganization but AiC analysis is essentially cognitive.

Focusing on epistemological concerns as mentioned earlier, we will only characterize the insights offered by TDS to AiC as described by Kidron and colleagues (2008):

> According to Hershkowitz et al. (2001), the genesis of an abstraction originates in the need for a new structure. In order to initiate an abstraction, it is thus necessary (though not sufficient) to cause students' need for a new structure. We may attain this aim by building situations that reflect in depth the mathematical epistemology of the given domain. This kind of epistemological concern is very strong in the TDS, and the notion of fundamental situation has been introduced for taking it in charge at the theoretical level. It could be helpful for AiC. (p. 254)

This was an invitation for AiC researchers to build an a priori analysis that reflects in depth the mathematical epistemology of the given domain. In the same vein the a priori analysis of TDS offers another perspective to IDS to think about the building of situations reflecting in-depth the mathematical epistemology of a given domain and the consequence of such reflection on the analysis of the social interactions.

The social dimension and its influence on the epistemological analysis

In the following, I analyze a case of networking between AiC and IDS which demonstrates mutual insights in the process of networking. In particular, we will observe how the epistemological analysis carried by the AiC researchers is influenced by the social dimension of knowing which characterizes IDS. This case of networking illustrates how the epistemological analysis might take into account the social dimension of knowing.

Kidron and colleagues (2010) focus on the idea of networking and on two theoretical concepts: the need for a new knowledge construct, and interest. IDS considers social interactions as basis which constitutes learning mathematics. Interest-dense situations provide motivation for processes of in-depth knowledge construction. AiC is a theoretical tool to investigate such processes. As already mentioned, in the AiC analysis, the first stage of the genesis of an abstraction is the learner's need for a new construct. Such a need might arise when the learner's existing knowledge is insufficient to solve a task or to understand a new concept. This individual need is related to the specific mathematical situation at hand. Analyzing this need is a part of AiC epistemological analysis. For IDS the situation is different: interest constitutes a psychological source to gain more knowledge. This need is nested in the situational interest rather than shaped by the epistemic nature of the topic. The aim of the networking was to relate these two concepts: need and interest. As mentioned earlier, the AiC researchers implemented the idea of a priori analysis. Their analysis was based on an a priori analysis of the knowledge elements intended by the design. The AiC analysis focused on the students' reasoning and mathematical meaning resided in the verticality of the knowledge constructing process. The AiC researchers identified students' constructs of the intended knowledge elements. They expected to identify students' need for the new constructs before or during the process of knowledge construction. However, the researchers found it difficult to identify a need for a specific new construct. Networking the two approaches was helpful: The IDS analysis focuses and reconstructs the whole situation sequentially on the basis of utterances that show intense social interactions, whereas the AiC analysis focuses on segments that appear relevant to the constructing process. In fact, the excerpts ignored at first by the AiC researchers did contribute to the constructing process thanks to the social interaction analysis provided by IDS which allowed the AiC researchers to focus on and incorporate these seeds of construction in their analysis. The networking helps AiC researchers realize that there are situations in which constructing actions can occur on the basis of a general epistemic need rather than on the basis of specific needs for new constructs. The benefit of networking was mutual thanks to the epistemological nature of AiC a priori analysis which makes the researchers sensitive for the mathematics at stake and implicit mathematical ideas were identified very early. This was very helpful towards IDS re-analyzing of the epistemic actions in the research study.

CONCLUDING REMARKS

In the last CERME we discussed cases in which the epistemological dimension permitted the networking. This was done, for example, by means of the idea of "reference epistemological model". In this paper, we notice how by means of networking, strong epistemological concerns in one theory might be integrated in another theory in a way that reinforces the underlying assumptions of this other theory. This was illustrated by the insights offered by means of a priori analysis. We also analyzed examples that demonstrate the influence of the cultural context as well as the influence of the social dimension on the epistemological analysis. The cultural context in which the different theories emerged is changing all the time. As a result of these changes, a new view on the epistemological dimension is offered. This new view should be further discussed.

Towards a confluence framework of problem solving in educational contexts

Boris Koichu

Technion – Israel Institute of Technology, Haifa, Israel, bkoichu@technion.ac.il

An exploratory confluence framework for analysing mathematical problem solving in socially different educational contexts is introduced. The central premise of the framework is that a key solution idea to a problem can be constructed by a solver as a result of shifts of attention that come from individual effort, interaction with peer problem solvers or interaction with a source of knowledge about the solution. The framework consolidates some existing theoretical developments and aims at addressing the perennial educational challenge of helping students become more effective problem solvers.

Keywords: Problem solving, networking theories, shifts of attention.

RATIONALE

It has been repeatedly asserted that problem solving is an activity at the heart of doing and studying mathematics. Its central feature is that problem solving requires the engaged person(s) to invent a solution method rather than to recall and implement a previously practiced method (e.g., Kilpatrick, 1982; NCTM, 2000). Accordingly, a central challenge associated with the use of mathematical problems in educational contexts – how to help learners to become effective or successful problem solvers – can be worded as the challenge of supporting learners' mathematical inventiveness in ways that preserve their problem-solving autonomy and self-efficacy.

For the last 50 years this challenge has been approached through various conceptual frameworks and models (see Carlson & Bloom, 2005; Schoenfeld, 2012; Törner, Schoenfeld, & Reiss, 2008, for comprehensive accounts of the state of the art). Each framework has aimed at addressing specific queries of pragmatic and theoretical importance. Some of the queries were:

- How do mathematicians solve problems? What phases and cycles are they going through while solving problems? (Carlson & Bloom, 2005; Pólya, 1945/1973). Can, and if yes, how problem-solving heuristics be taught? (Schoenfeld, 1985; Koichu, Berman, & Moore, 2007).
- What are the attributes of mathematical problem solving besides heuristics? (Schoenfeld, 1985). What is the role of affect in problem solving? (DeBellis & Goldin, 2006).
- How do the problem-solving attributes come to cohere? (Schoenfeld, 1992). How does decision making occur when an individual solves a problem? (Schoenfeld, 2012).
- What sociomathematical norms should be promoted for supporting learners' intellectual autonomy in problem solving? (Yackel & Cobb, 1996).

Some of these and such queries have been addressed. For instance, we know a lot about phases and cycles involved in problem solving by experts and by some categories of students. The use of problem-solving attributes and phases as a research tool has proven to be particularly helpful for analysing the phenomenon of unsuccessful problem solving. For example, if there is evidence that a particular belief about mathematics is depriving an individual from persisting when solving a problem, then that belief might provide a sufficient explanation for the problem-solving failure (see Furingetti & Morselli, 2009, for an elaborated example). When, however, one problem is solved and another is not by an individual who possesses all needed mathematical, cognitive and affective resources for solving both problems, the explanation of the success and the failure can sometimes be sought outside of the existing problem-solving models and frameworks (Koichu, 2010).

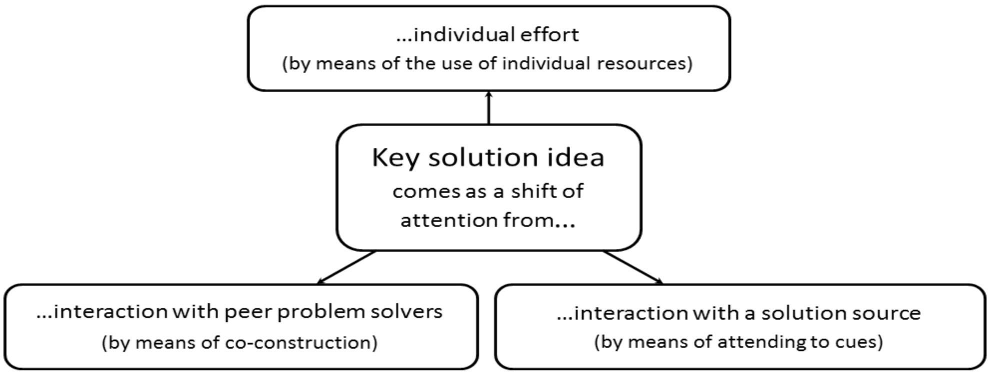

Figure 1: Confluence model of mathematical problem solving

Some of the queries about problem solving have proven to be hard nuts to crack (e.g., Schoenfeld, 1992, 2012). For example, Schoenfeld's (1992) question about how the problem-solving attributes – knowledge, heuristics, control and beliefs – come to cohere has been under research scrutiny for more than two decades. Furthermore, different problem-solving frameworks and models have emerged from different contexts and situations. As a result, it is sometimes difficult to use one model outside its original context. A recent example of extending the scope of a particular problem-solving model to another context is given by Clark, James and Montelle (2014) (their work is discussed in more detail below), but it is rather an exception than a trend (cf. Koichu, 2014, for a collection of views on the recent trends in research on problem solving). As a rule, problem-solving frameworks and models co-exist with little coordination. This is one of the reasons for which, in terms of Mamona-Downs and Downs (2005), a clear identity for problem solving in mathematics education has not yet been developed.

The goal of this article is to present an exploratory problem-solving framework that has the potential to consolidate some of the previous frameworks and can serve as a research and pedagogical tool in different educational contexts. The framework is, in a way, a tool for better understanding the process that Pólya (1945/1973) might term as a heuristic search embedded in the planning phase of problem solving. The central query of the framework is, simply stated, "Where can a solution to a problem come from?" A more precise formulation of the query is as follows: "Through which activities and resources can a chain of shifts of attention towards an invention of a key solution idea to a mathematical problem be constructed by a problem solver in socially different educational contexts?"

CONFLUENCE FRAMEWORK

The confluence framework is schematically presented in Figure 1. A *key solution idea* notion is in the core of the framework. It is a solver-centered notion. Along the lines defined by Ramon (2003), *a key solution idea* is a heuristic idea [1] which is invented by the solver and evokes the conviction that the idea can be mapped to a full solution to the problem. The full solution is a solution, which, to the solver's knowledge, would be acceptable in the educational context in which problem solving occurs.

Examples of key solution ideas include: an auxiliary construction that enables the solver to see a chain of deductions connecting the givens of a geometry problem with the claim to be proved, a way of reassembling the terms of a sophisticated trigonometric equation so that the solver begins to see the equation as a quadratic one, a way of representing a word problem (e.g., Euler Seven Bridge Problem) as a graph that makes the solution to the problem transparent. One can see connections between the notions of a key solution idea and of an illuminating or insightful idea. An insight, however, is frequently defined as restructuring the initial representation of the problem followed by so-called aha-experience. A key solution idea does not necessarily emerge at once and accordingly its invention is not necessarily accompanied by an aha-moment.

The framework relies on three premises. *First premise:* Even when a problem is solved in collaboration, it has a *situational solver*, an individual who invents and eventually shares its key solution idea. *Second premise:* A key solution idea can be invented by a situational solver as a shift of attention in a sequence of his or her shifts of attention when coping with the problem. *Third premise:* Generally speaking, a solver's pathway of the shifts of attention can be stipulated by: (i) individual effort and resources, (ii) interaction with peer solvers who do not know the solution and struggle in their own ways with the problem or attempt to solve it together, (iii) interaction with a source of knowledge about the solution or its parts, such as a textbook, an internet resource, a teacher or a classmate who has already found the solution but is not yet disclosing it. The possibilities (i)-(iii) are intended to embrace all frequent situations of problem-solving. These possibilities can be employed in separation or complement each other in one's problem solving.

The framework is a *confluence* framework because it consolidates ideas taken from several frameworks and theories by means of a strategy that has been introduced at CERME8 as *networking theories by iterative unpacking* (Koichu, 2013). Mason's theory of shifts of attention (Mason, 1989, 2008, 2010) serves as the overarching theory of the framework. Additional theories are embedded. Each of the next four sub-sections begins with a brief introduction of a particular theory and proceeds to show how the theory contributes to the confluence framework.

Invention of a key solution idea as a shift of attention

Mason's theory of shifts of attention had initially been formulated as a conceptual tool to dismantle constructing abstractions (Mason, 1989) and then extended to the phenomena of mathematical thinking and learning (Mason, 2008, 2010). Palatnik and Koichu (2014, submitted) adopted the theory as a tool for analysing insight problem solving.[2] Mason (2010) defines learning as a transformation of attention that involves both "shifts in the form as well as in the focus of attention" (p. 24). To characterize attention, he considers not only *what* is attended to by an individual but also *how* the objects are attended to. To address the how-question, Mason (2008) distinguishes five different *ways of attending* or *structures of attention*.

According to Mason (2008), *holding the wholes* is the structure of attention, where the person is gazing at the whole without focusing on particular. *Discerning details* is a structure of attention, in which one's attention is caught by a particular detail that becomes distinguished from the rest of the elements of the attended object. Mason (2008) asserts that "discerning details is neither algorithmic nor logically sequential" (p. 37). *Recognizing relationships* between the discerned elements is a development from discerned details that often occurs automatically; it refers to specific connection between specific elements. *Perceiving properties* structure of attention is different from recognizing relationships structure in a subtle but essential way. In words of Mason (2008), "When you are aware of a possible relationship and you are looking for elements to fit it, you are perceiving a property" (p. 38). Finally, *reasoning on the basis of perceived properties* is a structure of attention, in which selected properties are attended to as the only basis for further reasoning. Palatnik and Koichu (2014, submitted) added a *why*-question to Mason's *what*- and *how*- questions: Why does an individual make shifts from one object of attention to another in the way that he or she does? Possible ways of addressing this query are related to the obstacles embedded for the solver in attending to a particular object and to continuous evaluation of potential "gains and losses" of the decision to keep attending to the object or shift the attention to another one (Metcalfe & Kornell, 2005).

The process of inventing a key solution idea is seen as a pathway of the solver's shifts of attention, in which objects embedded in the problem formulation or *problem situation image* (this notion is used in the meaning assigned to it by Selden, Selden, Hauk, & Mason, 2000) are attended to and mentally manipulated by applying available schemata. The process at large is goal-directed, but particular shifts can be sporadic. A pathway of the shifts of attention depends on various factors, including: the solver's traits, his or her mathematical, cognitive and affective resources and a context in which problem solving takes place. I now turn to discussing the specificity of the process in three socially different educational contexts.

Shifts of attention in individual problem solving

The lion's share of the data corpus that underlies the development of the foremost problem-solving frameworks (e.g., Schoenfeld, 1985; Carlson & Bloom, 2005) consists of cases of individual problem solving. Carlson and Bloom (2005) consider four phases in individual problem solving by an expert mathematician: orientation, planning, executing and checking. The model also includes a sub-cycle "conjecture-test-evaluate" and operates with various problem-solving attributes, such as conceptual knowledge, heuristics, metacognition, control and affect. Generally speaking, Carlson and Bloom's framework offers a kit of conceptual tools that can be used for producing thick descriptions of individual problem-solving effort. These conceptual tools enter the suggested confluence framework as tools for addressing *how*- and *why*-questions about the shifts of attention.

For example, when solving a challenging geometry problem, a solver can direct her attention to proving similarity of a particular pair of triangles, and then shift her attention to another pair of triangles. The pre- and post-stages of the shift can be described as two "conjecture-test-evaluate" sub-cycles within the planning phase. The shift itself can be viewed in terms of the mathematical, heuristic and affective resources of the solver (see Palatnik & Koichu, 2014, for an elaborated example).

Shifts of attention when interaction with peers is available

While studying problem-solving behaviours in small groups of undergraduate students, Clark, James and Montelle (2014) extended Carlson and Bloom's (2005) taxonomy of problem-solving attributes by introducing two new categories/codes. They termed them *questioning* and *group synergy*. The former category was introduced in order to give room in the data analysis to various questions (for assistance, for clarification, for status, for direction) that the participants had asked. The latter category appeared to be necessary in order "to capture the combination and confluence of two or more group members' problem-solving moves that could only occur when solving problems as a member of a group... A key characteristic of this group synergy code is that it leads to increased group interaction and activity, sometimes in unanticipated and very productive ways." (pp. 10–11).

Indeed, when a possibility to collaborate with peers is available to a solver, his or her shifts of attention can be stipulated by inputs of the group members, especially when the inputs are shared in some common problem-solving space (e.g., a small-group discussion or an internet forum) in a non-tiresome way. Here I would like to stop on the word "sometimes" in the above quotation. The possibility to collaborate can increase one's chances to produce a key solution idea, but can also be overwhelming or distracting. When nobody in a group knows how to solve the problem, the other members' inputs of potential value are frequently undistinguishable for the solver from the inputs of no value. Consequently, it can become too effortful for the solver to follow and evaluate the inputs of the others.

Schwartz, Neuman and Biezuner (2000) deeply explored, in laboratory setting, the cognitive gains of two children, who fail to solve a task individually, but who improve when working in peer interaction. They characterized the situations, in which (in their words) *two-wrongs-make-a-right* vs. *two-wrongs-make-a-wrong*. The mechanisms of co-construction behind *two-wrongs-make-a-right* phenomenon were: the mechanism of disagreement, the mechanism of hypothesis testing, and the mechanism of inferring new knowledge through challenging and conceding. These mechanisms might be involved in those cases of collaborative problem solving, in which group synergy led the participants in Clark, James and Montelle's (2014) study to "very productive ways" (ibid) of solving the given problems.

The confluence framework seeks to consolidate the theoretical insights of the aforementioned studies. In particular, to further explore the phenomenon of group synergy, it seems me necessary to acknowledge that the above mechanisms can become active on condition that at least sometimes a solver shifts his or her attention from an object that he or she is being exploring to an object attended to by the peer.

An example of the processes of co-constructing a key solution idea as pathways of students' shifts of attention is drawn from an on-going study on high-school students' long-term geometry problem solving. The example concerns a situation, in which a group of 16 10th grade students were engaged in solving the following problem:

> Two circles with centres M and N are given. Tangent lines are drawn from the centre of each circle to another circle. The points of intersection of the tangent lines with the circles define two chords, EF and GH (see Figure 2). Prove that segments EF and GH are equal.

The students could solve the problem individually, but also share their ideas in a closed forum in one of the social networks. Interestingly, all the students indicated in the reflective questionnaires that they had worked collaboratively only for about 40% of time that had been devoted to the problem. (On average, the students worked on the problem for 3 hours). The

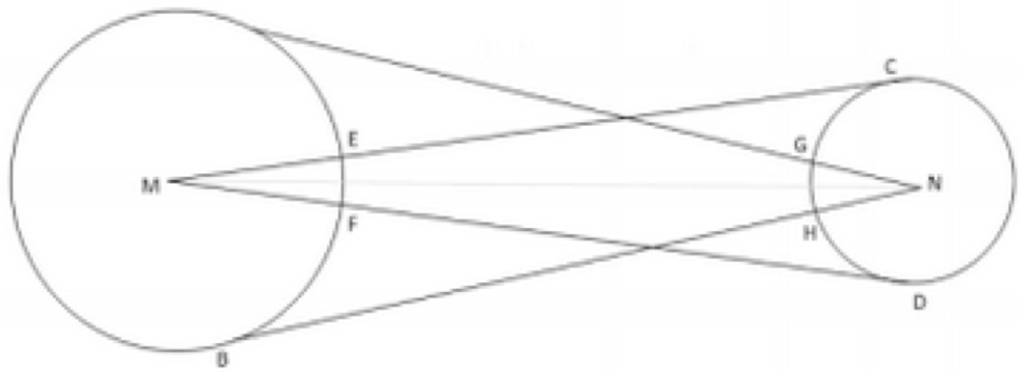

Figure 2: A problem about two chords

shifts of attention of individual problem solvers were stipulated either by individual or by shared problem-solving resources. As a rule, the students chose to collaboratively work in the forum when they were stuck and sought for new ideas or for the feedback on their incomplete ideas. In a few cases the students chose to shift their attention to the ideas of the other students.

Shifts of attention when interaction with a solution source is available

The option to interact with a source of knowledge about a key solution idea to a problem can drastically change a pathway of one's shifts of attention, up to the point that the entire process can stop being a problem-solving process and become a solution-comprehending process. The suggested framework seeks to encompass only the situations in which a solution source is present as a provider of cues to the solution or as a convenient storage of potentially useful facts, but not as a source of *telling* the solution. Such situations are common, for instance, when a teacher orchestrates a classroom problem-solving discussion.

When a source of knowledge about the solution is present but does not tell the solution, the solvers may attempt to extract the solution from the source (e.g., see *questions for assistance* and *questions for direction* in Clark, James, & Montelle, 2014; see also Koichu & Harel, 2007). In some cases, the solver's shifts of attention may occur as a result of a conflict that emerges when more knowledgeable and less knowledgeable interlocutors assign different meanings to the same assertions (cf. Sfard, 2007, for commognitive conflict).

For example, the assertion "Triangle similarity is a good idea" can either pass unnoticed in the group discourse or be a trigger for the solver to shift his or her structure of attention. The effect of the assertion would depend on who it has come from, a regular member of the group or a teacher or a peer who acts as if she has already solved the problem. The occurrence of the shift in one's attention as a result of another person's assertion depends not only on that person's status in the group. It is mainly the matter of different meanings that can be assigned to the assertion by different individuals. In one case, the assertion about triangle similarity may be perceived as, "It is possible that similarity helps," in another, "I've tried it and it helps," and in yet another, "This is the direction approved by the authority." Stimulated by Sfard (2007), I suggest that such a conflict of meanings can first be unnoticed, then it can hinder the communication, and then (when the assigned meanings are explicated), it can help the less knowledgeable solvers to progress.

SUMMARY AND FURTHER DEVELOPMENT

Developing a confluence framework of mathematical problem solving that would be applicable to different educational contexts is motivated by several causes. First, with few exceptions, the existing problem-solving frameworks utilize different conceptual tools for exploring problem solving in socially different educational contexts. Second, the foremost frameworks are comprehensive within the problem-solving contexts from which they have emerged but it is sometimes difficult to apply them to additional contexts. Third, in spite of the comprehensive nature of the existing frameworks, the central problem-solving issue of inventing (as opposed to recalling) a solution method is still not sufficiently understood. At the same time, theoretical tools that can help to progress the state of the art are available from the other sub-fields of mathematics education research. Hence, a *confluence* framework.

In this article, a particular way of constructing a confluence framework is presented. The confluence effect is pursued by considering common roots of problem solving in three socially different contexts. This is done in terms of Mason's theory of shifts of attention, which initially had been constructed for other reasons. Simultaneously, the specificity of the attention shifts in different problem-solving contexts is considered by means of additional theoretical constructs. The use of the model as a research tool for understanding heuristic aspects of problem solving is stipulated by availability of research methodologies for identifying and characterizing shifts of attention in socially different problem-solving contexts. In part, such methodologies are available from past research (e.g., Mason, 1989, 2008, 2010; Palatnik & Koichu, 2014) but they should be further developed. Our research group currently works in this direction and explores long-term geometry problem solving supported by online discussion forums.

As mentioned, the framework is only *exploratory*. The outlined mechanisms of attending to, proceeding of and shifting between objects of attention should be further unpacked. At this stage, it seems that further unpacking would require the adaptive use of selected theories that have been developed outside of the field of mathematics education. For instance, research on learners' decisions about how to allocate study-time (e.g., Metcalfe & Kornell, 2005) can be a source of insights about why some objects of attention are short-living, and the others are long-living. Research on hypothetical thinking and cognitive decoupling (Stanovich, 2009) can be useful for understanding how the attended objects are mentally manipulated. The hope is that, eventually, the confluence framework would have power not only to usefully describe, but also explain the emergence of problem-solving ideas in different educational contexts.

ENDNOTES

1. Ramon (2003) explains what a heuristic idea of a proof is as follows: "This is an idea based on informal understandings, e.g. grounded in empirical data or represented by a picture, which may be suggestive but does not necessarily lead directly to a formal proof." (p. 322). Note that not any heuristic idea is a key idea.

2. The next 10 sentences consist of an abridged version of the description that appears in Palatnik and Koichu (2014).

Theories to be combined and contrasted: Does the context make a difference? Early intervention programmes as case

Lena Lindenskov[1], Pia Beck Tonnesen[2], Peter Weng[2] and Camilla Hellsten Østergaard[2]

1 Aarhus University, School of Education, Aarhus, Denmark, lenali@edu.au.dk

2 Metropolitan University College, Department of School and Lerning, Copenhagen, Denmark

The constructivist paradigm is the primary underpinning of the Mathematics Recovery Programme (MRP) in Australia, the UK, the USA and Canada. The critical mathematics education paradigm is the primary underpinning of the Early Mathematics Intervention Programme for Marginal Groups in Denmark (TMTM for Tidlig Matematikindsats Til Marginalgrupper). The paper tells the story of how networking strategies have informed the design of TMTM: one strategy is combining elements from the two paradigms; another strategy is contrasting elements from the paradigms. The two constructs 'the six stages-construct' and 'the math holes-construct' have been decisive for the networking. Possible influences from the Danish educational contexts on the networking processes are put forward for further discussion.

Keywords: Networking theories, early intervention in mathematics, math holes, constructivism, critical mathematics education.

CULTURAL CONTEXT AND OUR CULTURAL CONTEXT

A main issue at CERME9 was cultural contexts in European research in mathematics education. What is meant by cultural contexts and what are the mechanisms by which cultural contexts influence research and practice in mathematics education were displayed in the plenary by Barbara Jaworski, Mariolina Bartolini Bussi, Edyta Nowinska and Susanne Prediger.

This paper primarily focuses at issues in primary school mathematics in a certain cultural context: the Danish educational culture. The development of school mathematics in Denmark is in no way isolated from Nordic, European or global tendencies and policies. For instance the 2004 OECD review of the Danish primary and lower secondary school emphasized the need to support failing pupils in mathematics in the first school years (Mortimore, David-Evans, Laukkanen, & Valijarvi, 2004). It is evident that the OECD review has influenced Danish policy, and so have Danish teachers' and researchers' initiatives to improve the school support for pupils at risk of falling behind in their mathematics learning.

It seems natural to Danish mathematics teachers and educational researchers to get inspirations from abroad, also when it comes to interventions for pupils at risk. Generally speaking, inspirations from theory and practice in school mathematics in especially the Netherlands have been strong since 1970s, and Realistic Mathematics Education from the Freudenthal Institute is still influential.

Still, some characteristic aspects of the Danish school mathematics seem evident and are visible in national goals and aims despite influences from international politics and tendencies. This paper will look into the tension between national and international trends for educational research and practice, by looking at the development processes behind the Danish early mathematics intervention programme for marginal groups (TMTM for Tidlig Matematikindsats Til Marginalgrupper) as a case. Especially the theoretical networking in the development processes is to be explored. We are ourselves central persons in these development processes, which we aim to document and critically assess.

We generally argue that how theories are being interpreted and networked locally is influenced by local contexts as for instance Danish school mathematics cultures. It is shown that culture does matter for values and practices in mathematics education. As an example, teachers in London and in Beijing hold different views on mathematical learning and teaching. Teachers in London see syllabus and textbooks as less important in determining the content taught than interest and meaningfulness, which is again opposite to teachers in Beijing (Leung, 2006). Similarly, teachers in London see students' ability as more important for their learning than effort, which is the opposite of teachers in Beijing. We claim that it is by now a well-known fact that culture matters for values and practices in mathematics education, but how culture matters in networking theories, is not yet well addressed.

CONSTRUCTIVIST THEORY UNDERPINNING MRP

Among the most common implemented programmes internationally for early intervention in mathematics the Mathematics Recovery Programme (MRP) is to our knowledge the most described and researched one. It is broadly implemented in Australia, the UK, Ireland and the USA (Wright, Martland, & Stafford, 2000) (Wright, Ellemor-Collins, & Tabor, 2011). We have studied programme materials and background papers and we have made personal contacts to leading figures like Robert J. Wright and like Noreen O'Loughlin, University of Limerick.

MRP is an intensive one-to-one tutoring offered to first graders falling behind and at risk of mathematics difficulties. Since 2006 the material *Teaching number – Advancing children's skills and strategies* has been suggested for whole-class teaching, too. Tutor training is a mandatory part of the programme. A learning framework and an instructional framework are described in detail. The tutoring is meant to be diagnostic, so that instruction can be adapted to pupils' reactions.

The mathematical content in MRP focuses on numbers and arithmetic. The MRPMP covers knowing and understanding numbers, names and symbols, basic strategies in the four operations (Wright, Martland, Stafford, & Stanger, 2006) and supplemented with basic understanding of part-whole concept (Wright et al., 2011).

Important for this paper are the theories behind the MRP, which is drawn primarily from Leslie P. Steffe and colleagues. Steffe was engaged as early as 1976 in establishing the research program, Interdisciplinary Research on Number (IRON). As documented in (Steffe, van Glasersfeld, Richards, & Cobb, 1983), (Steffe, Cobb, & van Glasersfeld, 1988) and (Steffe, 1992), a tremendous empirically based work has been going on to explore how children reason and meaningfully grasp processes and concepts related to numbers and arithmetic. The research has led to insights into many diverse aspects of children's mathematical knowledge and how this knowledge is developed.

The constructivist underpinning manifests itself by maintaining that knowing is not passively importing other peoples' knowledge as if you were receiving a birthday gift. It is maintained and underlined that knowing is an active endeavour for the person, who is acquiring/constructing knowledge through genuine problem solving.

THE SIX STAGES CONSTRUCTS

The idea of development through stages runs as a general structuring idea through the work of Steffe et al. Like the construct of the five stages of geometrical reasoning from van Hiele (1985/1959), it seems that an underlying idea of stage has been transformed into several constructs of several and often six stages by Steffe et al. and by their followers.

While the descriptions of the counting stages used in solving addition and subtraction problems is grounded through the work of Steffe et al., the stage constructs are further developed by Wright (1991, 1994) and by Wright and colleagues (2000, 2006, 2011). The stages of children's development of different areas of mathematical knowledge are put forward in the learning framework and in the instruction framework of MRP. The organisation of how tutors' come to observe pupils' development and how tutors adapt instruction to the pupils' present knowledge is facilitated by the lenses of stages.

In Wright and colleagues (2006), the idea of six early arithmetical strategies is used as the main organising principle. The six stages go from stage zero to perceptual, to figurative, to initial number sequence, to implicitly nested number sequence and end with explicitly nested number sequence. Each stage is described. At the last one, the explicitly nested number sequence, the child uses a range of non-count-by-ones strategies. The child also uses a known result, adding to ten and commutativity, and the child knows that subtraction is the inverse of addition (p. 9).

The Wright and colleagues' book from 2006 presents a network of stages in each of the mathematical area covered. Also for *forward number word sequences and number word after* six stages are described. The same for *backward number word sequences and number word before,* while *number identification* has five stages, and *base-ten arithmetical strategies* has three stages.

CRITICAL MATHEMATICS EDUCATION

The Nordic part of critical mathematics education has primarily been dominated by the Danish scholars Mogens Niss (1984) and Ole Skovsmose (1994, 2001) and the Norwegian scholar Stieg Mellin-Olsen (1987, 1991). Niss underlined that it is an important but difficult task for research and practice in mathematics education to relate to authentic applications of mathematics from a critical stance of view, and to let mathematics education address fundamental social functions of mathematics and school mathematics. For school mathematics this implies mathematical modelling and project work. Skovsmose added the philosophical view of learning mathematics as investigation of mathematical landscapes. For school mathematics this implies a critique towards exercise paradigm and a focus on communication between teachers and pupils. Skovsmose also invented the concept of pupils' foreground as just as important as pupils' background. Mellin-Olsen (1991) added the project work about authentic applications should be for all. It should be for less able and less motivated pupils as well as for all other pupils. He also added the metaphor of travelling as a tool to understand teachers' thinking about instruction. He recognised that teachers talked about their mathematics instruction as being the drivers in the busses full of pupils.

THE MATH HOLES-CONSTRUCT

Based on Nordic critical mathematics education we have researched special needs education in Denmark. We found that the ideas from Niss, Skovsmose and Mellin-Olsen of mathematics instruction and learning were all promising. For instance we found the idea of mathematics instruction and learning as a common teacher-pupil investigation of mathematical landscapes promising. Since 2003 Bøttger, Kvist-Andersen, Lindenskov and Weng (2004), we have therefore been involved in demonstrating mathematics learning as a journey in landscapes, which evolve with hills and holes as you travel. Many routes can be appropriate for the teachers and students involved, depending of their backgrounds and foregrounds and depending on available authentic (in Freudenthal's sense *realistic*) materials and activities for problem solving and for modelling.

Closely connected to the general idea of investigating or constructing mathematics landscapes, we needed to add a specific idea of pupils at risk of becoming low-level performers. Therefore we invented the math holes-construct.

The math holes-construct metaphorically describes pupils in difficulties as pupils, which for the moment are stuck and are not progressing further into the mathematics landscape. It is as if the pupil has fallen into a trap or – as we finally decided to name it – it is as if the pupil has fallen into a hole.

Sure, it is not our intention with the math holes-construct to see learning mathematics in a negative biased light. Neither is it our intention to avoid mathematical elements, which may cause obstacles, as for instance learning the rules of the positional decimal number system. Our intention is to develop pedagogical constructs to help teachers recognise and support every child's mathematical learning. Therefore it is important to identify when a child is stuck and to provide intervention models, materials and teacher training for how schools and teachers can help getting the pupil moving again.

Within the math holes-construct pupils in difficulties are not pupils lacking behind or pupils with special neurological characteristics as implied by some definitions of dyscalculia. Within the math holes-construct pupils in difficulties are pupils who stopped progressing learning. Gervasoni and Lindenskov (2011) describe the construct with the following:

> When mathematics is seen as a landscape it means that whenever students stop learning and feel stuck it is as if they 'fall into a hole'. There are several ways for a teacher to cope with a student's 'fall'. First, a teacher can invite the student to move to another type of landscape, maybe far away from the hole in which the student was stuck; this means that even when students fail to thrive in one area of mathematics there are still many other mathematics landscapes to experience and learn. Second, teachers can help students 'fill up' the hole from beneath with mathematical building stones; or third, teachers can 'lay out boards over the hole' in order to let the student experience new and smart mathematical approaches. (p. 317)

It is, in our view of the math holes-construct, crucial to draw attention to the individual pupil: Much still needs to be done, following Ginsburg's (1997) more than 15-years-old call for teaching experiments focusing on pupils with learning difficulties, as children today are exposed to physical and social environments that are rich in mathematical opportunities. In Denmark as in many other countries, children today are exposed for instance to even very big numerals in computer and board games and in family activities. This questions the generality of the existing cognitive models of children's reasoning and of the theories of instruction. For instance it questions the motivating effect as well as the learning effect of splitting instruction on numbers into first 1–20, and then 1–100, as it is done in MRP.

What children are exposed to rapidly develops, and no one can predict what will happen just a few years from now. This means that the generalisation of identified mathematics learning trajectories in research studies may not be generalizable to all children in the world. On the other hand, the learning trajectories, which are found in research, and upon which MRP have built their stages, do show valuable insight into children's learning, which is not visible for teachers even with profound training. We do advocate for teachers to obtain extended knowledge on researched learning trajectories.

NETWORKING THEORIES TO INFORM DEVELOPMENT OF TMTM

Our design processes towards the Danish model for early intervention for marginal groups TMTM were highly informed by networking theories from constructivism and from critical mathematics education. Tutor material is published in a 191 pages book (Lindenskov & Weng, 2013), but lots of work were done before.

Certainly some authors see the two paradigms as contradictory, and Mellin-Olsen is a prominent example. He disliked the focus on the cognitive development of the individual pupil in the constructivist paradigm.

But as researchers have showed for the last decade networking theories are much more than rejecting or approving specific theories. Bikner-Ahsbahs and Prediger (2010, p. 492) suggested the following illustration of a landscape of strategies for connecting theoretical approaches (Figure 1).

We chose to let the development processes for TMTM be informed by *contrasting* some of the above mentioned theories and constructs and by *combining* others.

The *combining* part includes the deep insight into individual pupils' problems and development coming from Steffe and colleagues' constructivistic research *combined* with the math holes-construct.

Also in the Danish programme tutor training is a mandatory part of the programme, and also the tutoring is meant to be diagnostic, so that instruction can be adapted to pupils' reactions.

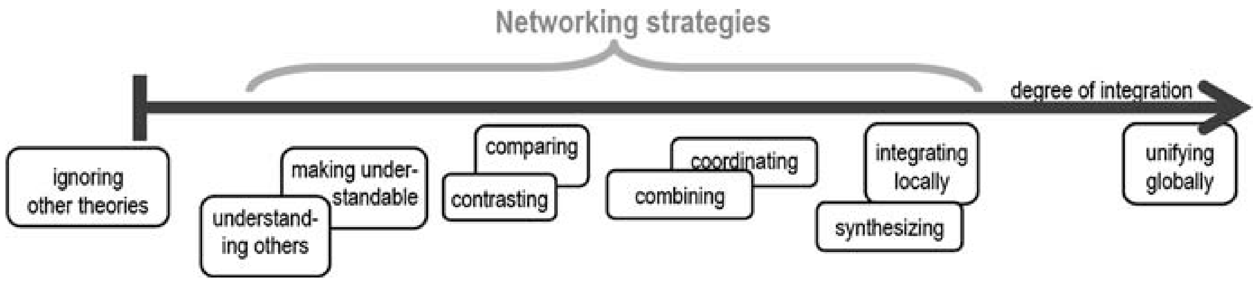

Figure 1

The *contrasting* part includes that Steffe and colleagues' focus solely on numbers and arithmetic *contradicts* the broader goals and aims in critical mathematics instruction. It is not enough for a Danish model to focus on numbers and arithmetic. We find them necessary, but not sufficient.

The *contrasting* part also includes that the stage constructs *contrast* the idea of learning mathematics as a journey where parts of the mathematical landscapes are being constructed as pupils and teachers travel together. The paths are chosen by teachers and pupils collaboratively, and the teachers take into account children's background and foreground in order to motivate the children. The stage construct does not allow that the teachers also take the pupils' foreground into account.

CONTEXTUAL INFLUENCE ON THE THEORY NETWORKING

School cultures in Denmark are influenced by the German/continental tradition in educational philosophy. Danish language has, like German language, two main concepts for 'Education': one is 'Dannelse' (German: Bildung), another is 'Uddannelse' (German: 'Erziehung').

At the level of school mathematics this tradition emerges in the common aim for primary and lower secondary school mathematics by pointing at everyday life, citizen life, creativity, problem solving, and democratic responsibility and impact:

> The aim is that students develop mathematical competences and acquire skills and knowledge in order to appropriately engage in math-related situations in their current and future everyday, leisure, education, work and citizen life.
>
> Subsection 2. Students' learning should be based upon that they independently and through dialogue and cooperation with others can experience, that mathematics requires and promotes creative activity, and that mathematics provides tools for problem solving, reasoning and communication.
>
> Subsection 3. Mathematics as a subject should help the students experience and recognize the role of mathematics in a historical, cultural and social context, and that students can reflect and evaluate application of mathematics in order to take responsibility for and have an impact in a democratic community. (Undervisningsministeriet, 2014, our translation)

On this background it was evident, that the constructivist paradigm had to be combined with the critical mathematics education. The constructivist paradigm gave a too narrow picture of what should be learnt.

According to the choice of subject matter, the school mathematics tradition emerges in broad scope throughout all school grades and for all pupils. Danish pupils are not streamed before Grade 10. This means that skills, conceptual understanding and authentic applications are taught to all pupils. Mathematical competences as well as mathematical conceptual fields like numbers and algebra, geometry and measurement, and statistics are included for all pupils from the very start of primary school.

Besides it is our impression that Danish teachers have a relatively high self-confidence and a relatively strong wish to influence. From the European comparative perspective it seems as if Danish teachers more than teachers in England prioritise the pupils' personal development and see the pupils' mathematical development as a means for personal development (Kelly, Pratt, Dorf, & Hohmann, 2013).

This led us to include a group of teachers, in a decisive way, in design cycles in the development towards a Danish model (Lindenskov & Weng, 2014), and it led us to make the material much open for teachers' adaptation. This also led us to *confront* the stage construct with the math holes-construct. With a stage construct less is up to the tutor to decide, and with a math holes-construct pupils' emotional and motivational background and foreground are easier to take into account.

CONCLUSION

Thus, the Danish developmental and research projects on early intervention are based on an original construct, the math holes-construct. But the whole development processes are very much informed by *combining* and *contrasting* theories.

With Skott (2015), in our view networking theories is very much depending on what we mean by theory, constructs and conceptual framework. Skott points to decisive elements as a) preliminary understanding of concepts involved, b) theoretical stance on interpretation of these concepts, and c) the overall rationale for engaging in the field of inquiry.

The math holes-construct implies differences compared to MRP concerning all three elements, although similarities between MRP and TMTM exist.

Tool use in mathematics: A framework

John Monaghan

University of Agder, Kristiansand, Norway, john.monaghan@uia.no
University of Leeds, Leeds, UK

In the course of research into the interpretation of tools in the didactics of mathematics I found both voids and conflicts. This paper presents the results of my research and a resultant statement on tool use in mathematics education. The statement incorporates constructs from several theoretical frameworks and I consider the consistency of my statement on tool use with regard to activity theory.

Keywords: Activity theory, agency, artefacts, mediation, tools.

INTRODUCTION

In the course of work on tool use in mathematics I examined literature which I summarise in this paper. The literature sit in various theoretical frameworks and this paper, in the language of Prediger, Bikner-Ahsbahs and Arzarello's (2008), can be considered as an attempt to 'synthesise' frameworks with regard to a statement on tool use in the didactics of mathematics. This synthesis, however, does not aim at synthesising complete theories but synthesising activity theory with principles from other theories. This paper has the following structure: a definition of tools; a survey of theoretical frameworks with regard to tools; an exposition of activity theory with regard to tools; actor network theory ideas that augment an activity theoretic account of tools; an activity theoretic statement on tool use in mathematics education which incorporates ideas from outside of activity theory, and a consideration of the consistency of this statement with regard to networking theories.

TOOLS: A DEFINITION

I define a tool via four action-related distinctions, the first of which is between an artefact and a tool. An artefact is a material object which becomes a tool when it is used by an agent to do something; a compass becomes a tool when it is used to draw a circle (its intended purpose) or to stab someone. This establishes that tool use cannot be separated from the animal using the tool and the purpose of use. After being used as a tool (for whatever purpose), the compass returns to being an artefact. The materiality of an artefact is not just that open to touch. An algorithm, e.g., for adding two natural numbers, is an artefact. It is material in as much as it can be written down or programmed into a computer. My second distinction is between an artefact/tool and ways of using the artefact/tool. For example, I could use a calculator to perform 45 + 67 by typing in '45 + 67=' or I could imitate the standard written algorithm (adding the units, storing the result) and adding the tens and adding on my stored results. My third distinction is between the mental representation of a tool and material actions in tool use. This distinction comes with an interrelationship: to carry out material actions with an artefact you need some form of mental representation, which may be quite crude, of how to act with the artefact-tool, but actions with the artefact-tool will provide feedback to the user which may change the mental representation. My fourth distinction is between signs and tools. Signs, like tools, are artefacts but a sign points to something whereas a tool does something. Having said this, signs or systems of signs, can function as tools. Similarly representations can function as tools but they may also have non-tool functions, e.g., to point to an object.

Is there such a thing as a 'mathematical tool'? – only in use, a compass is a mathematical tool when it is used to draw a circle but not when it is used to stab someone. When artefacts are used for mathematical purposes they generally incorporate mathematical features, e.g., a compass encapsulates the equidistant relationship between the centre and points on the circumference of a circle.

A SURVEY OF FRAMEWORKS WITH REGARD TO TOOLS

I conduct an historical tour of theoretical frameworks employed in Western mathematics education. I select papers from the 1960s to the present which reflect dominant 'grand theories' over this time that address or ignore tools. Behaviourism regarded artefacts as a means of stimulating a response in a subject. Suppes (1969), for example, considers computers as tutorial systems that can provide:

> individualized instruction [where the] intention is to approximate the interaction a patient tutor would have with an individual student ... as soon as the student manifests a clear understanding ... he is moved on to a new concept and new exercises." (ibid, p.43).

Suppes does not consider the environment in which the tool is used. During the period when behaviourism ruled two psychologists, E. and J. Gibson, ventured on a non-behaviourist route to the theory construct of affordances (and constraints):

> The *affordances* of the environment are what it *offers* the animal, what it *provides* ... If a terrestrial surface is nearly horizontal ... nearly flat ... and sufficiently extended (relative to the size of the animal) and if its substance is rigid (relative to the weight of the animal), then the surface *affords support*. (Gibson, 1979, p. 127)

There is no mention of tools in this quote but mathematics educators have learnt that the construct 'affordances' is useful in considerations of the relevance of artefacts and digital software environments to students' mathematical learning.

The demise of behaviourism in mathematics education saw the rise of cognitive studies and Piaget was the Guru. The interesting thing about Piaget's extensive output with regard to tool use is that he says nothing at all about the role of tools in cognitive development. Piaget's work inspired several 'local theories' in mathematics education: Brousseau's theory of didactical situations (TDS), constructionism and constructivism. TDS was developed over decades starting in the 1960s. The influence of Piaget in Brousseau's work is explicit. An important construct of TDS came to be called the 'milieu' which includes the teacher, the materials and the designed learning strategies. I know of no explicit consideration of mathematical tools in 20th century TDS but tools are a part of the milieu. Papert, who spent several years with Piaget, experimented with children using the computer language *Logo*. Constructionism views that learning occurs through the construction of meaningful products. *Logo* is integral to constructionism but, despite statements that these languages equip students with tools to think with, there is no clear statement as to what a tool is in Papert (1980) and a clearer constructionist view of tools did not emerge until Noss and Hoyles (1996) – by which time constructionism had relinquished its Piagetian roots and embraced socio-cultural viewpoints.

Piaget's ideas inspired constructivism, which focused on the ontogenic development of the individual child but developed to include a focus on microgenetic (child-environment) development (social constructivism). Yackel and Cobb (1996) is a developed form of social constructivism which examines teacher-student discussions and argumentation in a classroom context. This paper introduced the construct 'sociomathematical norms'. The classroom considered in the paper had various resources (centicubes and an overhead projector) but the paper does not mention tools. This neglect has been noticed by others, e.g., Hershkowitz and Schwarz (1999, p. 149) "... socio-mathematical norms do not arise from verbal actions only, but also from computer manipulations as communicative non-verbal actions."

In summary, 20th century mathematics educator frameworks influenced by Piagetian ideas had little to say on tools in learning and teaching but outside of mathematics education, deep ideas, published in the 1970s, on tools were in circulation.

Wartofsky (1979) includes an essay on perception, "an *historically* evolved faculty ... based on the development of historical human practice" (ibid, p.189). Practice is "the fundamental activity of producing and reproducing the conditions of species existence ... human beings do this by means of the creation of artefacts ... the 'tool' may be *any* artefact created for the purpose" (ibid, p. 200). Wartofsky extends the concepts of artefacts to the skills required to use artefacts as tools:

> Primary artefacts are those directly used in this production; secondary artifacts are those used in the preservation and transmission of the acquired skills or modes of action or praxis by which this production is carried out. Secondary artefacts are therefore representations of such modes of action (ibid, p. 202)

Vygotsky (1978), published posthumously, was to have a profound influence on mathematics education. Vygotsky was interested in language, signs and mediation. His interest in tools was in their mediating qualities, "the basic analogy between sign and tool rests on their mediating function that characterizes each of them" (1978, p. 54). The difference between signs and tools rests on:

> The tool's function is to serve as the conductor of human influence on the object of activity; it is *externally* oriented; it must lead to a change in objects ... The sign, on the other hand, changes nothing in the object of a psychological operation. It is a means of internal activity aimed at mastering oneself; the sign is *internally* oriented. (ibid, p. 55)

The reader, however, may note the influence of both Wartofsky and Vygotsky in my definition of tools above. I now move on to the work of B. Latour and P. Rabadel[1]. Latour is a sociologist and, around 1980 and with others, established what is now called actor network theory (ANT); Latour (2005) is a fairly recent exposition. ANT is a theory about how to study social phenomena – by following the actors, where an actor is "*any thing* that does modify a state of affairs by making a difference" (ibid., 71). ANT symmetrically views both society and nature as being in a state of flux and looks to the performance of the actors in situations. Objects (artefacts/tools) can make difference in performance and so can be actors, exerting agency, in the playing out of social situations. Pickering (1995), who is 'almost ANT' in my opinion, examines practices of 20th century elementary particles physics. He accepts ANT's human and material agencies and adds 'disciplinary agency' (in our discipline $a+a=2a$ regardless of what we might want it to be). He proposes a 'dance of agency' where, in the performance of scientific inquiry, human, material and disciplinary agencies "emerge in the temporality of practice and are definitional of and sustain one another" (ibid., p.21). I see this in 'dance' in techno-mathematics lessons – a myriad of influences between students, teachers, computers and mathematics.

Rabadel introduced the 'instrumental approach' which distinguishes between an artefact, as a material object, and an instrument as a psychological construct. An instrument is an emergent entity that begins its existence when a person appropriates an artefact to do something; this has influenced my distinction, above, between an artefact and a tool. The instrumental approach has been well known in mathematics education since Guin and Trouche (1999). This views an instrument as a composite entity composed of the artefact and knowledge (knowledge of the artefact and of the task constructed in using the artefact). Artefact and the agent(s) are interrelated: the artefact shapes the actions of the agent, *instrumentation*; the user shapes the use of the artefact, *instrumentalisation*. The process of turning an artefact into an instrument is called 'instrumental genesis'. The agent brings her/his knowledge and the artefact brings its potentialities and constraints to the artefact agent interaction.

I leave my historical tour at this point with the observation that a lot of the frameworks used in mathematics education pay scant regard to the nature of the tools used in doing mathematics but frameworks initiated by Wartofsky, Vygotsky, Latour, Pickering and Rabardel provide interesting, though diverse, insights into the role of tools in activity. I now turn to the focus framework of this paper, activity theory.

ACTIVITY THEORETIC CONSIDERATION OF TOOLS

I briefly outline activity theory (AT), trace its genesis into mathematics education research (MER) and consider differences in approaches.

AT is an approach to the study of human practices. It sees constant change (flux) in practice. Activity became a focus for Vygotsky in his conviction that consciousness originated in socially meaningful activity. In AT 'object orientated activity' is the *unit of analysis*, that which preserves the essence of concrete practice. 'Object' here refers to *raison d'etre* of the activity. Educators employing AT must take care that they do not merely employ the word 'activity' without considering the object and the unit of analysis. Vygotsky's AT is often presented via a triangle with 'subject', 'object' and 'mediating artefacts' at its vertices. Leont'ev (1978) developed Vygotsky's work by considering individual and collective *actions* (usually with tools) and *operations* (things to be performed or modes of using tools) involved in socially organized *activity*. Engeström (1987) extends Vygotsky's and Leont'ev's frameworks to 'activity systems' and extends the focus on mediation through signs and tools to multiple forms of mediation including the community and social rules underlying activity. Activity systems research often examines interactive activity systems with a focus on the objects of activity in the two systems; the place of tools in such research usually emphasises tool use in the context of the whole system. I now turn to the influence of activity theory in MER.

I was curious of AT's introduction into Western MER literature and I traced its introduction into the journal *Educational Studies in Mathematics* (ESM). Two AT papers appeared in ESM in 1996. Crawford (1996) is an exposition of Vygotskian AT and asks "What difference does the use of tools such as computers and calculators make to the quality of human activity?" (ibid, p. 47) but does not explore the nature of tools further. Bartolini Bussi (1996) reports on a teaching experiment on geometric perspective. The word 'tool' has two uses in the paper: Leont'ev's theory as a tool for analysis; 'semiotic tools', which are defined via examples. In 1998 two ESM AT papers considered tool use in different ways to Bartolini Bussi (1996). Chassapis (1998) focuses on the processes by which children develop a formal mathematical concept of the circle by using various instruments to draw circles: by hand; using circle tracers and templates; and using a compass. "The process of learning to use a tool ... involves the construction of an experiential reality that is consensual with that of others who know how to use [the tool]" (ibid, p. 276). Pozzi, Noss and Hoyles (1998) focuses on nursing and ask "how do resources enter into professional situations, and how do they mediate the relationship between mathematical tools and professional know–how?" (ibid, p. 110) The paper states that AT provides evidence that "acts of problem solving are contingent upon structuring resources, including a range of artefacts such as notational systems, physical and computational tools" (ibid, p. 105). Radford (2000) focuses on early algebraic thinking "considered as a sign-mediated cognitive *praxis*" (ibid, p. 237):

> to accomplish actions as required by the contextual activities ... The sign-tools with which the individual thinks appear then as framed by social meanings and rules of use and provide the individual with social means of semiotic objectification (ibid, p. 241).

The first mention of Engeström in ESM is in Jaworski (2003, p. 249). This outlines "*insider* and *outsider* research and *co-learning* between teachers and educators in promoting classroom inquiry" and is not concerned with tool use in mathematics.

Thus, although AT is quite an old theory, it is a fairly recent theory in terms of Western MER and there is wide variation with regard to the meaning of tools in ESM AT papers from 1996 to 2003. After 2003 a considerable number of ESM papers used AT as a theoretical papers but I do not have room to summarise. To get a handle on contemporary AT conceptions of tools in MER I go to a special edition of *The International Journal for Technology in Mathematics Education* devoted to AT approaches to mathematics classroom practices with technology. For reasons of space I focus on three (of 11) papers which illustrate a range of approaches.

Chiappini (2012) focuses on the learning and teaching of algebra with software with a visual 'algebraic line' and conventional algebraic notation, to draw students' attention to the culture of mathematics. Chiappini is interested in 'cultural affordances', which, "allow students to master the meanings, values and principles of the cultural domain" (ibid, p. 138). With regard to tools, Chiappini's focus is the evaluation of software designed to exploit visuo-spatial and deictic affordances and allow teachers to consolidate student learning. Ladel and Kortenkamp (2013) focuses on the design and use of a multi-touch-digital-table to engage young children in meaningful work with whole number operations, "We want to restrict the students' externalizing actions to support the internalization of specific properties ... mediation through the artefact is characterized by restriction and focussing." Artefacts are the focus of attention and the word 'tool' is not mentioned in the paper. They hold that "the artefact itself does not have agency and is only mediating ... [but] the artefact changes the way children act drastically and in non-obvious ways" (ibid, p. 3). Mariotti and Maracci (2012) outline the Theory of Semiotic Mediation (TSM) with regard to "the use of artefacts to enhance mathematics learning and teaching, with a particular focus on technological artefacts" (ibid, p. 21); like Ladel and Kortenkamp (2013) above, the word 'artefact' is favoured over the word 'tool'. This paper continues the work of Bartolini Bussi (1996) considered in the previous section and is critical of research where "the mediating function of the artefact is often limited to the study of its role in relation to the accomplishment of tasks" (ibid). TSM views that "teaching-learning ... originates from an intricate interplay of signs... mathematical meanings can be crystallized, embedded in artefacts and signs" (ibid) The paper presents a rather strange (to me) take on mediation, "The mediator is not the artefact itself but it is the person who takes the initiative and the responsibility for the use of the artefact to mediate a specific content" (ibid, p. 22). To mediate the learning of mathematics the teacher has to design specific circumstances, a didactical cycle, aimed at fostering specific semiotic mediation processes.

Differences in the papers outlined above include the unit of analysis, cognition, the words used, mediation and agency. Some papers explicitly state the unit of analysis, e.g., Chassapis (1998), but many do not. Chassapis' unit of analysis is 'quite small' compared to Engeström's, the activity system itself. I think the 'size' of the unit of analysis impacts on the extent to which the AT analysis permits a study of microgenetic learner development with tools (i.e., Chassapis' unit of analysis allows a focus on cognition and tool use but details of cognitive development are easily 'lost' when the focus is on activity systems). With regard to the words used it is clear that some scholars use 'artefact' for what I refer to as a tool. This seems unimportant but the difference between sign and tool is important and the fact that this difference is sometimes blurred does not downplay this importance; some of the papers do not consider signs vs tools. With regard to mediation the biggest difference is between Ladel and Kortenkamp, where artefact mediation is central, and Maracci and Mariotti, which holds that people and not artefacts mediates. My final consideration concerns agency. Only Ladel and Kortenkamp comment on this, to claim that artefacts do not have agency. The differences noted above show that AT in MER is a collection of approaches in which there are many ways to view tools within AT.

ANT IDEAS THAT AUGMENT AN AT ACCOUNT OF TOOLS

I am drawn to AT as a framework as it mirrors my view that tools are important but tool use is not an activity in itself though tool use and activity are interrelated. But I detect an anthropocentric position in AT – even though AT recognises that people think through/with tools, people are at the centre, they appear as 'the' agents. This anthropocentrism is explicit in Maracci and Mariotti's view that artefacts are not mediators and Ladel and Kortenkamp's statement that artefacts do not have agency. I think tools can be powerful things and I am drawn to an ANT view on material agency, but can ANT ideas be brought into AT? I first look at a potential major obstacle to networking these theories and a difference between Latour and Pickering.

Miettinen (1999) considers ANT and AT as approaches to studying innovations and locates the main division between these approaches as ANT's generalised principle of symmetry which states that the same "vocabulary must be used in the description and explanation of the natural and the social ... no change of register is permissible when we move from the technical to the social aspects of the problem studied" (ibid, pp. 172–173). This is a problem for AT because the object (of activity) is generated from human needs. OK, humans do generate the object but once the object is established the agency which follows in the activity can be distributed. Indeed, Latour (2005) states that he abandoned most of the symmetry metaphor because what he had in mind was a "joint dissolution of both collectors" (ibid, p. 76). Pickering (1999, p. 15) also considers the generalised principle of symmetry to be problematic, "As agents, we humans seem to be importantly different from nonhuman agents". With the generalised principle of symmetry 'put in to perspective' I now look to two commonalities in principles between Latour and Pickering: focus on performance; don't restrict agency to animals (humans) alone.

Latour (2005) mentions performance with to regard groups, social aggregates. Classical sociologists are accused of making *ostensive* definitions of groups – there's a group of teachers – and focusing on stability but, from an ANT point of view, "the rule is performance and what has to be explained, the troubling exceptions, are any type of stability over the long term [and this cannot be explained] without looking for vehicles, tools, instruments, and materials able to provide such a stability" (ibid, p. 35). This focus on performance is akin to flux in AT. A sketch of a performative view of science is presented early in Pickering (1995, p. 6), instead of a world where scientists only generate knowledge from facts, he sees a world filled with agency:

> The world ... is continually doing things, things that bear upon us not as observation statements upon disembodied intellects but as forces upon material beings ... Much of everyday life ... character of coping with material agency, agency that comes at us from outside the human realm and that cannot be reduced to anything within that realm.

Later, in Pickering (1995), 'disciplinary agency' and the 'dance of agency', as described above, are introduced. Neither Latour nor Pickering are concerned with mathematics education but their 'multi-agent' stance resonates with my experience of mathematics classrooms. When a teacher uses a tool in a mathematics class, then s/he is only one of the agents in the activity, other potential agents are: other teachers; students; the curriculum; the institution; other available artefacts; and the tool itself.

I now consider mediation and what mediates: language, signs, artefacts or people? I think the problem here can be viewed via the ostensive-performative distinction. Scholars have different interests and tend to point to something and say "that (those) is (are) the mediator(s)" whereas the mediator in a specific situation exists in relation to what is actually done (the activity/performance). I am, for instance, interested in artefact/tool-mediation but two learners may be involved in ostensibly similar activities with a mathematical tool but one learner may be heavily reliant on the tool whereas the use of this tool to the other learner may be peripheral; mediation by the tool comes down to the actual use of the tool. Similarly Mariotti and Maracci (2012) may expect the mediator to be the teacher but I doubt if this is always the case. Latour (2005, p. 39) appears to present a similar idea in distinguishing between mediators and intermediaries, "An intermediary ... is what transports meaning or force without transformation ... Mediators transform, translate, distort, and modify".

A STATEMENT ON TOOL USE IN MATHEMATICS EDUCATION

The considerations above, together with those in the previous three sections, provide a basis for the following statement (in italics) on tool use in mathematics education.

AT provides a framework to interpret tool use in practice but the level of detail on tool use will depend on the 'size' of the unit of analysis. An AT account of tools would benefit from being augmented by constructs from instrumentation theory and the theory of affordances. Activity is mediated by human and non-human mediators but this mediation cannot be stipulated in advance of the performance of the activity. Human and non-human agents impact the activity; as with mediation, the impact of these agents cannot be stipulated in advance of the performance of the activity.

I now state my networking argument. The theories of affordances and of instrumentation have few assumptions and a lot of application. Recognition of the relationship between learners and their environments is important in AT as is the process by which an artefact becomes a tool for learners. Both theories can be used in MER to shed light on the action and operation aspects of AT without compromising any tenets of AT. With regard to taking ideas from Latour and Pickering I focus on the two principles outlined above. The 'focus on performance' principle is entirely consistent with the concept of flux in AT. AT focuses on describing practice and tools (and, I add, other things) are used as they are used (or not) – there is no pre-ordained plan. As for not restricting agency to humans alone, well, this is a problem for many activity theorists because the object of an activity is generated by humans. But if the principle of non-human agency is weakened to restrict non-humans from initiating activity, then I don't think there is a problem.

ENDNOTE

1. I would have liked to have considered tool-focused work within the Anthropological Theory of Didactics as well but this was not possible in the length restrictions for this paper.

Structuralism and theories in mathematics education

Pedro Nicolás

University of Murcia, Murcia, Spain, pedronz@um.es

We present the structuralist conception of scientific theories as a Deus ex Machina which allows to resolve the entanglements of theories in Mathematics Education. We illustrate with examples how this conception, which forms a solid and solvent body of knowledge in Philosophy of Science, provides us with tools to perform a careful analysis of a theory, both by itself and in connection with other theories.

Keywords: Praxeology, theory, model, law, networking.

RECONSTRUCTION OF SCIENTIFIC THEORIES

As it is the case in many other disciplines, in Mathematics Education there are several theories living together: Theory of Didactic Situations (Brousseau, 1997), Anthropological Theory of the Didactic or ATD (Chevallard, 1999; Bosch et al., 2011), APOS[1] theory (Dubinsky & McDonald, 2002), Onto-Semiotic Approach (Godino, Batanero, & Font, 2007), Theory of Abstraction in Context (Dreyfus, Hershkowitz, & Schwarz, 2001), Theory of Knowledge Objectification (Radford, 2003)... Whereas the cohabitation of theories is perfectly normal, efforts aiming to connect some of them, especially from the CERME working team "Theoretical perspectives and approaches in mathematics education research" (CERME8, 2013), are also very natural and desirable.

We defend in this work that, for a better understanding of the possibility of connection of two theories, we must reconstruct them by using the same language. The reconstruction of a theory can be carried out from different conceptions. When we speak of 'conceptions' we mean ways of giving an account of what a scientific theory is, and not of how a scientific theory (in particular, a scientific law) is constructed. Thus, a priori these conceptions do not pay attention to methodological aspects.

The one favoured here is the so-called *structuralist conception* (Balzer, Moulines, & Sneed, 1987). This is an elaboration of the *semantical conception* (initiated by Suppes and Adams in the 1970s), and it seems to reconcile the most important aspects of the *syntactical conception* (advocated by Reichenbach, Ramsey, Bridgman, Campbell, Carnap in several works from the 1920s to the 1950s) and the *historicist conception* (advocated by Kuhn, Lakatos, Laudan in several works in the 1960s), while it avoids their problems (Diez & Moulines, 1997).

Now we will give a brief explanation of the main points of the structuralist conception. For a more extensive treatment, see (Balzer et al., 1987).

According to the structuralist conception, a scientific theory is a net of many nodes (which will be called *elements of the theory* or *theory-elements*) connected in several via *specialization*, see Definition 2 below. Of course, such a net does not appear out of the blue, but it is developed little by little along the time. This is how the structuralist captures the diachronic character of a theory. The synchronic character of a theory appears in the description of the theory-elements.

Definition 1: To determine a *theory-element* one has to specify:

1) The portions of reality the theory-element conceptualizes, i. E. The portions of reality the theory can speak of, called *potential models*. These potential models are described as portions of reality which can be modelled by using a *structure* (that is to say, a tuple $(D_1, D_2, ..., R_1, R_2, ...)$ of sets D_i and relations R_j between these sets) and a list of properties applicable to the structures of the former type. We call M_p the set of potential models.

2) The *laws* with which the theory-element aims to enlighten reality. Each law is a property applicable to the structures of the specified type. The laws distinguish the so-called *actual models* among the potential models. We call M the set of actual models.

3) The *partial potential models*, which are these portions of reality which can be checked to be potential models without assuming the laws of the theory-element. Notice that to verify that a portion of reality is a potential model we check, in particular, that the relations R_j appearing in the type of structure are satisfied. In this checking we use some method and this method might, or might not, assume the laws of the theory-element. A relation R_j is *theoretical with respect to a theory element T* (or, in short, *T-theoretical*) if every method of determination of R_j assumes the validity of the laws of this theory-element. Thus, a partial potential model of a theory-element is nothing but a potential model in which we omit the theoretical relations. We call M_{pp} the set of partial potential models.

4) Those partial potential models that are expected to be actual models. These partial potential models are, after all, the *intended applications* of our theory-element. We call I the set of intended applications of our theory-element.

Thus a *theory-element* is an ordered pair $T = (K, I)$ where I is the set of intended applications and $K = (M_p, M_{pp}, M)$ is the *core*, formed by the set of potential models, the set of partial potential models, and the set of actual models.

The *empirical claim* of a theory-element is just the statement which asserts that the intended applications are actual models, $I \subseteq M$, that is to say, that in certain portions of reality, which can be detected without assuming the laws of the theory-element, these laws actually hold.

In the next section we will give several examples of theory-elements but, unfortunately, we will not point out a theoretical relation in any of them. It is an important open question whether there are theoretical relations in the current theories of Mathematics Education. In Classical Mechanics (CM), the relations of *position* or *time* are not CM-theoretical, since you can determine them without assuming any proper law of Classical Mechanics. However, the relation *mass* is CM-theoretical, since any method of determination of the amount of mass of an object assumes a law proper of the CM. For examples in other disciplines see (Balzer et al., 1987).

NETWORKING THEORIES

In what follows we use the structuralist approach to present different kinds of possible connections between theory-elements.

Definition 2: A theory-element T' is a *specialization* of another theory-element T, and we write $T' \sigma T$, if:

1.

   1.1. $M'_p = M_p$, that is to say, both theory-elements conceptualize the world in the same way.

   1.2. $M'_{pp} = M_{pp}$, that is to say, both theory-elements consider the same theoretical relations.

   1.3. $M' \subseteq M$, that is to say, every law in T is also a law in T'.

2. $I' \subseteq I$, that is to say, every portion of reality aimed to be explained by T' is also a portion of reality aimed to be explained by T.

In short, to specialize consists of increasing the amount of laws without changing the conceptual architecture.

Definition 3: A *net-theory* is a pair $N = (\{T_i\}, \sigma)$ where $\{T_i\}$ is a non-empty set of theory-elements and σ is a specialization relation on $\{T_i\}$.

Next we are defining the notion of *theorization*, but first we need the following:

Definition 4: Given two structures (see Definition 1) $x = (D_1, ..., D_m, R_1, ..., R_n)$ and $y = (D'_1, ..., D'_p, R'_1, ..., R'_q)$, we say that y is a *substructure* of x if:

1. $p \leq m, q \leq n$.
2. Every D'_i is a subset of some D_j.
3. Every R'_i is a subset of some R_j.

Definition 5: A theory-element T' is a *theorization* of a theory-element T if:

1. Every intended application of T' admits an actual model of T as substructure.

2. There are potential models of T' which are not substructures of potential models of T (because they contemplate new domains and/or new relations).

The first condition says that every portion of reality T' aims to explain satisfies the laws of T. The second condition says that T' includes new (not necessarily T'-theoretical) concepts not contemplated by T.

Next I will show in examples some tentative structuralist descriptions of some elements of the ATD.

Example of theory-element: Our first example is inspired in the so-called *Herbartian scheme* (Chevallard, 2015), which is probably the most general structure proposed by the ATD to deal with situations of study. In this structure there are things like a task or question which requires some answer, a series of partial answers, and a final answer. Therefore, the structure corresponding to our theory-element T_1 will be the tuple $(\{1, ..., n\}, P, s)$ where $\{1, ..., n\}$ is the set of the first n natural numbers, P is a non-empty set P, and s is a map from $\{1, ..., n\}$ to P. The image of 1 is said to be a *generating question*, the image of n is said to be a *final answer* and the other images are said to be *partial answers*. Since no law is stated, there is no distinction between potential, partial potential and actual models. Notice that every temporal sequence of n events fits in this structure, but, of course, not every such sequence is an intended application of T_1. This is why it is important to explain which are our intended applications, namely, those sequences of events consisting in finding an answer to a question.

Example of theorization: If, moreover, in each of the partial answers of T_1 we distinguish between tasks, techniques and *logos* elements, that is, if we look at the constituent parts of the so-called *praxeologies* (Chevallard, 1999), we would have reached a theorization, T_2, of T_1. The structure corresponding to T_2 will be a tuple $(\{1, ..., n\}, S_T, S_t, S_L, s)$ where S_T, S_t, and S_L are non-empty sets whose elements are called *tasks*, *techniques* and *logos-elements*, respectively, and s is a map from $\{1, ..., n\}$ to $S_T \times S_t \times S_L$. Since no law is stated there is no distinction between potential, partial potential and actual models. Now not every temporal sequence of n events fits in the structure of T_2. Not even every temporal sequence of n events consisting in finding an answer to a question! In fact, our intended applications are temporal sequences of events consisting in finding an answer to a question such that in each of these events we find three components and such that, moreover,

— all the first components of the events are "of the same nature" (this is encoded in the fact that they belong to the same set), namely, tasks;

— all the second components of the events are of the same nature, namely, solutions to the task specified in the corresponding first component, and

— all the third components of the events are of the same nature, namely, explanations of why the corresponding second element solves the corresponding first element.

Example of theorization: If, moreover, we take into account the dynamics of each of these praxeologies, recognizing the so-called *study moments* (Chevallard, 1999), we would have a theorization, T_3, of T_2. The structure corresponding to T_3 will be a tuple $(\{1, ..., n\}, S_T, S_t, S_L, \{0,1\}, \{*\}, s)$ where

– $\{1, ..., n\}$, S_T, S_t and S_L are as before;

– s is a map from $\{1, ..., n\}$ to $S \times (S \cup \{*\}) \times (S \cup \{*\}) \times \{0, 1\} \times \{0, 1\} \times ([0, 1] \cup \{*\}) \times (\mathbb{N} \cup \{*\}) \times (\mathbb{N} \cup \{*\})$, where S is the union of S_T, S_t and S_L, called the *study sequence map*, and its images are called *events*.

The structure is now more complicated because it has to model more ambitious intended applications. Indeed, in the events of the sequence we still look at tasks, techniques and logos, but we also pay attention to the way they are related:

– The first (respectively, second, third, fourth and fifth) component of an event refers to the first (respectively, second, third, fourth and fifth) study moment (Chevallard, 1999).

– The last three components of an event refer to the sixth study moment, namely, to the evaluation moment. More precisely, the sixth component refers to the scope of the technique (it is a bounded magnitude which reaches the value 1 if the technique covers all the possible cases of the task), the seventh component refers to its economy and the eighth component refers to its reliability (see Sierra, Bosch, & Gáscon, 2013)[2].

For example, an event which is an element of $S_T \times S_t \times S_L \times \ldots$ is regarded as a task followed by an elaboration of a technique followed by an explanation of why this technique works, whereas an element of $S_t \times S_T \times \{*\} \times \ldots$ is regarded as a technique followed by a task which is solved by the technique followed by no explanation of why the technique works. We use * to express absence of activity in the second, third, sixth, seventh and eighth components, and we use 0 (respectively, 1) to express absence (respectively, presence) of activity in the fourth and fifth components. We can add some axioms devoted to prevent us from considering impossible events, for example:

Axiom 1: There are not events starting with a task and continuing with a *logos* element.

Axiom 2: If an event starts with a technique, then it cannot continue with a *logos* element.

Axiom 3: In an event there are not two tasks, two techniques or two *logos* elements. Thus, for instance, there are not events which are elements of $S_T \times S_T \times \ldots$

Axiom 4: If in an event there is no task, then the last three components of the event are (*, *, *).

Axiom 5: If the fourth component of an event is *, then the last three components are (*, *, *).

Examples of specialization: Imagine we create a new theory-element T_4 by adding the following law to the theory-element T_3:

Law: The last three components of every event are (*, *, *).

The new theory-element T_4 is a specialization of T_3. Indeed, there are actual models in T_3 which are not actual models in T_4, namely, those study sequences having at least an event in which the last three components are not (*, *, *). After the axioms, it is clear that the former law holds for those study sequences in which each event $s_i = (s_{i1}, s_{i2}, s_{i3}, s_{i4}, s_{i5}, s_{i6}, s_{i7}, s_{i8})$ satisfies that none of the s_{ij} are a task or that $s_{i4} = *$. Hence, those study sequences would be actual models of our theory-element T_4.

The notion of *didactic contract* (Brousseau, 1986) is a good source of laws for theory-elements dealing with study sequences. Indeed, a didactic contract can be regarded as a special family of *clauses* or *conventions*, and, inspired in Lewis (1969), we could express a convention as a law stating that a certain regularity in the events of a study sequence holds (see for instance the law above).

Remark: In Chevallard (1988b), there is a sketch of the possible sets and relations of the structures an anthropological theory of the didactics would deal with. It would be interesting to compare them with the ones used in our examples above.

Remark: Brousseau (1986), inspired among others by Suppes (1969, 1976)[3], used finite automata to give a structuralist formulation of the notion of *situation*. Our structuralist formulations of notions of the ATD are more in the spirit of the Stimulus-Sampling Theory (Estes & Suppes, 1959). It is worth noting that, as proved in Suppes (1969), given any finite connected automaton there is a stimulus-response model that asymptotically becomes isomorphic to it.

Finally, let us consider the relation of *reduction* between theory-elements.

Definition 6: A theory-element T is *reducible* to a theory-element T^* if there exists a relation $\rho \subseteq M_p(T) \times M_p(T^*)$ such that:

1. If $(x, x^*) \in \rho$ and $x^* \in M(T^*)$, then $x \in M(T)$.

2. If $y \in I(T) \cap M(T)$ then there exists $y^* \in I(T^*) \cap M(T^*)$ such that $(y, y^*) \in \rho$.

The underlying idea is to regard the elements (x, x^*) of ρ as pairs of portions of reality so that x^* is the T^*-version of x. The first condition says that the laws of T can be derived from those of T^*. The second condition says that all the successful applications of T admit T^*-versions which are also successful applications of T^*. In other words, the successes of T can be explained in virtue of those of T^*. Notice that, in contrast to what happened with the *theorization* (Definition 5), reduction does not require an increase in the conceptual map, that is to say, the kind of structures contemplated as potential models. Indeed, the conceptual map of T^* might be completely different to the conceptual map T.

Examples of reduction: The *classical mathematics education* (see Gascón, 1998) explains certain phenomena with laws involving cognitive or motivational concepts. Indeed, these would be the kind of concepts used by the classical mathematics education to explain the kind of phenomena presented in IREM de Grenoble (1979). One can use Chevallard (1988a) to sketch how part of this classical mathematics education can be reduced to a theory-element including among the laws the clauses of the *didactic contract*. On the other hand, one can also use (Chevallard, Bosch, & Gascón, 1997) to reduce part of this classical mathematics education to a theory-element with laws stating the *incompleteness* of scholar study processes (this incompleteness can be expressed in terms of the study moments, for example, by saying that *the moment of the construction of the technological-theoretical frame* or *the moment of the work of the technique* is lost).

In Bikner-Ahsbahs and Prediger (2010) the following "networking strategies" are presented: to ignore other theories (as an extreme strategy of non-connection), to make your own theory and foreign theories understandable, to compare/contrast, to coordinate/combine, to integrate locally/synthesize and to unify globally (as an extreme strategy of total connection). Next, let us clarify this taxonomy by presenting, in a brief and simplified way, possible translations of these strategies to the structuralist language:

- To ignore other theories: not to consider the possibility of (even partial) specialization, theorization or reduction (see Definitions 2, 5 and 6) as a relation among two theory-elements.

- To make your own theory and foreign theories understandable: to accomplish this, as we said at the beginning of this paper, one need to translate both theories to the same language. What we suggest here is to use the structuralist language. So, in a sense, in the present work we take seriously this second networking strategy.

- To compare/contrast: to check which are the potential models shared by two theory-elements. Thus, when comparing/contrasting we could be performing a theorization.

- To coordinate/combine two theory-elements T and T' consists in saying that a common intended application is both an actual model of T and an actual model of T'. It is important to notice that, for this to happen, T and T' must share the partial potential models. This last sentence explains the meaning of the following statement of Bikner-Ahsbahs and Prediger (2010): "Whereas all theories can of course be compared or contrasted, the combination of (elements of) different theories risks becoming difficult when the theories are not compatible."

- To integrate locally/synthesize two theory-elements T and T': to find a third theory-element T'' to which we can reduce the theory-element derived from T when considered just some sub-structures z of the structures x of T, as well as the theory-element derived from T' when considered just some sub-structures z' of the structures x' of T'. Notice that the structures x'' of T'' should admit both z and z' as sub-structures.

- To unify globally: to find a theory to which any other theory could be reduced.

CONCLUSION

Here we suggest to use the structuralist formalization of scientific theories to the benefit of the questions about the theoretical status of different approaches in Mathematics Education. Needless to say, we do not mean one cannot work properly in theory unless this is formalized. For example, it is not reasonable to say that Newton was not doing Mechanics just because he did not have at hand a strict formalization. On the other hand, theories in Mathematics Education are still far from being formalizable, being this (even partial) formalization a long-term project in any case. Concerning this, it is important to point out that the degree of resistance of a theory to be formalized is inversely proportional to its degree of development. For example, if we cannot distinguish the actual models among the potential models, then we cannot identify any law of the theory (and at this point we should wonder whether this forces us to accept this theory is nonexistent...). Anyway, regardless of the difficulty of a complete formalization, we defend that:

- The framework offered by the structuralist conception of scientific theories is illuminating to the extent that it provides us with high order tools which allow a better understanding of the theoretical scene in Mathematics Education.

— Even if we were not interested in networking theories, the attempt to formalize a theory in the structuralist way forces us to consider extremely interesting questions about this theory. For instance: which are the underlying structures? Which are the laws? Which are the theoretical relations?

Among many other things, it is still an open question which are the links between our structuralist approach, the definition of *theory* by Radford (2008) and the notion of *research praxeology* by Artigue,Bosch, and Gascón (2011a, 2011b).

ACKNOWLEDGEMENT

I thank Josep Gascón for his reading of a previous version of this article and his helpful comments.

ENDNOTES

1. This is the short form for "Action, Process, Object and Scheme".

2. For the sake of simplicity, we do not distinguish between *task* and *type of task*, and between *technological* and *theoretical* elements among the logos elements, even if they are important distinctions in the ATD.

3. Actually, the last two components should be interpreted as evaluations of a technique in comparison with another technique. Indeed, we typically speak of a technique as being more or less economic or reliable than another technique. However, for the sake of simplicity, we do not take into account this aspect here.

4. It is a remarkable fact that Suppes was the main promoter of the semantic conception, direct precedent of the structuralist conception.

Adaptive conceptual frameworks for professional development

Miguel Perez

Linnaeus University, Faculty of Technology, Växjö, Sweden, miguel.perez@lnu.se

In this paper, the notion of adaptive conceptual frameworks is presented. These frameworks have been used to conduct educational design research aiming at developing ICT supported mathematics instruction. In this approach, empirical data is connected with various theories in an adaptive and iterative process. Differentiation is made between conceptual framework for development (CFD) and conceptual framework for understanding (CFU) depending on how the frameworks are used in the design process. The use of adaptive conceptual frameworks contributes to the transparency in the design process by making explicit the levels at which different theories operate and how the design process is evaluated.

Keywords: Conceptual framework, educational design, professional development.

INTRODUCTION

During the last decades, several similar methodologies have emerged that address the desire to conduct educational research with relevance for school practices. For example, design-based research aims explicitly at developing theories that could do "real work" by providing theoretically underpinned guidance on how to create educational improvement in authentic settings (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003; McKenney & Reeves, 2012). A common feature of these approaches is the design of teaching activities in an iterative design process that shares many similarities with teachers' daily work.

This paper contributes to research by describing how the design process may be co-determined by the interaction between different stakeholders such as researchers and teachers, disciplinary knowledge, theoretical frameworks, and other resources. This approach has been inspired by co-design, as a design methodology that highlights the importance of involving different stakeholders such as teachers in the design research process in order to address the issue of ownership of innovation (Penuel, Roschelle, & Shechtman, 2007). Furthermore, working in close collaboration with teachers deepens our knowledge about pragmatic issues and promotes development of "*innovations that fit into real classroom contexts*" (ibid, p. 52). Following the conceptualization of knowledge proposed by Chevallard (2007) in the Anthropological Theory of the Didactic (ATD), the two different perspectives of understanding and development could be viewed as two inseparable aspects of knowledge, integrating a practice that includes the things teachers do to solve different educational tasks (*praxis*) with a discursive environment that is used to describe, explain, and justify that practice (*logos*). The adaptive conceptual frameworks presented in this paper explicitly address both perspectives.

The purpose of this paper is to describe the development of adaptive frameworks and how they were used to meet the emerging needs in a design process of ICT supported mathematics instruction during one design cycle. The empirical data presented in this paper is therefore only used to motivate the development of the adaptive conceptual frameworks and not analyzed with respect to the intended learning objectives.

ADAPTIVE CONCEPTUAL FRAMEWORKS

In this approach the researcher connects empirical data with various existing theories that are chosen in retrospect and that are used to generate additional empirical data in an iterative, incremental and adaptive process. In other words, theory is not applied onto practice, it is more about a "progressive interaction between theory and practice, by means of appropriating existing theoretical tools" (Bartolini Bussi, 1994, p. 127). Furthermore, the adaptive conceptual frameworks are considered in a state of flux and changeable according to the different challenges that might emerge when conducting design-based research in authentic settings. Thus, the adaptive conceptual frameworks should be regarded as tentative and a result of a research work that has similarities with research that sometimes is portrayed by the "bricolage" metaphor (Kincheloe, 2001), particularly regarding the efforts of embracing methodological flexibility and plurality of theories. From this perspective, this research approach aligns with the Singerian inquiry system (Churchman, 1971; Lester, 2005).

The workflow of the formal stages of a design cycle is illustrated in Figure 1. Each design cycle starts with a planning phase, followed by an implementation phase involving the teachers. The cycle is completed with an evaluation of the outcomes. Three different frameworks are distinguished depending on their role in the different phases:

— methodological framework for professional development (MFPD),

— conceptual framework for development (CFD),

— conceptual framework for understanding (CFU).

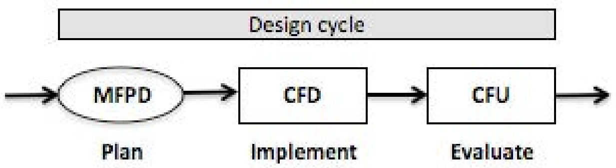

Figure 1: The adaptive frameworks for research and professional development

The researcher uses the methodological framework for professional development (MFPD) to plan and support the teachers' participation in the design process. The conceptual framework for development (CFD) is used to describe and justify the different activities that the researcher engages in together with the teachers. Finally, the conceptual framework for understanding (CFU) is used to understand the outcomes of an intervention in order to decide how proceed in the next cycle. While the conceptual frameworks for development and understanding (CFD and CFU) naturally share similarities, since they both put focus on the design process, the methodological framework for professional development should be regarded as a separate framework for organizing and supporting the teachers' professional development.

The different frameworks in this approach consist of multiple theoretical components. In order to consider how they interact, the categorization presented by Prediger, Bikner-Ahsbahs, and Arzarello (2008) was used. In their landscape of different levels of integration, the authors present a scale ranging from one extreme of ignoring other theories to the other extreme of unifying theories globally. Those strategies that are intermediate are called networking strategies and include strategies such as *comparing*, *combining*, *coordinating* and *integrating locally*. According to Prediger and colleagues (2008), the strategies of *coordinating* and *combining* are mostly used for a networked understanding of an empirical phenomenon or a piece of data and are typical for conceptual frameworks that, as in our case, not necessarily aim for a coherent theory. While *comparing* and *contrasting* always are possible the strategies of *coordinating* and *combining* can be a more difficult task especially if the theories are not compatible relative a specific purpose. The *coordinating* strategy is in turn used when a conceptual framework is built on well-fitting theoretical elements (ibid). The networking strategies used in this study were *comparing* and *coordinating*.

THE BACKGROUND OF THE CASE STUDY

The participating teachers were involved in a developmental project in their school related to how ICT could enhance their students' learning of mathematics. As part of this project, the teachers participated in a one-day event with lectures and hands-on learning activities developed by researchers from media technology and mathematics education. One specific learning activity was designed to stimulate students to communicate, collaborate and generate general problem solving strategies (Sollervall & Milrad, 2012). Mobile phones were used in this activity to bridge between formal and informal learning spaces. During the discussions about this activity the teachers seemed to be more worried about the practical issues (e.g., handling the mobile phones) rather than the didactical issues. It seemed that the teachers perceived the didactical challenge of connecting between students' activities outdoors and a mathematical content as unproblematic. In fact, a successful orchestration would depend on the quality of the student-generated artifacts as well as the teachers' ability to orchestrate this remaining part of the activity performed indoors.

Later on, two of the mathematics teachers from the school and a researcher from mathematics education met to discuss the prospects of developing new activities supported by ICT. The teachers expressed their concerns about their students' inability to use the distributive law and wanted to address this issue. The teachers had themselves completed the above-mentioned activity, which also could be used to address students' conception of the distributive law by connecting multiple representations (ibid). Using the activity with this particular focus would not require any modifications of the activity itself but would require the teacher to orchestrate the activity towards this content. None of the teachers seemed to perceive this opportunity and the continued discussions revealed that they did not know about possible geometrical representations of the distributive law. These events influenced the direction of design process. Based on the overall goal of creating educational improvement, it seemed important for the researcher to address the teachers' ability to use ICT for different goals and purposes. This issue was perhaps more important than developing new activities with the teachers. With this pre-understanding the planning phase of the design was initiated.

METHODOLOGICAL FRAMEWORK FOR PROFESSIONAL DEVELOPMENT

The methodology of collaborative design based research is at the same time a process of professional development (Penuel et al., 2007) that should be regarded as gradual and difficult for the teachers (Guskey, 2002). In this case, the teachers' insufficient understanding of mathematical representations was taken as a constraining factor for the teachers' participation in the design process. To address this issue, two complementary theories were used to guide and plan for the teachers' professional development. One of the frameworks specifically focuses on knowledge for teaching mathematics: Mathematical knowledge for Teaching (Loewenberg Ball, Thames, & Phelps, 2008) and the other framework focuses on the affordances provided by ICT and on the integration of ICT in different subject areas: Technological Pedagogical Content Knowledge (Koehler & Mischra, 2008).

The strategy of *comparing* (Prediger et al., 2008) was used to identify common principles in these two theories related to the use of ICT for supporting students' learning of mathematics. Based on this comparison, the researcher decided to specifically support teachers' understanding of the affordances for representation provided by ICT. The idea was to use the dynamic geometry software GeoGebra (www.geogebra.org) to develop an application, with focus put on providing affordances for representation, that the teachers could use later in a learning activity to address their students' conception of the distributive law. Thus, depending on the user, the software was used with different purposes.

CONCEPTUAL FRAMEWORK FOR DEVELOPMENT

Inspired by the work of Duval (2006) the dynamics of GeoGebra is used in the application to illustrate how numerical expression can be interpreted and represented geometrically (Figure 2).

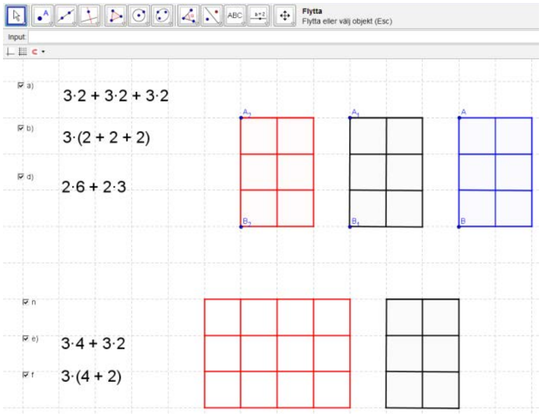

Figure 2: Snapshot of the application, implemented in GeoGebra

The teachers were not familiar with the software so the application was designed for them as end-users to operate only by using "click and drag" features. Even if the teachers were provided with the application, the teachers needed to create a *hypothetical learning trajectory* (HLT), i.e. "the consideration of the learning goal, the learning activities, and the thinking and learning in which students might engage" (Simon, 1995, p. 133). In other words, while the researcher took responsibility for the didactical design (the application), the pedagogical design was intended for the teachers to decide.

When the application was presented to the teachers they wanted immediate access to it. They seemed to recognize the limitations of the explanations that they normally used that were exclusively based on instructions on how to manipulate different variables. They also agreed on using the application with their students but they never did. Therefore, there was an additional meeting where the researcher demonstrated a possible way to use the application in a learning activity. The demonstration was followed by a discussion about possible ways to orchestrate the interplay between different representations and the dynamical affordances (dragging mode, show/hide figures) supported by the application. By discussing related pedagogical issues and offering the teachers opportunities to adapt the application according to their needs, the researcher wanted to challenge the teachers to create their own hypothetical learning trajectory (HLT). The teachers were offered additional support on how to adapt or use the application but the teachers did not use this possibility. In the following section, the crosscutting features of the enacted lessons will be presented.

The teachers used different interpretations of multiplication simultaneously and alternately without making explicit why and when an interpretation was preferable in some situations and not in others. This lack of explicitness resulted in vague connections between the numerical and geometrical representations. Justifications were based on computations or algebraic manipulations instead of referring to the available geometrical representations in the application. When the teachers became uncertain on how to proceed with the activity they tended to rely more on the more familiar numerical and algebraic representations to maintain the flow of the lesson. A significant part of the lessons was also dedicated to what seemed to be other more familiar activities such as formulating expressions for area and perimeter. Furthermore, the teacher-initiated communication with the students did not seem to support a discussion on how and why things work the way they do. Occasional misinterpretations of students' responses, not acknowledging their responses as correct, and not connecting their responses to the available representations, further contributed to the activity not proceeding as intended.

In summary, the CFD was developed by using the networking strategy of *coordinating* (Prediger et al., 2008) theoretical components (i.e., mathematical *representations*, *GeoGebra* and *HLT*) for practical reasons without aiming for a deeper integration. The purpose of this framework was to outline the theoretical underpinnings of the activities with the teachers. In contrast to the other components in the CFD, the notion of hypothetical learning trajectory (HLT) was not presented explicitly to the teachers.

CONCEPTUAL FRAMEWORK FOR UNDERSTANDING

The enacted lessons were also different compared to the suggestions the teachers had themselves when discussing different ways to orchestrate a lesson supported by the application. During the first two phases of this design cycle, the focus was on different types of teacher knowledge but the crosscutting features of the lessons revealed another dimension. How does teacher knowledge come into play in the moment of teaching? Why did the teachers not make use of the ICT-supported affordances for connecting representations? To address these emerging questions the researcher decided to go beyond the theories of representation and different categories of teacher knowledge used previously and focus on the teachers' overt orchestration of the lessons. In other words, a different representation was chosen to evaluate the design process and in particular the teachers' professional development.

Developing the CFU

A different conceptualization of knowledge was found in the Anthropological Theory of the Didactic (ATD). In this theory a body of knowledge, a *praxeology*, consists of two inseparable blocks, the *praxis* and the *logos*. The praxis block refers to the kind of given *tasks* that you aim to study and the different *techniques* used to face these problematic tasks. In this sense, the praxis block represents the "know-how" of the praxeology. The logos block provides a discourse that is structured in two levels with the purpose to justify the praxis. The first level of the logos is the *technology*, which provides a discourse about the technique. The second level of the logos is the *theory*, which provides a more general discourse that serves as explanation and justification of the *technology* itself (Chevallard, 2007) by providing a framework of notions, properties and relations to organize and generate technologies, techniques and problems (Barbé et al., 2005). The *praxeology* is the minimal unit of human activity

The ATD includes the study of didactic transpositions processes, which concerns the transformation of knowledge through different institutions. The transposition is a process of de-constructing knowledge and rebuilding different elements of knowledge into a more or less integrated whole with the aim of establishing it as "teachable knowledge" while trying to keep its character and function (Bosch & Gascón, 2006). It consists of the four following steps; *scholarly knowledge*, *knowledge to be taught*, *taught knowledge* and *learned knowledge*. The notion of *didactical transposition* provided a new way of putting the intervention into perspective. As the researcher provided the teachers with competence development in terms of the didactical value of multiple representations, the focus of this design cycle was on the step between intended and enacted knowledge, that is, between knowledge to be taught and taught knowledge (shaded in Figure 3). The researcher could therefore use the recordings of the enacted lessons to understand the teachers' professional development from this new perspective.

Moreover, teaching is a didactic *type of task* that teachers can solve in a complex process of *didactic transposition* by using a set of available resources (*didactical techniques*), both external resources (curriculum, textbooks, tests, ICT-tools, colleagues, manipulatives, etc.) and teachers' internal resources that in our case of ICT-supported instruction could be related to technological-pedagogical content knowledge (Koehler & Mischra, 2008). The logos block of a didactical praxeology then serves as means to describe and justify teaching and learning practices in the considered institution (Rodríguez, Bosch, & Gascón, 2008).

A specific adaptation to the new empirical data was to replace the notion of *HLT* by the notion of *routines* (Berliner, 2001) with focus on the *IRE* sequence (Initiate, Response, Evaluate). The IRE sequence is a three-part pattern where the teachers ask a question, students reply, and teachers evaluate the response or gives feedback (Mehan, 1979; Schoenfeld, 2010). In its most basic form the teacher initiates the sequence by posing a question to a student to which the teacher already knows the answer. The student then replies and the teacher evaluates by using phrases such as "yes" or "that's fine" and continues with the next question or next problem. Communicational exchange patterns, such as the IRE sequence, can be regarded a didactical technique that teachers use in the creation of a mathematical praxeology. This adaptation was made in order to better describe the teachers' overt orchestration of the lessons and especially the communication patterns between teachers and students. This theoretical component was further developed in a second design cycle into a didactical resource (Perez, 2014).

The role of *representation* is multifaceted. From one perspective it is a generic property of many ICT tools (Koehler & Mischra, 2008). From a second perspective, mathematical representations have important didactical affordances (Ainsworth, 1999), and finally representations are essential to mathematics as a discipline (Duval, 2006). Thus, mathematical representation is closely related to both praxis and logos of a mathematical praxeology. In addition, instructional strategies that systematically focus on knowledge about representations could be conceptualized as an element of a didactical technique and consequently a part of a didactical praxeology. Thus, depending on the purpose in which representations are used, the role of representation for a discipline as mathematics could be attributed to both a mathematical and a didactical praxeology. Thus, r*epresentations* were placed within the notion of praxeology instead of being treated as a separate theoretical component as in the CFD. These adaptations allowed the researcher to provide a more comprehensive description of the crosscutting features of the enacted lessons and to understand the teachers' professional development.

In summary, the conceptual framework for understanding (CFU) consists of several theoretical components where the ATD is used as overarching perspective. The CFU was developed by using the strategy of *coordinating* different theoretical components (Prediger et al., 2008). To achieve this, the theoretical components of representations and routines (the IRE sequence) were interpreted as knowledge resources in accordance with the ATD and its focus on the epistemic dimension of teaching and learning processes in different institutions.

Evaluating the first design cycle

The theoretical notions provided by the CFU allowed the researcher to capture the essence of this part of the design process and to better understand the

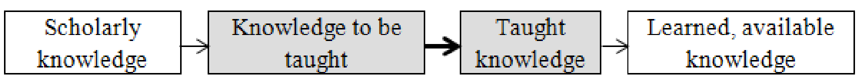

Figure 3: The transposition of knowledge

crosscutting features of the enacted lessons. The researcher's intention was to introduce the geometrical representation as a technological element in a mathematical praxeology. Instead, the teachers used the application to allow the students to work with more open-ended tasks. The result was that only some aspects of knowledge (praxis) were addressed during the lessons. Furthermore, the didactical techniques used by the teachers did in many cases not support the creation of a mathematical praxeology including a well-developed logos discourse. In other words, the underlying principle-based learning objectives did not survive the transposition from how the researcher intended the application to be used and how it was actually used by the teachers. The step from knowledge to be taught and taught knowledge in the didactical transposition proved to be a greater challenge requiring more scaffolding than the researcher had anticipated and planned for (in the MFPD). With this understanding, a new design cycle could be initiated.

SUMMARY

In this research the possibility of viewing design research as incremental and adaptive has been considered. For example, the common goal of designing a new activity supported by ICT was adapted to include the teachers' ability to use ICT for different purposes. Thus, the researcher decided to address the teachers' understandings of the affordances for representation and communication provided by ICT and used the software GeoGebra for this purpose. Towards the end of the design cycle, additional adaptations were made in order to meet the emerging challenges originating from the teachers practices. New theoretical notions were introduced and others were replaced in order to evaluate design process from a prospective view – what could be done differently in the next cycle? This resulted in a more comprehensive conceptual framework for understanding (CFU) based on the Anthropological Theory of the Didactic (ATD). The ATD served as an overarching theoretical perspective although only some aspects of the ATD have been particularly highlighted in this research project. The flexibility of the ATD allowed the researcher to attend to all the didactical issues that the researcher decided to pursue during the research process.

It is important to stress that adaptability should not be interpreted as a matter of searching for whatever works in the current situation. Instead, it is about the problematic task of assuring that the activity of inquiry is meaningful relative to the research objectives, i.e. the problem of developing systems guarantors (Churchman, 1971). This is a basic problem for any researcher but in this case, the problem of guarantors was not settled a priori and once and for all. The design problem of knowing when and how to revise becomes therefore even more difficult because there is no a priori authority to rely on. Instead, the decision to pursue a revision depends on an ambition to improve the performance of the system according to a specific measure and relative to the purpose (Churchman, 1971). Furthermore, when the system has been revised a new measure may be adapted to the new system. In order to make such tactical decisions, the researcher must be prepared to consider a "whole breadth of inquiry in its attempt to authorize and control its procedures" (ibid. p. 196). In other words, the development of adaptive conceptual frameworks could be understood as a modeling process that aims at developing system guarantors while preserving a high level of complexity in order to achieve high ecological validity.

Finally, the use of adaptive conceptual frameworks specifically affords transparency in the design process by making explicit the levels at which different theories operate and how the system performance is evaluated. In other words, it allows the researcher to cast light on how theory and practice interact throughout the design process.

Communities of practice: Exploring the diverse use of a theory

Helena Roos and Hanna Palmér

Linnaeus University, Växjö, Sweden, Helena.Roos@lnu.se, hanna.palmer@lnu.se

The social learning theory of communities of practice is frequently used in mathematics education research. However, we have come to recognise that the theory is used in diverse ways, regarding both the parts that are used and the ways in which those parts are used. This paper presents an overview of this diverse use of the theory based on three themes: Are communities of practice viewed as pre-existing or are they designed within the study? Are individuals or groups foregrounded in the study? Which parts of the theory are mainly used? The aim of the paper is twofold: to make visible the diverse possibilities within one single theory, and to make visible how, even though we might think we know what a theory implies in research, if we look beneath the surface we may find that "the same" theory can imply many different things.

Keywords: Communities of practice, theory, social, learning, Wenger.

INTRODUCTION

Since Etienne Wenger published his book *Communities of Practice: Learning, Meaning, and Identity* in 1998, the notion of communities of practice has become common in mathematics education research as well as in other areas of educational research. Both authors of this paper have been using Wenger's social theory of learning in research within mathematics education. In reading other researchers' work we have discovered that the theory of communities of practice is frequently used in mathematics education, but there are many differences regarding both *which* parts are used and *how* those parts are used. In this paper, we will explore some of the ways in which the theory of community of practice is used in different mathematics education studies. The aim of this is twofold: to make visible the diverse possibilities and uses of one single theory, and to make visible how we in research may think we know what using a specific theory in a study implies, but when we look beneath the surface we may find that "the same" theory can imply different things to different researchers.

The notion of communities of practice has been investigated and discussed before, for example by Kanes and Lerman (2008). They investigated similarities and differences in how the notion is used by Lave and Wenger (1991) and by Wenger (1998), respectively. (However, we find Kanes and Lerman's (2008) description of Wenger's communities of practice very different from our own interpretation and the interpretations we found when preparing this paper.) In this paper, we focus only on research referring to Wenger's 1998 book, in which he writes that his aim is to present a conceptual framework where learning is placed "in the context of our lived experience of participation in the world" (p. 3). In this paper, we will not present Wenger's theory more than that, in order to avoid imposing our own interpretations of which concepts are the main ones in his theory. Instead, the use of communities of practice will be explored according to the differences we found when reading other researchers using Wenger's theories. Hence, the exploration is divided based on the following three themes: Are communities of practice viewed as pre-existing or are they designed within the study? Are individuals or groups foregrounded in the study? Which parts of the theory are mainly used? These three themes will be presented under each heading followed by a concluding discussion.

SELECTION OF STUDIES

Our selection of studies to explore was limited to those focusing on mathematics teaching or learning and/or mathematics teachers' professional development. We searched 19 databases, using the search words *communities of practice, mathematic** and/or *teach**;

the search was limited to peer reviewed journals or books. From this selection, consisting of more than 8000 articles, we limited the search to *communities of practice* and *mathematic** and/or *Wenger*; although that reduced the number of articles, there were still too many in some of the databases. We then removed "or" *teach**. Thereafter we were able to browse through all the titles and keywords to find a selection of research articles using *communities of practice*. This selection is not at all comprehensive, however, the purpose is not to generalise but to illustrate some of the differences we have found. Wenger's theory is also used frequently in studies within economy and management, but such studies are not explored in this paper.

Due to space limitations, this paper cannot present all the articles we have read; instead, we present articles that together illustrate the differences we found based on our three themes. The following ten studies will be discussed in relation to the three themes in the paper: Bohl and Van Zoest (2003); Corbin, McNamara and Williams (2003); Cuddapah and Clayton (2011); Cwikla (2007); Franke and Kazemi (2001); Goos and Bennison (2008); Graven (2004); Hodges and Cady (2013); Pratt and Back (2009) and Siemon (2009).

DESIGNED OR PRE-EXISTING COMMUNITIES OF PRACTICE

Some studies using Wenger's social theory of learning view communities of practice as pre-existing. In some other studies, for example, Bohl and Van Zoest (2003), Cuddapah and Clayton (2011), Goos and Bennison (2008), Hodges and Cady (2013) and Franke and Kazemi (2001), communities of practice are designed by the researcher(s).

In the study by Goos and Bennison (2008), a web-based community of practice is designed within teacher education. After graduation, interaction in the community of practice continues through the web-based tool developing an "online community" (p.41). In their article, Goos and Bennison discuss the issue of emergent versus designed communities of practice. Although, in their study Goos and Bennison design the external frames for the community of practice, their interest is in whether or not the web-based community develops into a community of practice. To give the community the best chance to develop into a community of practice on its own, the researchers provide only a minimum of structure concerning how community members are to communicate using the web-based tool. As such, they design a community, but it is its emergence as a community of practice they investigate in their study.

Hodges and Cady (2013) seek to expand on the work of Goos and Bennison (2008) by investigating the development of communities of practice within a professional mathematics teacher's development initiative. In this study a web-based tool is used to "foster the development of communities of practice" (p. 302). Hodges and Cady design a virtual space in order to see the emergence of communities of practice. However, unlike Goos and Bennison (2008), Hodges and Cady do not highlight the issue of an emergent or a designed community, even though the emergence of potential communities of practice is in focus.

Cuddapah and Clayton (2011) design a community of practice by arranging physical sessions with a group of novice teachers. They focus on one of several groups of novice teachers that, within a university-sponsored project, meet every second week. The novice teachers meet 15 times during the study. Every session has a theme and the sessions are planned and led by experienced educators. Cuddapah and Clayton write that the group of novice teachers "itself was a community" (p. 69) and they use Wenger's theories to analyse the development of the group and its function as a resource for new teacher support. In their analysis they present how the "community was observed throughout and between the data" (p. 72). As such, the group of novice teachers being a community of practice was both a precondition and a result of their analysis.

A fourth example of researchers who design communities of practice is Franke and Kazemi (2001). In their study they design communities of practice with mathematics teachers with the purpose of providing teachers with opportunities to learn about mathematics teaching and learning. The teachers in this study do mathematical tasks with their students in their classrooms and then they meet and discuss their experiences. The researchers take part in the discussions and they also visit the teachers at their schools several times. Franke and Kazemi do not describe why or how the group of teachers is a community of practice, but they analyse and describe the interactions in the group connected to teacher professional development.

Examples of studies in which communities of practice are treated as pre-existing, developed before the study began and without the influence of the researchers, are studies by Bohl and Van Zoest (2003), Corbin and colleagues (2003), Cwikla (2007), Graven (2004), Pratt and Back (2009) and Siemon (2009). In some studies the communities of practice are identified in the research process based on concepts from Wenger's theory, whereas other studies do not explain how they are identified as communities of practice.

Bohl and Van Zoest (2003), Graven (2004), Corbin and colleagues (2003), Cwikla (2007) and Pratt and Back (2009) are examples of studies where communities of practice are viewed as pre-existing at the start of the study, where the researchers do not explain how the communities have been identified as such.

Bohl and Van Zoest (2003) analyse how different communities of practice in which novice teachers participate influence their mathematics teaching. They give an empirical example of one novice teacher, in relation to whom they discuss differences in the role of novice teachers in different communities of practice, but they do not present how they identified these as communities of practice, nor do they explain how they identified the novice teacher's membership in these communities.

Graven (2004) investigates teacher learning in a mathematics in-service program. In this study an in-service program is considered to be a community of practice, but it is not explained how this community of practice has been identified as such. This is also the case in the study of Corbin and colleagues (2003), who investigate numeracy coordinators in an implementation of a national numeracy strategy. They use the notion of communities of practice as a tool to describe the participation of the coordinators in different communities, but they do not explain how they define the communities.

Pratt and Back (2009) investigate participation in interactive discussion boards designed for mathematics students. They simply state that "two idealised communities of practice" (p. 119) were adopted as a means to understand the discussion boards. How these communities were created and why they can be seen as such is not explained. They even describe the communities of practice as "hypothetical communities" (p. 128). Cwikla (2007) uses the concept of communities of practice in her study of the evolution of a middle school mathematics faculty. The concept of communities of practice is used to identify boundary encounters, but the article does not present any definition of communities of practice, nor does it specify which communities of practice are identified within the study.

Siemon (2009) is an example of a study where communities of practice are viewed as pre-existing at the start of the study, but where the researcher explains how the communities of practice have been identified as such. Siemon (2009) investigates improvements in indigenous students' numeracy skills after they worked on key numeracy issues in their first language. Three pre-existing communities of practice are described and it is explained, using Wenger's concepts, why these are considered to be communities of practice. In the study, the intersection between the acknowledged pre-existing communities of practice is investigated. The members of these communities are not described in detail, only as, for example "members of the local Indigenous community" (p. 225), or "all those that by virtue of their responsibilities are concerned in some way with school mathematics" (p. 225). The intersection between the communities of practice is not highlighted, although the author states that the edges of the communities took time to emerge.

FOCUS ON INDIVIDUALS OR GROUPS

Wenger's theory makes it possible to foreground groups (communities of practice) or individuals (learning and/or identity) or both. Since Wenger's theory is very broad and yet detailed, it is not surprising that either groups (communities of practice) or individuals are foregrounded in the studies. Wenger explains that this is not a "change of topic but rather a shift in focus within the same general topic" (p. 145). Franke and Kazemi's (2001) study is an exception, however, and an example of "both" since they analyse both the interaction within the community of practice and the identity development of individual participants.

In the studies by Cwikla (2007), Cuddapah and Clayton (2011), Goos and Bennison (2008), Hodges and Cady (2013) and Siemon (2009), groups of teachers are in the foreground and individuals are in the background or are not mentioned as individuals at all. Bohl and Van Zoest (2003), Corbin and colleagues (2003), Graven (2004) and Pratt and Back (2009), however, foreground the individuals, trying to understand how they are influenced by the different communities of practice in which they participate.

The issue of communities of practice or individuals being foregrounded in the studies as presented in this section is connected to which parts or concepts from Wenger's theory are used in the analyses, which is the focus of the next section.

WHICH PARTS OF THE THEORY ARE MAINLY USED?

Another consequence of Wenger's theory being very broad and yet detailed is that researchers focus on and use smaller parts of the theory, selecting just some of the concepts within it.

Graven (2004) uses the concepts of *practice, meaning, identity,* and *community* to describe and explain teacher learning. These four concepts are, according to Wenger "interconnected and mutually defining" (p. 5). Graven also mentions Lave and Wenger's (1991) concepts of *co-participation* and *participation*, but these are not used in her analysis. Even though Graven describes communities of practice in her study, the "three dimensions" (p. 72) that according to Wenger are the source of a community of practice, *mutual engagement, joint enterprise* and *shared repertoire*, are not used. However, Graven instead wants to add *confidence* as a supplement to *practice, meaning, identity,* and *community.*

Cuddapah and Clayton, like Graven (2004), initially refer to Lave and Wenger (1991) but to the concept of *legitimate peripheral participation.* They discuss this concept as one that can be used when analysing novice teachers as newcomers in teaching. However, as all novice teachers in their study are new members of a new community of practice designed by the researchers, they instead, like Graven (2004), use *practice, meaning, identity,* and *community* when coding their empirical material. They briefly mention the concepts of *mutual engagement, joint enterprise* and *shared repertoire,* but they do not use them in their analysis.

Those three concepts, *mutual engagement, joint enterprise,* and, *shared repertoire*, are used by Goos and Bennison (2008), Hodges and Cady (2013) and Siemon (2009) in their studies. As shown in the last section, these three studies have communities of practice in the foreground. Goos and Bennison (2008) use the three concepts when they analyse the emergence of their designed web-based community of practice. To investigate mutual engagement they count the number of interactions in the web-based tool. By analysing the content in these interactions they also investigate the joint enterprise and the shared repertoire that develops. Siemon (2009) uses the three concepts by making lists of what it is in the different communities of practice identified in the study that indicates joint enterprise, mutual engagement and a shared repertoire. Consequently, in her study communities of practice are pre-existing, but she defines them by mutual engagement, joint enterprise and shared repertoire. Three communities of practice are acknowledged this way. Hodges and Cady (2013) use the three concepts in the same way, but their approach is somewhat different. They use the concept in order to find and/or see development of communities of practice in a designed web-based tool. In their analysis they look for evidence of joint enterprise, mutual engagement and a shared set of ways of interacting in order to see if a community of practice has been developed. As such, the concepts of *mutual engagement, joint enterprise* and *shared repertoire* are used to identify both designed (Goos & Bennison, 2003; Hodges & Cady, 2013) and pre-existing (Siemon, 2009) communities of practice.

In addition to mutual engagement, joint enterprise and a shared repertoire, Siemon (2009) also uses Wenger's concept of *negotiation of shared meaning* when referring to a space where the participants in the different communities of practice can meet. This space is used both as a place to negotiate meaning and as a research tool to "explore the processes involved in building community capital" (p. 226). Furthermore, Siemon uses the concept of *boundary objects* when defining Probe Tasks as a boundary object in the negotiation described above (a Probe Task is described in the paper as a specifically chosen or designed task to support indigenous teacher assistants as they teach key aspects of number). Cwikla (2007) also uses the concept of *boundary objects.* In her investigation of the evolution of a middle school mathematics faculty, she uses this concept together with the concept of *brokers*, which is also from Wenger. She mentions communities of practice, but she does not define them. When using the concept of brokers, she refers to Wenger's definition, stating, "a broker can serve as a conduit for communication and translation between communities of practice" (p. 558). Corbin and colleagues (2003) also use the concept of *brokering* when investigating numeracy coordinators in an implementation of a national numeracy strategy. The concept is used to theorise tensions in the work of the coordinators. Corbin et al. find signs of brokering in their analysis by using three more of Wenger's concepts: the *modes of belonging: engagement*, *alignment* and *imagination*. Pratt and Back (2009) also use the concepts of *engagement, alignment* and *imagination* in their analysis. They also use Lave and Wenger's (1991) concept of *legitimate peripheral participant* as well as *peripheral and central participation* in their analysis. These concepts are used to describe a person's participation, and changes in participation, in two different communities of practice.

Bohl and Van Zoest (2003) mention that communities of practice develop through mutual engagement, joint enterprise and shared repertoire, but in their analysis they use two other concepts of Wenger's: *modes of participation* (their term for what Wenger refers to as *modes of belonging*) and *regimes of accountability*. They use these two concepts to analyse how novice teachers have different roles in different communities of practice and how this influences their mathematics teaching.

As mentioned, Franke and Kazemi (2001) analyse both the interaction in one community of practice and the identity development of individual participants. However, they do this without explicitly using any of Wenger's concepts. The artefacts they mention are not identified explicitly as artefacts used by Wenger but as used in sociocultural theories in general. They also mention *identity* and *negotiation of meaning*, both of which are thoroughly elaborated by Wenger, but they do not refer explicitly to how the concepts are used by Wenger. As such, Franke and Kazemi refer to, and use, Wenger's social theory of learning, but not explicitly or solely; rather, they present it as part of a general sociocultural view of learning.

Overall, several of Wenger's concepts are used in the studies presented in this paper, including *practice, meaning, identity, community, mutual engagement, joint enterprise, shared repertoire, modes of belonging, engagement, alignment, imagination, identity, brokering, negotiation of meaning, boundary objects, regimes of accountability, co-participation* and *participation*. However, seldom are more than three or four concepts used in the same study. Since the theory is broad and yet detailed, it is not surprising that researchers focus on and use only parts of it. Even so, none of the articles referred to in this paper draws attention to the fact that only certain parts of Wenger's theory will be used. Neither do they discuss the eventual consequences of not using the theory in its entirety. Hence, anyone reading only one of the articles may easily believe that the whole of Wenger's theory is used.

DISCUSSION

As seen in the examples in this paper, Wenger's social theory of learning is used in different ways in different studies. Wenger (1998) terms his work a "conceptual framework" (for example, p. 5), a "social theory of learning" (for example, p. 4) and/or a "perspective" (for example, p. 3). According to Eisenhart (1991), there are three kinds of research frameworks: theoretical, practical and conceptual. Eisenhart distinguishes these as theoretical frameworks based on formal logic, practical frameworks based on practitioner knowledge and conceptual frameworks based on justification. Somehow Wenger's social theory of learning comprises all three of these features. According to Niss (2007), theories are stable, coherent and consistent systems of concepts that are organised and linked in hierarchal networks. Those criteria apply to the content of Wenger's book. However, when researchers use only some of Wenger's concepts the criteria are no longer met. Furthermore, Niss (2007) writes that one purpose of theories "is to provide *a structured set of lenses* through which aspects or parts of the world can be approached, observed, studied, analysed or interpreted" (p. 100). The diverse uses of Wenger's social theory of learning presented in this paper show that the *structured set of lenses* used in these studies differ substantially.

According to Lester (2005), a framework provides structure in research when it comes to the questions being asked and the concepts, constructs and processes being used. Connected to the overview in this paper, the use of Wenger's social theory of learning appears to coincide with the first (questions), but not the rest. Even though the use of Wenger's social theory of learning differs in the studies presented in this paper, one similarity is the type of questions asked. These questions imply that the theory is considered suitable for studies of mathematics teachers', novice teachers', student teachers' and/or students' learning. Furthermore, in several of the studies (for example, Bohl & Van Zoest, 2003; Siemon, 2009) the social dimension of learning provided by Wenger is emphasised as its main strengths. As such, the use of Wenger's theory in mathematics education research seems to be part of the "turn to social theories in the field of mathematics education" (Lerman, 2000, p. 20). According to Lerman (2000), social theories make it possible to foreground individuals (practice in person) or practice (person in practice). However, both elements (person and practice) are always present and part of the analysis, which is in line with Wenger's "shift in focus within the same general topic" (p. 145).

As shown in this paper, there are differences in the presented studies in terms of communities of practice being viewed as pre-existing or designed as well as communities of practice being identified based on Wenger's concepts or not. In his book Wenger actually writes that since communities of practice are about content and negotiation of meaning – and not form – they are not "designable units" (p. 229). That is, according to Wenger, it is possible to design the outer limits but not the practice that may, or may not, emerge. As presented above, there is also diversity with respect to whether individuals or (communities of) practice are in the foreground. As also shown, there are differences regarding which of Wenger's concepts is used, even when the same perspective (individuals or communities of practice) is in the foreground. In terms of the concepts used, we were surprised by the rare presence of *reification* and *negotiation of meaning*, as these two concepts recur frequently throughout Wenger's book. Furthermore, there are many other concepts of Wenger's that are not used in any of the studies we read, including *local/global, identification, economies of meaning, ownership of meaning* and *trajectories*.

Finally, what can be learned from this overview of how Wenger's social theory of learning is used in different ways in mathematics education research? Well, often we (think that we) know what researchers imply when they say they have been using a specific theory in their research. However, from the overview presented in this paper, we know that if a researcher says that (s)he has been using Wenger's social theory of learning, we can be quite sure that we do *not* know exactly what that use of Wenger's theory might imply. In this paper, we have highlighted some of the diverse uses of Wenger's social theory of learning based on three themes: Are communities of practice viewed as pre-existing or are they designed within the study? Are individuals or groups foregrounded in the study? Which parts of the theory are mainly used? Probably further comparisons based on other themes will reveal other diversities. Further, based on the breadth and wealth of details in Wenger's social theory of learning, the list of themes and diversities may become quite long.

Beyond orchestration: Norm perspective in technology integration

Rüya Şay and Hatice Akkoç

Marmara University, İstanbul, Turkey, sayruya@gmail.com, haticeakkoc@yahoo.com

The aim of this study is to bring a socio-cultural dimension to "instrumental orchestration" framework. Our claim is that social and socio-mathematical norms endorsed by teachers are crucial for their pedagogies. A case study was designed to investigate how orchestration types and norms affect each other in technology-enhanced learning environments. Participants are five pre-service mathematics teachers. Data were collected through lesson plans, semi-structured interviews and observations. Analysis of data indicates that there is a two-way interaction between norms and orchestration types. In some cases, norms are determinants of orchestration types used by participants. In other cases, orchestration types challenge participants' endorsed norms.

Keywords: Socio-cultural approach, Social norm, Socio-mathematical norm, Instrumental orchestration.

INTRODUCTION

Recently, mathematics teaching in technology-enhanced environments has been widespread and mathematics teachers are faced with a large number of resources (Drijvers, 2012). Various official curriculum documents around the world emphasise the importance of using technology to support learning (NCTM, 1999, 2000; DfES, 2013a, 2013b). This requires certain knowledge and pedagogy. For example, International Society for Technology in Education describes technology standards and performance indicators for teachers. Teachers should be able to "plan and design effective learning environments and experiences supported by technology" (ISTE, 2000, p. 9).

Teachers play a key role in effective use of technology in the classroom and the way they integrate technology into teaching affects the way students learn mathematics (Ely, 1996, as cited in Besamusca & Drijvers, 2013). Therefore, mathematics teachers and teacher educators should be guided for the design of learning environments using technological tools and resources (Şay, Kozaklı, & Akkoç, 2013).

One of the theoretical frameworks to investigate the use of technological tools in the classroom is "instrumental orchestration" which is based on the framework of instrumental genesis (Trouche, 2004). Considering the literature on orchestration, it can be claimed that this theoretical framework focuses on classroom organisation but fall in short to explain psychological and sociological development of teachers. Teachers and pre-service teachers have different pedagogical approaches and go through different professional development phases. Therefore, an investigation of technology integration purely based on physical organisation of technology-enhanced learning environments and certain teacher behaviours is only one part of the whole picture. Teachers might have different norms and these affect the way they integrate technology into their lessons. However, there is little research in the literature on how teachers' activities in the classroom are shaped by their norms and very few of them investigated this in the context of technology. The aim of this study is to bring a socio-cultural dimension to instrumental orchestration. Socio-cultural theory aims to investigate human action and its relationship with cultural, institutional and historical situations. Therefore, it focuses on social interactions and the effects of culture on psychological development (Wertsch, del Rio, & Alvarez, 1995; Lerman, 2001). Technological tools can turn into effective instruments for learning mathematics via effective classroom interaction. Social and socio-mathematical norms, as one of the aspects of socio-cultural theory, might take a role in shaping student-teacher-tool interaction in the classroom. Furthermore, they are also shaped by this interaction. Therefore, one could elucidate how teachers use technological tools by embracing a norm-perspective within socio-cultural approach. Our claim is that social and socio-mathematical norms (Višňovská, *Cortina*, & Cobb, 2007) endorsed by teachers are crucial for their pedagogies and their choices for different orchestration types. To support this argument, this study investigates the interaction between orchestration types used by pre-service mathematics teachers and social and socio- mathematical norms.

INSTRUMENTAL ORCHESTRATION

An instrumental orchestration is defined as the teacher's intentional and systematic organisation and use of the various artefacts available in a learning environment in a given mathematical task situation, in order to guide students' instrumental genesis (Trouche, 2004).

Drijvers (2012) distinguishes three elements within an instrumental orchestration: a didactic configuration, an exploitation mode and a didactical performance. "A didactical configuration is an arrangement of artefacts in the environment, or, in other words, a configuration of the teaching setting and the artefacts involved in it" (p. 266). An exploitation mode is defined as the teacher's decisions on the way she or he configures a task by providing certain roles for the artefacts to achieve his or her didactical intentions.

> A didactical performance involves the ad hoc decisions taken while teaching on how to actually perform in the chosen didactic configuration and exploitation mode: what question to pose now, how to do justice to (or to set aside) any particular student input, how to deal with an unexpected aspect of the mathematical task or the technological tool, or other emerging goals (Drijvers, p. 266).

Drijvers and his colleagues (2010), Drijvers (2012) and Tabach (2013) distinguish ten types of instrumental orchestrations as seen in Table 1 (The last three orchestration types are not in the original table and were added from the literature). In this study, pre-service teachers' lessons will be analysed considering the orchestration types in this table.

The orchestration types	Didactical configuration	Exploitation mode
Technical-demo (Drijvers and his colleagues, 2010)	Whole-class setting, one central screen	The teacher explains the technical details for using the tool.
Explain-the-screen (Drijvers and his colleagues, 2010)	Whole-class setting, one central screen	The teacher's explanations go beyond techniques and involve mathematical content.
Link-the-screen board (Drijvers and his colleagues, 2010)	Whole-class setting, one central screen	The teacher connects representations on the screen to representations of the same mathematical objects that appear either in the book or on the board.
Sherpa-at-work (Drijvers and his colleagues, 2010)	Whole-class setting, one central screen	The technology is in the hands of a student, who brings it up to the whole class for discussion.
Not-use-tech (Tabach, 2011)	Whole-class setting, one central screen	The technology is available but the teacher chooses not to use it.
Discuss-the-screen (Drijvers and his colleagues, 2010)	Whole-class setting, one central screen	Whole class discussion guided by the teacher to enhance collective instrumental genesis.
Spot-and-show (Drijvers and his colleagues, 2010)	Whole-class setting, one central screen	The teacher brings up previous student work that he/she had stored and identified as relevant for further discussion.
Work-and-walk-by (Drijvers, 2012)	Students work individually or in pairs with computers	The teacher walks among the working students, monitors their progress and provides guidance as the need arises.
Discuss-the-tech-without-it (Tabach, 2013)	Every students have own laptops or laptops bring classroom with wheeled vehicles	The teacher uses mobile transport system if he/she needs computers in teaching
Monitor-and-guide (Tabach, 2011)	----	The teacher uses a learning management system by giving guidance to students

Table 1: Orchestration types (Tabach, 2013, p. 3)

SOCIAL AND SOCIO-MATHEMATICAL NORMS

In mathematics education literature, it is widely recognised that social interaction promotes learning opportunities. Norms construct how students learn mathematics and how they become mathematically autonomous (Cobb & Bowers, 1999; Pang, 2000). Norms regulate the way teachers and students participate in learning and teaching activities within a classroom culture (Cobb & Yackel, 1996). While norm emerges from social interaction; belief, value, opinion and attitude are concerned with the individual.

Cobb and Yackel (1996) propose social and socio-mathematical norms to investigate how students' mathematical values and beliefs develop within the classroom culture from the psychological and socio-cultural perspectives. Cobb and his colleagues (2007) also investigated teachers' professional development through social and socio-mathematical norms (Visnovska, Cortina, & Cobb, 2007). Social norms apply to any subject matter area. Students' cooperation when solving problems or privileging a logical explanation over other correct answers are examples of social norms (Hershkowitz & Schwarz, 1999). Another example is the way teachers promote students' thinking and value different ideas. On the other hand, socio-mathematical norms are specific to mathematics and are concerned with the way mathematical beliefs and values develop in the classroom. For example, acceptability of a mathematical explanation or a justification is a socio-mathematical norm (Yackel & Cobb, 1996; McClain & Cobb, 2001).

METHODOLOGY

This study embraces the interpretive paradigm to investigate how orchestrations types and norms affect each other in technology-enhanced learning environments. A case study was designed to answer the research question. Participants are five pre-service mathematics teachers who were enrolled in a teacher preparation program in a state university in Istanbul, Turkey. It was a four-month program which will award its participants a certificate for teaching mathematics in high schools for students aged between 15 and 18. The program accepts graduates who have a BSc degree in mathematics. There were two kinds of courses in the program: education and mathematics education courses. The study was conducted during "Instructional Technologies and Material Development" and "Teaching Practice" courses. The former course focused on six software, namely Geogebra, Graphic Calculus, Derive, Geometry Sketchpad, Excel and Probability Explorer. Participants were involved in hands-on activities in front of a computer and prepared teaching materials. Participants also taught lessons in partnership schools during "Teaching Practice" course.

There were thirty-six participants in the program. They were all interviewed on their approach to the use of technology for teaching mathematics. Five participants were purposefully selected. Two of them (one male and one female) had positive attitudes and two of them (one male and one female) had negative attitudes towards the use of technology. One participant was selected because she had neutral attitude.

The data collection methods are observation and semi-structured interviews. Each participant taught a total of five lessons in a partnership school. At least two of these lessons were technology-based. Each participant taught at least two same classes of students. They were interviewed after their lessons. During the semi-structured interviews they were asked what kinds of norms they endorsed, how they used technology in their lessons and differences between their lessons with or without technology. Their lessons were video recorded. The first author of this paper observed lessons using an observation form. The aim of the observation form was to reveal social and socio-mathematical norms endorsed by pre-service teachers. Interviews and lesson videos were verbatim transcribed. Data from different sources such as interviews, observations and field notes were triangulated. Common themes emerged from verbal discussions among pre-service teachers and students, patterns in pre-service teachers' behaviours and statements about their endorsed norms during the interviews. For instance, the socio-mathematical norm "Answers which are logical are acceptable" was determined considering pre-service teachers' discussion with students and how they defined "an acceptable answer" during the interview.

FINDINGS

This section presents orchestration types and social and socio-mathematical norms used by participants. First we demonstrated how participants used orches-

Orchestration types	Pre-service teachers
Technical-demo	Nil, Orkun, Melek
Explain-the-screen	Mahir, Orkun, Melek
Discuss-the-screen	Melek
Sherpa-at-work	Orkun, Melek, Nil
Not-use-tech	Oya, Mahir, Nil, Orkun, Melek

Table 2: The orchestration types used by pre-service teachers

tration types and then how norms and orchestration types affected each other.

The analysis of the data indicated that participants mostly used *technical-demo, explain-the-screen, link-the-screen-board, discuss-the-screen, Sherpa-at-work and not-use-tech* orchestration types as seen in Table 2.

Explain-the-screen promoted the social norm "the authority is the teacher". For example, Mahir taught a lesson on parabolas using Geogebra software. He started his lesson by explaining how to draw a parabola and adding a slide which is defined as the determinant. He then moved the slide and explained what happened to the graph of parabola. At this stage he did not questioned the mathematical meanings behind what the software performed, but just explained how to use the software.

When participants used *link-the-screen*, they explained a concept or a mathematical idea on the board followed by an elaboration using the software. For example, Orkun taught a lesson on how to draw the graph of $y = \sin x$ using Geometry Sketchpad. He first plotted a few points and then drew the graph on the board. However students claimed that points should be joint using straight lines. He then moved to the software and constructed a unit circle. He defined a point A on the unit circle and a point B which defines the sine function. Using "trace" feature, he obtained the graph of $y = \sin x$. Up until now, the authority was the teacher. Therefore, it can be claimed that *link-the-screen* orchestration type promoted this social norm. Afterwards he asked students how to draw $y = \cos x$ and $y = \tan x$ themselves. His question is an indication of a social norm "Students are challenged with the questions of why and how". This social norm required using *discuss-the-screen* orchestration type.

Another participant who used *discuss-the-screen* discussed with their students the actions they performed using the software. For example, Melek used Geometry Sketchpad to explain how to draw trigonometric functions. She first drew the graph of $y = \sin x$ and then asked one of her students to draw $y = \cos x$. Later she discussed with her students how to draw $y = \tan x$ using the software and tried to reach a common ground ($\tan x = \sin x/\cos x$):

Melek:	Is there anyone who wants to draw the tangent line?
Student A:	This time, we will construct a point with x and y (on the unit circle)...
Student B:	Slope
Melek:	What else? What is slope? One of the definitions is opposite over adjacent. It's the ratio of opposite side over adjacent side or what is $\tan x$?
Student C:	$\sin x$ over $\cos x$
Melek:	Isn't it $\sin x$ over $\cos x$. That's the expression that everybody knows. Therefore, when we want to find the ratio of $\sin x$ over $\cos x$, that is when we think graphically (showing the point on the unit circle) if we vertically projected this point onto x-axis, we say opposite over adjacent to find the tanjant

When pre-service teachers were using *discuss-the-screen* they endorsed the socio-mathematical norm "Answers which are logical are acceptable". For example, Melek who used *discuss-the-screen* aimed at having her students discuss mathematical meanings behind what the software perform. When doing this, she considered different student answers and did not impose her answers or solutions. She encouraged her students discover their own solutions which were meaningful for them. As can be seen in this case, the orchestration type used by this pre-service teacher affected her endorsed norm. In other words, a norm has emerged which support *discuss-the-screen* orchestration type.

Pre-service teachers chose not to use technology (not-use-tech orchestration type) at least once out of five lessons they each taught. Before participants had teaching experiences with using technology in the classroom, they had the socio-mathematical norm which gives the teacher the mathematical authority and believed that technological tools were not necessary for teaching mathematics:

> Oya: I'm quite conservative. I believe that mathematics should be taught using the blackboard. I think that maths would be better understood this way

Oya was a unique case who's social or socio-mathematical norms did not change after she started using technological tools in her lessons. On the other hand, Orkun who has negative attitudes towards using technology in a mathematics lesson changed his endorsed norms and this situation is illustrated with the following excerpt:

> Orkun: In my first lesson (which he did not use any technological tool) I wished that student would not ask me any questions. Because I was teaching inverse trigonometric functions and the questions I prepared were very difficult ones... students in this school were very clever and I was worrying about receiving different questions. And there was no help from technology. I had to teach on the blackboard. But on the next lessons when I used technology, I wasn't afraid of their questions. When I'm stuck on the board I knew that I could switch to technology

As can be seen from the excerpt above, he sees technological resources as a helpful tool which gives him confidence. This confidence changed his norms and pedagogy.

Another orchestration type observed in this study is *Sherpa-at-work*. Participants in this study used this orchestration type in a different way when compared to the related literature. In the literature, when using Sherpa-at-work students work in front of a computer individually or in pairs and "the technology is in the hands of a student, who brings it up to the whole class for discussion" (Tabach, 2013, p. 3). However, there was a lack of technological resources in partnership schools and students did not get the chance to use their own computers during the lessons. Participants had their own computers which were projected on to a screen. This situation prevented active participation of students. Orkun, Melek and Nil tried to resolve this problem by having students use the teacher's computer. This corresponds to *Sherpa-at-work* orchestration type which emerges as a result of "students who answers correctly go to the blackboard" social norm.

DISCUSSION

This study investigated how orchestration types and norms affect each other in technology-enhanced learning environments. The findings indicated that pre-service mathematics teachers used some of the orchestration types frequently such as *link-the-screen-board* and *not-use-tech*. On the other hand, some of the orchestration types such as *spot-and-show*, *work-and-walk-by*, *discuss-the-tech-without-it* and *monitor-and-guide* were not used because of lack of technological resources in the partnership school. All classrooms in this school have smart boards but students did not have their own computers or tablets. Therefore, some of the orchestration types were not observed.

Drijvers and his colleagues (2010) claimed that teachers make pedagogical choices based on their views about how to teach mathematics. This study has similar findings by illustrating how orchestration types and norms support each other. Social and socio-mathematical norms endorsed by participants affected their choices of technological tools for teaching mathematics and as a result orchestration types they used.

Our claim was that there was a two-way interaction between orchestration types and social and socio-mathematical norms. This study attempted to justify this claim. As a matter of fact, Drijvers (2012) described *technical-demo*, *explain-the-screen* and *link-the-screen-board* orchestration types as teacher-centred and *Sherpa-at-work*, *spot-and-show* and *discuss-the-screen* orchestration types as student-centred. Therefore, participants who used teacher-centred orchestration types endorsed socio-mathematical norms accept the teacher as the mathematical authority. On the other hand, participants who used student-centred orchestration types endorsed social norms which puts students into the centre.

Findings of this study also revealed that instrumental orchestration framework fall in short in explaining the socio-cultural aspect of technology integration. In terms of teacher-student-tool interaction, technological tools provide a language which supports communication between students and teachers (Noss & Hoyles, 1996). Examining the micro-culture of the classroom provided by this kind of language and social and socio-mathematical norms required by that culture expanded our understanding of orchestration framework. Integrating instrumental orchestration framework into norm perspective provided an insight on the question of why and how particular orchestration types are used.

This study suggests some implications for researchers and teacher educators. First of all, as mentioned above, there is not satisfying research which explicitly investigates norms in the context of technology integration. In this study, this was investigated in the context of a short-term teacher preparation program in Turkey. There is a need for further studies. Second, teacher education programs which aim successful technology integration should develop an awareness of social and socio-mathematical norms and monitor pre-service teachers' development with regard to their endorsed norms.

5 BIFIE, Wien, Austria

A project group was commissioned to develop a content- and action-related competency grid in order to enable quality assessment and comparability of mathematics examination questions in the Austrian Matura (final examination at the end of the Secondary School Level II). Based on theoretical grounds, in the competency grid the three dimensions operating, modelling and reasoning are distinguished and described on four levels.

Keywords: Competency level model, school, final exam, operating, modelling, reasoning.

Obtaining information on the development of mathematical competency is a central concern of mathematics education (e.g., Leuders, 2014) and empirical educational research (e.g., Hartig, 2007). In Austria, an approach with the goal of a standardized competency-based written final examination – the so called 'Matura' at the end of Secondary Level II – (cf. AECC Mathematik, 2009; BIFIE, 2013a) in the context of mathematics as a general education subject (cf. Fischer, 2001; Fischer & Malle, 1985; Klafki, 1985; Winter, 1975, 1996) was applied. Examinees are expected to have both mathematical (basic) knowledge and (basic) ability, as well as general mathematical skills such as reasoning skills, problem solving skills, and also the ability to use mathematics in different situations, i.e. modelling skills. However, in PISA 2000, a lack of modelling competency was observed, when students failed to solve (real-life) problems with the help of models in a satisfying way (cf. Klieme et al., 2001). Based on this result, modelling competence was crucial for competency orientation in the curriculum enhancement of mathematics education in the German-speaking region (thus also for the *Matura* in Austria). With reference to Weinert's definition of competencies (2001, p. 27) as

> the cognitive skills and abilities which the individual possesses, or which can be learned, to solve certain problems, as well as the associated motivational, volitional and social readiness and skills in order to successfully and responsibly use problem solutions in a range of situations.

In an iterative process we developed a competency level model for the written final exam in mathematics at the end of Secondary School Level II. The process consisted of four elements: the discussion of competency specifications and developments, the discussion of mathematical tasks, task rating in due consideration of the competency model and the discussion of these ratings. Against the background of theoretical and also experience-based ideas about the current development of mathematical skills in school learning, we described the following three domains of mathematical competencies: operating, modelling, and reasoning[1] (O-M-A) on four levels.

In close cooperation with the Federal Institute of Educational Research, Innovation and Development of the Austrian School System ('BIFIE'), we developed a competency level model facilitating the description and comparison of the exam requirements, especially with regard to examination questions in the final examination in mathematics (Siller et al., 2013).

COMPETENCY LEVEL MODEL

In the competency models of the German-speaking countries Austria, Switzerland and Germany (AECC Mathematik, 2008; HarmoS, 2011; KMK, 2012), content areas (such as geometry or arithmetic), general mathematical competencies (such as reasoning) and skill levels (usually three-stage) are considered. The elements of the model in each country are therefore different when compared to one another. The competency levels are somewhat vague. Therefore, they can only be described on the basis of empirical task difficulty. To put our competency level model in a wider scientific context, we follow Leuders (2014, p. 10): "A model is discussed which (i) a priori postulates levels in acquiring a certain competence, is describing (ii) through stepped task situations and (iii) hierarchically ordered categorical latent ability variable. This allows (iv) determination about which competency pupils possess at each level."

In comparison to earlier statements, the development that has taken place in this area is evident. For example, Helmke and Hosenfeld stated in 2004 (p. 57):

> Neither are the currently available versions of the educational standards derived at the time from comprehensive and didactic accepted competency models (...) nor is there already in all relevant areas of content expertise models which meet the abovementioned requirements, particularly theoretically coherent developmental and learning psychology based levels concepts.

Thinking in (competency) levels is common in schools since curricula and teaching materials are based on this view (cf., e.g., Kiper, Meyer, Mischke, & Wester, 2004). Competency level models contribute to the diagnosis of the learners' levels of competency by the assessment of their achievements. Moreover, the models aim at describing the development of competencies. Their weaknesses, however, are embodied in the fact that it usually remains undetermined how a change to the next level can be accomplished and what conditions are necessary for this. Furthermore, a fixed sequence is assumed, which implies that neither can any steps be skipped nor regressions occur, but which assumes steady, cumulative learning.

For the present competency level model we have agreed on four stages, which can be identified in a manner analogous to Meyer (2007), who described the following four levels (Meyer, 2007, p. 5):

1) Execution of an action, largely without reflective understanding (level 1)

2) Execution of an action by default (level 2)

3) Execution of an action after insight (level 3)

4) Independent process control (level 4)

The activity theory forms the background for the didactic interpretation of such initially pragmatic levels (cf., e.g., Lompscher, 1985) with the corresponding concept of different cognitive actions and their specific dimensional structure. Nitsch and colleagues (2014) developed and empirically verified a competency structure model that describes relevant student actions when translating between different forms of representations in the field of functional relationships. For example, they could show that the two basic actions of acquirement *Identification* and *Implementation* (Construction) and the basic cognitive actions *Description* and *Explanation* differ in their cognitive demands, i.e. they are based on different facets of competency. Therefore, we used the theoretical model of hierarchical structure of cognitive actions (Bruder & Brueckner, 1989) for the description of competency levels.

DEVELOPMENT OF A COMPETENCY LEVEL MODEL

Currently existing competency models are primarily based on empirical analyses: Based on the solution probabilities of tasks (items), competency levels are modelled in the context of large-scale studies. An alternative approach is to primarily derive a model from theoretical concepts. This also requires the recognition of central instructional goals such as a sustainable understanding of mathematical relationships, which in turn presupposes a high level of cognitive activation in the teaching processes (cf. Klieme et al., 2006). This can, for example, be achieved by the following measures:

— the preparation of relationships for basic knowledge and skills learned;

— the challenge to describe mathematical relationships or solutions in application contexts;

— the creation of occasions for reasons or reflections.

Such criteria of demanding instruction should also be appropriate to form a competency level model.

THE COMPETENCY LEVEL MODEL O-M-A

Competency level models that are empirically based indicate to what extent tasks differ in their level of difficulty in terms of processing. Evidence of existing difficulties can be obtained by carefully analysing potential and actual solutions. Normative stipulations of difficulty levels imply that it is not possible to successfully process the task on a lower level. The levels of the competency model postulate what skills are needed to solve them. This does not exclude that there are multiple solution strategies, particularly for complex task definitions.

For designing the domains of mathematical competencies, we follow an orientation to Winter's basic experiences (cf. Winter, 1996, p. 37):

1) To perceive and understand phenomena of the world around us that concern or should concern all of us, from nature, society and culture in a specific way,

2) to learn and comprehend mathematical objects and facts represented in language, symbols, images and formulas as intellectual creations as a deductive-ordered world of its own kind,

3) to acquire task problem-solving skills that go beyond mathematics (heuristic skills).

While the first basic experience corresponds to mathematical modelling as a fundamental action area in learning mathematics, there are the other two basic experiences "operating" and "reasoning", which serve the second fundamental experience as well as "problem solving" for the third basic experience. In various competency models „communicating" is included to emphasize the linguistic aspects, as well as other domains of mathematical competencies.

"Problem solving" is not separated as an independent domain in the Austrian requirements for the final examination (BIFIE, 2013). "Problem solving" is defined as a more complex aspect of action and therefore includes the domains of the mathematical competen-

	Domains of mathematical competency		
Level	**Operating**	**Modelling**	**Reasoning**
1	Identify the applicability of a given or familiar method; Implementing/executing a given or familiar rule	Implementation of a representation change between context and mathematical representation Using familiar and directly recognizable standard models for describing a given situation with appropriate decision	Perform basic technical language reasoning Examine the application of a relationship or method and the fit of a term for a given (intra-mathematical) situation
2	Implementing/executing multi-step methods/rules, possibly with the use of computers and use of control options	Description of the given situation by mathematical standard models and mathematical relationships Recognizing and setting general conditions for the use of mathematical standard models	Understand, comprehend, explain mathematical concepts, principles, methods, representations, reasoning chains and contexts
3	Determine whether a particular method/specific rule is appropriate for a given situation, make and perform the appropriate method/rule	Apply standard models to novel situations, find a suitable fit between suitable mathematical model and real situation	Examine and complete mathematical reasoning, perform and describe multi-step mathematical standard reasoning
4	Develop/form macros[1] and join together macros already available	Complex modelling of a given situation; reflection of the solution variants or model choice and assessment of the accuracy or adequacy of underlying solution methods	Form independent chains of reasoning, technically correct explanation of mathematical facts, results and decisions

[1] aggregated mathematical rules

Figure 1: O-M-A Grid

cies Operating, Modelling and Reasoning, especially in higher levels of performance. “Communicating” is seen as an important domain of mathematical competencies for teaching mathematics, but cannot be specifically differentiated from Operating, Modelling and Reasoning and is therefore included in the other aspects.

The domain “Reasoning” is related to the suggestions of Bruder and Pinkernell (2011), who also pick up on considerations of Walsch (1972). “Modelling” served as the basis of the fundamental work of Niss (2003) and other ideas, e.g. of Boehm (2013) or Goetz and Siller (2012). There are relatively few preparations for a levelled conception of competencies in the mathematical domain “Operating”.

For example, Drueke-Noe (2012) shows that complex algorithms are required already in early grades. But for a high level of expertise, it is not only necessary to use complex algorithms, but also to find the right algorithm to apply in a given situation and to combine different algorithms where appropriate.

The result of our considerations as part of this project is a model with three domains of mathematical competencies (cf. Figure 1) that substantially captures the key aspects of mathematical work at school. The competency level model is aimed at fulfilling all essential requirements with regard to the conception of mathematical learning outcomes in Austrian mathematics education of the Secondary School Level II (cf. BIFIE, 2013a). Complex problem solving situations can be described by the interaction of the three domains of mathematical competencies.

EMPIRICAL EVIDENCE FOR THE COMPETENCY LEVEL MODEL

The question about an empirical verification of the theoretical competency level model with respect to the separation of domains of mathematical competencies and the gradation can be answered only in the context of a sufficient number of processed tasks for each area of expertise.

Data were taken from the so-called “school experiment” in 2014. Before the central final examination throughout Austria will be implemented in the school year 2014/2015, secondary academic schools and mathematics teachers were invited to voluntarily take part in a pilot study on graduating students’ math competences. In this study, the math tasks were processed under the same conditions as they would be processed at the mandatory central final examination. It is important to note that the performance in the tasks contributes to students’ final grade. For the school experiment whose data are being reported here, there were 803 students (m = 345, f = 458) from 42 classes from 9 districts in Austria. The examination consisted of two separated parts with so-called type 1 and type 2 tasks (cf. BIFIE 2013b).

Type 1 tasks “focus on the basic competencies listed in the concept for written final examination. In these tasks, competence-oriented (basic) knowledge and (basic) skills without going beyond independence are to be demonstrated.” (cf. BIFIE, 2013a, p. 23). They are coded as solved against non-solved. The various bound response formats such as multiple-choice format and a special gab-fill format enable accurate scoring. For the award of points in tasks with open and semi-open response format, solution expectations and clearly formulated solution keys are specified.

The characterization of type 2 tasks presents serious challenges to the basic principles of modern test theory. The tasks are considered “for the application and integration of the basic competencies in the defined contexts and application areas. This is concerned with extensive contextual or intra-mathematical task assignments, as part of which different questions need to be processed and operative skills are, where appropriate, accorded greater importance in their solution. An independent application of knowledge and skills is necessary” (cf. BIFIE, 2013a, p. 23). These tasks are also consistently structured in design and presentation, as well as in terms of scoring (cf. BIFIE, 2013).

A total of 16 (type 1) tasks in the competency domain of operating, 2 tasks (type 1) in the competency area of modelling, and 4 tasks (type 1) in the competency area of Reasoning were tested in the 2014 school experiment. Thus, no level analyses could be conducted.

There is a relatively high variation of the solution frequency within competency domain Operating (cf. Figure 2), which can be explained by the heterogeneity of tasks presented, especially with regard to high profile / over-training. Variation of solution frequency was also observed for the competence do-

Task	Competence domain	level of difficulty (% solved)
3	Operating	0.81
4	Operating	0.84
7	Operating	0.98
8	Operating	0.94
9	Operating	0.84
10	Operating	0.88
12	Operating	0.87
13	Operating	0.59
14	Operating	0.88
15	Operating	0.56
17	Operating	0.84
18	Operating	0.57
21	Operating	0.80
22	Operating	0.49
23	Operating	0.81
24	Operating	0.58

Figure 2: Difficulty level of the tasks for the competence domain Operating (n = 803)

Task	Competence domain	level of difficulty (% solved)
19	Modelling	0.51
20	Modelling	0.91

Figure 3: Difficulty level of the tasks for the domain Modelling (n = 803)

Task	Competence domain	level of difficulty (% solved)
1	Reasoning	0.80
5	Reasoning	0.73
6	Reasoning	0.94
11	Reasoning	0.64

Figure 4: Difficulty level of the tasks for the domain Reasoning (n = 803)

main Modelling (cf. Figure 3) as well as Reasoning (cf. Figure 4). The parameter "difficulty" was not measured, only the percentage of solution as an indicator for the level of difficulty of a task.

Two of the type 1 tasks are positioned on competency level 2 and could be analysed. A heterogeneous picture emerged for these two tasks: While task 2 could rarely be solved, task 16 was easily mastered by the students.

Can the pre-defined four levels be confirmed empirically in all the three areas of competency? This question can be answered in a first approximation only on the basis of type 2 tasks for levels 1 and 2 due to the fact that higher graduations did not appear in these exam booklets.

As can be seen in Figure 5 (in general) and Figure 6 (separated among O-M-A), the level 2 tasks seem to be more difficult in general. Thus the competency level of the task gives us a good statement about the level of difficulty.

SUMMARY AND OUTLOOK

The provided model with the three domains of mathematical competencies Operating, Modelling and Reasoning (O-M-A) distinguishes three basic mathematical operations on four levels. It is based on considerations from educational sciences and

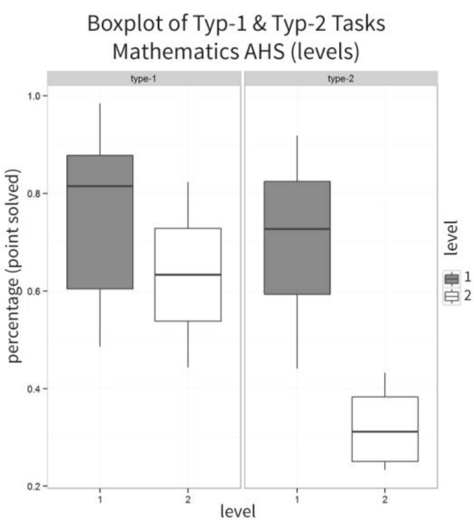

Figure 5: Empirical difficulties of type 2 tasks separated by type and level (n = 803)

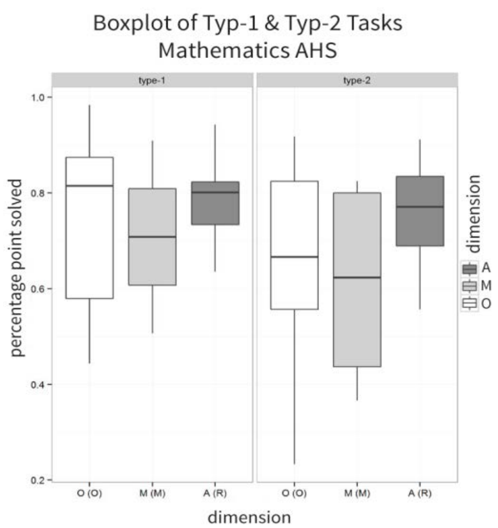

Figure 6: Empirical difficulties of the type 1 and type 2 tasks among O-M-A (n = 803)

learning theories as well as insights and experiences with regard to relevant factors for learning mathematics in school. It is part of a complex effort to gain a sound basis for competency diagnostics and performance assessment in mathematics in the German-speaking countries. It differs from other models by its consistent theoretical foundation and by the focus on potential lines of development for long-term competency building. The model O-M-A provides a normative setting for relevant levels of requirement in the three domains of mathematical competencies. This facilitates a certain comparability of type 1 and type 2 tasks provided for the final examination.

The added value of the developed model lies in several areas:

— It provides guidance both for the assessment of (written) performance and for the learning tasks in the classroom.

— It serves the purpose to reveal potential for development in the classroom.

— It allows for the identification of development potential in the task structure.

Limitations of the competency level model O-M-A lie in the coarseness of the approach. Neither can all the differences between the test tasks relevant to their level of difficulty be considered in detail (such as linguistic complexity), nor can individual developmental trajectories be mapped in learning processes. Further restrictions of the model are also indicated by the fact that of all the mathematical content and activities implied in each task only a basic competency referring to the list of basic skills (cf. BIFIE, 2013a) can be adopted. The specific situation of each school class or priorities of teachers cannot be reflected. Thus, many tasks can prove to be easier, but also more difficult than in the rating.

The competency level model O-M-A aims at describing levels of competencies by identifying the qualitative differences of each competence. The growing body of research on mathematics learning served as the theoretical background. The data and results presented so far are preliminary and did not account for not controllable influence factors such as training effects. However, they can be interpreted as a first clue that the O-M-A can be rudimentarily verified empirically. Therefore, further research is necessary to empirically test the levels of the model and to test the model against level 3 and level 4 tasks.

The model O-M-A is indefinite in explaining the attainment of the next higher level. For this reason we define it as a competency *level* model and not a competency *development* model. To answer the question as to whether this model could map potential lines of students' long-term competency development, more theoretical and empirical work is needed. So far, it cannot be applied to the development of a math learning process.

ACKNOWLEDGEMENT

The project "Competency Level Modelling" was funded with support from the Federal Institute of Educational Research, Innovation and Development of the Austrian School (BIFIE). This publication reflects the views of the authors, and the BIFIE cannot be held responsible for any use that may be made of the information contained therein. We acknowledge the contribution of Martin Schodl, who has been working in the project as a coordinator and who has helped selecting certain data.

Inferentialism in mathematics education: Describing and analysing students' moves in sorting geometrical objects

Abdel Seidou

Örebro University, Örebro, Sweden

This poster presents a language for describing and analysing students' language "moves" while reasoning in an open-ended sorting activity. A close analysis of one individual student's language moves in a collaborative activity is supposed to shed light on individual contribution to the collaborative reasoning process. Furthermore, these moves give indications on what pupils decided to be relevant in the simultaneous enterprise of reasoning in collaboration, and even the prior knowledge available in the classroom.

Keywords: Inferentialism, deontic score-keeping, mathematical reasoning, collaboration.

THEORETICAL FRAMEWORK

The purpose of this poster is to present an inferentialist language for describing reasoning in terms of moves in language game. Inferentialism is introduced by Robert Brandom (1994), and it advocates a new order of explanations. Inference is to prioritize over reference or representation, and it is set at the heart of human knowing. Inferentialism identifies the meaning of an expression by its inferential relationship to other expressions. Brandom (2000) stated:

> To grasp or understand [...] a concept is to have practical mastery over the inferences it is involved in – to know, in the practical sense of being able to distinguish (a kind of know-how), what follows from the applicability of a concept, and what it follows from. (Brandom, 2000, p. 48, his italics)

The introduction of inferentialism to mathematics education research is recent. Nevertheless, ideas based on inferentialism have already been used in different ways in mathematics education research. Schindler and Hußmann (2013) used the status of claims (commitments and entitlements) to investigate 6th grade students' individual learning process and concepts formation in the topic of negative numbers. Bakker and Derry (2011) draw upon inferentialist epistemology, to design tasks in teaching statistics inferences. Based on inferentialism, this poster will present a language to describe and analyze young learners' collaborative mathematical reasoning.

Geometrical objects (2D) of different sizes and shapes were presented to groups of four first grade young learners (6–7 year olds) by the teacher. They were challenged to collaboratively come to an agreement on ways of sorting. The open-ended aspect of this task creates favorable conditions for a fruitful game of giving and asking for reasons.

Brandom (1994; 2000), used the term deontic scorekeeping to name a process embedded in the game of giving and asking for reasons. During this process, different competent interlocutors keep track of their own and others' linguistic performance. It describes the course by which different interlocutors converge toward the same meaning, in search of agreement or/and objectivity. It comprises both collaboration and the reasoning. The analysis of the deontic scorekeeping, especially the "moves" will serve as tool to characterize and analyze young learners' collaborative mathematical reasoning.

The "moves" express how claims are put forward: *Attributing*, *acknowledging* and *undertaking*. Attributing is just a kind of reporting, and it does not indicate an understanding or knowing. Acknowledging is to take something to be true. Undertaking a claim is to be aware of the premises and consequences of it.

The moves are interrelated and depend on each other. For instance undertaking a commitment is something that makes it appropriate for others to attribute it (Brandom, 2000).

I believe the "moves" could also show signs of participating norms/rules in a classroom if they are investigated with appropriate quest. To illustrate the analytical points of the proposed theoretical framework, the poster presents video recorded data from a Swedish classroom.

Crossroads of phenomenology and activity theory in the study of the number line perception

Anna Shvarts, Andonis Zagorianakos

Lomonosov Moscow State University, Moscow, Russia, shvarts.anna@gmail.com
Manchester Metropolitan University, Manchester, UK

The research is a study of the productivity of a dual analysis of the same phenomenon from the cultural-historical activity theory (CHAT) and from the Husserlian phenomenological perspective. It analyses the eye-movements of children and their parents while they were operating with the number line. We also were focused on the interaction between children and parents while each parent was teaching the child and we analyzed it in correspondence with eye-movements. The implementation of the dual theoretical perspective to our eye-tracking data sources disclosed the subtle synchronization of intersubjective communication, already starting in the embodied, pre-reflective area of the cognitive experience. The two theoretical perspectives exerted a significant complementarity in bringing about the social and the subjective – intentional aspects of the phenomenon of learning.

Keywords: Activity theory, phenomenology, intentionality, eye-tracking, number line.

Radford (2010) considers the development of perception in mathematics education from a cultural-historical activity theory (CHAT) perspective and argues that only through social practice the "domestication" of a perceptive organ (an eye) can occur, and that the phenomenological approach towards perception as a system of intentional acts cannot explain acquiring of the new, culturally specific ways to approach objects. Our research shows the productivity of a dual analysis of the same phenomenon from CHAT and phenomenological perspectives. We analysed the eye-movements of participants while they operated with the number line. An SMI RED eye-tracker was used with sample rate 120 Hz. The task was to specify the point on the number line from 0 to 10 a grasshopper was sitting. There were 6 pairs of adults and pre-schoolers. We collected three sorts of data: adults' perception; interaction between children and parents when we asked each parent to teach their child; and children's perception. The results in our poster from qualitative analysis presented as series of pictures, which represent synchronized data of short time interval (0,5–5 seconds) tracks of eye-movements, speech oscillograms, audio transcriptions and pictures of gestures, taken by an external camera. Here is a space-saving summary of interweaving ways to address results from the two perspectives.

(1) Adults' perception and teaching strategies revealed a vivid difference in how the parents detected the point on the number line themselves, and how they taught the children to do it. All adults either immediately grasped the answer by one fixation, or by a couple of fixations while they were counting from the midpoint or the last point. While teaching, most of our adults showed the child a strategy of counting from zero up to the point, making arc movements with their finger from point to point, and rhythmically counting or making pauses for the child to count. From the CHAT perspective that focuses on cultural practices and artefacts (Vygotsky, 1981) we need to interpret the adults' kind of perception as *mediated* by previous knowledge and by the number line itself—which is a visual semiotic means that has sedimented the activity of counting. We can judge the way that adults performed counting as a developed perception that has a form of mental action that keeps only a general form of real action and misses the intermediate parts (Davydov, 1959). Following the Husserlian phenomenology by adopting the first person perspective in our analysis, we see the adults' perception as *immediate*, where a number line is "taken for granted" (Husserl, 2001, p. 338), i.e., approached as a natural object of their living world without treating it as a product of previous mathematical work.

(2) In the teaching stage the attention of the children was strongly driven by a system of means used by the adult. Each pointing movement of the finger of the adult corresponded to a prosodic stress and to a fixation of the child's glance on a point on the number line; the adult made a theoretical perception possible through involving the child into *social practice*, "through an intense recourse to pointing gestures, words, and rhythm", as Radford (2010, p. 5) puts it. Now let us look more closely at the children's eye-movements. In one case the child followed the adult's movements precisely in counting from zero up to ten, but at the moment when her finger was passing the point where the grasshopper was sitting, the child found time to look at the written question of the task. In another example a child misperceived an adult's gestures: she was moving her eyes one point ahead of where the adult was pointing. But being in contact with the original task she managed to correct herself at the end of the counting: she was making two fixations on the same point where the grasshopper was, corresponding to two separate arc movements of her father's finger. Thus, being "moved" by the adult activity the children caught up the meaning of it through the goal, which was retained at a grounding level of the children intentionality. So, our data show that it is exactly a complex system of *intentionality* that makes possible the "crucial form of communication in which two consciousness meet in front of the cultural mathematical meaning" (Radford, 2010, p. 6) within the social practice. From a phenomenological perspective this meaning should not be perceived as a "ready-made entity" which a child is expected to follow; instead, only a serious and genuine move back to the intentional origins of this meaning gives us a real understanding of its constitutive potential (Husserl, 1970, 2001).

CONCLUSIONS

CHAT analysis focuses on cultural means and social practices, which necessarily mediate the transformation of perception, while phenomenological analysis aims towards understanding of the role of intentionality in acquiring new forms of immediate perception. Hence these two perspectives attempt to grasp two important aspects of the educational/learning complexity, and seem to be neither contradictory nor reducible to each other, but rather essentially complementary.

Mathematics teacher education and professional development

Introduction to the papers of TWG18: Mathematics teacher education and professional development

Stefan Zehetmeier[1], Marc Bosse[2], Laurinda Brown[3], Alena Hošpesová[4], Nicolina Malara[5] and Bettina Rösken-Winter[6]

RATIONALE

The study of mathematics teacher education and professional development has been a central focus of research over recent decades. Research activities have focused on topics such as reflection, collaboration and teachers' professional growth. In particular, models and programmes of professional development, as well as their respective content, methods, and impacts have been described and analysed. Research has increasingly focused not only on the participating teachers, but also on the role of teacher educators and academic researchers. So far, the research community has attempted to develop theoretical and methodological frameworks to both *describe* and *explain* the complex topic of mathematics teacher education and professional development.

The goal of TWG18 was to offer a communicative, collegial and critical forum for the discussion of these and other related issues, which would allow diverse perspectives and theoretical approaches to contribute to the development of our knowledge and understanding as researchers, educators and practitioners.

PARTICIPANTS

39 papers underwent a peer review process in TWG18: during this process, all papers were revised, according to reviewers' remarks, by authors. 34 papers were accepted as contributions and five were re-submitted for poster presentation. Four of the accepted papers were withdrawn. Finally, 30 papers were presented during the TWG sessions.

19 posters (14 original submissions and 5 former paper submissions, see above) underwent a peer review process in TWG18: all authors revised their posters, according to the reviewers' remarks. All of the posters were accepted. Four of the accepted posters were withdrawn. Finally, 15 posters were presented during the conference poster session.

ORGANISATION

Due to the high number of participants and presentations, the TWG sessions comprised both plenary and sub-group working phases. During the plenary phases, three (or four) papers were presented for a maximum of five minutes each, in which the authors provided their respective paper's central message(s) and challenging questions for discussion. These plenaries were followed by parallel sub-groups, which were each managed by one of the presenting authors. Participants were free to choose and join one subgroup, where they discussed the paper for 20-30 minutes. Afterwards, the TWG's participants met in plenary to hear reports of each sub-groups' central topics and to summarise emerging issues.

TOPICS

The presentations were categorised into seven main topics:

— Models of Teacher Education Programmes

— Pre-Service Teacher Education

— Lesson Study and Videos in Teacher Education

— Tasks, Problems and Assessments

— Mathematics Teacher Educators

— Reflecting Teaching Practices

— Cooperative Communities

Within the topic "Models of Teacher Education Programmes", the papers dealt with teacher education programmes, teacher educators, teachers' professional growth, training models, teachers of levels K-8, teacher empowerment, problematisation of knowledge, meta-didactical transpositions and praxeologies.

The topic "Pre-Service Teacher Education" comprised teacher preparation, pre-service primary and secondary mathematics teachers, inquiry based mathematics education, students' mathematical thinking, scaffolding, one-to-one interactions, deficits pertaining to core mathematics, positive attitudes towards mathematics, analyses in one-on-one interviews, diagnostic strategies, subject matter knowledge and knowledge base for teaching.

The session on "Lesson Study and Videos in Teacher Education" focused on lesson study, video-based professional development, mentor teachers, pre-service and in-service teachers, pedagogical content knowledge, theory-practice problems, initial teacher education, classroom situations, teacher expertise, peer discussions, anthropological theory and mathematical knowledge for teaching.

The papers of "Tasks, Problems and Assessments" dealt with task design, learning scenarios, problem posing, problem solving, teacher professional competencies, a four-step dynamic model, characteristics of a good (mathematics) teacher, and levels of cognitive demand.

The topic "Mathematics Teacher Educators" comprised practices of teacher educators, prospective teachers, mathematical knowledge, awareness, students' errors, non-standard reasoning, instructional coherence of teacher educators, teaching-learning environments, impact on teacher and student learning, professional development and social network sites.

The focus of "Reflecting Teaching Practices" was on self-reflection, beginner teachers' practices, content and methods of professional development courses, mathematical quality, didactical analysis competency, pedagogical content knowledge, didactic transposition, anthropological theory of didactics, content representation, spatial visualisation ability, teaching experiments, common games and childhood education.

Within the topic "Cooperative Communities" the papers dealt with communities of practice, inquiry communities, developmental research on tasks, identity and social perspectives on learning.

EMERGING ISSUES

This section provides several questions and issues which emerged during the sessions of TWG18:

Models of Teacher Education Programmes

— How do we deal with the differences between the role of the mentor and the mathematics educator?

— How can we evaluate teachers' changes from their classroom actions?

— How can we assess the stability of change induced in the teachers?

— If we analyse ourselves when we work as teacher educators, what are possible problems, or advantages?

Pre-service Teacher Education

— How does our take on the nature of mathematics affect our studies?

— Perspectives are hard to change and student teachers learn to answer what their teacher educators want – do you consider this when designing research?

— How are student teachers able to identify and imagine key aspects of development and the learning trajectories of their students?

— How can we measure the effectiveness in the development of prospective teachers of 1-1 interactions with students? How do we research this?

— How do we measure immediate and long-term effects?

Lesson Study and Videos in Teacher Education

— How does Lesson Study literature fit into wider perspectives such as teacher knowledge?

— Lesson study across countries and across different subjects is different due to cultural background. How can we map the territory?

— How to make change visible?

— How to keep the balance between quantitative and qualitative aspects within conference papers with reduced length?

Tasks, Problems and Assessments

— There is a job to be done in mapping and bringing together, rather than separating mathematics, didactics and pedagogy. After the mapping, what is our vision, what would we propose?

— Theoretical frameworks that are too general are not helpful for teachers. Which tasks could illustrate more specific points of frameworks?

— Notions and definitions: what is problem-posing, problem-solving; is problem-posing a part of problem-solving? How clear are we with notions and definitions?

— It is important to work with teachers in PD programmes. But the question remains: What will the teachers do with the PD in their classrooms?

— Mathematics Teacher Educators

— Thinking through our roles as teacher educators we are also researchers – how can we manage this?

— How to reflect on philosophy of mathematics and the philosophy of mathematics education? How do they meet?

— How can we assess a chain of effects in teachers' professional development?

— How to conduct research on the internet with social communities? There are ethical issues and how do we deal with these? How to intervene in a group as a researcher?

Reflecting Teaching Practices

— How to deal with being (at the same time) a researcher, a teacher, and an educator?

— How to access practice if we want to use that as a research object?

— How to optimise teaching time? How to focus during that time on the deep questions teachers face about mathematics?

— Teacher education is heterogeneous across one country. How can we make comparisons between countries?

— Culture is so important in comparing countries. What are the valid lenses we can use in comparisons?

Cooperative Communities

— Difference between 'community of practice' and 'community of inquiry' – what makes an inquiry community? How will we recognise it in the data?

— What is relevant to the teachers within the community?

— The roles of researchers and teachers when we do research on practice – symmetry, asymmetry?

— How can we actually observe identity development in terms of practice?

TWG18

Research papers

Developing mathematics teachers' pedagogical content knowledge through iterative cycles of lesson study

Aoibhinn Ni Shuilleabhain

University College Dublin, Dublin, Ireland

This research presents features of knowledge of content and students (KCS) and knowledge of content and teaching (KCT) as empirical evidence of mathematics teachers' pedagogical content knowledge (PCK) utilised and enhanced through their participation in iterative cycles of lesson study. Over the course of one academic year, twelve teachers in two secondary schools engaged in this research as a double case study of teacher learning within a lesson study community. Qualitative data was generated through audio recordings of teacher meetings and through multiple teacher interviews. Dialogue within the lesson study communities was mapped to a framework of PCK as proposed by Ball, Thames and Phelps (2008). Results of this study find empirical evidence of the features of KCS and KCT in teachers' planning and reflection conversations and demonstrate teacher learning over iterative cycles of lesson study.

Keywords: Pedagogical content knowledge, lesson study, reflection, teacher knowledge.

INTRODUCTION

Lesson study is growing in popularity as a form of professional development for Mathematics teachers (Dudley, 2013). Although much research has shown that teacher knowledge is developed through participating in lesson study (Fernandez, Canon, & Chokshi, 2003; Lewis, Perry, & Murata, 2006; Murata, Bofferding, Pothen, Taylor, & Wischnia, 2012) this learning has not yet been explicitly mapped to a framework of knowledge for teaching. Furthermore, lesson study research has mainly focused on primary mathematics teachers and on single cycles of lesson study (e.g., Corcoran, 2011; Lewis, Perry, & Hurd, 2009; Murata et al., 2012).

In this research the development of secondary mathematics teachers' pedagogical content knowledge (PCK) is investigated through their participation in iterative cycles of lesson study. Twelve mathematics teachers in two schools were introduced to this model of professional development and participated in multiple cycles over the course of one academic year. As teachers' participation in lesson study continued, they began to incorporate and develop more elements of PCK in their planning and reflection meetings around research lessons.

Utilising Ball and colleagues' (2008) framework of PCK, qualitative data generated through teachers' conversations and interviews were analysed in terms of knowledge of content and students (KCS) and knowledge of content and teaching (KCT). Features of KCS and KCT emergent from the data are presented here as empirical evidence of PCK in teachers' planning and reflection conversations around research lessons and also as evidence of teacher learning in lesson study.

LESSON STUDY

Lesson study is a systematic inquiry into teaching and learning where teachers collaboratively plan, examine, conduct, observe, and reflect on research lessons (Fernandez et al., 2003; Lewis et al., 2006; Lewis et al., 2009; Murata et al., 2012). The aim of lesson study is not to construct a "perfect" mathematics lesson, nor is it to study lessons in detail, but rather it aims to engage teachers in dialogue around their pedagogical practices. Lesson study also incorporates many of the features of teacher community advocated as a form of sustainable professional development (Grossman, Wineburg, & Woolworth, 2001).

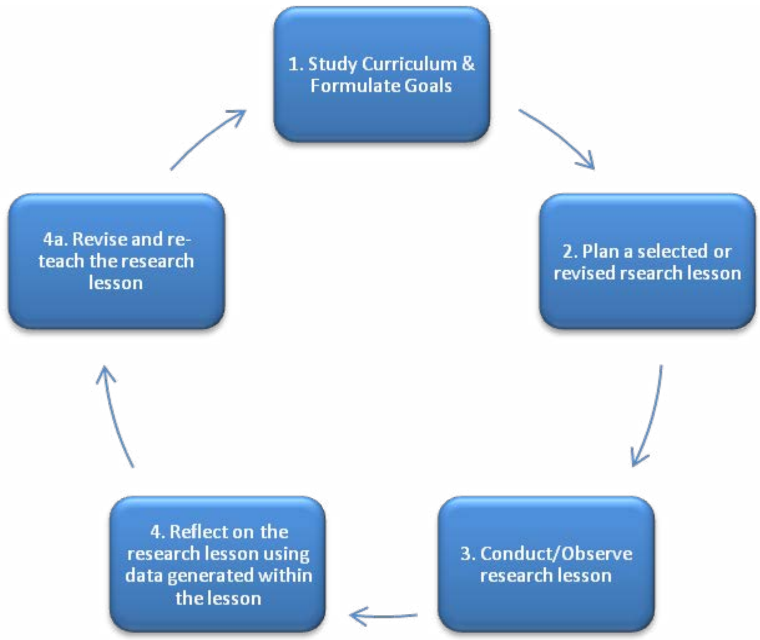

Figure 1: Lesson study cycle – adapted from (Lewis et al., 2006)

A modelled description of the lesson study cycle can be seen in Figure 1 (adapted from Lewis et al., 2006):

1. Study curriculum and formulate goals
2. Plan a research lesson
3. Conduct or observe research lesson
4. Reflect on research lesson and planning process

4a. Option to revise and re-teach the research lesson.

Teacher knowledge is enhanced through participation in lesson study (Lewis et al., 2006; Murata et al., 2012) and this research aimed to consider such learning relative to a particular framework of teacher knowledge. In this paper, detailed analysis focused on fine-graining the features of KCS and KCT evident within teachers' planning and reflection conversations in lesson study as a lesson study community.

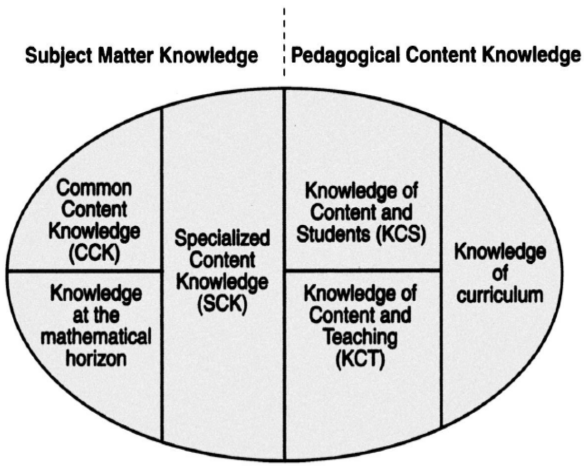

Figure 2: Mathematical Knowledge for Teaching (Ball et al., 2008)

PEDAGOGICAL CONTENT KNOWLEDGE: KCS AND KCT

In attempting to define teacher learning in this research, teacher knowledge was mapped to a particular framework of PCK proposed by Ball and colleagues (2008) (Figure 2).

KCS and KCT are important elements of PCK which combine teachers' knowledge of mathematics with their knowledge of students and of mathematical didactics respectively. KCS and KCT incorporate elements of knowledge specific to mathematics teachers from developing an awareness of students' mathematical thinking (Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Simon, 1995), to more effectively sequencing learning trajectories (Ball et al., 2008; Simon, 1995). Features of KCS and KCT utilised and developed in teachers' planning and reflection conversations in lesson study were identified as part of this research.

DATA GENERATION

This research took place in two urban secondary schools, Doone and Crannog (all pseudonyms), over the course of the 2012/2013 school year. Teachers were invited to participate in the research with 5 teachers in Doone and 7 teachers in Crannog (varying in teaching experience from 1 to 33 years) agreeing to take part.

Each lesson study community was taken as a case study within which the development of teachers' conversations around the teaching and learning of mathematics could be analysed. Data was generated through audio recordings of each of the lesson study meetings in both schools (3 cycles in Crannog and 4 cycles in Doone) and through individual teacher interviews held at three stages during the research.

Teachers had autonomy over the content they taught, the class group involved, their overall lesson study goal, the construction of their lesson plans, and how they reflected on their students' learning. As participant-observer the researcher was present in each of the meetings and research lessons as an additional member of each lesson study community and participated as lesson study facilitator in the first cycles in both schools. In each of their subsequent lesson study cycles teachers rotated roles of conducting teacher and of facilitator.

In total, 38 hours and 17 minutes of teacher discussions around planning and reflection were recorded (over 18 hours in Crannog and over 20 hours in Doone). Teacher interviews with all participating teachers served as an additional data source in providing teachers with opportunity to self-report on their own learning and on any changes to their classroom practices that may have changed as a result of their participation in lesson study.

DATA ANALYSIS

The data was transcribed and analysed over four phases as a chronological evolution of teachers' planning and reflection conversations over iterative cycles of lesson study. A framework of analysis of KCS and KCT derived from the literature (Ball et al., 2008; Hill et al., 2008) and incorporating codes emergent from the data was utilised in the analysis. Analysis involved reading all of the transcript text, identifying if the text qualified as a legitimate code, and deciding if the text was relevant to the codes within the framework of analysis.

A unit of analysis was defined as any episode of conversation which a) was relevant to the lesson study cycle and b) was relevant to constructing content of a lesson from either the perspective of the student or from a pedagogical perspective. This parsing approach of conversation excerpts, also utilised by Cjakler and colleagues (2013), aimed to encapsulate elements of teachers' conversation where teachers introduced elements of KCS and KCT within their planning and reflection phases. For example, the following conversation excerpt identifies an episode of learning for Lisa who, prior to participating in lesson study, had not recognised how her students might interpret variables within Pythagoras' theorem. This discussion occurred as part of the final cycle in Doone where teachers planned a series of lessons introducing students to Pythagoras' theorem.

Lisa	The thing about learning for the students is that they can learn the theorem but then it is confusion when the diagrams are labelled in any given way... We think it's saying $a^2 + b^2 = c^2$ but it's meaningless to them when you give them a thing and 'a' is the hypotenuse and then you go, $a^2 + b^2 = c^2$ ... They don't actually understand.
Owen	So that's rote learning.
Kate	Yeah, concept rather than formula...
Lisa	*We* know it. We know that this is the formula but we don't look at it from the kids [perspective]. And it's only that you talking about it today – if they label the hypotenuse 'a' – I hadn't actually realised that that is what's causing the problem.

This conversation higlights Lisa's realisation of seeing the mathematical content through the eyes of a student (Fernandez et al., 2003), where she made sense of students' common conceptions – developing her KCS as part of this lesson study community's planning dialogue.

The final two phases of analysis led to a further determining of the categories of KCS and KCT relevant to these elements of lesson study such as: noticing students' mathematical strategies, developing contextualised questions, and reflecting on student talk. These features, linked to existing literature on teacher learning, formed the basis of codes for a final phase of analysis and are presented below as indications of teacher learning through participation in iterative cycles of lesson study.

FINDINGS

Features of KCS and KCT are presented as empirical evidence of PCK in teachers' planning and reflection conversations in lesson study and also as evidencing teacher learning, since the frequency of these features increased as teachers' participation in iterative cycles of lesson study continued. As part of both teacher communities' initial engagement with lesson study, not all of these features were present in the initial cycles of lesson study but began to be incorporated as teachers began to observe research lessons, focus on students' mathematical thinking, and plan subsequent lessons.

Teacher learning through the development of these features of KCS and KCT in iterative cycles of lesson study may be modelled as proposed in Figure 3. As an example of developing KCS, following the observation of students within research lessons (noticing and interpreting students' mathematical responses) teachers became more cognisant of anticipating how their students would mathematically engage in planning subsequent lessons. From an increased focus on anticipating students' thinking, teachers became more aware of the value of engaging students in their own learning and began designing relevant, contextualised questions (KCT) which, in turn, focused teachers on noticing and reflecting on students' mathematical strategies in attempting these activities (KCS).

This model is included as suggested theoretical frame of teacher learning in iterative cycles of lesson study and further research is required in refining and developing this model.

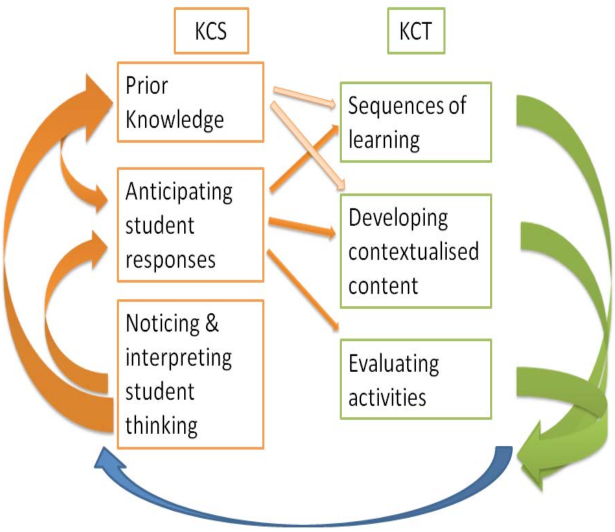

Figure 3: Features of KCS and KCT developed in iterative cycles of lesson study

Findings: Features of KCS

From the analysis of the data three features of KCS were identified as being utilised and enhanced through teachers' participation in iterative cycles of lesson study:

- Identifying students' prior knowledge (Ball et al., 2008)
- Anticipating students' mathematical responses (Ball et al., 2008; Hill et al., 2008)
- Noticing students' mathematical thinking (Carpenter et al., 1989; Jacobs et al., 2010; van Es & Sherin, 2008)

A number of narrative samples of each of these features will now be explored.

Identifying students' prior knowledge

While at the beginning of their engagement in lesson study teachers in Doone did not incorporate students' prior knowledge in their planning, this became more and more important to them as their planning of research lessons continued. From their observation of research lessons, teachers reflected on the need to correctly identify students' prior knowledge in being able to then anticipate students' responses (KCS) and plan a relevant sequence of learning (KCT). In their final research lesson, teachers identified and incorporated the mathematical content students had already met and used this information to build on students' mathematical thinking over a series of lessons. This development of KCS in turn benefitted teachers' KCT in outlining sequences of learning over a number of lessons.

Anticipating students' mathematical responses

From observing particular students within the first research lesson, teachers in both schools began to anticipate how students might engage with and respond to mathematical tasks within subsequent lessons. Within their planning, teachers began to anticipate and identify various strategies which students might employ for particular mathematical activities and also began to articulate how students might think about particular topics. In Crannog's first research lesson, teachers began to anticipate how students might respond to a planned activity exploring quadratic patterns:

Stephen	Because some would look as if it is 1, 4, 9. Some will look at it as being squared. Some will look at it as being –
Fiona	Add 3 and 5 –
Stephen	And 7, and that is...if you give them a pattern, if you give them a list of numbers of 1 to 9, that is what they do. They will actually see how much it is going up whereas some don't relate it to being anything squared.

This anticipation of students' mathematical responses began to also impact on teachers' practices outside of lesson study as reported by Eileen (a newly qualified teacher) in her mid-point interview:

Eileen	Yeah, I probably would ask myself a bit more how would they react to this or what questions will they have. Pre-empt their questions or pre-empt their confusion. Yeah, I would think about that a little bit more.

Noticing students' mathematical thinking

Through the detailed planning and anticipation of students' mathematical responses within teacher meetings, teachers began to focus on and notice more of students' mathematical thinking during their observation of research lessons. This noticing of students' mathematical thinking was an important element of developing teachers' perspectives on their own pedagogy (Carpenter et al., 1989; Corcoran, 2011; Jacobs et al., 2010; van Es & Sherin, 2008) and as the cycles continued teachers began to explicitly reflect on elements of student strategies and student talk in their post-lesson discussions. Teachers self-reported that this noticing and interpreting of students' mathematical thinking also impacted on their classroom practices outside of lesson study, such as extending the 'wait time' for students to answer questions in.

Findings: Features of KCT

From the analysis of the data three features of KCT were identified as being utilised and enhanced through teachers' participation in iterative cycles of lesson study with their colleagues:

— Sequencing learning trajectories (Ball et al., 2008)

— Designing contextualised questions (Schoenfeld, 2011)

— Evaluating mathematical activities (Ball et al., 2008)

A number of narrative samples of each of these features will now be explored.

Sequencing learning trajectories

It was a surprising result that in both schools, as teachers continued their participation in lesson study they began to plan series of lessons along a learning trajectory within which the research lesson was incorporated. In Crannog's second cycle teachers realised that planning a number of lessons would be more beneficial to students in revising and developing important mathematical concepts.

Fiona	I suppose what we have to do in a pre-runner class, we have to go back with them over the concept of factors: "What are factors?" and then they need to look. Because we kind of gloss over that a bit when we go into factorising usually.
Stephen	That we don't make up two numbers in algebra.
Fiona	Yeah, so go back into factors.
Gerald	Yes and I think the discussion of factors should start with prime numbers because they have only got two factors to talk about then.

In their final research lesson teachers planned a series of 6 lessons which incorporated students' prior knowledge and guided students towards a necessity for differentiation in Calculus.

Similarly in Doone, their final research lesson was planned as part of a series of lessons which teachers felt was far more valuable to both the lesson study community and to students in building their mathematical understanding.

Kate	This is the first time we've actually kind of planned a little scheme.
Nora	For the whole thing. Take you, follow it – follow it through. Because I think you know exactly where you stand or where they [the students] should stand.

Designing contextualised questions

As teachers continued to participate in lesson study it became more and more important to them to design mathematical activities that were relevant and context-based for their students. In Doone's first cycle students' activities were of a traditional textbook format (O'Sullivan, Breen, & O'Shea, 2013) which were not particularly relevant to their group of secondary students. In their subsequent cycles teachers developed activities that were both context and content based but were also of interest to these students, such as a rugby based problem designed for a particular class of 15 year old male students.

Evaluating mathematical activities

As a further feature of KCT, teachers also began to critically analyse and evaluate mathematical activities during planning. This evaluation of activities during planning impacted on how they taught or introduced such activities during the research lesson as exemplified in the following conversation excerpt where teachers modified a question in order to necessitate students multiplying two fractions together:

Lisa	The Ireland rugby squad: 1/5 of these have eye problems. Of this 1/5, ½ wore contact lenses. What fraction of the players wore contact lenses?
Kate	But – they're going to get 30 players.
Lisa	30 multiplied by 1/5 is 6.
Kate	Well, they're going to divide by 5. So unless we said "a squad" instead of saying 1/5 of the "players". Don't give them a number of players because they'll divide by 5 and get 6.
Lisa	I think that's what we're doing wrong. We just want a fraction –
Owen	So it's one whole squad.
Lisa	So it's "a squad". Brilliant!

This evaluation of mathematical activities also encouraged teachers in developing and designing their own activities instead of their traditional reliance on textbook questions (O'Sullivan et al., 2013).

CONCLUSION

Over a number of lesson study cycles, teachers developed in their perspectives of and approaches to teaching and learning mathematics through planning research lessons, observing students' mathematical responses during those lessons, and reflecting on students' interactions and responses. This research maps the learning of these teachers in their lesson study community to a framework of PCK suggested by Ball and colleagues (2008). Furthermore, the research provides empirical evidence of KCS and KCT in the context of teachers' planning and reflection conversations of research lessons in lesson study.

In this paper, three features of both KCS and KCT were identified within the data as part of teachers' planning and reflection conversations in lesson study. While these features were not all present in the data in initial lesson study cycles, they began to be incorporated as teachers' participation in cycles continued where their PCK was developed through structured conversations with their colleagues. While some of these emergent features of PCK were expected from literature on teacher learning and lesson study (such as highlighting students' prior knowledge), others (such as designing contextualised questions and interpreting students' mathematical responses through reflection) were added to this proposed framework of PCK as part of teacher learning in lesson study.

The presentation of these features of KCS and KCT as empirical evidence of PCK in planning and reflection phases of lesson study represents a contribution to the literature in identifying teacher learning through participation in iterative cycles of lesson study.

Applying the structured problem solving in teacher education in Japan – A case study

Yukiko Asami-Johansson and Iiris Attorps

University of Gävle, Gävle, Sweden

In this paper, we examine the implementation of a Japanese teacher educators' lesson, where he applies and, at the same time, inform the students about "structured problem solving". We describe a specific lesson titled "Quantity and Measurement" for elementary school teacher students and we show how the educator make the students aware of the didactic transposition of the material and how he makes the students experience and learn about applying "structured problem solving" in practice. We also show how the Japanese curriculum influences the scale of the mathematical praxeology to be learned and how the students are given opportunities to develop their insight into the PCK during their education in mathematics.

Keywords: Teacher education, pedagogical content knowledge, didactic transposition, anthropological theory of didactics, content representation.

INTRODUCTION

In recent years, the need to train teachers' and teacher students' skills for teaching mathematics has been strongly emphasized by both politicians and mass media in Sweden. One of main reasons for this is that the performance of Swedish students in international surveys of education, such as the TIMSS and Pisa study in mathematics has radically declined since 1990's. According to Brown and Borko (1992), one of the most important purposes of teacher education is the acquirement of pedagogical content knowledge (PCK). It is recognized, that such knowledge forms the essential bridge between the academic subject matter knowledge (SMK) and the teaching of the subject matter. Furthermore, it includes an understanding of which representations are most appropriate for an idea, which ideas are difficult and which are easy for learners and what conceptions and preconceptions students of different ages hold about an idea. Specifically, if the preconceptions are erroneous conceptions, teachers need to know about strategies for reorganisation of the learners understanding (Shulman, 1986).

This is a part of a future comparative study project between Japan, Finland and Sweden concerning teacher education that aims to identify and analyse differences of institutional settings in several countries (Artigue & Winsløw, 2010). Our intention is to illuminate teacher educators' perception of the SMK and PCK, by analysing the mathematical and didactical organisations in the countries' primary school teacher education. In this paper, we present our first study from Japan, where the focus is on how the teacher educator applies *the structured problem solving* in his lecture. Structured problem solving has the emphasis on creating learning opportunities for students by using challenging problems and to stimulate students' corrective reflection on their solutions.

Shimizu (1999) explains some pedagogical terms which are used daily by Japanese teachers in mathematics class: *hatsumon*: *asking a key question, kikan-shido*: *teachers' instruction at students' desks, neriage*: *whole-class discussion, matome*: *summing up.* Having such common didactical terms indicates that Japanese teachers have acquired an institutionalised perception about the teacher's role in the classroom. Many Japanese teacher educators in mathematics apply and instruct on this teaching pattern in classes for their students. We observed and analysed the mathematical and didactical organisation of a lesson concerning "Quantity and Measurement" in a course named "Arithmetic Education" for prospective elementary school teachers in Japan.

THEORETICAL FRAMEWORK

Teacher knowledge

The importance of teacher knowledge both in teaching and in teacher education has been cogitated by researchers in several articles (see, e.g., Shulman, 1986; Kind, 2009). A number of models of teacher knowledge have been generated in this field. Although researchers differ in their definitions of various components in teacher knowledge, three areas of teacher knowledge can be seen as the cornerstones of the emerging work on professional knowledge for teaching: subject matter knowledge (SMK), general pedagogical knowledge and pedagogical content knowledge (PCK) (e.g., Shulman, 1986). PCK is a term to describe 'the ways of representing and formulating the subject that make it comprehensible to others' (ibid, p. 9). It has been found that PCK is a useful tool for understanding the professional practices of teachers (Kind, 2009). Investigating PCK in teaching practice is a difficult process, but Kind (2009) points out that using Content Representation (CoRe), developed by Loughran, Mulhall and Berry (2006), might give a unique awareness into the teachers' PCK and their practices relating to specific topics and subject areas. CoRe focuses on different parts of PCK and offers a way to give an overview of the teaching approaches for a specific subject area and to motivate teaching decisions.

The didactical transposition theory and the anthropological theory of didactics

Chevallard developed the conceptualisation of a didactical transposition: how the knowledge content is adapted for the purpose to be taught within a given institution. It means a transposition from *scholarly knowledge* (Bosch & Gascón, 2006), which is produced in the community of mathematicians, into the knowledge for teaching at different levels within the teaching system. Bosch and Gascón (2006) illustrated the steps of a didactical transposition process through different institutions as *Scholarly knowledge → Knowledge to be taught → Taught knowledge → Learned, available knowledge* (ibid, p. 56). Chevallard's attempt to describe the mathematical knowledge in an institutional context extended into "*the anthropological theory of didactics*" (ATD) (ibid). There, mathematics learning holds to be modelled as the construction within social institutions of *praxeologies* (ibid). A praxeology supplies both methods for the solution of a domain of problems (*praxis*) and a framework (*the logos*) for the discourse regarding the methods and their relations to a more general setting. The block of "praxis" is usually described as "know-how" and the "logos" is described as "know-why". The praxis can be described by the set of *tasks* and *techniques* and the logos is constituted of a *technology* that informs and describe techniques and a *theory*, which is used to motivate and establish the technologies. A praxeology that describes some mathematical knowledge is also called *mathematical organisations* (*MO*) (Barbé, Bosch, Espinoza, & Gascón, 2005). In the same way, *didactical organisations* (*DO*) (ibid) is a praxeology that describes the knowledge and know-how used by teachers to teach the subject matter knowledge to their students.

Table 1 A CoRe Template

Year level for which this CoRe is designed:____________	Important Science ideas/concepts					
Content Area:___________	Big Idea A	Big Idea B	Big Idea C	Big Idea D	Big Idea E	Big Idea F
What do you intend the students to learn about this idea?						
Why is it important for students to know this?						
What else do you know about this idea (that you do not intend students to know yet)?						
What are the difficulties/limitations connected with teaching this idea?						
What is your knowledge about students' thinking that influences your teaching of these ideas?						
Are there any other factors that influence your teaching of these ideas?						
What are your teaching procedures (and particular reasons for using these to engage with this idea)?						
Specific ways of ascertaining students' understanding or confusion around this idea (include a likely range of responses).						

Figure 1: CoRe Template (Bertram & Loughran, 2012, p. 1029)

METHOD

We applied two methods for data acquisition in this study: Firstly, we used classroom observation with video recordings and, secondly, an interview, using a Content Representation (CoRe) template as a reflection document. CoRe, was developed, by Loughran and colleagues (2006), to help to focus on different parts of the PCK. An illustration of a Core Template is given here below.

CoRe is originally developed for science teachers' practice. It used before a lesson is conducted as a collaborative tool helping teachers to identify important aspects of the content within the specific area. After the lessons, the experiences by the teachers' can be documented in a Pedagogical and Professional-experience Repertoire (PaP-eRs), which are linked to the CoRe, and illuminate the decisions underpinning the teacher's actions intended to help the students better understand the content (Loughran et al., 2006). In our study we have used the CoRe template in a different way: After the lesson, the teacher educator answers to the items on the CoRe template to reflect and to consider on the content of the lesson. Thereby making explicit his different conceptions and decisions about teaching the specific topic. The reason we chose to apply CoRe as an interview format is that it is a convenient way to map how the teacher perceives the association between *scholarly knowledge* and the *knowledge to be taught*. Furthermore, by conducting the interview afterwards, it is possible to analyse the association with *the taught knowledge*. Thus we may illustrate the teacher educators take on the discourse on techniques and technologies – the praxis and the knowledge, in the sense of ATD, into account when he/she designs the lessons.

"Quantity and measurement" in Japanese curriculum

The guideline of the Japanese curriculum "The Course of Study" for primary school describes determination of area and volume in the domain "Quantity and Measurement". It states that (Ministry of education, culture, sports, science and technology (MEXT), 2008, pp. 23–26), pupils need to learn to "*compare* length, area and volume of different objects" in grade 1, learn about "standard units of length and volume (e.g., meters and liters) and measurement" in grade 2, "the units of area and its measurement" in grade 4 and they are obligated to learn "to determine area of triangles and parallelograms" in grade 5. Thus, area and volume determination is considered as a part of learning "Quantity and Measurement". Hence, it is not located in the domain "Geometry" in the Japanese Curriculum. The introduction to "Quantity and Measurement" in Japanese elementary schools usually consists of four phases (Miyakawa, 2010): 1. Direct comparison of two objects. 2. Indirect comparison of two objects with a third object, having the same kind of quantity. 3. Comparison of two objects with arbitrary object as a unit (e.g., a pencil). 4. Comparison using standard units (e.g., meters).

RESULTS AND ANALYSIS

The lecture "Quantity and Measurement" in "Arithmetic Education"

A main focus for the course "Arithmetic Education" is the content of primary school mathematics and how to teach such content. The lecturer of this course Mr. Matsui, has himself worked as a mathematics teacher in lower secondary school for 14 years. We observed 55 teacher students in Matsui's class.

Mr. Matsui begins the lecture by instructing the students to read the description of the domain "Quantity and Measurement" in the "Guidelines of the Course of study". He remarks that the comparison of two objects' areas and volume is a new addition from 2008 in the Course of Study for grade one. Furthermore, he refers to the Guidelines of the Course of study and explains the four phases in the process of pupils learning about quantities. Mr Matsui picks up two pens and asks his students "How do you compare the length of these two pens?" He requests that a student show the class how to put the pens together in a way so that the difference in lengths demonstrates clearly and he explains the term *direct comparison* of two quantities. Secondly, Mr. Matsui clarifies an example of the *indirect comparison* of two quantities by comparing the length and the depth of his desk. A student answers that one can use an object such as paper tape and so on to compare the length of the two sides of the desk. Accordingly, Mr. Matsui takes up a pencil and describes how to *use an arbitrary object as a unit* to measure and compare the two sides of the desk. He illuminates the disadvantages of this method using an arbitrary unit, (the length of the pencils varies), and he explains the reason why *standard units*, like meters and centimetres, are finally introduced in order to get exact measurements. Finally, Mr. Matsui writes down these four phases on the blackboard and then shows the class a digital textbook that shows how the first three phases are handled in the textbook.

In the textbook for grade 4, the author uses a small grid of $1cm^2$ squares to determine the area of a rectangle by counting and then to demonstrate that it is obtained by multiplication of the width times the length. Moreover, the textbook describes that the area of a square is determined in same way and defining what it calls a *formula* that determines the area of *any* kind of rectangles and squares. Mr. Matsui explains that the area of triangles, parallelograms, trapezoids and rhombs will be learned in the fifth grade and mentions that most textbooks nowadays consider the determination of the area of parallelograms before that of triangles; it used to be taught in the opposite order.

Here, Mr. Matsui's actions indicate that he is making the students aware of the process of didactic transposition: That is, the transformation from the *knowledge to be taught* to the *taught knowledge*. The knowledge to be taught, i.e. the curriculum as stated in the "Course of Study", is designed by Chevallard calls the *noosphere* (1992), which is a non-structured set of experts, who have a big influence within the educational system. In Japan, the contents of the textbooks are controlled by MEXT before publishing. Therefore, the contents of the textbooks can be treated almost as the knowledge to be taught. Mr. Matsui's students verify how the textbook treats the area of rectangles and how to think of a formula as a generalised computation. The textbook treats the determination of the area of rectangles as an initial task and where some techniques are eventually justified by algebraic reasoning. It is clear that the theory, which justifies this technology, is both algebra and geometry and, in that sense, the praxeology of the textbook is large since it follows the stipulated praxeology in the Course of Study.

The *taught knowledge* is created by the teachers' praxis when conducting lessons in their classrooms. By referring to the four phases of learning "Quantity and Measurement" in the curriculum guidelines and relating it to the *taught knowledge* – by referring to textbooks – the students are given an opportunity to reflect deeply upon the SMK (or MO) and PCK (or DO). Thereby, the teacher students can avoid the "*illusion of transparency*" (Chevallard, ibid), i.e., that one believes that the mathematical knowledge is fixed and known and that one does not question the form it is presented in the curriculum since one feels that it is already known.

The praxeology of the lecture

The students are now going to find out several different methods for the determination of the area of parallelograms with the intention of teaching pupils of grade five. For this reason Mr. Matsui distributes grid papers with parallelograms and reminds that grade five pupils have learned the how to determine the area of rectangles and squares but not of triangles. He gives his students several minutes to reflect, and starts to walk between the students' desks (kikan-shido) and gives them hints and decides which students' solutions will be presented later, due to the variation of their methods for the solutions. Mr. Matsui lets four students draw and explain their solutions on the blackboard. Student A has combined some incomplete grid squares with the corresponding incomplete squares on the opposite side of the parallelogram. Thus transforming the parallelogram to a rectangle (see Figure 2 in the middle) without changing the area.

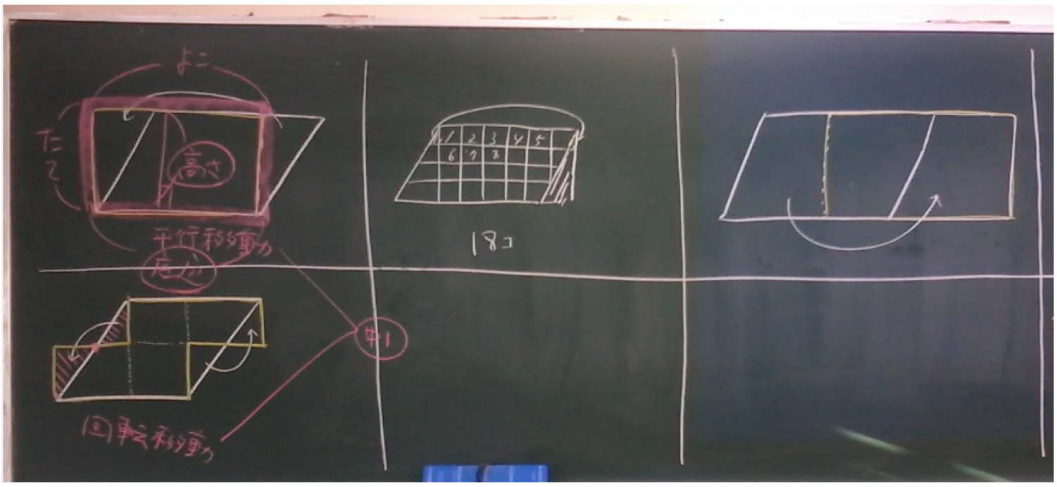

Figure 2: Students' presented methods for determination of area of parallelogram

Matsui remarks that student A is using an arbitrary unit to determine the area.

Student B has divided the parallelogram into a triangle and a trapezoid to shift the triangle to the other side to make a rectangle (Figure 2 in the top left). Student C has divided the parallelogram into two small rectangles, two trapezoids and two triangles. Then she rotates the triangles in order to construct two rectangles (Figure 2 in the bottom left).

Finally, student D has divided the parallelogram in the middle and shifted one of the two trapezoids to the other side (Figure 2 in the top right). Mr. Matsui points out the different kinds of "shifts" used by student B, D and C. Student B and D used parallel *translation* and student C also used *rotation*.

Mr. Matsui notes that the operations of translation and rotation will be covered in more detail in grade seven. He continues by writing "previous knowledge" on the blackboard. He goes on to explain the formula for the area of the parallelogram as $w \times l$ (width times length), since the geometric transformations shows that the width (or height) and length of the parallelograms exactly corresponds to those of rectangles. He mentions that once pupils have learned how to determine of area of a parallelogram, they are able to consider the area of any triangles.

Thereafter, Mr. Matsui gives as task to find out methods for determining the area of trapezoids, using same didactical approach. He chooses 7 students. Three of them shift parts of the trapezoid in different ways so to transform it to a rectangle. Two of them divide the trapezoid in different ways. One student adds a small triangle on the top of the trapezoid to make a big triangle. Finally, the last student doubles the trapezoid so as to transform it into a big parallelogram. From the last method, Mr. Matsui establishes the formula for the area of trapezoid, which is $(a + b)h/2$.

To finish, Mr. Matsui shows an article, written by a teacher in service, about a case study of teaching the area of trapezoids using the structured problem solving approach. By doing this, he institutionalises the conception of the structured problem solving as a general didactical approach.

Mr. Matsui's didactical task is to make his students consider how pupils would reason about such tasks concerning area determination. At the same time, he is letting the students *experience*, how the taught knowledge in domain of "Quantity and Measurement" might *look like*. In this sense, the knowledge disseminated in the lecture has a double focus – one is for the students to construct the didactical praxeology based on structured problem solving and the other is to discuss the viability of different mathematical organisations to be taught in grade five.

The mathematical organisation for the educator/teacher students (MO_1); *Types of tasks*: comparison of lengths and areas of different objects. *Techniques*: measuring with direct comparison, indirect comparison, comparing with arbitrary units and standard units, transformation of shapes, using formulas. *Technology*: comparison, figures, translation, rotation, formulas. *Theory*: Quantity and Units, Euclidean geometry.

The didactical organisation for the educator to be used in teaching teacher students (DO_1); *Tasks*: determine how pupils in various grades would reason during a class with area determination of polygons, by considering the pupils' previous knowledge. *Technique*: make the student participate in an example lesson using the structured problem solving approach, and follow it up with discussions. *Technology*: statement of previous knowledge, mathematical textbook and curriculum used as reference. *Theory*: structured problem solving.

The mathematical organisation for the teachers/pupils of grade five (MO_2) of this area determination: *Task*: to derive a formula for the area of parallelogram/trapezoid, *Technique*: transformation of shapes, using formulas for rectangles. *Technology*: figures, parallel shift, rotation. *Theory*: Quantity and Units, Euclidean Geometry.

The didactical organisation for teachers of grade five (DO_2): *Task*: making the pupils participate in the lessons and to reason about the determination of area of parallelogram and trapezoids. *Technique*: questioning, giving the task (hatsumon), and using graph paper (grid of 1cm) to draw their ideas on. *Technology*: group discussion, whole-class discussion (neriage). *Theory*: Structured problem solving.

Interview with Core template

As the Big ideas in CoRe template for the theme "determination of the area of a parallelogram and trapezoid", Mr. Matsui named: 1. Area of geometrical figures, 2. The concept and properties of geometrical figures, 3. Formula to generalize the calculation of the area. These ideas show how Matsui understands how the knowledge to be taught is derived from the scholarly knowledge. He considers that "determination of area of parallelogram and trapezoid" originates from the domain "Quantity and Units" (according to the big idea 1), "Euclidean Geometry" (according to the big idea 2) and "Algebra" (according to the big idea 3). In order to illustrate his perception of these ideas, the outcomes of the interview, is presented below.

Mr. Matsui's intention for students learning about this idea is that *Area of parallelogram, triangle, trapezoid and rhombus* can be determined in various ways by using the previously learned knowledge – the area of a square and rectangle by dividing those shapes into standard areas. Matsui mentions also that his students should be able to apply some mathematical terms such as *tosekihenkei* (*same area transformation*: transformation of the shape without changing the quantity of the area), *baisekihenkei* (*double area transformation*: transforming the shape of with a duplication of the area). These terms describe the various ways for determination and helps in understanding the methods. Mr. Matsui intends that the students should learn the process of finding out the formulas for area of various geometrical figures, rather than memorising those formulas.

As a starting point for the planning of teaching, Mr. Matsui takes up the pupils' previous knowledge. It is an important component in the teacher PCK; the pupils' previous knowledge has a strong impact when choosing techniques. The sharing of terms like *tosekihenkei* and *baisekihenkei,* (for which we could not find exactly corresponding terms in English), indicates that the technology is institutionalised among teacher educators in Japan. Emphasising the learning process of finding out formulas, shows that Mr. Matsui acknowledges the importance of developing conceptual knowledge, rather than procedural knowledge. He also emphasises the necessity for his students to understand the meaning of the algebraic generalisation.

Matsui names some concepts which the students do not yet need to know within this area: 1. additivity, 2. *bunriryo* (discrete quantity, where the range of possible values are not continuous), 3. *gaienryo* (extension quantity with additivity, e.g., length, time and area), 4. *naihoryo* (inclusion quantity, a quantity that does not have additivity, e.g., temperature, velocity and density), 5. other remarks as Cavalieri's principle.

The mathematical concepts named by Mr. Matsui above, shows his awareness of the technology within the praxeology MO_1. He links these concepts to the domain "Quantity and Units". This shows that MO_1 is strongly influenced by the knowledge to be taught, which are denoted by the curriculum.

Concerning teaching procedures listed in the CoRe template, Mr. Matsui names several detailed methods. As preparation, he proposes to use graph papers (grid of 1cm), an article written by a teacher in service and to refer to corresponding pages of in digital textbooks of the subject matter.

He states that the teacher educator should stress the importance of the children's perspective during the lecture, so that when the students perform their own lessons in the future, they are able to confirm previously learned items and acknowledge various ways of solutions (including wrong answers) during their lessons. According to Mr. Matsui, the teacher students know intimately the flow of working with tasks: reason individually → discuss with neighbors → present the solutions in class → respond to comments from the lecturer.

Mr. Matsui uses different didactical methods in order to transform SMK to PCK, making the subject understandable to the teacher students. For instance, without using graph paper, student A would never come up with the idea for her solution to determine the area of parallelogram. The didactical contract (in this case, both the teacher and the students are aware of the basic flow of working with tasks) is required in order to apply the structured problem solving approach in the classroom. This holds both for the lessons instructing teacher students and classroom lessons for pupils in elementary school.

CONCLUSION

Our aim was to analyse a lesson titled "Quantity and Measurement". Our impression is that the act of didactical transposition from the scholarly knowledge to the knowledge to be taught is insightfully done by the Japanese noosphere. For example, the area and volume determination is located within the topic of

"Quantity and Measurement" and not in "Geometry", which is the case in many other countries (e.g., Sweden). Compared to the Swedish curriculum, the Japanese curriculum provides a relatively detailed fundament for the large mathematical (and also didactical) organisations that are also replicated in the textbooks. As a consequence, the transposition from the knowledge to be taught to the taught knowledge becomes more explicit and more uniform. It also makes the progression of the content visible. For instance, the "four phases of comparison" in different grades is clearly institutionalized within the discourse of the teachers in Japan. Furthermore, the curriculum sets the scale of the mathematical praxeologies in the textbooks, which in turn influences the complexity of the mathematical organisations that are discussed in the teacher education classes. The scale is also enhanced by the use of the structured problem solving when reviewing the mathematical organisations in these classes, since it gives a natural setting to discuss and enrich the associated technologies. It is also a way to consolidate the didactical organisations implied by the problem solving approach. By combining an analysis of the interview with the analysis of the didactical transposition and ATD, we have illuminated the teacher educator's perception of the PCK and the SMK. This case study indicates that prospective teachers in Japan are given good opportunities to develop their insight of the PCK during their teacher education in mathematics.

When working together to plan a lesson in a Swedish professional development initiative

Anna Bengtsson

Linnaeus University, Faculty of Technology, Kalmar, Sweden, anna.bengtsson@lnu.se

This paper is based on a study that draws on Wenger's Communities of Practice perspective and accounts for the coherence of mutual engagement, joint enterprise and shared repertoire in a community of Swedish upper secondary mathematics teachers participating in a professional development initiative. The aim of this paper is to describe and understand practice when teachers are working together to plan a lesson. An overall characteristic of practice is that it develops in a teaching culture, and as the community lacks of awareness of how it organises their teaching, practice becomes resistant to change when planning the lesson. Also, this paper addresses further research considering teaching culture when teachers work together to plan a lesson as a way to obtain, and maintain collegiality.

Keywords: Collegiality, lesson, teaching culture, community of practice.

INTRODUCTION

The present trend aimed at improvements in schools is through collegial collaboration. Today "communities of practice" fill the air (Putnam & Borko, 2000). However the shift towards collegiality is a new setting for many teachers. Teachers in secondary education primarily feel responsibility for their own classroom practices, resulting in largely autonomous and isolated work and private learning activities (Hodkinson & Hodkinson, 2004). The discussions in many staff development sessions are characterised as "style shows". These sessions provide few opportunities for meaningful reflection and growth and maintain the individualism and isolation of teaching (Ball, 1994). Collegiality is de-privatising the work of teaching, and it means being able to disagree constructively about professional practice (Evans, 2012). It is more than simply sharing ideas, it means confronting traditional practice – the teacher's own and that of his or her colleagues.

The Swedish upper secondary school was reformed 2011 and a new curriculum was formulated. It emphasises that teachers should cooperate with other teachers in order to achieve the educational goals (National Agency for Education, 2013). This paper is based on a case study that captures the characteristics of a community of four upper secondary mathematics teachers in a professional development initiative. A version of the Japanese lesson study – learning study – gave access to empirical data of the study. Learning study involves teachers and researchers working together to plan a lesson. The lesson is taught by the teachers in one or several cycles, and is observed, evaluated, and modified by the team before the next cycle is taught (Marton & Lo, 2007).

The aim of this paper is to describe and understand practice when Swedish upper secondary mathematics teachers work together to plan a lesson.

BACKGROUND

In order to understand practice I will review literature regarding a Swedish lesson and a Japanese lesson, as the idea of working together to plan a lesson was imported from Japan.

In Japan teachers work in collegiality and Japanese lesson study was chosen as model for Swedish learning study.[1] The premise behind lesson study is simple; if you want to improve teaching, the most effective place to do so is in the context of a classroom lesson.

1 The difference between learning study and lesson study is that the former comes with a theory of learning. Most often learning study draws on the theoretical assumptions of the variation theory. However, in this paper, the variation theory is not in focus.

Yoshida (2004) writes that Japanese teachers spend hours planning a single lesson in a lesson study. The teachers first engage in the problem from which the lesson will be launched, as the Japanese mathematics lessons are based on structured problem solving. Then the anticipated solutions, thoughts and responses that students might develop as they struggle with the problem will be explored. This is in relation to the kinds of questions that may be asked to enhance student thinking during the lesson, as the type of guidance that could be given to students who show misconceptions in their thinking. The end of the lesson, the moment at which students understanding can be advanced, is carefully considered in the lesson study (Yoshida, 2004; Stiegler & Hiebert, 1999).

Swedish lessons however, are largely synonymous with solving of exercises. The teacher presents a few tasks on the whiteboard, while the students are listening. Similar exercises will then follow and the remaining time of the lesson is spent for individual work in the textbook. The exercises are solved with a specific method and have a correct answer. It is not necessarily that the students are practicing the same skills in their individual work in the textbook as those the teacher presented at the beginning of the lesson (Lundin, 2008). Swedish teaching resemble in many ways with U.S. teaching. Evans (2012) writes that teaching is highly personal in the U.S., and over time, every teacher develops a unique instructional repertoire, a set of personal, artful, assumptions and responses.

Stiegler and Hiebert (1999) stress that teaching is a cultural activity, it is composed of elements that interact and reinforce one another. The methods teachers use, are not determined by their qualifications as much as by the culture in which they teach and the role of the teacher will follow his/her assumption of the nature of learning. When a lesson takes the form of following the teacher's directions by practicing a procedure during seat-work, the teacher believes his/her responsibility is also to keep students engaged and attending. Moment to moment attention is fundamental. Teaching in this typical culture is about enhancing students' interest by increasing the pace of the activities, by praising students for their work and behaviour, by the cuteness or real-lifeness of tasks and by their own power of persuasion through enthusiasm, humour and "coolness". This practice should be relative error-free, as the importance of the feeling of success is not underrated in a learning situation. The teacher acts as if confusion and frustration are signs of them not succeeding at their jobs (Stiegler & Hiebert, 1999). The Japanese teaching culture on the other hand is reinforced by that learning occurs by first letting the students struggle to solve mathematical problems.

Stiegler and Hiebert (1999) write about challenges in importing lesson study to another teaching culture. Trying to improve teaching by changing individual features usually makes little effect, positive or negative, especially when the feature is imported from another teaching culture. Lewis (2009) however, argues that there is evidence that lesson study can be used effectively outside Japan. She reports changes in teachers' professional community in terms of, capacity to improve instruction, shared language, processes, and frameworks for analysing instructions.

Collegiality is not a feature in the Swedish teaching culture, and in this case, the model of working together to plan a lesson is imported from Japan. It is above given that planning a Swedish lesson is different from planning a Japanese lesson.

THEORETICAL FRAMEWORK

Within the paradigm of social practice theory, Wenger (1998) conceptualised Communities of practice as a social theory of learning.

> Practice is doing in historical and social context that gives structure and meaning to what we do. [...] In this sense, practice is always social practice. (Wenger, 1998, p. 47)

Wenger (1998) writes that communities of practice are groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly. A community of practice has a shared domain of interest. Membership therefore entails a commitment to the domain and a shared competence distinguishes members from other people. In pursuing their interest in their domain, members engage in joint activities and discussions and share information. They develop a shared repertoire of resources: experiences, stories, tools and ways of addressing recurring problems. We belong to several communities of practice, in some we are core members, in many we are merely peripheral.

The framework is not about whether the practice is right or not. It is about the active involvement and how it takes place; what is brought to the table in a community of practice (Wenger, 1998). The teachers in the case are an active part of their community but at the same time they are influenced by a teaching culture. The teachers are accountable to the quality of the community of the practice. Their experience of teaching and learning mathematics will be negotiated in the community of practice and validated as competences. The tension between competences and experience is very important for the dynamic in a community of practice. When the core is too strong there is a lack of tension between competences and experience and the community of practice may become static and stand in the way of learning (Wenger, 1998).

The framework of Communities of practice has been used in previous mathematics education research examining teacher learning, with different focus, and in different ways. My approach to the framework is neither attempting to design, nor analysing if a community of practice emerges or not. *I see the mathematics teachers as a community of practice; it is my unit of analysis*.

Framing this case as a community of practice pays attention to the teachers' negotiation of meaning. Meaning is defined as an experience of everyday life and is located in a process; in the negotiation of meaning[2] (Wenger, 1998). That is the negotiation of their experiences of teaching and learning mathematics. A community has dimensions of source of coherence through mutual engagement, a joint enterprise and a shared repertoire. Mutual engagement defines a community and being engaged gives a sense of belonging. It can give rise to differentiation as to homogeneity, as it involves competences and competences of others (Wenger, 1998). The teachers' practice draws on what the teachers know, and their ability to negotiate what they do not know. The joint enterprise is what is being negotiated and reflected upon in the community. It does not imply that everybody agrees with everything. This reflects the complexity of mutual engagement (Wenger, 1998).

> Communities of practice are not self-contained entities. They develop in larger contexts – historical, social, cultural, institutional – with specific resources and constraints. Some of these conditions are explicitly articulated. Some are implicit but are no less binding. (Wenger, 1998, p. 79)

An explicit condition for the practice of this case is that it takes place in a setting; the teachers are to plan a lesson. The process of defining a joint enterprise is keeping the practice in check, just as it also pushes it forward (Wenger, 1998). A history of teaching culture may also be a binding condition, as it is so fully integrated into teachers' worldview. A shared repertoire is the development of the joint enterprise, it is the words, tools, concepts that are produced or adopted throughout the community of practice.

My approach to Communities of practice and the aspects of practice have been characterised by concepts from the theory. This is for the analysis of empirical data. Next methods will be discussed.

METHODOLOGY

This research has arisen in response to the shift towards collaborative work in schools. This is a search for understanding rather than establishing explanations and looking for causes. This is a distinction between qualitative and quantitative research (Stake, 1995).

Stake (1995) writes that we study a case when it itself is of very special interest, when we look for details of interactions with their context. This case constitutes four upper secondary mathematics teachers in a setting of learning study, taking place at an upper secondary school in Sweden. The four teachers have been teaching mathematics in upper secondary school for 4–12 years and they have been employed at the school for 3–12 years. An external advisor, based at a university, is also participating in the learning study. The teachers and advisor met on 7 occasions and in between the teachers were set up for work. Each meeting had a purpose and the work in between was also defined. Their meetings focused discussions on what and how to teach the mathematical concept of slope aiming to plan a lesson.

2 The negotiation of meaning involves the interaction of two constituent processes, participation and reification. Participation is defined as active social involvement but also as personal membership. Reification is defined as a shortcut for communication, a focus, a projection of what they mean. Participation may refer to the active involvement in planning the lesson (Wenger, 1998).

The choice of method in this case study is based on it being qualitative research as well as on the nature of the selection of case. Through the setting of the learning study there was access to 14 two-hour meetings. Empirical data was therefore generated through observation of these meetings. Previous research regarding learning study has mostly aimed at developing practice and the advisor and the researcher is then the same person. In this case study, I was a strict observer (Bryman, 2001) meaning that I did not interact with the respondents. Field notes were taken during these observations, and transcribed as soon as possible after the observation. The field notes did not follow a structure or include any categories. I was writing down my immediate reflections, trying to make sense of the case as it unfolded in practice (Flyvberg, 2006). The meetings were also video-recorded. The video-recordings have not been important for the purpose of hearing the exact words; it was the meaning that was important. It gave access to the source of empirical data again, and again. Hence I would not capitalise on making sense of the case (Stake, 1995).

An interview took place once the learning study was conducted, a month later. Interview questions were used to confirm the empirical data (Bryman, 2001). The interview was also held to provide a complement, to find out what was not understood or not heard through the observations. The interview was consequently semi-structured, i.e., a set of questions had been prepared but there was also space for further questions. The themes focused on in the interview were the teachers' expectations and experience of collegiality. The interview was also aimed at complementing and confirming issues of the setting of learning study.

The case study has an abductive approach, rather than a deductive or an inductive approach. Eriksson and Lindström (1997) say abduction is a way to discover meaningful underlying patterns. It makes possible to connect surface and deep structures. The abduction has a starting point in interpreted knowledge. The interpretation is made in a wide sense, including literature, conceptual analyses and historical sources. The perspectives determine which of the deep structures that are tangible. From this approach new knowledge is established (Eriksson & Lindtröm, 1997). By focusing on different aspects, the interpretations have helped to define the unit of analysis. Alvesson and Sköldberg (2000) define abduction as entailing a commutation between data and theory in a scientific and systematic way to look for answers to research questions of interest. They continue that the researcher is minimising the risk of interpreting what they think they are seeing in light of their own unreflected preunderstandings or to reinvent the same theory but in new words and concepts. A chronologically analysis and an attempt has been made to capture the case through short, impressionistic scenes that focus on one moment or give a particular insight into meaning and community (Stake, 1995).

WHEN THE LESSON IS THE UNIT OF ANALYSIS

The teachers have focused discussions on teaching and learning slope, which has resulted in a mapping of the concept of slope and relating mathematical concepts. The lesson will take the form of the teacher presenting the concept, increasing the difficulty and pace of the activities. They have identified that understanding the meaning of a coordinate in the Cartesian coordinate system is crucial for the students to fully understand the rate of change. The following scene captures the teachers planning an initial part of the lesson concerning coordinates:

Teacher 1: So now I have drawn four points here. [...] Then they will be named A, B, C and D.
Teacher 3: Will you name them A, B and C?
Teacher 1: They can be named anything. Or?
Teacher 3: I was thinking that you have the points and that you fill out the coordinates, the coordinates should not be given. [...] Or will you display all the three coordinates at the same time?
Teacher 1: Four [points]. But it might be a smart idea to present one point at a time.[...] I did not plan to write the coordinates out, but of course you can do that as well.
Teacher 2: It becomes clear if you write them out.
Teacher 3: Why did you not want to write them out?
Teacher 1: I can write them out!
Teacher 3: I think there is a value in introducing one point at a time.

The community negotiate how the points should be labelled, if they should be introduced one by one, if they are to write them up on the whiteboard. It is typical for this case that as the community plans the lesson they start to negotiate teaching techniques. The mutual engagement concerns how to create a presentation maximizing the students' attention and understanding of the content. It gives rise to differentiation, as it involves competences of three teachers. The teachers' practice draws on different techniques of presenting content, developed in larger implicit contexts. As history of how to maximize the students' attention may be a binding condition, as it is so fully integrated into teachers' worldview. The joint enterprise is what is being negotiated and that is different techniques introducing coordinates. The process of defining a joint enterprise when planning the lesson is keeping the practice in check, just as it also pushes it forward (Wenger, 1998). The scene captures that it is hard to coordinate practice to move forward.

To give a dimension to the above their previous experience of collegiality, will be included. I asked them about their experience of working together:

> Teacher 2: We have never experienced anything like this [learning study] together. We are very traditional, those who teach the same courses in parallel classes might construct tests, mark tests and assess students' grades together.

Asking to what extent they have experience of planning lessons together, they say:

> Teacher 1: Yes, sometimes, as an outline of a lesson. It is more often the activity we plan, rather than the lesson. We plan the courses together, in term of its schedule; let's cover this chapter by then, let the students take a test then and so on. In addition we also talk about what we have done today as in how far [in the textbook] we have come. We have done this for a long time, more or less. When it suits us.

The teachers have no previous experience of planning lessons together; they are rather collaboratively engaged in more organisational matters in the faculty.

Discussing the model of working together to plan a lesson, the teachers reflected:

> Teacher 2: It does not feel that the primary goal of this learning study is to plan a perfect lesson. What is important to me is that I have got something from this. When I teach my lessons later, that are not in a learning study, then I take this with me. Those lessons will not be ruled by manuscript.
>
> Teacher 4: That is also my experience, that it was everything around that gave me that good feeling when processing the lesson. The lesson was very tightly structured and I felt by the end, as I was teaching, that the students were quite exhausted. Normally I would have cut it, or done something different. It rarely happens that you have such a controlled lesson for 60 min. The last 20 min you often let them work on their own.

As the teachers reflect about the role of the lesson they reflect that the lesson is not the primary goal of the learning study, it is the teachers' professional development that is their mutual engagement. Still the lesson has a value, for them to imagine and to engage around. The analysis gives that it is the joint lesson that keeps the practice check, as it moves forward. However the shared repertoire is not defined by a lesson as a product. The projection of the joint enterprise is what was negotiated as they planned the lesson.

When planning the lesson further they negotiate to let the students discern the relation between distance and change:

> Advisor: We want the students to discern what a distance is and what a positive and negative change is.
>
> Teacher 3: But then.....I don't know. As I do, I always let Δx be positive, should we talk about negative and positive change on the x-axis then. (...)
>
> Advisor: I have experienced that students do not have the meaning of positive and negative change. I always say to them to follow the direction of the axis. If you go with the axis then it is a positive direction and if you go in the other direction then it is negative.
>
> Teacher 2: That is a way of going through the structure of the coordinate system! (...)

Teacher 3: What comes with this is that Δx can become negative and then we have the negative sign in the denominator to handle. If we instead always treat Δx as positive then if Δy is negative the m-value ($y = mx + c$) is also negative. (...)

Teacher 2: It is still the structure of the coordinate system.

(...)

Teacher 3: We create a natural structure for the student. We say we call them point one and two. It says in their formula-booklet.

Advisor: Yes, but this could be point one and this point two, it doesn't matter which point is point one.

Teacher 2: I think, (...) we should not decide which point that is the first and the second. It is rather the structure [of the coordinate system].

Teacher 3: You think? I do not! I think the students will drown in minus signs and they need to consider going left or right.

Teacher 2: Why should we be afraid of minus signs?

Teacher 3: Because it becomes wrong. Minus signs are shit. [Laughing]

This scene rather captures a lack of discontinuity; it shows a static core in the community. The challenge in the community is to allow discontinuity, to keep the tension between competence and experience (Wenger, 1999). The competence is formulating questions from your experience, but from a new perspective.

The core is very static regarding the negotiation of Δx; students' difficulties with negative numbers will cause frustration and confusion in the classroom, thus it is better to avoid it in the teaching. The idea is to always let the leftmost point be point number one and hence the right most point number two. Then the students can use the algorithm in the formula booklet, without any risk of ending up with a negative denominator. It saves students from "drowning in minus signs". The community does not agree when they are negotiating how to teach the content in the lesson. A shared repertoire does not imply shared as in a common view on what is negotiated (Wenger, 1998).

Wenger (1998) writes that practice develops in historical, social and cultural contexts that give structure and meaning to what we do. The analysis will be discussed in relation to the background.

DISCUSSION

An overall characteristic of practice is that it develops in a teaching culture. As the community lacks awareness of how it organises their teaching, practice becomes resistant to change when planning the lesson. This case captures the fact that the teachers value the lesson and negotiates its importance, but their mutual engagement is in regard to their teacher professional development. They say they were engaged around everything that was learned as were working together to plan the lesson; it was not an engagement to produce a perfect lesson in itself. Stiegler and Hiebert (1999) write that the unit of the lesson has validity for the teachers, as it does not lack of generalisation to real life experience. The lesson is also a part within a teaching culture and coincides with teachers' thoughts on the nature of mathematics and how learning takes place. The Japanese mathematics lesson tells a story, it is tightly connected with a beginning, a midpoint and an end. They are different from the Swedish mathematics lesson, which are described to be more modular with fever connections. Yoshida (2004) writes that a lesson is highly sharable among teachers in Japan. Teachers plan these lessons in collegiality and all work in lesson study is done after school. According to both Evans (2012) and Stiegler and Hiebert (1999), U.S. teachers find professional communities as "more work" and they would rather go home early to plan tomorrow's lessons. Even so:

> Teaching can only change the way cultures change: gradually, steadily, over time as small changes are made... (Hiebert & Stigler, 2004, p. 13)

Working together to plan a lesson in professional development initiatives might be challenged in certain teaching cultures; when teaching is highly personal, underpinned by a unique instructional repertoire; if the lesson is more modular with fewer connections and not a unit in itself. In the introduction I have problematized that; collegiality is a new setting for many teachers; collegiality requires structure that goes beyond simply sharing ideas, that sustains the individualism and isolation of teaching and collegiality requires de-privatising of the work of teachers to start to engage critically with issues of practice. This paper addresses further research considering teaching culture when teachers work together to plan a lesson as a way to obtain, or maintain collegiality.

How to improve spatial visualization ability of preservice teachers of childhood education: A teaching experiment

Ainhoa Berciano and Guadalupe Gutiérrez

University of the Basque Country, Faculty of Teachers Training, Bilbao, Spain, ainhoa.berciano@ehu.eus, guadalupe.gutierrez@ehu.eus

In this paper, we describe a teaching experiment designed and implemented in a classroom of preservice teachers of Childhood Education with the main purpose of measuring the improvement of their spatial visualization ability. Indeed, taking into account some common materials and games, we have designed a four-sessions experiment in mathematical classroom of an Undergraduate Degree of Childhood Education of the University of the Basque Country. After the implementation of the experiment in a classroom with 27 students, the analysed results assert that the spatial visualization ability of the students is better than before, implying that this ability can be achieved and improved even in adults.

Keywords: Spatial visualization ability, teaching experiment, common games, pre-service teachers, childhood education.

INTRODUCTION

Nowadays, we get more and more information through symbols and images that has to be analysed and interpreted in order to extract the meaning.

Understanding symbols is not the only application of the visual-spatial ability that we use in daily life, moreover we are actually surrounded by actions that need it like parking a car, where ideally we need to be able of visualizing the parking spot and calculate if our car fits in. This involves making decisions about how we see objects in a three-dimensional world and how they behave in it. That means we are constantly using our natural ability to position objects, project them on a plane, moving or rotating them mentally. But how can [these abilities] be acquired? And more important, are they susceptible of being taught?

Among the objectives of the book "principles and standards for school mathematics" of the National Council of Teachers of Mathematics (NCTM, 2000) we can find we need to develop the spatial sense and appreciate the geometry as a way to describe and model the physical world. These goals are completely related with the orientation and spatial visualization and, as "Curriculum Focal Points" of geometry points out, they should be studied from childhood Education to 8th course.

In our case, the curriculum of the Childhood Education of the Basque Country has as one of its main goals the "Identification of flat and three-dimensional elements of the environment" (therefore, the visualization skill is required) (EJ / GV, 2010).

These facts imply the visualization ability should be taken into account in the mathematics classroom, developing the necessary activities to improve the skills related with spatial visualization. In this sense, many studies have been done with the purpose to research the factors involved in the teaching-learning of visualization (Bishop, 1983; Gaulin, 1985; Gutiérrez, 1996; Gonzato, 2013; Hershkowitz, Parzysz, & Van Dormolen, 1996; Presmeg, 2006) and one of the open questions is the influence of teacher's ability in this process.

SPATIAL VISUALIZATION

According to Eurydice and Culture Executive Agency (EACEA, 2011), mathematical competence is one of the key skills for personal development that facilitates social and labour inclusion of citizens satisfactorily. After a thorough analysis of the results of the Programme for International Student Assessment (PISA) and Trends in International Mathematics and Science Study (TIMSS) studies at European level, training and professional development of teachers of mathematics highlights as one of the key issues in education.

About mathematical competence, one of the sections analysed by PISA is the "space and form" section, in which the phenomena and geometric and spatial relationships are examined. Indeed, the development of this competence requires observe similarities and differences, analyse the components, recognize shapes in different representations and dimensions and understand the properties of objects and their relative positions. Summarizing it, we must learn how to visualize objects in space and understand the two-dimensional representation thereof, but what does "*visualize*" mean?

Spatial visualization can be defined as "the ability, the process, and the product of creation, interpretation, use of and reflection upon pictures, images, diagrams, in our minds, on paper, or with technology tools, with the purpose of depicting and communicating information, thinking about and developing previously unknown ideas and advancing understandings" (Sarama & Clements, 2009, p. 183).

Furthermore, Presmeg specifies spatial visualization ability as a collection of processes involved in generating and manipulating mental images, as well as guiding the drawing of figures or diagrams on paper or computer screens (as cited in Sarama & Clements, 2009, p. 184).

These processes and skills of subjects have been extensively studied to perform certain tasks that require spatial visualization ability. In fact, these investigations figure out the visualization throughout focusing on different tasks depending on mathematical content: planar representations of 3D-objects (Gutiérrez, 1996; Hershkowitz, Parzysz, & van Dormolen, 1996), planar developments of 3D-objects and 3D-constructions of planar developments (Cohen, 2003; Fischbein, 1993), classification of figures, comprehension of concepts and properties, geometrical transformations (rotations: Battista et al., 1982), compose and decompose 3D-objects in their parts (Bishop, 1983).

About visualization in education, according to NCTM and Basque government, spatial thinking can be learned and should be taught at all educational basic levels. Regarding this, Bishop (1980) proposes questions about teaching that, nowadays, some remain still unanswered: a) Should experimental teaching methods in this area take into account the spatial abilities of the teacher; b) How much responsibility should mathematics teachers take for the training and teaching of spatial abilities? Is this perhaps an area like language, which is every teacher's responsibility?

Hershkowitz, Parzysz and van Dormolen (1996) underline that the nature of mathematics is the search of patterns and therefore visualization is a fundamental tool to recognize them, but even though this relevance, the visual education is often neglected in the curriculum.

In the same way, but some years later, Presmeg (2006, p. 227) gives a big perspective of the researches done in mathematics education and, again, she proposes 13 open questions, some of them related with visual ability: 5. What conversion processes are involved in moving flexibly amongst various mathematical registers, including those of visual nature, thus combating the phenomenon of compartmentalization? 9. How may use of imagery and visual inscriptions facilitate or hinder the reification of processes as mathematical objects? 10. How may visualization be harnessed to promote mathematical abstraction and generalization? 13. What is the structure and what are the components of an overarching theory of visualization for mathematics education?

Actually, different studies have been published giving partial answers to these questions, for example, Gaulin (1985) outlines some activities connecting coding and decoding of spatial information through representations. One of the conclusions was that even the teachers had problems to interpret some graphical representations.

Likewise, Battista, Wheatley and Talsma (1982) show that a specific design of a course based on manipulative materials and some concrete models (symmetry of polygons and polyhedral, paper folding, tracing and using a Mira), improves the specific part of the spatial ability of prospective teachers related with rotations (the test used was "Purdue Spatial Visualization").

In this sense, the work presented here tries to analyse the influence of a specific teaching experiment designed for prospective teachers of Childhood Education, where the methodology is based on common materials, games and working as collaborative teams (see, for example, Gutiérrez & Berciano, 2012).

METHODOLOGY

Context of the study and objectives of the research

The research showed here is included in a bigger project where the main objective is to improve the skills of our students with respect to their didactical competency in spatial visualization as teachers of childhood education (this project has the restriction of time: in 60 hours a big curriculum related with childhood mathematics has to be given); but, first of all, we will analyse if their spatial visualization ability can be improved and how. For this purpose, we will focus on the first question, measuring the improvement of the spatial visualization ability of our students after the implementation of a designed teaching experiment.

Participants

The group chosen for the teaching experiment was a Spanish group of the 3rd level of the Undergraduate Degree of Childhood Education of the University of the Basque Country of the topic "Mathematical thinking and its Didactics", formed by 27 persons, 26 women and 1 man. All of them usually went to classroom and participated actively. This group was divided in small groups of 2 or 3 persons to work in a collaborative way during the entire course.

Instruments to measure the spatial visualization ability

The instruments used to analyse the results have been mainly two: the diaries of the students, where their evolution could be seen, and a test to measure their competency about spatial visualization (used as a pre-test and a post-test).

About this second tool, we have seen that different authors focused their research in a specific task related with spatial visualization ability, but in our case, to measure it, we have taken into account all of them, that is, we have focused on studying the tasks of interpreting perspectives of three dimensional objects (activities requiring recognize and change views (change of perspective)), rotate objects mentally, interpret different planar representations of three-dimensional objects (perspectives, views,...), turn a planar representation into another, build objects from one or more planar performances, ...

For this purpose, we have used the test called "Test of Three-Dimensional Objects" (VOT), designed and validated by Gonzato (Gonzato, Fernández, & Godino, 2011; Gonzato, Godino, & Neto, 2011; Gonzato, 2013). In this test, the mathematical knowledge and the knowledge of teaching Spatial Visualization in elementary education are measured. As the author shows in her PhD thesis, the tasks proposed in the test involve the following actions: *change the representation type* (planar or three-dimensional object); *rotate* the object or parts of the object, or equivalently, *change* mentally *the perspective* of it; *fold* a planar development to create a three-dimensional object (physical or represented), or vice versa, *expand* the object for obtaining one of its developments; *compose* and *decompose* in parts; and, given a solid, *count* the component parts (units of volume, faces, edges, vertices, etc.).

In fact, the test has 5 items (with sub items), each of them dedicated to a previous action. Let's see the first item and its parts (extracted from (Gonzato, 2013), question 1b') has been adapted to Childhood Education):

> *1a)* From which positions have been taken the pictures you can see at right side? *1a')* Justify the answer. *1b)* Identify the knowledge involve in the resolution of *1a). 1b')* Indicate how should you change *1a)* to be able to work it at Childhood Education classroom.

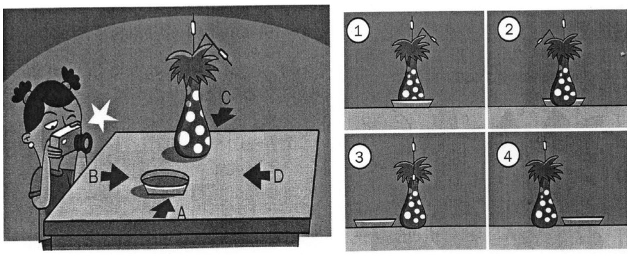

Figure 1

> *1c)* The following figure shows a building drawn from front-right angle. Draw the view from back. *1c')* Justify your answer.

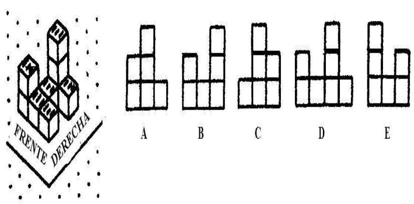

Figure 2

The way to correct this test is:

1) To measure the skills our students have about mathematical knowledge, we have analysed the results given by them in the first sections of each item. In this case, the correction is right, partially right or wrong (1a, 1c). In the same way, it is possible to do a qualitative analysis of the errors given by the students to obtain more information about the error types.

2) To study the skills that the students have about didactical knowledge, we have examined the answer given in sub item 1b' (not included in this paper).

We have used this test as a pre-test and post-test to, on one hand, study the starting point of our students and, on the other hand, see the variance of the ability of our students after the implementation of the teaching.

Mathematical task

In all the activities of the experiment, the task requested to the students is *to determine which mathematical concepts and properties are needed* to realize a specific exercise where visualization skills are involved. These are some questions:

1) Which properties of a 3d-object should be used to do its planar development (and the reverse)?

2) Given a 3d-object, how many different projections can be done, and which mathematical properties are involved?

3) Which are the mathematical concepts involved in the movement of a 2d-object in the plane, which properties do they have and how can be they composed?

Design of the experiment, schedule of the materials used and the activities done

Previously to the experiment, the students filled out the pre-test. The experiment has been realized inside the topic "Geometry" in 3 sessions of 2 hours each and another hour and a half of a fourth session has been used to evaluate the results after the implementation using the post-test. The way to design the session has been the same, that is, first the students should become familiar with a selected material (a specific game or common material); second, they should realize different activities to explore the characteristics of the material from mathematical point of view; third, they should formulate a hypothesis about a given question; fourth, they must compare the hypothetical results with the real answer; fifth, they had to give an explanation about the result with mathematical arguments. All of these activities were done in small collaborative teams and the students had to talk to each other at all times.

Next, we describe each session with the given instructions to the students:

Session 1: *Visualization and spatial representation (01/04/2014)*

The activities done: VOT test and playing with boxes, where the main objective is to learn how are the cardboard boxes constructed from their planar development, and vice versa.

This activity has two different parts, but the way to work with the material is always the same. Each pair of students should complete a diary where the next steps should be done:

1) Observe the given object (3d or 2d).

2) Describe it verbally and graphically.

3) Make a hypothesis about its planar development/ the 3d object that can be done with it (3d and 2d object respectively).

4) Do the planar development/ the 3d object.

5) Describe verbally and graphically the planar development/ the 3d object.

6) Compare the hypothesis with the experimental result.

The materials selected were a commercial box for the first activity and a common planar development for the second activity.

Next, let's see a small part of the diary realized by a student with respect to the first exercise, the planar development of a cardboard box that contains coffee capsules.

Take the box	*Describe it verbally*	*Describe it graphically*	*Make an hypothesis about its planar development*
	It is a cube-shaped box that has all the edges equal (where two faces meet), which is measuring the same. It also has 6 faces.		
Table 1: Theoretical planar development of a given box and part of the diary of a student

Session 2: *Identification of 3d objects and their component parts* (08/04/2014). The activities done: constructions with multilink cubes and constructions of buildings with the game called "*Skyscraper*".

The way to give the instructions is the same than in session 1. Two different parts, but with the same line of argue.

With the multilink cubes, the students should construct different structures, describe them verbally to other colleagues of the same collaborative group and the other students should replicate the construction only with the explanations, without see it.

In the second part of the session, students should play with Puzzle Skyscraper. Each puzzle consists of a 4x4 grid with some clues along its sides. The object is to place a skyscraper in each square, with a height between 1 and 4, so that no two skyscrapers in a row or column have the same number of floors. In addition, the number of visible skyscrapers, viewed from the direction of each clue, is equal to the value of the clue. Higher skyscrapers block the view of lower skyscrapers located behind them.

When the construction is done, the students should describe all the projections of the construction verbally and graphically.

Session 3: *Geometric transformations* (symmetries, turns) (15/04/2014). In last session, the main purpose is to recognize the differences between symmetries, translations and turns. For this end, the material used was: game reflections, game "the prince and Munster" and mirrors. The instructions were given following the next steps:

1) To distinguish between symmetries and translations, the students should find examples at the classroom.

2) Next, taken into account the symmetry, a classification of alphabetic letters was done.

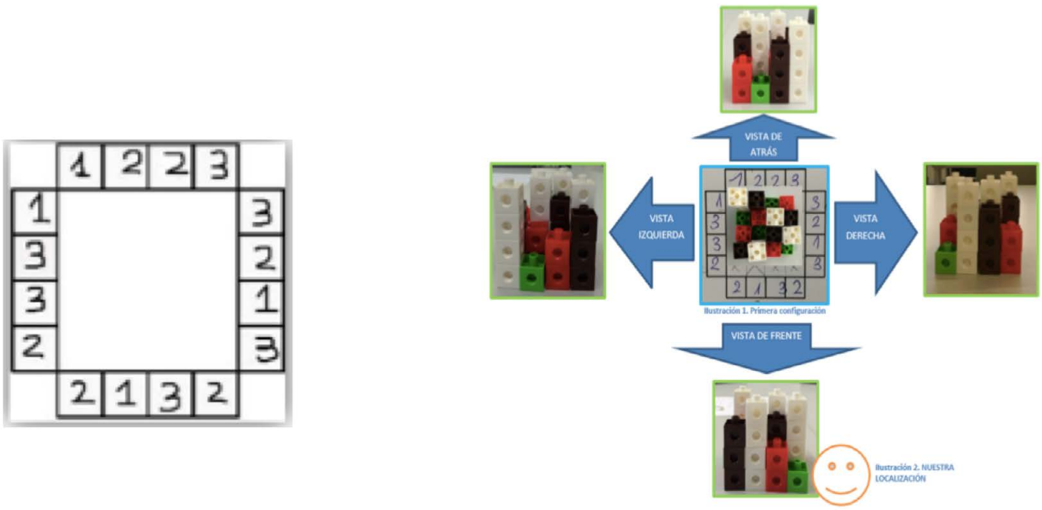

Figure 3: A given square and its construction with all the perspectives done by a student (left and right respectively)

3) Find the differences between a photo and an image in front of a mirror.

4) Finally, the students should anticipate the hypothetical answer of the reflections of the mirrors to create a copy of the asked image (reflection) or the face of the prince (prince and Munster). Again a verbal explanation should be given to their colleagues.

Session 4: *Evaluation of the spatial visualization ability* (29/04/2014). Again, VOT test was used to evaluate the results after the experiment.

RESULTS

To show the main results, first of all we've focused in the analysis of the differences between the results in the pre-test and the post-test considering that the maximum score is 20.

As Figure 3 shows (left graphic), it is clear that in a big percentage, the students have improved their results in the test. Only 4 students have obtained worse result in the post-test than in the pre-test (right graphic), but this can be biased because two of them showed no interest in doing right both the pre and the post-test. Furthermore, the average in the pre-test is 10.04 and 11.56 in the post-test, the median is 10 and 12 respectively and the standard deviations are almost the same (3.5 and 3.6). All this implies that their spatial visualization ability is better, which is the main objective of this teaching experiment.

On other hand, if we count the students who have done successfully each task in pre-test and post-test (Figure 4, left graphic), we can see that, apart from task 1A and 5A, this number has increased, implying again that the students have developed their spatial visualization (see Figure 4, right graphic).

CONCLUSIONS

As we have shown along the paper, we have designed and implemented a new didactical proposal to work visualization with preservice teachers of childhood education. The main part of the design is the use of common materials and games, which normally are known by the students, but with the main purpose of focusing their attention in activities related with visual skills. The activities have the same structure, beginning with an experimental part with verbal and

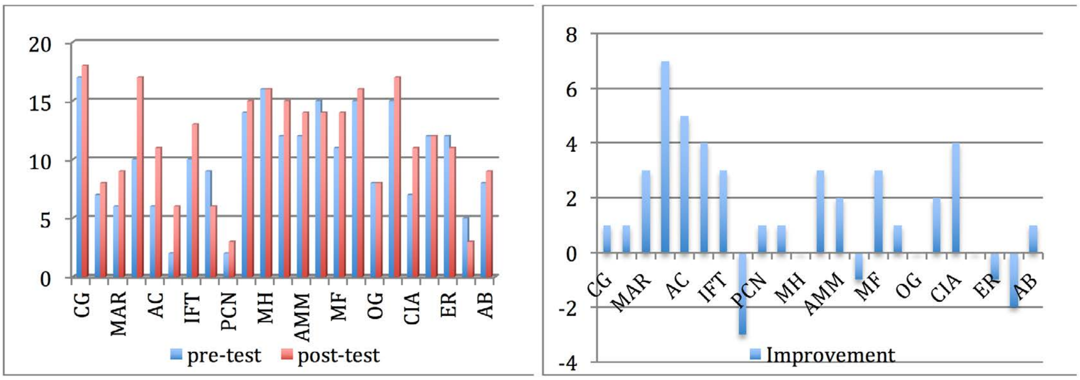

Figure 3: Quantitative results in pre-test and post-test about total punctuation of spatial visualization and the improvement about it (left and right respectively)

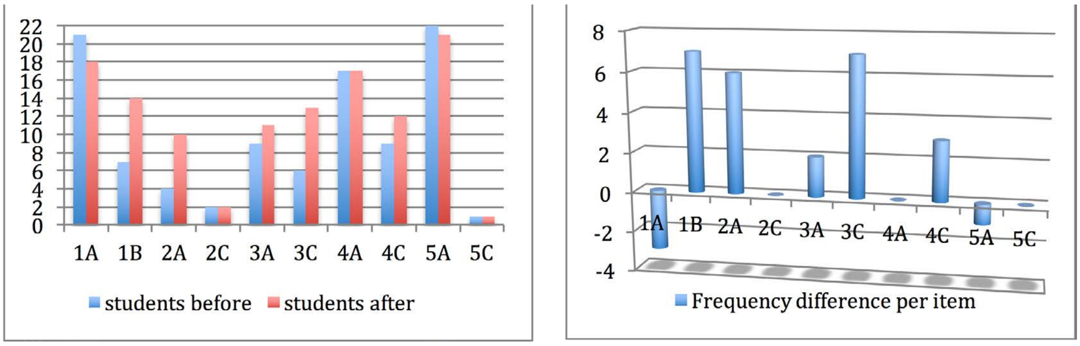

Figure 4: Number of students with correct answer per item and the frequency difference after the experiment (left and right)

graphical descriptions; later, they ask for a hypothesis about a question and a verification of the veracity of the hypothesis and finally end with a question about the description of mathematical properties and concepts involved on it. Regarding to results, our students have significantly improved their spatial visualization.

This new perspective allows us to go from a simple activity to abstraction, opening a new research line where Realistic Mathematics Education is the basis of the methodology for designing new teaching experiments, where the goal is to evaluate the impact and the possible improvement of mathematical competencies.

ACKNOWLEDGEMENT

The authors of the paper thank the financial support given by the research project EHUA11/13 of the University of the Basque Country.

What questions do mathematics mentor teachers ask?

Raymond Bjuland, Reidar Mosvold and Janne Fauskanger

University of Stavanger, Faculty of Arts and Education, Stavanger, Norway, raymond.bjuland@uis.no

Lesson study was originally a professional development initiative from Japan. In some of the previous attempts to introduce it into initial teacher education, the role of the teacher educator has been highlighted. In this study, we analyse the questions that two mathematics mentor teachers ask in mentoring sessions, one in a lesson study intervention and one in a regular practice period in teacher education. Our findings indicate that the mentor teacher's questions in the lesson study intervention were more focused on planning, observation and pupil engagement and less focused on a deep understanding of the mathematical content.

Keywords: Lesson study, initial teacher education, mentoring sessions, questioning.

INTRODUCTION

A main goal in teacher education is to develop reflective practitioners who are able to carry out the work of teaching mathematics with high quality and proficiency. Lesson study has a focus on teachers' critical reflection about the content and organisation of lessons in order to develop more high-quality teaching and learning. A decisive feature of lesson study is that groups of teachers conduct focused observation of lessons along with collection of data necessary to collectively analyse the lesson (Lewis, Perry, & Murata, 2006). Although originally used in systematic professional development in Japanese schools, lesson study has lately been applied also in teacher education (Hart, Alston, & Murata, 2011). When Murata and Pothen (2011) implemented lesson study in mathematics methods courses for student teachers, they devoted 8–9 weeks to preparation and lesson planning, and they also underlined the importance of the written guidelines in creating lesson plans as well as carrying out the entire lesson study. Dudley and Gowing (2012) argue that lesson study is relevant for student teachers because it enables them to learn from detailed micro-level practices and allows them access to the tacit knowledge of their experienced mentor teachers.

The teacher educator has an important role when lesson study is applied in teacher education (Potari, 2011). In the school-based part of initial teacher education in Norway, the mentor teachers have the role of teacher educators (Nilssen, 2010), and the interaction between the mentor teacher and student mathematics teachers is important in this respect. Recently, lesson study has been implemented in a Norwegian teacher education context, and the role of the mentor teacher is a natural focus of investigation. Initial teacher education in Norway is organised as a four-year bachelor programme with 20 weeks of field practice. For this research project, the student teachers were in their second year (fourth semester), preparing for a three-week long field practice.

In this paper, we focus our attention in particular on the questions posed by two mathematics mentor teachers in the pre- and post-lesson mentoring sessions. We approach the following research question:

> What kind of questions does the mentor teacher ask in mentoring sessions in a lesson study intervention compared with the questions asked in a regular period of teaching practice?

As our initial attempt to investigate this question, we analyse two cases: one mentor teacher and a group of student teachers in the lesson study intervention, and another mentor teacher with her group of student teachers in a regular teaching practice with no lesson study intervention.

MENTOR TEACHERS ASKING QUESTIONS

In a review of research on the role of mentor teachers in mentoring dialogues, Hennissen and colleagues (2008) found that mentor teachers are normally directive and focused on organising activities. This coincides with analyses of mentoring sessions in Norway (Helgevold, Næsheim-Bjørkvik, & Østrem, 2014). In this paper, we investigate the questions that mentor teachers pose to student teachers when mentoring them in connection with the teaching practice that is part of their initial teacher education. Asking questions is related to characteristics of mentor teachers with non-directive supervisory skills, highlighted as important for student teachers' learning (Hennissen et al., 2008).

Gadamer (2004) proposes that questions are imperative to the development of knowledge, but this requires that the questions are "true". He refers to questions where the answer is already settled as apparent questions; questions where the answer is not settled are referred to as true questions. Following Gadamer, it can be argued that mentor teachers should ask true questions, which guide the student teachers toward subject matter knowledge (SMK) and pedagogical content knowledge (PCK) in the mentoring sessions (Johnsen-Høines, 2011).

Posing questions that guide the student teachers toward SMK and PCK relates to Shulman's (1986) early categorisation of teacher knowledge. His categories have been important for the development of several frameworks for teacher knowledge. Shulman divided teachers' content knowledge into three domains: SMK, PCK, and curricular knowledge. PCK relates to instruction, integrating teachers' knowledge of content with their knowledge of pedagogy. SMK, on the other hand, relates to content knowledge only. Shulman's work, in particular PCK, has created debate and has given rise to new categorisations (e.g., Graeber & Tirosh, 2008), all including knowledge of instructional strategies and knowledge of pupils' understanding (e.g., Ball, Thames, & Phelps, 2008). Both types of content knowledge are highlighted as important for high quality teaching (e.g., Ball et al., 2008). A focus on SMK and PCK is therefore emphasised as important in mentoring of student teachers (Johnsen-Høines, 2011). Therefore, it is of importance to study the content of questions posed by mentor teachers while mentoring student teachers.

METHODS

The present study is a part of the larger TasS ("Teachers as Students") project. This project aims at investigating student teachers' learning in field practice through a time-lagged design experiment (Hartas, 2010). Two groups of student teachers from each of four subject areas (mathematics, science, English as a foreign language, and physical education) participated in a control group situation; the same number of groups participated in an intervention situation. The control group is referred to as the "business as usual condition" (BAU), and the intervention group is referred to as the "lesson study approach condition" (INT). In BAU, data collection included video observations from student teachers' planning lessons with their mentor teacher (pre-lesson mentoring sessions), from carrying out lessons and from mentoring sessions after carrying out the lessons (post-lesson mentoring sessions). In INT, data collection included video observations from pre-lesson mentoring sessions, from carrying out lessons, from mentoring sessions after carrying out the lesson for the first time, carrying out the lesson for a second time, and from post-lesson mentoring sessions. In mathematics, which is in focus here, data were collected from four groups of student teachers (two BAU and two INT groups) altogether. In one of the INT groups, the mentor teacher was replaced by a colleague during the lesson study cycle due to sick leave. In this paper, we therefore analyse the four mentoring sessions from one BAU group and one INT group. The duration of the mentoring sessions varied from 18 to about 46 minutes (see Table 1). Both the mentor teacher from the BAU group (we have called Rut) and the mentor teacher from the lesson study intervention (referred to as Ina) are experienced mathematics teachers.

The mentor teachers in the lesson study intervention participated in three workshops on lesson study. In the first workshop, the mentor teachers were introduced to important ideas concerning lesson study and the different phases of the lesson study cycle. The aim of the second and third workshops was to develop a draft version of a "Handbook for Lesson Study". Inspired by Munthe and Postholm (2012), this handbook provided suggestions for possible questions to ask throughout the lesson study cycle. More specifically, crucial elements of the handbook were to highlight questions that could help the student teachers to make a detailed lesson plan, emphasising careful planning and focused observations with a clear content goal for the research lesson. The handbook also stressed the importance of posing a research question for the research lesson. This research question would normally have a focus on increasing pupils' learning of the mathematical content. An aim of the planning and observation throughout the lesson study cycle is to answer this question. The aspects stressed in the handbook are closely related to SMK and PCK.

The unit of analysis is the mentor teachers' questions as posed in the mentoring sessions. The analytical approach is directed content analysis (Hsieh & Shannon, 2005), and the coding was inspired by important elements emphasised in the handbook. In order to increase the reliability of the coding, the first and third authors coded the questions independently. The codes were discussed and agreement reached in the few instances where there was a mismatch. The second author then revised and ensured that the coding was consistent.

Initially, we identified three main categories: *Observation*, *Planning* and *Other*; these were further split into sub-categories of questions (see Table 1, first column). The mentor teachers' questions that are related to more general comments, concerning observation in the classroom were coded as *Observation* (Obs). The subcategory Obs-Goal is related to the goal for the lesson. Obs-Content focuses on mathematical observations from the classroom. The subcategory Obs-Pupil highlights observations about pupils' learning. The subcategory Obs-Teaching is related to observations based on incidents from the student teachers' teaching in the classroom.

The questions that are related to the planning of a lesson were coded as *Planning* (Plan). The subcategory Plan-Goal focuses on the planning of a lesson with a more general focus on the goal. The subcategory Plan-Content is related to a focus on the mathematical content. The subcategory Plan-Pupil Engagement highlights questions, emphasising how the chosen problems or activities could lead to increasing or decreasing pupil involvement and motivation. Plan-Prediction refers to the subcategory of questions that is related to possible teaching problems or pupil difficulties that may arise in a lesson. The subcategory Plan-Teaching focuses on questions that are related to practical considerations about the organisation of the teaching activities.

The third category, *Other*, refers to questions that do not fit into any of the other categories, for instance, a question about practical issues and clarifications. Two particular consecutive questions, challenging the student teachers to reflect on what they have learned about the pupils' learning, were also included in this category.

In Table 1, MS1 and MS2 refer to the mentoring sessions before and after the first (research) lesson that was recorded; MS3 and MS4 refer to the mentoring sessions before and after the second lesson. The four student teachers of the INT group had written in their lesson plan document that the plan for the research lesson was to teach the pupils in this particular tenth grade class about algebraic factorisations and how to simplify algebraic expressions. In the BAU group, the three student teachers' plan for the first lesson was to teach the pupils in this eighth grade class about the equal sign and the unknown, helping the pupils understand the balance in a simple equation like box (x) + 3500 = 5000. In the second lesson of the BAU group, the student teachers planned to teach the pupils about the difference between an unknown and a variable.

RESULTS

In our analysis, we mainly focus on the qualitative differences between the two mentor teachers' questions. When applying content analysis, however, a combination of counting the frequency of particular words or content and a more qualitative interpretation of the content is often used (Hsieh & Shannon, 2005). In our study, the counting of frequencies was useful to discover patterns in the data that were later investigated more qualitatively. Table 1 displays the comparison of relative frequencies of the different categories of questions posed by Ina and Rut.

Planning for pupil engagement

In lesson study, there is a focus on planning for pupil engagement, not only on how to deliver the content (e.g., Dudley & Gowing, 2012). Rut, the mentor teacher in BAU (Table 1, shaded columns), did not ask any questions related to planning for pupil engagement. She was more focused on questions related to prediction and planning the teaching. Ina, the mentor teacher in the intervention (Table 1, white columns), on the other hand, asked a number of questions about planning for pupil engagement. In the first mentoring session, when discussing pupils who were not active,

Table 1: Relative frequency of questions in the four mentoring sessions

Ina asked: “Yes, what do you think we as teachers can do then, in order to include these pupils?” Later in the same mentoring session, they were getting more practical and discussed tasks that are suitable for a diversity of pupils: “Do you feel these tasks are suitable for all levels? I mean, to start with what is known in order to move them along.” As a third example from the same mentoring session, Ina addressed the issue of motivating pupils to learn algebra: “Yes, how are you going to motivate all pupils to learn algebra? Because that should be the goal, right?” Later on she asked about the potential use of manipulatives and games to motivate pupils.

In the second mentoring session, after the teaching of the first research lesson, Ina asked: “Could you have done it differently in order to get more pupil engagement?” Later, when commenting on how two of the student teachers reported that they had ignored some initiatives from the pupils, she asked: “Do you think you managed to activate the pupils? Could they have been even more active, participated more, contributing more verbally?” Towards the end of this mentoring session, she commented on the diversity of pupils in the class, and she asked: “Looking back at this group of pupils, I’m thinking: how could we ensure that everyone is following us?” She returned to these questions in the next mentoring session, where the student teachers were planning for the second teaching of the research lesson. One of the student teachers commented that she would observe whether or not the pupils are active, and Ina challenged her on this: “Yes, you say that you will observe if they are active, but there are some pupils who never participate or say anything. How are you going to ensure that they participate?” This question was followed by some questions about how they were going to observe the pupils during the research lesson. This leads to another interesting difference between the two groups. In the intervention, the mentor teacher posed more questions related to observation, which is also highlighted in lesson study research (e.g., Dudley & Gowing, 2012).

Focus on observation

A feature of lesson study is that teachers use observation as a means to collect data in order to analyse a lesson (Lewis et al., 2006). We find examples of such questions about observation in the first mentoring session in the intervention group. Having grasped this aspect of lesson study, Ina challenged the student teachers with regards to observation: “How are you going to observe to see that the pupils actually learn something from the teaching, in relation to what you have been planning and the goals you have?” One of the student teachers responded that they are going to observe which pupils are active and which not. Ina followed up by asking: “Yes, but what about pupils who are not active in the lesson, who you don’t observe raise their hands, would that imply that they have not received anything, or that there is no learning?” When the student teachers responded that they plan to ask the pupils after the lesson, Ina continued to challenge them on this: “Yes, what do you think is the reason that they – if it appears that they have really learned something from the lesson – that they are not active; what is the reason for that?"

In the second mentoring session, Ina reminded the student teachers about what they had planned to observe, and she asked: "What issues were the observations supposed to focus on? [...] [W]hat questions did you pose yourselves there?" Later on in the same mentoring session, she asked: "How did you plan this thing about observation before [the lesson]? Did you ask yourselves how, what you were going to observe, how, and why?" When planning for the second teaching of the research lesson, in the third mentoring session, Ina returned to this and asked: "And how are you then going to see and evaluate whether or not the pupils learn?" She followed up with questions about how they were going to plan for pupil engagement, before she posed some more questions about how they were going to observe the pupils.

Rut also posed some questions concerning observation in the mentoring sessions in the BAU group, but her questions were different from Ina's. Whereas Ina focused on challenging the student teachers about how they were planning to observe, using observation as a tool to collect data (e.g., Lewis et al., 2006), Rut mainly asked questions related to observation in the sessions after the lessons. Her questions were mainly focusing on what the student teachers asked and what the pupils responded. As an example, they were discussing some observations from the first lesson (in the second mentoring session), and Rut said: "And then you underlined this and said: Yes, so you thought the opposite, how many ice creams do you need?" This question was related to an observation of pupils, but Rut was mainly referring to the student teacher's question rather than asking about the pupil's learning. Shortly after, she asked a question related to an observation concerning the content: "Is this a correct use of the equal sign?" This leads to another observed difference between the two mentor teachers. Whereas Ina asked more questions about planning and observation, Rut asked more questions that focused on content. This is interesting, since a deep reflection about content is emphasised in lesson study research (e.g., Murata & Pothen, 2011).

Focus on content

In the third mentoring session, prior to the second lesson, Rut asked several questions about how the student teachers planned to present the content. At the beginning of the session, she asked the following question to clarify the focus of the lesson: "So, the lesson is really about variables then?" Shortly after, she posed another question about the content: "Are you going to end up with some kind of definition, or are you only going to teach them about variables?" After having discussed this for a while, they started to discuss the concepts of 'unknown' and 'variable'. Rut asked: "Why do we use two different words [variable and unknown] in this situation?" When one of the student teachers responded, Rut continued to challenge them about the connection between these two concepts by asking: "Because we end up with letters in both, don't we?"

Later, in the third mentoring session, Rut posed some more questions about planning and observation related to content: "It is about an expression that contains parentheses, but we mentioned yesterday that we are missing a small revision really, about what a parenthesis really is? And then one of the pupils also asked: What is it really, what does a parenthesis mean?" She followed up by challenging the student teachers about the meaning of a parenthesis by asking: "How would we respond to that, what does a parenthesis really mean?"

In comparison, Ina asked fewer questions that focused on content. Her questions seemed less focused on challenging the student teachers about their understanding of the content and more focused on the pupils' learning of the content. Some examples from the second mentoring session, after the first research lesson, illustrate this: "If you had asked her [referring to one of the pupils] if she knew prime factorisation, do you think she would have known what to do then?" In the third mentoring session, she posed some more questions about prime factorisation, but this time with a focus on the planning of the second research lesson: "And then you mentioned about prime numbers, because in the previous lesson you started off directly with factorisation and didn't mention prime numbers a lot. And I observed that, and if this is what is important, that they should be able to do prime factorisation, then you should probably mention it?" Later she followed up by asking another question about their planning of this: "Yes, and then you are going to explain factorisation and reducing?" When comparing the two, it appears that Ina focused less on asking questions about the content than Rut, and when she did, her focus was more on how the student teachers were going to plan their teaching of the content in order for the pupils to learn. Rut was more focused on challenging the student teachers' own understanding of the content.

CONCLUDING DISCUSSION

Teachers who participate in lesson study are supposed to have a strong focus on specifying a clear goal for the lesson. In addition to this, a deep reflection about content as well as pupil engagement and prediction of pupils' responses is often emphasised in lesson study groups (Munthe & Postholm, 2012; Murata & Pothen, 2011). When implementing lesson study in teacher education, the role of the teacher educator has been stressed (Potari, 2011). In our study, the mentor teacher had the role of a teacher educator, and it is thus interesting to observe the differences in emphasis in the mentor teachers' questions in these two groups. We notice that the mentor teacher in the business as usual condition asked far more questions regarding the mathematical content and teaching (Table 1, shaded columns). The questions on teaching were, however, mostly related to practical issues such as organisation. Contrary to what one might believe, we observe that this mentor teacher also had more questions relating to prediction of pupil learning than the mentor teacher in the lesson study intervention. More specifically, the analyses of the BAU-sessions have revealed that the mentor teacher (Rut) posed several questions on Plan-Content and Obs-Content, and these questions have the potential of being true questions (Gadamer, 2004). We suggest that these types of questions, emphasising the mathematical content to be learned by the pupils in the classroom, could be an important affordance that might inform future implementations of lesson study (Table 1, white columns). Our analyses have also illustrated that these types of questions were not that prominent in the INT sessions.

Murata and Pothen (2011) emphasise the importance of spending a lot of time on preparation and lesson planning, discussing the mathematical theme in focus. The student teachers in this study did not have the same opportunity to work on their lesson planning for several weeks and future implementations of lesson study might consider this. The student teachers in our study had also finished their course work in mathematics before their period of teaching practice and the subsequent lack of involvement from the teacher educator at the university could have led to a lack of focus on the mathematical content in the lesson study cycle. The lack of time for preparation and lesson planning as well as the lack of involvement by the teacher educator could represent serious constraints for the lesson study implementation. It is also possible that the "Handbook for Lesson Study", developed during the TasS workshops, was too focused on more general questions related to planning and observation since it was designed for use across subjects. In that respect, the handbook could function both as an affordance (initiating pedagogical questions), but at the same time it could function as a constraint (too little emphasis on the subject matter).

Lesson study seems to have several benefits when implemented in the right way and one benefit is the focus on important aspects of SMK and PCK such as planning and student engagement, observation as a means to collect data in order to analyse a lesson (Lewis et al., 2006) and content. The handbook inspired by Munthe and Postholm (2012) used in this study provided suggestions for possible questions to ask throughout the lesson study cycle highlighting these important aspects of SMK and PCK. Our study indicates that implementing lesson study in teacher education is far from straightforward. The mentoring dialogues in the intervention had a stronger focus on planning and pupil engagement, as well as observation, but a weaker focus on content. The questions on content in the lesson study intervention were also more related to planning for pupils' learning of the content, whereas the questions in the business as usual condition had a stronger focus on the student teachers' own understanding of the mathematical content. Further studies are needed to investigate whether or not this is a general tendency, or if a stronger focus on the content can be achieved by revising the handbook.

Teachers' professional development in terms of identity development – A shift in perspective on mathematics teachers' learning

Marc Bosse and Günter Törner

University of Duisburg-Essen, Faculty of Mathematics, Essen, Germany, marc.bosse@uni-due.de

The theory of Communities of Practice (Wenger, 1998) provides a model of social learning whose assumptions differ from those made in the common theoretical frameworks of teachers' professional competencies. This shift in perspective on learning takes into account the concept of identity and connects it to the concept of practice. In this theoretical paper, we will clarify how teachers' learning works in terms of selected elements of Wenger's theory. Simultaneously, we will refer to empirical research findings on teachers' professional development and check whether they are in line with the theoretical considerations derived from the social perspective on learning.

Keywords: Teacher identity, teacher learning, professional development, identity development, communities of practice.

INTRODUCTION AND MOTIVATION

Facilitators of mathematics teachers' professional development are looking for effective ways of promoting teachers' learning. The term *learning* normally refers to a psychological-individual process of gaining professional competence, i.e., the capacity, skills or abilities to be more effective when teaching. A targeted aim of professional development programs is therefore not only to improve teachers' knowledge but also to change teaching practice on this basis and thereby to improve students' competencies (Lipowsky & Rzejak, 2012).

Schoenfeld (2011) considers that teachers' implementations of goal-oriented decisions – that make up an important part of teaching practice – do not only base on knowledge (and other resources) but also on context-dependent *orientations*. This summarizing term comprises beliefs, attitudes, dispositions etc. and can be regarded as a notion that describes the affective-motivational characteristics of a teacher's professional competence. In this respect, Schoenfeld's term *orientation* frames, extends and in particular refines belief theory, since especially beliefs are very often discussed isolatedly from the complex surrounding framework.

Current research on teachers' professional competencies (Döhrmann, Kaiser, & Blömeke, 2012) as well as guidelines for professional development programs (Deutsches Zentrum für Lehrerbildung Mathematik, 2013) include both, cognitive competencies *and* motivational-affective characteristics of professional competence in the respective theoretical frameworks. This extension also marks a progress since the older postulate 'teaching should be cognitively enhancing' lacked the axiom that mathematics lessons should also be emotionally inspiring.

In accordance to Zehetmeier and Krainer (2011), teachers' learning can also be described in terms of knowledge, beliefs, and teaching practice. However, they conclude that further categories like "in-school levels" and "beyond-school levels" have to be considered when analyzing teachers' professional development: Which roles do colleagues and principles play for teachers' learning? Which impact is induced by students and the teachers' experiences in the classroom? And how does personal experience beyond professional practice in school constitute hindering or fostering factors for learning?

Particularly in our studies dealing with the professional development of so-called *out-of-field* teaching mathematics teachers, i.e. teachers without formal qualification for teaching mathematics, we realized that considering cognitive competencies is not enough if we want to understand their actual professional practice (Bosse & Törner, 2014). In an ongoing analysis of interviews with this group of mathematics teachers, we can observe that identity-related aspects (e.g., experiences made with mathematics when the teachers were students themselves) influence their present teaching.

On this account, we want to change the perspective on teachers' *learning* from a psychological-individual transformation to a more holistic socio-cultural process in terms of *identity development*.

We will delineate teachers' learning as identity development as follows:

Firstly, we will give a short overview of the relevant literature locating teachers' learning as a social process in the field of theories of teachers' professional development.

Secondly, we will define the terms *identity*, *identity development* and *learning* by using the theory of *Communities of Practice (CoP)* (Wenger, 1998).

Thirdly, some important components of the CoP framework will be selected and discussed with the aim of explaining research findings and illuminating considerations of why mathematics teachers' professional development may be sustainable and effective or not.

Finally, we will critically reflect on our theoretical considerations and derive reasonable conclusions for designing effective professional development courses for mathematics teachers

TEACHERS' LEARNING IN COMMUNITES OF PRACTICE

The socio-cognitive approach and identity in practice

Rösken (2011) comes to the conclusion that recognizing professional development as identity development means integrating "personality as a relevant variable in the classroom" (p. 25). In the same way, Alsup (2006) postulates that teachers should be seen as intellectuals in a lifelong process of learning but not as technicians whose possible shortcomings in knowledge, beliefs, and practice have to be overcome via professional development programs.

This understanding of teachers' learning entails a *temporal-historic dimension:* Learning can be seen as the holistic process of turning an actual identity into a designated identity (Sfard & Prusak, 2005). Moreover, the notion of identity is directly connected to the role of *contexts* of teachers' learning. Beijaard, Meijer, and Verloop (2004) highlight that context is an important factor for analyzing and understanding identity development while Zehetmeier and Krainer (2011) even claim that communities and socio-cultural contexts have an impact on the sustainability of teachers' learning. Similarly, Beauchamp and Thomas (2009) come to the conclusion that information about contexts as well as communities and their influence on shaping teacher identities should be integrated into professional development courses.

Bohl and van Zoest (2002) have picked up the idea of using identity as an analytical and descriptive category of teacher development as well. In terms of our introduction, identity from their point of view is not exclusively located either "In-the-brain" or fully in the "Social". In fact, they assume identity being a "combination of aspects of self-in-mind and aspects of self-in-community" (p. 142).

Having this in mind, mathematics teachers' identities are therefore located within a socio-cognitive continuum: On the one hand, the aspects of self-in-mind relate to the areas of knowledge and beliefs, involving the domains of content, pedagogy and professional participation. This is in line with the perspective on teachers' professionalism and teachers' professional development in terms of competencies referring to individuals' psychological realms. On the other hand, Bohl and van Zoest (2002) consider identity as the "self-in-community", referring to processes of participation and perception within communities of practice.

In this paper, we want to focus on the social perspective of this mediating model. Of course, identity can be seen at various positions within the continuum, depending on the researchers' own identities (Grootenboer, Lowrie, & Smith, 2006). However, Grootenboer and colleagues (2006), reasonably sympathize with the idea that "identity is always connected to activity or practice" (p. 614), and *therefore* a "useful construct for understanding the formation of mathematical teaching" (Grootenboer et al., 2006, p. 614). We want to follow this assumption when illustrating teachers' learning under the notion of identity development.

In the same respect, Skott, Moeskær Larsen, and Hellsten Østergaard (2011) argue in favor of shifting the research perspective on teachers' learning from the "underspecified" concept of beliefs (Skott, 2013, p. 548) to the patterns-of-participation framework. By doing so, it is possible to consider the relationships between teachers' identities and their participation in social practices (Skott, 2013, p. 511) which naturally comprise both, teaching in classrooms and teachers' learning in professional development courses.

Wenger's theory of Communities of Practice

In the theory of Communities of Practice (=CoP) (Wenger, 1998), identity development can be positioned at the very 'social end' of the above mentioned continuum. By doing so, Wenger describes learning from two points of view: The perspective of practice, in which learners are characterized as individuals taking part in socially-determined, community-based practices, and the perspective of identity, in which learners are considered as individuals, each being a member of different communities.

The crucial point of the CoP theory is a complex process called *Negotiation of Meaning* (=NoM), comprising the process of participation and the interconnected process of reification. It is a fundamental statement of the theory that NoM does not necessarily involve direct interaction with others but is a constant process in terms of experience in everyday life. Therefore, CoP theory can be applied to all mathematics teachers who are able to take part in a specific process of NoM, even though they are not able to interact directly because of geographical distance. Certainly, the theory can also be used naturally when referring to the learning of a group of mathematics teachers who attend a particular professional development course.

CoP-definition of identity: The assumption is that identity is the fully lived and negotiated *experience* of engagement in the practice of a community. In this sense, the definition of identity can be derived from the extent and quality of participated experiences and corresponding reifications through the process of NoM. Accordingly, identity exists as a constant work of negotiating and therefore, identity is not a static entity but a constant "becoming".

CoP-definition of identity-development: Because of the definition of identity alone, the historic-temporal dimension of a development process is already considered. Identity in the CoP theory is neither a core of personality that already exists at a particular beginning of a development nor a final state. Identity development occurs when so-called *trajectories* are formed due to the participation in communities of practice. These trajectories connect the past, the present and the future; however, they are not predefined paths but continuous motions occurring through the negotiated experiences which are made in the process of NoM.

CoP-definition of learning: In CoP theory, learning is characterized as "the engine" of practice and practice is described as "the history" of learning. This means that practice as an ongoing, social, and interactional process of NoM goes hand in hand with learning processes. As a consequence, educational processes based on actual participation in practice are effective in promoting learning since they are "epistemologically correct". As a further consequence, Wenger (1998) underlines that there was a "match between knowing and learning, between the nature of competence and the process by which it is acquired, shared, and extended" (pp. 101–102). This assumption requires a competence term that basically differs from the individual-psychological one: Competence means knowing how to engage in practice, understanding the enterprise of a community of practice, and being able to use the shared repertoire of resources that is available to a community for using it in practice. In this sense, learning is becoming a member of a community by being familiar with its practices. However, since being a member of a community and being engaged in its practices is tantamount to the work of identity formation, learning and identity development are two interconnected, inseparable processes in the CoP theory.

MAPPING THE THEORY TO MATHEMATICS TEACHERS' PROFESSIONAL DEVELOPMENT

The coherence of a community and translations from community membership to identity

According to the theory, the practice of a community is based on three dimensions: *Mutual Engagement*, a *Joint Enterprise* and a *Shared Repertoire.* As a community membership is defined by these dimensions, they are important when newcomers are supposed to become a new member of the community or peripheral members turn into core members. Applied to mathematics teachers' professional development, the extent of how these three dimensions are proportioned is an indicator of how likely the practice in a training course actually becomes a practice of teaching in a classroom – or in terms of identity – of how likely participating in a course transcribes identity as a form of competence into a teacher.

The mutuality of engagement in this manner is a crucial factor for teacher learning (Goos & Bennison, 2008). Are the teachers able to interact with each other and take part in the process of NoM? Is it possible that the teachers are actually in a position to be involved in the practices desired by the teacher educators? Or is the training course designed in a way that the teachers have no opportunities to engage at all? Research shows that participant-orientation is an important and effective element of teachers' professional development (Clarke, 1994).

In the CoP theory, a community additionally bases on a joint enterprise, i.e. the negotiated goals and the corresponding ways to achieve them. Here it is also a matter of how and how far the members of a community are actually accountable for the enterprise. According to the theory, teachers attending a professional development course will be more likely to develop their identities by gaining new perspectives on interpretations, choices and values if they are actually included in the process of negotiation. This issue is discussed in literature as the question of "ownership" of professional development (Zehetmeier & Krainer, 2011).

Becoming a member of a community in terms of the theory also means that newcomers have to learn how to use and interpret the repertoire of practice (styles, artefacts, actions, tools, concepts, discourses, stories, etc.). Therefore, effective professional development programs manage to translate the shared repertoire of the training course into a personal repertoire as a feature of a teachers' identity. Only by doing this, the teacher is able to apply the repertoire to new practices outside of or peripheral to the practices of the course. Hence, the question is if there should just be exposure to the repertoire and the related practices or if the teacher should actually participate in the practice using the repertoire. Effective professional development is characterized by opportunities to try out practices in the classroom and by referring to the practices or cases of the teachers' actual teaching (Lipowsky & Rzejak, 2012; Timperley, Wilson, Barrar, & Fung, 2007). Therefore, one can further conclude that teachers need sufficient time during the professional development program in order to make use of the new repertoire of the course (Penuel, Fishman, Yamaguchi, & Gallagher, 2007) even if it is negotiated and not only presented.

In terms of the theory, mutual engagement, a joint enterprise and a shared repertoire are conditions for a coherent and robust community. Such communities or networks contribute to a sustainable and effective teacher learning. (Cochran-Smith & Lytle, 1999; Lipowsky & Rzejak, 2012; Zehetmeier & Krainer, 2011). If facilitators of mathematics teachers' professional development intend fostering collaboration in this sense, they should reflect on whether the three dimensions have actually been considered and how they can be integrated into the program.

Boundaries and multi-membership

Boundaries between different communities are defined by practice, not by institutional or organizational structures. All participants of professional development courses for mathematics teachers are teaching mathematics in school; however, they each have each experienced different practices of mathematics teaching in their individual professional life. It is therefore the usual case that a training course for teachers is an encounter between different communities whose respective members form a new community via practices negotiated within the frame of the course.

As a consequence, a professional development course implicates several boundaries between the practices of the respective teachers and a further significant boundary between the teachers and the teacher educators. The aim of a successful course in terms of the CoP theory is to allow crossing the boundaries by allowing the teachers to engage in the practice of other communities and especially in the teacher educators' practice. In this way, teachers should be able to use practices of other communities for the NoM at their own schools (Lipowsky & Rzejak, 2012). In other words, boundary crossing means the construction of an identity that includes different forms of practice.

On the one hand, this "multi-membership" requires the work of reconciliation: Teachers attending professional development programs must often cope with conflicting forms of practice, because they are supposed to develop identities and gain competences defined by teacher educators or even by outsiders. On the other hand, various forms of practice can offer new learning trajectories for the teachers and therefore constitute a basis for identity development.

The CoP theory considers two mechanisms of boundary crossing. Firstly, so-called *brokers* are able to transfer elements of one practice into another. In our case, the teacher educators themselves are brokers as they are able to translate, coordinate and align between different perspectives. Furthermore, teacher educators are capable of opening new possibilities for the process of NoM. The question is: Who is actually an effective broker, being able to allow boundary crossing and to promote identity development? In our opinion and with respect to the theory, successful brokers are teacher educators and mentor teachers who have strong experience in multi-membership themselves. This means that they have made experiences in teaching the content of the course in school as well as in educating teachers in the topic. This also means that these educators have experienced the content in a perspective of practice as well as in a perspective of theory. In conclusion, when it is not possible to find one single teacher educator who has experienced that multi-membership, the tandem approach could be helpful for initiating boundary crossing (Rösken, 2011, p. 81).

The second mechanism for initiating boundary crossing is the use of boundary objects like artefacts, documents, terms, concepts, styles and so forth. An object can become a boundary object if it allows different interpretations, each interpretation being based on the perspective of the respective community of practice. Such objects are particularly suitable for discussions: In which ways can a mathematical concept like derivations be taught? What kinds of activities are possible in order to teach the aspect of covariation between two variables? In which manner can the graphing calculator be a reasonable tool for teaching stochastic? Each answer and each corresponding perspective represents a specific practice and therefore individual experiences and identities teachers bring with them into professional development courses. We also know from literature that discussions and collaborative reflection are effective elements of teachers' professional development leading to processes of change (Zehetmeier & Krainer, 2011). Furthermore, students' documents, actually used textbooks, and videotaped lessons are suitable for being used as boundary objects in training courses since they connect the practice in school with the practice in the professional development program.

Modes of Belonging

As a part of his conclusion, Wenger (1998) introduces the three *Modes of Belonging* to a community and therefore having access to its practices: *Engagement*, *Imagination* and *Alignment*. Since engagement as an "active involvement in mutual processes of negotiation of meaning" (Wenger, 1998, p. 173) has already been discussed, we want to draw attention to the remaining two.

Imagination: This mode refers to the process of extrapolating from one's own experiences to future images of the world, future practices and future identities. Since imagination in terms of the CoP theory is not exclusively considered as an individual process but also as an integral feature of the collective process of NoM, imagination can be used as a source of identity development in a professional development program. In order to initiate processes of imagination, teacher educators should enable discussions and activities of self-reflection. By doing so, new learning trajectories are generated: How do teaching practices that are different from the experienced ones improve students' learning? What is it like to adopt teaching practices that vary from one's own teaching style? Lipowsky, Rzejak, and Dorst (2011) suggest that showing teachers videos of teaching practices that lead to an improved students' learning generate such trajectories. Teachers having observed these scenarios rather change their practices (Lipowsky & Rzejak, 2012) as they are able to see their own identities in the light of a different practice by means of imagination.

Alignment: Professional development programs usually intend aligning teachers to intended curricular requirements. Alignment in terms of the CoP theory comprises activities which lead to the adjustment of practices to broader structures and enterprises. In this context, Wenger (1998) emphasizes that the "challenge [...] is to connect local efforts to broader styles and discourses" (p. 186). In other words: Curricular requirements are commonly political or administrational specifications which are not in line with the mathematics teachers' needs on a local level in the sense of a community of practice. Hence, the task for the facilitators of teachers' professional development is to negotiate the different perspectives by "convincing, inspiring and uniting" (Wenger, 1998, p. 186). A means for doing this might be coordinating boundary practices and reconciling diverging perspectives with the help of brokers and boundary objects.

CRITICAL REFLECTION AND CONCLUSIONS

With respect to educational designs, Wenger (1998) claims: "The primary focus must be on the negotiation of meaning rather than on the mechanics of information transmission and acquisition." (p. 265). This is in a particular way in line with the postulation of avoiding deficit-oriented approaches in teachers' professional development: Instead of analyzing deficits and filling the holes in teachers' professional competence profiles, philosophies of teachers' growth and empowerment are named (Rösken, 2011). We want to join the attitude of valuing the teachers' practice and the experiences they make in their classrooms every day. Therefore, we have the opinion that the CoP theory provides a framework of learning that respects the teachers' individual backgrounds they bring along into the professional development programs. In addition to that, we have shown that the shifts in perspective on teachers' learning are in line with the empirical findings concerning the effectiveness of professional development programs.

Nevertheless, we still have to think about how our considerations concerning teachers' learning in terms of identity development might be implemented in practice. A next step in this sense could be pondering appropriate teaching methods based on Wenger's ideas of learning and respecting the specific situation in mathematics teachers' training courses.

To be honest: Modeling professional development is a never completed, challenging task which involves many, partly cultural and administrative variables. We have learned that what is working in country x may be an unrealistic measure in country y. Last not least any theory has to handle these eventualities. It seems to us that Wenger's theory possesses this potential; however, this quality finally complicates its structure. To put it in another way: Wenger's contribution is not just a straight and lean theory.

Some characteristics of learning to notice students' mathematical understanding of the classification of quadrilaterals

Ceneida Fernández[1], Gloria Sánchez-Matamoros[2] and Salvador Llinares[1]

1 Universidad de Alicante, Alicante, Spain, ceneida.fernandez@ua.es, sllinares@ua.es

2 Universidad de Sevilla, Sevilla, Spain, gsanchezmatamoros@us.es

The goal of this study is to examine how prospective secondary school mathematics teachers learn to notice students' mathematical thinking about the process of classification of quadrilaterals. Findings point out that when prospective teachers identified the inclusive classification of quadrilaterals as a "key developmental understanding" (Simon, 2006), they modified what they considered evidence of secondary school students' understanding of quadrilaterals classification process.

Keywords: Noticing skill, classification of quadrilaterals, students' mathematical thinking, prospective teachers learning.

INTRODUCTION

Previous research focused on prospective teachers education has underlined the importance of learning to notice what it is happening in a classroom (an important teacher's skill) (Mason, 2002). Furthermore, research has shown that this skill could be developed in teacher education programs in some contexts designed ad hoc (Coles, 2002; Fernández, Llinares, & Valls, 2012; Sánchez-Matamoros, Fernández, & Llinares, 2014).

A particular focus of this skill is how prospective teachers notice students' mathematical thinking. Magiera, van den Kieboom and Moyer (2013) showed that prospective teachers demonstrated a limited ability to recognise and interpret the overall algebraic thinking exhibited by students in the context of one-to-one interviews. Furthermore, research has underlined the relationship between mathematical content knowledge (MKT, Ball, Thames, & Phelps, 2008) and the process of recognising evidence of students' understanding (Sztajn, Confrey, Wilson, & Edgington, 2012). For instance, Bartell, Webel, Bowen and Dyson (2013) examined the role mathematical content knowledge plays in prospective teachers' ability to recognise evidence of children's conceptual understanding. After an instructional intervention (based on lessons where prospective teachers had to examine many examples of students thinking), their ability to analyse children's responses improved. Fernández, Llinares and Valls (2012) indicated that discriminating between proportional and non-proportional situations was a key element in the development of prospective mathematics teachers' abilities to identify evidence of different levels of students' mathematical understanding in the domain of proportionality. Sánchez-Matamoros, Fernández and Llinares (2014) examined the development of prospective teachers noticing skill of students' mathematical understanding of the derivative concept. This study indicated that a key element in this development was prospective teachers' progressive understanding of the mathematical elements that students use to solve problems in the domain of the derivative. However, difficulties in developing the skill of noticing students' mathematical understanding make more research in this line necessary, and particularly, in the different mathematical domains. In this study, we are going to identify key elements in the development of this skill in the domain of the classification of quadrilaterals.

Learning how to classify quadrilaterals causes difficulties for secondary school students. These difficulties are related to the relationship between inclusive and exclusive classifications of quadrilaterals since students recognise the different quadrilaterals by means of prototype examples without considering the inclusion relations associated with the classification processes (De Villiers, 1994; Fujita, 2012). Inclusive classifications result when the application of a classifying criterion to a specific set creates subsets in which it is possible to establish an inclusion relation (hierarchical chain) among its elements. For example, in an inclusive classification of parallelograms, the square can be considered a special type of rhombus; while in an exclusive classification (partition) the square and the rhombus belong to separate groups. Understanding the role inclusive and exclusive classifications plays when classifying the quadrilaterals in order to define different types of quadrilateral (Usiskin & Griffin, 2008) is important in learning about students' mathematical understanding. In this context, understanding inclusive classifications and how they are related to the process of defining geometric figures can be considered as a *key developmental understanding* (KDU) (Simon, 2006) since the understanding of inclusive classifications implies a conceptual advance for students that enables them to understand inclusive definitions (for example, that a square is a special type of rhombus).

Taking these aspects into account, our research questions are: (1) how do prospective teachers use their knowledge of quadrilateral classification in order to identify evidence of students' understanding? (2) What teaching decisions do prospective teachers take in order to support the development of students' understanding?

METHOD

Participants and design principles

The participants of the study were six Spanish science graduates (mathematics and engineering) enrolled on an initial training programme that provided them the skills needed to teach mathematics in the secondary school (we will refer to the prospective teachers as PSTs). The programme included subjects such as school organisation, psychology of instruction, mathematics education and teaching practice in secondary schools. In the part corresponding to mathematics education, the prospective teachers were studying a subject aimed at learning the characteristics of secondary school students' mathematical understanding. This subject was taught for 4 hours a week, for 13 weeks, and focused particularly on students' understanding and how to select tasks that would promote a conceptual understanding. One of the topics was students' understanding of the classification of quadrilaterals.

The module focused on the classification of quadrilaterals consisted of 3 sessions of two hours, and the participation in a week-long online debate. The design of the module incorporated a socio-cultural perspective (the spiral of knowing, Wells, 2002) and considered four aspects: Experience, Information, Knowledge Building and Understanding. "Experience" is the prior knowledge that prospective teachers have constructed during their participation in learning and teaching situations. "Information" consists of our understanding (as a scientific community) of the quadrilateral classification processes (theoretical information) that we provided to prospective teachers. "Knowledge Building" is related to how prospective teachers engage in meaning-making with others in an attempt to extend and transform their understanding of a student's mathematical thinking and their own understanding of mathematics. Finally, "Understanding" constitutes the interpretative framework in terms of which prospective teachers make sense of new situations, that is, what they mobilise to identify students' mathematical thinking in order to anticipate and monitor student response, select and sequence tasks and make connections with students' responses.

In the module, firstly, PSTs had to answer a task where they had to anticipate, individually, the way in which students' answers to the classification problems reflected evidence of understanding and had to take decisions to promote students' understanding ("Experience"). Next, the teacher trainer presented information about the characteristics of the quadrilaterals classification process and about students' understanding of quadrilaterals classification (inclusive and exclusive classifications, De Villiers, 1994; Usiskin & Griffin, 2008), and discussed this with the

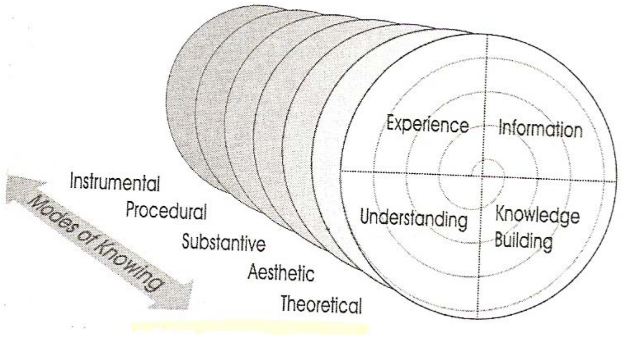

Figure 1: The spiral of knowing (Wells, 2002, p. 85)

PSTs ("Information" in the spiral of Wells). Finally, the PSTs compared their answers in pairs in order to explore differences and similarities in the way they recognised evidence of students' understanding of the classification process (Knowledge building) and take teaching decisions to promote students' understanding ("Understanding" in Wells' spiral of knowledge).

The task (instrument)

Prospective teachers had to answer a task consisted of two quadrilateral classification problems (ages 14–15) from secondary school textbooks (Figure 2), and six professional questions aimed at prompting prospective teachers to anticipate the response of students with different levels of conceptual understanding and propose tasks to improve their understanding:

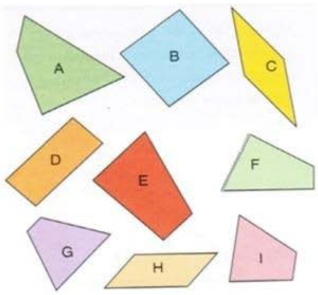
A1. Indicate exactly what Maria, a 3rd year secondary school student (aged 14–15), would have to do and say in each problem in order to demonstrate that she has achieved the learning objective assigned for the problem (Classify the quadrilaterals according to different criteria).

A2. Explain which aspects of Maria's answer to each problem make you think that she has understood the classification of quadrilaterals. Explain your answer.

B1. Indicate exactly what Pedro, another 3rd year secondary school student (aged 14–15), would have to do and say in each problem in order to demonstrate an understanding of certain elements of the classification of quadrilaterals while remaining unable to achieve the learning objective. Explain your answer.

Problem 1

Which of these quadrilaterals



have the properties described below:

a. Only have two parallel sides

b. Have two parallel sides and two right angles

c. Their sides are equal, but their angles are not

Problem 2

2.1 Look at the figures and complete the table below, putting YES or NO in the empty boxes:

	Square	Rectangle	Rhombus
The four sides are equal			
The four angles are equal			
The opposite sides are equal			
The diagonals are equal			
The diagonals intersect at the middle point			
The diagonals form right angles			

2.2. Indicate the similarities and differences of the diagonals when comparing:

a) rectangle and square

b) rhombus and rectangle

c) rhombus and square

2.3. How are the parallelograms classified when using the diagonals as criteria? Justify the answer.

Figure 2: The two quadrilateral classification problems of the task

> B2. Explain which aspects of Pedro's answer to each problem makes you think that he has not achieved the intended learning objective. Explain your answer.
>
> C. If you were the teacher of these students,
>
> How would you modify/extend the task in order to confirm that Maria has achieved the intended learning objective? Explain your answer.
>
> How would you modify/extend the task so that Pedro achieves the intended learning objective? Explain your answer.

The first four questions refer to the teacher's ability to anticipate possible answers to the problems that reflect different levels of secondary school students' understanding of the process of classifying quadrilaterals. The last two questions (section C) are related to the teaching decisions; the decisions that the teacher should take in order to promote student progress.

The aim of problem 1 is to classify a set of nine quadrilaterals using three different criteria. The different sections of the problem could be solved by identifying the figures that met the criterion and grouping them together. The problem 2 requires the use of some elements of the geometric figures (sides, angles and diagonals of the square) to classify the parallelograms on the basis of the diagonals.

Analysis

We analysed PSTs answers to the individual task (Experience) and the modifications introduced when solving the task in pairs (knowledge building) on the basis of the theoretical information related to students' understanding of the classification process (Information). Initially, we focused on how the PSTs considered that the hypothetical answers they gave individually to problems 1 and 2 indicated different levels of students' understanding of the classification process. We then identified the decisions they took to help students consolidate or improve their understanding. In the analysis of the task resolution carried out in pairs we tried to identify how the previously discussed theoretical information modified what the PSTs understood as evidence of secondary students' understanding of the classification process (taking into account how PSTs considered the understanding of inclusive and exclusive classification as a key development understanding). We also identified modifications in the decisions taken to help students to improve or consolidate their understanding.

The data was analysed by four researchers creating categories. The initial categories were redefined as new data was added. Points of agreement and disagreement were discussed, with the aim of reaching a consensus on the inferences from the data by means of a process that looked for evidence that did or did not confirm the characteristics initially produced.

RESULTS

The results section is organised in two parts. In the first part, we identify the changes in how the PSTs characterised students' understanding and, in the second part, the changes in how they decided to support students understanding.

Changes in how the PSTs characterised students' understanding

The 6 PSTs, initially, considered the use of just one criterion as evidence of the understanding of the classification process: the one that generated exclusive classifications. For example classifications in which a square is a parallelogram but is not a special type of rectangle or rhombus. One PST considered as criteria whether the diagonals were congruent and if they formed a right angle (item 2.3 of problem 2). From this perspective the parallelograms formed three groups: squares (parallelograms with congruent and perpendicular diagonals), rectangles (parallelograms with congruent diagonals that do not form a right angle), and rhombuses (parallelograms with non-congruent diagonals).

On the other hand, PSTs considered evidence of an incomplete understanding of the classification process of parallelograms when the secondary school student was not capable of generating exclusive classifications. Anna, one of the PST, justified this fact by stating that:

> (the student with an inadequate understanding of the classification process) does (would do) problem 1 correctly but not problem 2. The student's error comes (would come) from considering that the diagonals of the square do not intersect at right angles – perhaps because of a

printing error- (referring to Figure B in problem 1), which means that the classification of item 2.3 only creates two large groups: those that have equal diagonals (square and rectangles) and those that do not (rhombus).

After the discussion of the theoretical information ("Information" in the Wells' spiral of Knowing) focused on the relations between the inclusive and exclusive classifications and definitions, PSTs started to consider the inclusive relation as a key developmental understanding when they tried to identify evidence of students' understanding. Putting the relation between inclusive and exclusive classifications in the focus of their noticing allows them to accept that a square can be considered a special type of rhombus or rectangle and this understanding should be considered as an advance in the student understanding.

For example, a pair of PSTs anticipated using a criterion based on diagonals (item 2.3 in problem 2, Figure 1) and the possibility of generating an inclusive relation. They used the criterion "congruent diagonals", which leads to a classification in which the rectangles and squares are in the same set and the rhombuses and rhomboids in another. Then, in both sets they considered the criterion "the diagonals intersect at a right angle". From this way, they obtained an inclusive classification that allowed them to define, for example, that "*a square is a rectangle whose diagonals intersect at a right angle*". To demonstrate an inadequate understanding of the classification of parallelograms, they considered that the student was not capable of generating inclusive classifications that could allow him/her to get definitions where a square can be considered a rectangle. So, for example, they evidenced the difficulties involved in handling inclusive relations assuming that the student could define squares and rectangles with no relationship: a square is a parallelogram with equal diagonals that form a right angle; a rectangle is a parallelogram with equal diagonals that do not form a right angle.

Changes in the PSTs' teaching decisions to support students' understanding

The changes in teaching decisions were linked to how PSTs understood the inclusive classification as a key factor in the understanding of classification processes. Initially, when PSTs considered that the understanding of the classification process was linked with exclusive classifications, they supported their teaching decisions in helping students to identify and apply classification criteria that generate singleton subsets. For example, to consolidate students' learning of the classification process, Anna proposed the following problem:

a) In problem 1 find a square, a rectangle and a rhombus, and check the characteristics in the table (section 2.1. of problem 2).

b) Analyse the characteristics in the table for all the figures in problem 1. What do you observe?

c) Give definitions for the parallelograms

Furthermore, to help better understanding of the classification process, Anna tried that the student was capable of recognising a second criterion "diagonals intersect at right angle" that produce an exclusive classification with singleton subsets. Anna stated:

> First I would ask the student about the differences between the square and the rectangle in their classification (observing the answers given in activity 2.1); and then I would make the student draw different squares with their diagonals and measure the angles with a protractor.
>
> If it is possible, in a computer room, I would also make sure that the student correctly draws and measures the angles the diagonals form with enough squares so as to be sure that they fully understand that this characteristic is common in all squares.

After the discussion of the theoretical information ("Information" in the Wells' spiral of Knowing) the PSTs understood that inclusive classifications were a key factor in the understanding of classification processes and they took different teaching decisions. For example, to consolidate understanding of the classification process in students that accepted inclusive classifications, Anna and Robert proposed *extension* activities aimed at establishing the equivalence of different definitions.

a) Analyse the characteristics in Table 2.1. in the figures in problem 1.

b) Give two different definitions of parallelograms

With students that hypothetically only generated exclusive classifications, they recognised that inclusive classifications are a key factor in helping them to understanding the classification of quadrilaterals. To this end, they designed tasks that serve, through analysis and reflection, to underline the possibility of seeing a figure as a special case within a larger group. For example, Anna and Robert modified sections 2.1 and 2.2 in problem 2, incorporating the figure of a rhomboid and asking *Classify Figure H in Table 2.1. Is it a parallelogram?* and *Classify the parallelograms into only two groups. Can you do it in another way?* In this way, in their view, the new problem 2 forces the student to choose classification criteria for the parallelograms in two groups and thereby creates an opportunity to generate an inclusive classification.

These changes in the PSTs' teaching decisions can be linked to the knowledge building (an aspect from the Wells' spiral of knowing) in which the inclusive classification was considered as a key developmental understanding in the task of attempting to recognise evidence of students understanding of quadrilaterals classification.

DISCUSSION

This research aims to examine some characteristics of PSTs learning. Our focus is how the changes in the way that PSTs understand the classification process of quadrilaterals influence on what they consider evidence of students' understanding, and on how they decide to assist students in their development. Initially, the PSTs only considered exclusive classifications, which implied that the definition of the different parallelograms was a succession of properties without the establishment of relationships between them. This meant that the way in which they were able to help students was to propose tasks in order to identify the largest possible number of characteristics in the figures, but without establishing relationships between them. The recognition of inclusive classifications of quadrilaterals as a key mathematical factor for conceptual development enabled them to modify the way in which they characterised students' understanding. This led the PSTs to focus their attention on helping students to identify relationships between the characteristics of figures as a means to generate inclusive definitions. To some extent, the prospective teachers set the development of the understanding of inclusive classifications (a "key developmental understanding", Simon, 2006) as a learning objective. For example, to define a rhombus as a parallelogram with four congruent sides and the opposite angles congruent two by two, and to consequently be able to define a square as a rhombus with four congruent angles. This result is in line of previous studies which shown the importance of prospective teachers' mathematical knowledge when attempting to interpret students' understanding (Fernández et al., 2013; Magiera et al., 2013; Sánchez-Matamoros et al., 2014; Son, 2013). To summarise, participation in this module enabled prospective teachers to recognise the understanding of inclusive classification as a conceptual advance in the development of classification and definition of geometric figures. As a consequence, prospective teachers identified the understanding of inclusive classification as a learning objective, recognising it as a necessary qualitative transition in the ability of students to think about and perceive relationships between elements of geometric figures. This recognition was demonstrated in the way they posed new tasks to support the understanding of classifications and the process of defining geometric figures.

Although more research is still needed to help us to identify the factors that influence the development of prospective teachers' noticing of teaching and learning, our data provide characteristics of the learning of knowledge needed to teach and its use in noticing evidence of students' understanding. Although the intervention might be considered short in terms of time, these results provide ideas that can help in the design of sequences of learning activities for prospective teachers, aimed to make explicit what they considered "key knowledge" when notice students' understanding and make teaching decisions in order to support students in their learning.

Pre-service teachers' growth in analysing classroom videos

Marita Friesen, Anika Dreher and Sebastian Kuntze

Ludwigsburg University of Education, Ludwigsburg, Germany, friesen@ph-ludwigsburg.de, dreher@ph-ludwigsburg.de, kuntze@ph-ludwigsburg.de

Analysing classroom situations belongs to the everyday requirements of mathematics teachers. From the perspective of professional development, empirical evidence related to the growth of this aspect of teacher expertise however is still scarce. Consequently, this study focuses on developments in the way pre-service teachers analyse classroom situations. In a first approach, we concentrated on pre-service teachers' analysis of how representations are dealt with in the classroom, which is a key for fostering students' understanding. The study examined whether it is possible to develop the pre-service teachers' analysis through a specific university course. The results suggest that the quality of the participants' analyses increased significantly according to several relevant criteria.

Keywords: Teacher education, video analysis, noticing, representations.

INTRODUCTION

What expert teachers should "see" in classroom situations does not only consist of noticing in the sense of identifying and describing relevant events in classroom interaction, but it also encompasses linking their observations to criteria, giving arguments and discussing the interaction against this background. As several studies have shown, differences in noticing between samples of expert and novice teachers (van Es & Sherin, 2011), it is widely accepted in the scientific community that a development in this aspect of expertise takes place over a long-term process of professional development. However, the base of empirical evidence whether pre-service teachers' analysis can be developed, in the framework of a one-semester university course, still needs to be broadened.

This study aims to respond to this research need by focusing on pre-service teachers' analyses of how representations are dealt with by students and their teachers in classroom videos. What we understand by *growth in analysing* is the pre-service teachers' development in analysing the use of representations in classroom videos and their use of theory as fostered by a university course. We build on prior work related to research methods (e.g., Dreher & Kuntze, 2013) and examine whether it is possible to develop the pre-service teachers' analysis through a specific one-semester university course (Dreher & Kuntze, 2012). To our knowledge, this is the first study that combines quantitative and qualitative methods in order to describe pre-teachers' growth in this specific context.

We will, in the following, introduce the theoretical background of this study (1), derive the research interest of this study (2), inform about the sample and methods (3), present results (4) and discuss their implications for theoretical and practical contexts (5).

THEORETICAL BACKGROUND

There is a broad consensus that expert mathematics teachers should be able to foster learners by providing them with challenging learning opportunities and help according to their needs. Both of these requirements can be considered to be closely linked to activities of analysing – in this case analysing learning opportunities and analysing the learners' thinking or potential difficulties, for instance. Such analysis makes use of professional knowledge (e.g., Shulman, 1986; Ball, Thames, & Phelps, 2008; Kuntze, 2012), for example, when referring to criteria that are necessary for the analysis. For the case of analysing classroom situations, the concepts *teacher noticing* or *professional vision* (van Es & Sherin, 2008; Sherin, Jacobs, & Philipp, 2011) describe elements of teachers' analysis of such situational contexts in the classroom. These elements are identifying relevant events for learning mathematics, describing the events from a criteria-oriented perspective as well as reflecting about their role and about potential implications connected with the analysis of classroom situations. These aspects make it almost obvious that noticing should be considered as knowledge-based (van Es & Sherin, 2008).

In the following, we would like to give an example of such criterial knowledge – and how this knowledge may enable teachers to analyse classroom situations – namely professional knowledge related to dealing with representations of mathematical objects. Representations stand for mathematical objects (Goldin & Shteingold, 2001), and they are the only possibility to approach these abstract and 'invisible' mathematical objects (Duval, 2006). This highlights the importance of dealing with representations in the mathematics classroom. Connecting different representations in the learning process can enrich a learner's concept image (Ainsworth, 2006; Lesh, Post, & Behr, 1987), however, changing between representations is often very demanding for learners and can hence also be an obstacle for the learning process (e.g., Duval, 2006; Dreher & Kuntze, 2015).

Expert teachers (cf., e.g., Kunter et al., 2013, for the notion of 'expertise') are expected to be able to use such criterial knowledge when analysing relevant classroom situations regarding the use of representations. For instance, whether representations are carefully connected in the classroom by explicitly emphasising how properties of a mathematical object can be seen in different representations, whether the learners are encouraged to reflect on representations, on their use and on changes between representations, or whether a learner's difficulty is connected with the interpretation of a specific representation (Dreher & Kuntze, 2015).

This discussion is mainly in line with the teacher-noticing framework (e.g., van Es & Sherin, 2008). However, diverse conceptualisations of teacher noticing can be found in the literature (Sherin, Jacobs, & Philipp, 2011), so the full spectrum of criterion-based analysing is not always reflected in what is understood by "noticing". Given this situation, it may be useful to include the perspective of *systematic observation* (Schwindt, 2008), in which analysing videotaped classroom situations comprises of aspects such as *describing, explaining* and *evaluating situations*, *highlighting* (*making focused and structured comments*), as well as *articulating critical incidents*.

Bringing together these approaches under the focus of using representations in the mathematics classroom, we define "analysing" in this study to be an interaction of the following processes: 1) Identifying relevant situations concerning the use of representations, which marks the "starting point" of an analysis; 2) evaluating such situations in a critical way based on connecting relevant situations and arguments with corresponding elements of theory regarding the use of representations; and 3) presenting/articulating the results of the analysis. These processes should neither be considered to be ordered nor completely separable, as there may be jumps between processes or simultaneous and interacting processes.

In order to develop the process of analysing with the pre-service teachers as described above, we carried out a one-semester university course. The core of this course was the analysis of videotaped classroom situations and the analysis of tasks from textbooks, both focusing on the learning potential related to using multiple representations. At the beginning of the course, key elements of theory (e.g., Duval, 2006) were introduced and the pre-service teachers developed criteria based on literature about dealing with representations. Such criteria concerned, e.g., changes between different representations (treatments and conversions); possible obstacles to students' understanding connected to representations; or the teachers' support in using and reflecting on representations. The criteria were used in two ways. First, as a framework for analysing and evaluating videotaped classroom situations as well as textbook tasks and second as a basis to further develop the analysed material regarding the use of representations. In case of the textbook tasks, the pre-service teachers were encouraged to change and enrich the tasks concerning the use of representations. In the case of the videos they were asked to conceive improved classroom situations regarding the use of representations. The course sessions provided the opportunity to share and discuss the ideas and material that the pre-service teachers developed throughout the course.

RESEARCH QUESTIONS

For evaluating whether it is possible to develop the process of pre-service teachers' analysing, the study aims at answering the following research questions:

- How do pre-service teachers who participated in a specific university course analyse videotaped classroom situations before and after the course?
- Is there a growth in linking relevant situations with criteria related to the use of representations?
- To what extent do the pre-service teachers examine the observed classroom situations critically against the background of corresponding elements of theory before and after the course?

SAMPLE AND METHODS

In order to answer these research questions, a video-based test was developed which comprised of two videotaped classroom situations and a corresponding questionnaire with different questions (see Table 1). The test was completed by 18 pre-service teachers (14 of them female) in a pre-post test design at the beginning and the end of a four-month university course (one 90-minute-session per week). The participants were all advanced or last-year students at Ludwigsburg University of Education, preparing to teach mathematics at primary or secondary schools.

The first video clip lasted about six minutes and shows a classroom situation with individual work. A student working on a problem in her book has difficulties creating three-digit numbers where the sum of the digits would be nine. The teacher asks her to draw three columns in order to represent the hundreds, tens and units on a place-value board. He then gives her nine chips, asks her to arrange them in the three columns and to tell him the number she had arranged. As the girl appears to have problems in translating the chips into numbers, the teacher shows her how to write down the number of chips under each column. At the end of the video, the teacher leaves the student with the instruction to arrange and write down more numbers.

The second video clip lasted about seven minutes and shows a whole-class activity where a teacher works out the solution to an age word problem with her class. First she lets the students read the problem in their book and they explain in their own words the relation between the age of a father and his son. Then she draws a table on the board to set up the variables and asks the students to label them with their definitions. At the end of the clip, the teacher tells the students to use the information from the table to set up equations and reminds them of important solution steps.

Although the two classroom videos seem to be quite different, they share important aspects concerning the use of representations that appear suitable to evoke pre-service teachers' attention and elicit analysing in this context. In both videos, the teachers use different registers of representations in order to support their students' understanding. However, both teachers miss important opportunities to offer their students help in dealing with those representations, for example, in the sense of translating between them, connecting them or reflecting on their use.

Table 1 shows the open-ended questions of the questionnaire the pre-service teachers had to answer at the beginning and the end of the university course. Item 1 aims at eliciting pre-service teachers' analysis without specifically prompting them to look at representations. Items 2 and 3 prompt the pre-service teachers to look at representations and motivate evaluations of corresponding events.

The answers to the open-ended questions were coded by two researchers, according to a top-down coding manual. The inter-researcher agreement was found to be good (κ = .83). For item 1, it was coded whether representations were mentioned, whether critical

evaluations of the teachers' support were made, and whether there was a reference to elements of theory regarding the use of representations. Critical evaluations were defined as evaluations that also included negative judgements of the teachers' support as shown in the videos. Regarding elements of theory related to the use of representations, it was coded whether an answer was related to at least one of the following five aspects: support in using representations, translating/changing between representations, enhancing reflections on the use of representations, clarification why certain representations were used, and how learning was fostered by the way representations were dealt with.

Before answering items 2 and 3 in which the participants were prompted to look at representations (see Table 1), the pre-service teachers were given a definition of representations in the mathematical context in which examples of different registers of representations such as symbolic or iconic were mentioned. Accordingly, it was coded whether the answers contained both a reference to the corresponding elements of theory (teachers' support in using representations or translating between representations) and critical evaluations of the teachers' support.

RESULTS

We would like to start with two sample answers, which may also illustrate the coding process (see Figures 1 and 2).

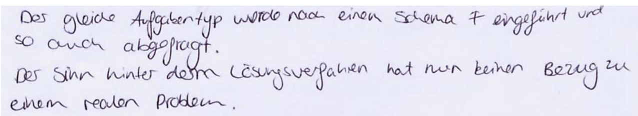
Already in the pre-test answer, the pre-service teacher in Figure 1 (see below) appeared to give critical evaluations, but these evaluations are not connected to representations and the way they are dealt with (e.g., "The way of problem solving has no relation to a real-world problem"). The criterion of using or dealing with representations is not referred to. However, in the post-test the pre-service teacher does not only attend to the representation registers from the video clip ("word problem", "table", "equation"), but also manages to analyse their use according to different elements of theory (e.g., "But what about the connections?"). Further, both positive and negative evaluations of corresponding events are given (e.g., "Chance unfortunately not optimally taken"), which was coded as critical evaluation.

Comparing the answers in pre-test and post-test, the analysis of this case suggests a progression in the quality of the analysis.

In the sample answer for item 2 (see Figure 2 below), the pre-service teacher's analysis of the video clip remains somewhat incomplete both in pre-test and post-test.

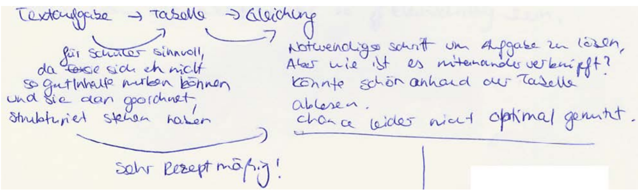
Although referring to the teachers' support in using representations in the pre-test as prompted by the question, there is no critical evaluation of this support. The pre-service teacher mainly sticks to mere descriptions of events (e.g., "student was asked to draw the place-value board herself; numbers were written directly under the board"). In the post-test, the pre-service teacher suggests alternatives for the teacher's action. The expressions used (e.g., "could have explained") suggest that the participant sees the video clip critically with respect to the suggest-

Pre-test



The same type of problem has been introduced before and is now recalled from the students in a very schematic way. The way of problem solving has no relation to a real-world problem.

Post-test



word problem → table → equation

useful for students as they often cannot keep all information in mind and so they get it sorted and structured	Necessary step to solve the problem. But what about the connections? Could be nicely done with the help of the table. Chance unfortunately not optimally taken.

Figure 1: Sample answer and translation for item 1, video 2, questionnaire #9

Pre-test	
• Schülerin sollte die Tafel selbst malen und Nägel hineinlegen • Zahlen wurden direkt darunter geschrieben um den Bezug zwischen Stellenwerttafel und Zahl zu zeigen • Anregungen durch Fragen: Sollen wir das mal machen?	— student was asked to draw the place-value board herself and to arrange the chips — numbers were written directly under the board to show the connections between the place value and the number — stimulating questions: Should we try to do this?
Post-test	
• L hat Material eingebracht • hat die Schülerin handeln lassen • hätte evtl. dieses Material ausführlicher behandeln & nutzen können	— he brought in material — [he] let the student take action herself — [he] could have explained and used the material — in more detail

Figure 2: Sample answer and translation for item 2, video 1, questionnaire #16

ed alternatives. However, the coding yielded no clear direct reference to the criterion of using representations beyond rather general remarks (e.g., "could have explained and used the material in more detail"). In the case of these answers, we could thus not detect a progression in the quality of analysis according to our coding categories.

On the basis of the coding of answers in the pre-test and post-test, we could count how often the corresponding codes were assigned to the pre-service teachers' answers. Table 2 shows the results of all 18 pre-service teachers for the first item by displaying the relative frequencies of the codes in per cent. The data mainly suggests an overall growth in analysing for this item. In the post-test, nearly all pre-service teachers mentioned representations when asked about the teachers' support of students' understanding in the video clips and there is also a growth in referring explicitly to the use of representations as analysis criterion.

Figure 3 shows the results for the code frequencies related to items 2 and 3. The data reveals a strong growth of the pre-service teachers' criterion-based analysing consisting both of the reference to the teachers' support in using representations or translating between them, and of the critical evaluation of corresponding

	video 1		video 2	
	pre	post	pre	post
mentioned representations	72%	94%	78%	100%
gave critical evaluations of the teachers' support	50%	67%	61%	39%
referred to the use of representations/elements of theory	50%	56%	50%	67%

Table 2: Code frequencies related to pre-service teachers' analysis in item 1

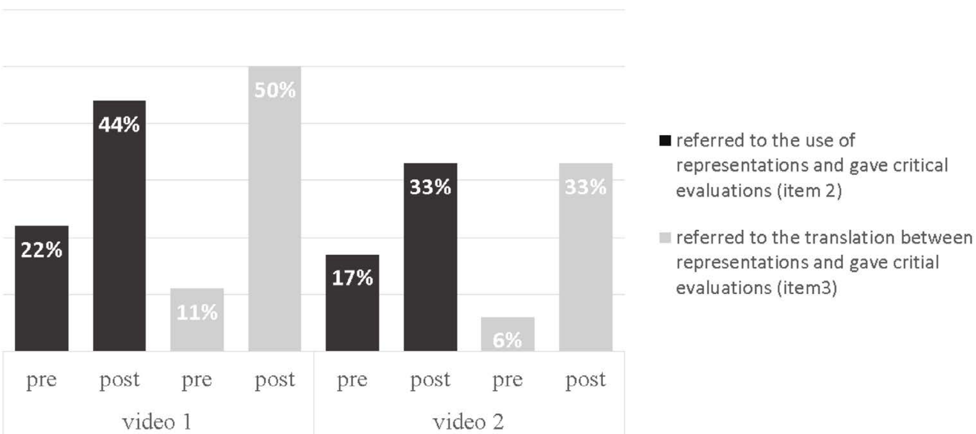


Figure 3: Code frequencies related to pre-service teachers' analysis in items 2 and 3

events in the video clips. However, even in the post-test, not more than half of the students carried out an analysis satisfying the code definition.

Concerning the pre-service teachers' connections to elements of theory, data analysis shows a growth in the number of references to *translations between representations* from pre-test to post-test (see Table 3). While the majority of the pre-service teachers mentioned only up to one translation in the pre-test, most answers contained two or even three connections to this element of theory in the post-test. Comparable to these findings, there was a growth in the number of references to additional elements of theory in the answers to items 2 and 3: nine pre-service teachers made additional connections to the elements of reflection or goal transparency in the pre-test, whereas 17 pre-service teachers additionally referred to elements such as reflection, goal transparency or the fostering of learning processes in the post-test.

In a further step in our data analysis, we made use of indicator scores, which can be seen as an exploratory first step towards quantitative forms of describing how criteria-based pre-service teachers analyse classroom situations. For this explorative quantification approach, code-based scores were created as follows.

In the case of the answers to item 1, one point was given if the answer mentioned representations. In this case, an additional point was obtained if not only the mere existence but also the *use* of representations was mentioned explicitly, and another point corresponded to the code of "critical evaluation given". Like this, the participants could reach a range from 0 up to 3 points for each video, resulting in a total score ranging from 0 up to 6 points. In the case for the answers to items 2 and 3, one point was given only if the answers contained both critical evaluations and relations to the teachers' support in using representations (item 2) or the teachers' support in translating between representations (item 3), resulting in a total score ranging from 0 up to 4 points.

Data analysis for the score based on item 1 showed that the pre-service teachers had on average higher scores in the post-test (M = 4.22, SE = 0.25) than in the pre-test (M = 3.33, SE = 0.38). This increase is significant and corresponds to a medium-sized effect (T = -3.06, df = 17, $p < .01$, $r = 0.60$, $d = 0.55$).

For items 2 and 3, the comparison between the scores yielded comparable results: the pre-service teachers reached on average higher scores in the post-test (M = 1.73, SE = 0.32) than in the pre-test (M = 0.53, SE = 0.19). This increase is also significant and corresponds to a strong effect (T = -3.52, df = 14, $p < .01$, $r = 0.69$, $d = 1.62$).

DISCUSSION AND CONCLUSIONS

Before discussing the results in detail, we would like to recall that the data has to be interpreted with care. We do not have data from a control group so far and the sample size restricts the possibility of making any broader generalisations from the results.

However, the research questions of the study could be answered and the findings show the pre-service teachers' development in analysing classroom videos throughout the university course. Even if not all pre-service teachers have reached the level of in-depth analysis with an extensive reference to aspects of relevant theory, the overall results suggest a deeper and more careful analysis of the videotaped classroom situations after the university course. On average, more pre-service teachers referred to representations in their analyses after the course, more critical evaluations of the teachers' support in the videos were given and the pre-service teachers made more connections between the classroom situations and criterial knowledge related to the use of representations. A particular growth could be detected in the pre-service teachers'

	video 1		video 2	
number of references to the translation between representations	pre	post	pre	post
0	67%	22%	28%	17%
1	28%	17%	50%	11%
2	6%	28%	17%	33%
3 or more references	0%	33%	6%	39%

Table 3: Pre-service teachers' connections to theory in items 2 and 3

analysis of relevant situations where the translation between different representations played an important role, which is a key to students' understanding.

At first sight, a possible explanation of the observed growth might be the pre-service teachers' increased awareness of representations and their use in the post-test. Taking a closer look, however, this interpretation of the findings appears too simplified. Already in the pre-test, the teachers were prompted to the criterion of dealing with representations in items 2 and 3, which was not reflected in their answers. Moreover, in the post-test, many pre-service teachers still were not able to analyse the classroom situations in depth as the corresponding coding only showed frequencies of up to 50% (Figure 3), indicating that the potentially higher awareness of dealing with representations was not sufficient for carrying out successful analysis. This underpins the significance of both components of the analysing process: the identification of relevant classroom situations as well as their critical and theory-based evaluation.

The quantitative results suggest that it is possible to describe the quality of teachers' analyses by quantitative measures and thus to tap into a key aspect of their expertise in follow-up research. Corresponding instruments are currently being developed.

For practice in teacher education, the findings clearly highlight needs of professional development. The analysis of classroom situations offers challenging learning opportunities for pre-service teachers and corresponding competencies should be fostered. This study can offer a first orientation to how criterion-based analysing of classroom situations could be the subject of a focused university course (cf., Dreher & Kuntze, 2012) in which pre-service teachers showed growth in this aspect of professional expertise.

We thus conclude, that pre-service teachers' growth in analysing classroom videos can be encouraged in the framework of a university course, but that this growth should be seen as one step in a longer chain of ongoing professional development.

Mathematical tasks for preservice primary teachers

Mercedes García, Victoria Sánchez and Rocío Toscano

University of Seville, Department of Didactics of Mathematics, Seville, Spain, rtoscano@us.es

This paper tries to delineate principles and frameworks for task design in primary mathematics teacher education. The reflection process developed both for mathematics teacher educators and members of a community of inquiry led us to identify a four-step dynamic model relating theory and practice, which is used here in a specific part of mathematics teacher educators' practice: the design of tasks. The identification and characterization of two dimensions, related to what to teach during a course in mathematics for preservice primary teachers, allowed us to design tasks that seek to consider specific features of each one. For us, task design is a process in which mathematics teacher educators are involved through the development of their professional activity.

Keywords: Task design, four-step dynamic model, task design as a process.

INTRODUCTION

Some years ago, with the aim of discussing our ideas within our community of practice, we presented in CERME3 an ongoing research related to the knowledge and the learning process of preservice elementary school teachers. The objective of the research was to determine how student teachers used conceptual tools provided in mathematics methods courses (García, Sánchez, Escudero, & Llinares, 2003). The results were later published (2006) and provided us with a theoretical framework leading with the relationship between theory and practice (García, Sánchez, & Escudero, 2007). The study of learning processes led us to focus on the specific mathematical background that these teachers could need, leading us to focus on the key aspects of the mathematical activity. Six years later, in CERME6, we focused on the characterization of secondary students' justifications and their persistence (or not) when making decisions related to tasks that involve defining, proving and modelling, considered as metaconcepts that constitute a background to advanced mathematical thinking (García, Sánchez, & Escudero, 2009). Now, we focus on the design of tasks that can incorporate theory in practice and develop a specific teachers' mathematical knowledge.

THEORETICAL FRAMEWORK

The reflection process developed both for mathematics teacher educators and members of a community of inquiry led us to identify (in previous research) the 'skeleton' of a process of relationship between theory and practice (García, Sánchez, & Escudero, 2007). From there, we have been able to build the model schematised in the Figure 1.

In the figure, the model starts from the practice (P). As a first step (Step 1), we seek the theoretical aspects more closely related to the practical problem under consideration (TE) in the general theory (T). In a second step, we are aware of some implications of adopting the theoretical framework provided by TE in our practice. The analysis of this new way of considering practice led us to a third step in which, from the identification of practical problems, some research questions are formulated. In the final step (Step 4) there is a return to the theory, which is now enlarged.

This four-step dynamic model relating theory and practice is used here in a specific part of teachers' practice: the design of tasks. Design of tasks has been considered by several authors with very different aims. Special issues of journals (e.g., *Journal of Mathematics Teacher Education*, 10(4–6), December 2007); books (e.g., the edited collection by Clarke, Grevholm and Millman, 2009), or specific research projects (e.g., the QUASAR project see (Silver & Stein, 1996; Stein, Smith, Henningsen, & Silver, 2000)) have

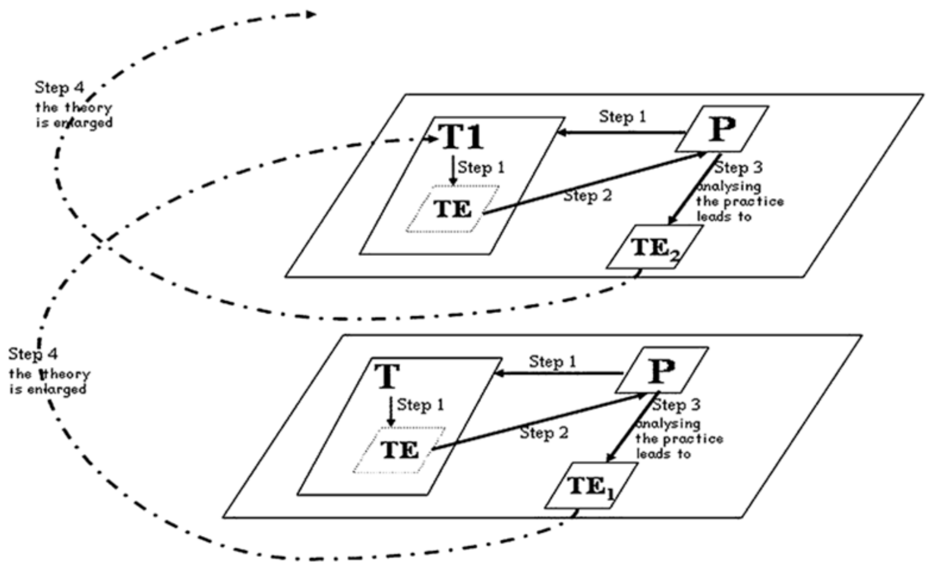

Figure 1: A four-step dynamic model relating theory and practice (García, Sánchez, & Escudero, 2007, p. 15)

emphasised the importance of the design of tasks in mathematics education.

Here we consider the design of tasks as a part of mathematics teacher educators' practice, focusing on the connection between theory and practice in this particular context.

SPECIFYING THE FOUR-STEP MODEL IN THE DESIGN OF PRESERVICE MATHEMATICS TEACHER TASKS

Starting from the practice (P)

Some years ago when we planned the organisation of our courses in our Primary Teacher Education program, we started to take into account the fact that, in the future, Primary Teachers will have to use mathematical ideas in the classroom from the perspective of mathematics and from consideration of them as teaching/learning objects. As mathematics teacher educators, we looked for key ideas that were the background to our decisions. We were aware of the need for theoretical perspectives that could be the base for our decisions. Thus, we looked to theory.

A look to theory (T)

At that time, researchers such as Brown, Collins, and Duguid (1989), Cobb (1994), and Lave and Wenger (1991) had started to develop theoretical ideas that have been summarized by different authors (García, 2003, 2005; Putnan & Borko, 1997). These ideas enabled us to understand the characteristics of cognition in an educational context. Our approach was rooted in some of them, in particular, the situative perspective (Brown et al., 1989), which allows us to characterize the activity of teaching mathematics, the specific knowledge and skills that are needed for this activity, and the learning processes that allow student teachers to develop this knowledge. At that point, we asked ourselves the following question: What should a primary teacher know about mathematics?

From general theory to specific aspects to be used (TE)

At that moment, we particularised the general theory (T).

We started by considering that primary teachers' mathematics knowledge should be related to contexts and situations where that knowledge was used, i.e., with activities, educational goals and contexts of teaching of mathematics. In addition, the identification of authors such as Shulman (1986), Llinares (1991), and Bromme (1994) of different mathematics teachers' domains of knowledge, allowed us to infer components of content of the curriculum of primary teacher education related to mathematics (García & Sánchez, 2002). In particular, we started to consider that a component of such a curriculum should be knowledge "of" and "about" mathematics (Ball, 1990). Thus, we went back to practice (P).

Going back to practice: designing tasks (P)

The identification and characterization of the two aspects in the component mentioned above allowed us recognition of specific features, such as problem solving and its consideration as a deductive science with empirical tools, and to incorporate processes, concept and procedures in its conceptualization. At that moment, we tried to design tasks that sought to consider these new aspects (García, Sánchez, 2002).

At that point, we asked ourselves the following question: Are these tasks appropriate to generate specific mathematical knowledge in primary teachers? That is to say, is the activity generated by the task valid for this purpose? We turned to theory (TE1), in search of some theoretical elements that allowed us to answer those questions. At that time, we reinitiated the process, moving on to a new plane and reformulating the practice question into a research question: What specific mathematics does a primary teacher have to know? What are the characteristics of that knowledge?

Starting another time

Assuming that, even with different characteristics and characterizations, and regardless of the theory that is taken into account, a knowledge of mathematics exists among the different domains of knowledge that are part of the knowledge base of mathematics teachers, from our point of view, this knowledge of mathematics has two subdomains, which are complementary as well as autonomous and necessary. On the one hand, there is a subdomain related to the particularities of mathematical content when it becomes a mathematical content to teach at the considered level. We consider this knowledge analogous to Ball's (2008) *specialized content knowledge*. On the other hand, we identify a knowledge related to the particular characteristics of the subject matter itself, which is essential to ensure the teacher can generate mathematical knowledge in his/her future students. We have called this knowledge *intrinsic mathematical knowledge*. To consider the features that *intrinsic mathematical knowledge* entails, we have taken into account the works of some authors that enable the identification of aspects that are indispensable in mathematical knowledge (Anderson, 1976; Hiebert & Lefevre, 1986; Lesh & Landau, 1983; Skemp, 1976; Thompson, 1985).

From general theory to other specific aspects to be used (TE1)

We focused on the characterization of mathematical intrinsic knowledge, considering it as a knowledge that considers mathematical elements from a dual point of view, integrating "operational"/"structural" aspects (Sfard, 1991), and also the mathematical competence of analysing said elements, allowing "packing and unpacking" of the mathematical elements. Other people who understand and use mathematics in other contexts and situations do not necessarily have to share a particular teacher's competence. Specificity adds to their knowledge and expands the common content knowledge in Ball's sense (2008).

For instance, when, from a mathematical point of view, we talk about operations, we may know, for instance, their meaning, use, properties, and algorithms related to them. A teacher also needs to identify the mathematical elements involved in these operations, as well as the role these elements have in the different ways of establishing relationships between, for example, different properties and different algorithms.

In some cases, intrinsic mathematical knowledge can be confused with the mathematical knowledge coming from other levels or contexts. The lack of recognition of the existence of that specific knowledge has led, on many occasions, to a repetition of topics corresponding to previous levels, or has contributed to generating a certain inaccuracy between what future teachers need to know and what their students have to know.

As researchers, this led us to look for the dimensions that must become operative in practice (Sánchez & García, 2008, 2009). These dimensions were:

- On the one hand, we consider activities of mathematical practice such as defining, justifying and modelling, among others (Rasmussen, Zandieh, King, & Teppo, 2005). These activities underlie any mathematical content and are part of what we consider to be "doing mathematics" (García, Sánchez, & Escudero, 2009).

- On the other hand, we consider mathematical content to be organized into areas, taking into account those that have traditionally been considered part of mathematics. These areas include, among others, analysis, geometry, algebra, statistics, and probability. The manner in which the content of these areas is considered will depend on the specialization of the teachers (primary or secondary school teachers).

In the Figure 2 we show the dimensions and the spaces generated by them.

Mathematical practices' activity / Mathematical content areas	Defining	Justifying	Modelling	....
Analysis				
Geometry				
Algebra				
Statistic/Probability				

Figure 2: Dimensions related to what to teach in a course of mathematics for primary teachers. (Sánchez & García, 2008, p. 286)

Designing new tasks (P)

As teacher educators, we will start again to put the theoretical ideas into practice, looking for new tasks that incorporate the above mentioned dimensions. In Figure 3, we include a task that we use as a starting point (basic task). This task corresponds to justifying in Algebra and is based on the Remainder Theorem (extracted from García & Sánchez, 2012).

We think that in these tasks preservice teachers could:

— analyse the different elements of a theorem carefully and in detail,

— think about the algebraic elements that intervene,

— identify axioms, definitions and theorems, and distinguish between them,

— notice that justifying is a characteristic of theorems, and not a characteristic of axioms or definitions.

In the process of solving the task, preservice teachers could:

— verbalize their ideas, recognize explicitly what they "see" and give reasons to support their comments;

— "unpack" characteristics and particularities that give form to a specific theorem and

— "pack" them only in a property that has been justified.

TASK

a) Give the axiom, theorem, or definition justifying each step in the following proof, indicating the mathematical elements that intervened.

Proof	What you say
a) $p(x) = g(x)q(x) + r(x)$	
b) the degree of $r(x)$ is less than that of $g(x)$	
c) if $g(x) = (x-a)$ as the divisor	
d) degree of $r(x)$ as 0	
e) $r(x) = r$	
f) $p(x) = (x-a)q(x) + r$	
g) setting $x=a$ in the above equation	
h) $p(a) = (a-a)q(a) + r$	
i) $p(a) = r$	

b) Identify premise/statement/proposition, and the different roles they play; state the property that is proven with that proof.

Figure 3: Task corresponding to justifying in Algebra (García & Sánchez, 2012, p. 25)

This process of unpacking and packing favours the characterization of the different parts of theorems and the role of premises, statements, and propositions.

From our point of view, this type of task can contribute to the generation of specific mathematical knowledge that allows preservice teachers to construct and deconstruct mathematical elements.

If we consider the task (Figure 3) as a 'basic task', its characterization as a task for concept development could be associated with the incorporation of the following questions: Can you give an example of any concept/idea in which they are part? Can you characterize any other concept/idea/mathematical property in which some of the identified elements take part? If our aim is a generalizing task, we can ask for the way in which the identified process can be generalized.

CONCLUSIONS

On the basis of the selection from the many different proposals related to tasks for mathematics teacher education that were sent to the above mentioned special issue of JMTE, Zaslavsky (2007) pointed out that "they provide insight into different theoretical foundations and discourses which are used to inform and justify choices in task structure, task presentation, and exploitation of learner experience arising from the consequent activity" (p. 433). She schematised the information obtained in a diagram, showing the dynamical nature of task design for teacher education that emerged from the analysis.

In this work, we have enlarged this information, considering in addition the design of tasks as a mean of connecting theory and practice in mathematics teacher educators' professional activity.

For us, task design is a process, not a product. It is a process in which a teacher is involved through the development of his/her professional activity, in which he/she is going to incorporate aspects originating from several sources: for example, his/her practice, interaction with colleagues, textbooks, and information from specialized journals. Nevertheless, unlike what happens in other scientific fields (for example, scientific research in the field of medicine), where results (once validated) are quickly incorporated into professional activity, the results of mathematical education research are not incorporated so readily into task design activities. Fostering their incorporation is our task.

A prospective secondary mathematics teacher's process of developing a progressive incorporation perspective

Gulseren Karagoz Akar[1], Ali Delice[2] and Emin Aydın[2]

1 Boğaziçi University, İstanbul, Turkey, gulserenkaragoz@yahoo.com

2 Marmara University, İstanbul, Turkey

In this study, during a secondary mathematics methods and practice-teaching course, we investigated one prospective secondary mathematics teacher's, Denise's, development of a progressive incorporation perspective from a traditional perspective on mathematics, mathematics learning and mathematics teaching. We analyzed data from Denise together with data from classroom discussions with 28 prospective secondary mathematics teachers. Results showed that the awareness of the quantitative and numerical operations, tasks focusing on logico-mathematical and empirical learning processes, conceptual analysis, and clinical interviewing afforded Denise's shift towards a progressive incorporation perspective by the end of the study.

Keywords: Teacher preparation, prospective mathematics teachers.

INTRODUCTION

Preparing teachers to teach mathematics effectively is an ongoing concern for teacher educators. There has been research on mathematics teachers' knowledge (e.g., Ball, Thames, & Phelps, 2008) and beliefs (Ernest, 1989); the relation of teacher's beliefs to their practice (Beswick, 2005) and the role of methods and/or practice teaching courses on prospective teachers' knowledge and/or beliefs (e.g., Ebby, 2000). However, compelling evidence suggests that rather than focusing on prospective teachers' knowledge and beliefs separately, research needs to address the consistencies between knowledge and beliefs prospective teachers hold and practices they engage in so that they can '... learn to use their knowledge base to provide the grounds for choices and actions' (Shulman, 1987, p. 13) during methods and practice teaching courses (Ebby, 2000).

In this respect, some researchers have made important contributions regarding teachers' perspectives (e.g., Heinz, Kinzel, Simon, & Tzur, 2000; Simon, Tzur, Heinz, & Kinzel, 2000). These researchers postulated perception-based (PBP) and conception-based (CBP) perspectives on mathematics, mathematics learning, and mathematics teaching, and contrasted these with the traditional approach (see Table 1). Extending the results of these studies, Jin and Tzur (2011) also proposed a progressive incorporation perspective (PIP). These researchers argued for the need to investigate the promotion of teacher development from a traditional perspective towards a PIP. PIP is a conglomerate of thinking about mathematical construction both dialectically independent and dependent of the knower. The dependency relates to mathematics learning occurring through active mental participation of the knower and the dialectic independence relates to mathematical concepts having commonalities/differences amongst each other. In this respect, PIP regards mathematics teaching involving prospective teachers' frequent questioning (ibid) to take their students' attention to the commonalities/differences among mathematical concepts.

Informed by the aforementioned studies, done mostly with in-service teachers, and coordinating these with quantitative and numerical operations (Thompson, 1994), logico-mathematical and empirical learning processes (Simon, 2003), conceptual analysis (Thompson, 2008) and clinical interviewing (Hunting, 1997), the work reported in this paper is an attempt to go beyond understanding particular knowledge and beliefs in the context of the *practices of prospective secondary mathematics teachers (PSMTs)*. We investigated the following research questions:

How does a prospective secondary mathematics teacher develop a progressive incorporation perspective on mathematics, mathematics learning and mathematics teaching?

What practices in a secondary school methods and practice teaching course are likely to afford changes towards a progressive incorporation perspective on the prospective teachers' part?

CONCEPTUAL FRAMEWORK

Simon and his colleagues (2000) postulated a CBP on mathematics, mathematics learning and mathematics teaching and stated that it dwells on the basic principles of radical and social-constructivism. Therefore, *mathematics* knowledge, compatible with the Problem Solving view, is considered to be "a dynamic, continually expanding field of human creation and invention, a cultural product" (Ernest, 1989, p. 250). By the same token, *mathematical learning* occurs through one's transformation (accommodation) of existing ideas (assimilatory schemes) through their own logico-mathematical mind activities rather than empirical learning processes (Simon, 2003). So, *mathematics teaching* requires that; first, the teacher is aware of her/his current mathematical understandings being qualitatively different from her/his students' understandings (Jin & Tzur, 2011); second, a teacher focuses on what students currently *do* know rather than what they *do not* know (Heinz et al., 2000). Jin and Tzur (2011) stated that developing a CBP on teachers' part is a hard endeavour.

On the other hand, one important difference between a CBP and a PIP is that, in the latter, mathematics is also dialectically independent. This means that mathematics concepts have commonality in themself and it is the teachers' responsibility to bring such commonality to students' attention through focused and frequent questioning. In this regard, a teacher with a PIP might focus on both what the students *do* know and *do not* know. Though similar to a CBP, in this perspective, *mathematics learning* is an active mental process, and, therefore mathematics is also dependent on the knower. That is, although teachers engage in frequent questioning to point to commonalities among mathematical concepts, students are thought to have such ability to re-construct the mathematical knowledge on their own. Jin and Tzur (2011) stated '...a PIP-rooted teacher' practice can endenger students' learning processes envisoned by CBP without requiring the teacher's explicit awareness of such view...' (p. 20). It is in this respect that we think that *effective mathematics teaching* (Hiebert, Morris, & Glad, 2003) corresponds with a PIP and a CBP.

The difference of a PIP and a CBP from a PBP is that, in the latter similar to a traditional perspective, mathematics is an ontological reality independent of the knower, compatible with the Platonist view of knowledge (Ernest, 1989). Thus, *mathematics learning* means, coming to see a *first-hand* experience of mathematical reality shared by all through *discovery*. That is, mathematics is obvious to everyone in engagement in materials interconnecting it on her/his own. That is why teachers with PBP *do not* realize that their mathematics is different from their students mathematics. Also, they focus *only* on what students *do not* know. It is in this respect that researchers postulated a PIP to be more powerful than a PBP. They further stated '... Whereas, fostering teachers' progress toward a CBP was found rather challenging, it seems much more reasonable to expect teachers to adopt teaching stra-

	View of knowing	View of learning	View of teaching
Traditional perspective (TP)	Independent of the knower, out there	Learning is passive reception	Transmission; lecturing; instructor
Perception-based perspective (PBP)	Independent of the knower, out there	Learning is discovery via active perception	Teacher as explainer ('points out')
Progressive Incorporation Perspective (PIP)	Dialectically independent and dependent on the knower	Learning is active (mentally); focus on the known required as start; new is incorporated into known	Teacher as guide and engineer of learning-conducive conditions
Conception-based perspective (CBP)	Dynamic; depends on the knower's assimilatory schemes	Active construction of the new as transformation in the known (via reflection)	Engaging students in problem solving; Orienting reflection; Facilitator

Table 1: Placing PIP within Ernest's (1989) and Simon and colleagues' (2000) frameworks

tegies ...' (p. 20) corresponding with a PIP (Jin & Tzur, 2011). Jin and Tzur (2011) proposed the following table to refer to the differences among these perspectives

METHOD

Participants

This study was done in a teacher education program at a university in Turkey for which the language of instruction is English. Twenty-nine PSMTs (including Denise) participated in the study. They were in their fifth year of undergraduate studies. Denise had a GPA of 3.53, being at the first rank among her classmates, whose GPAs ranged between 2.35 and 3.53. Denise was eager to become a mathematics teacher. She was one of the prospective teachers who have attended classes regularly doing all the tasks. We used data from Denise because it was representative among data coming from the rest of the participants in the study and allowed for a full account on the development of a PIP perspective.

Data collection

Data were collected for a total of eleven weeks during the methods course and the practice teaching course taught by the first author. We used classroom teaching experiment methodology while collecting the data (Cobb, 2000). The first author planned the teaching sessions in advance. However, for each teaching session in the methods and practice teaching courses, the (sub)learning goals depending on the hypotheses about what PSMTs knew were revised. Each of the teaching sessions was videotaped and transcribed. PSMTs also kept weekly journals concerning in-class and out-of-class discussions, due online before midnight of the same day of class. Also, a pre-assessment and two post-assessments, which collected their thoughts on learning and teaching mathematics and assessed their understanding of multiplication of fractions (the topic in the case study), were given at the end of the methods and the practice-teaching courses. Finally, PSMTs' practice teachings and an interview with Denise afterwards were videotaped and transcribed.

In the classroom teaching experiment methodology, prior to the enactment of the study, the teaching sessions are planned in advance. For instance we conjectured that once the PSMTs knew the nature of mathematics, this could help establish the nature of mathematics learning (with understanding) towards a PIP: we used Thompson's (1994) theoretical framework on quantitative and numerical operations, aligned with a CBP and Problem-Solving view of mathematics (Ernest, 1989). For that, prospective teachers read the understanding of improper fractions provided and pointed to the quantitative operations. For the out-of-class activity, they considered the understanding of exponential numbers in three ways.

Similarly, to assist prospective teachers to develop the view of mathematics learning occuring through the abstraction of the regularities in their own logico-mathematical activities, such as subdividing, matching, etc., we brought Simon's (2003) logico-mathematical and empirical learning processes to their attention. Additionally, we included the conceptual analysis framework Thompson (2008) proposed for teachers to provide lenses through which they could analyse a case study (Stein et al., 2000) because it created an opportunity to reflect on both the teachers' and students' focus of attention (Karagöz Akar, 2010). Also, researchers argued for the addition of clinical aspects of teaching (such as interviewing) to (prospective) teachers' knowledge repertoire. Thus, we brought clinical interviewing (Hunting, 1997) to the PSMTs' attention. Finally, prospective teachers did peer-teachings and practice-teachings and reflected on them (Hiebert et al., 2003).

Data analysis

We read each of the data sources line-by-line looking for Denise's explanations for the questions in the within and outside classroom activities regarding her perspectives on mathematics, mathematics learning and mathematics teaching. Using the characteristics of teachers' perspectives given in Table 1, we looked for both Denise's existing and developing meanings on them. For instance, after working on Thompson's (1994) framework, Denise provided the articulation of the exponential numbers. This made us realize that she was able to think through students' mind activities. Similarly, once we had spotted the changes in her meanings in any of the data sources, we also checked other data sources that chronologically provided us further evidence on such change. Then, we went back to the whole data set to challenge our conjectures and check the chronologies. When our conjectures were challenged we modified them to cohere with the whole data. This way we were able to write the narrative on data from Denise.

FINDINGS

We show data in five sections regarding Denise's views on the nature of mathematics, mathematics learning and mathematics teaching.

Section 1 – The beginning: Prior to any instruction, Denise answered the written pre-assessment questions. Data showed that she had a traditional perspective with similarities to a PBP. One prompt was: 'Please draw a model of what effective mathematics teaching means and explain the components'. Denise drew the following:

The first picture represents a teacher. Text beneath: "guides, helps, encourages to ask questions." The second picture represents a student. Text beneath: "research, ask questions, is curious." The third column reads: "Mathematics learning: The ability to analyze and synthesize. The ability to problem solve. Internalizes the mathematical concepts."

Denise's explanation for the components of effective mathematics teaching involves teachers' and students' roles, such as questioning and guiding. These practices Denise mentions seem to fit with a PBP.

To examine how Denise and her classmates think about how connections occur in conceptual understanding, during the first teaching session after the discussion on Van de Walle (2007, pp. 21–25), the first author asked them to think about it again. This generated the following discussion:

R: Okay guys. How do connections occur in conceptual understanding?

A: Could it occur when you remember something? When you see something you remember another thing and then you make a connection.

B: It happens when you observe something. Then you observe something else and then you connect them, relate them.

Denise: I think making connections is not only limited to making observations. If the student is making connections between what she knew before this is important too, the connections might be logical or not logical but what she knew before has an important place. It is like, there is a diagram on page 23 (referring to Van de Walle, 2007, p. 23). It is like showing earlier knowledge and the new knowledge and how we see them related in our minds. It is like making new chains into the already existing ones.

F: What if we learn something totally new? What will happen then?

Denise: Then, we put it somewhere else. For example, its place is somewhere totally different than others.

C: She puts it and then she makes the connection later on.

Denise: Yes, but when she cannot make a relationship this happens, when she makes the relationship then they are connected.

Denise's uttering "then we put it somewhere else" is important because when a "totally new" topic is learned, it might not be related to the students' current knowledge. This suggests that, for Denise and her classmates, some mathematics topics are connected, but others are compartmentalized. This indicates that Denise's perspective on mathematics deviated from a PBP, in which mathematics is viewed as interconnected. In addition, Denise agrees with her classmates that connections in learning occur through remembering and observing. Viewing *learning* this way also leads away from a PBP and towards a traditional one. To ex-

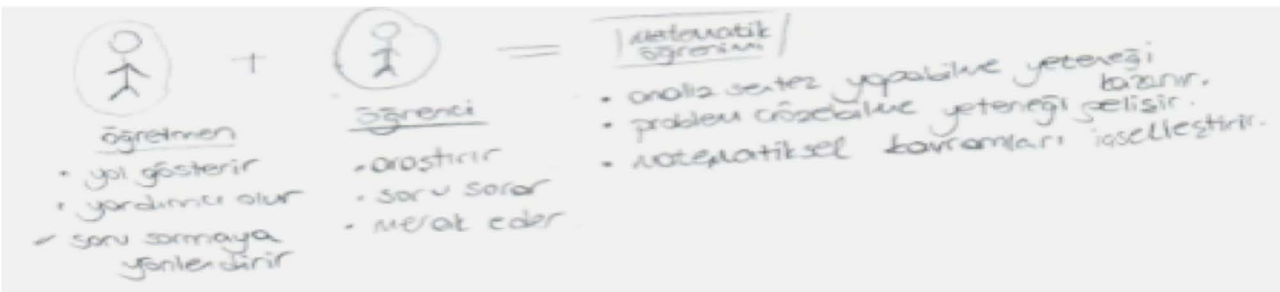

Figure 1: Denise's model for effective mathematics teaching

amine Denise's thinking further, we read her journal after this class. She wrote:

> A mathematical idea is to go one step further in the mathematical knowledge by making some logical inferences from the prior mathematical knowledge. ... Let us think about an example we discussed in class. Assume that a teacher wants to teach proper fractions. He/she gave the definition of the proper fractions and showed some examples about the proper fractions and their representations with shapes. Then a student realized that the shape of ¾ and 12/16 are the same. Then the student thought these two fractions are equivalent.

Denise's statement about a mathematical idea suggests that she views *mathematics* as interconnected. For Denise, *mathematics learning* proceeds with a) teacher giving a definition, (b) students recognizing from the example an equivalence (teacher showing with representations) and (c) students arriving at the conclusion that both fractions are equivalent. That is, for Denise, students *learn mathematics* through observation: a second-hand experience. These data also indicate that Denise thinks of *mathematics teaching* from a traditional approach, although she thinks of using representations.

Section 2 – Quantitative versus numerical operations: Data from this section showed that, after engaging in the activities regarding quantitative and numerical operations, there was a shift in Denise's reasoning on *the nature of mathematics and mathematics learning, the relationship between the tasks, and teachers' learning goals for their students*. Also, she was able to articulate a mathematical idea from a student's perspective. After working on a task during the class on the understanding of exponential numbers, Denise wrote: Figure 2.

Data show that Denise splits the quantity into identical copies, repeating the same process for the newly found whole until she reached the desired power. Also she finds the number of groups using the base as a measuring unit, showing that for her *mathematical understanding* is the result of one's mind activities, splitting and measuring. So, mathematical learning (with understanding) is dependent on the knower, suggesting a shift on her part towards a PIP. Denise also wrote the following.

Here, Denise has constructed a relationship among the teachers' *learning goals for their students, selection of effective tasks,* and *knowledge of students' thinking*: For Denise, once a teacher has a task focusing on quantitative operations, she has access to the quantitative/numerical operations, which in turn provides access to her students' thinking. This then assists in determining the learning goals. Strikingly, Denise started with the task rather than other components. Unfortunately, we failed to ask her why she chose to do so.

At this point in the semester, we discussed the meanings of logico-mathematical and empirical learning processes. First, PSMTs did the two tasks on equivalent fractions in Simon (2003) on their own to determine

I think, understanding the exponential numbers with positive number base requires a quantitative reasoning rather than a numerical reasoning. Now an exponential number with a positive base means for me that there is a positive number which is the base of the exponential number and for each increase or decrease in the power of that base means multiplication or division of the latest result by the base. Maybe it is more understandable to think in such a way: now every positive number base of an exponential number is a whole for me, say 1st whole. If I want to make it gain a power of 1, I should increase the number of 1st whole at my hand to the base many identical 1st wholes. Now, I get a bigger whole, say 2nd whole, than the 1st one. If I increase the power of the base to 2, then I increase the number of the 2nd whole to the base many identical 2nd wholes which forms another whole, say 3rd whole. For each increase in the power, I increase the number of the wholes at hand to form a bigger whole. Similarly, for any decrease in the power, I divide the whole into the positive number base, so I find base many smaller wholes that are identical. Each whole shows me the whole of the exponential number which lost one power. It is clearly seen that increase or decrease of the power causes an increase or decrease of the dimension of the wholes, but the amount of the changes are related the dimension of the whole at hand. There is an exponential growth or decrease in the amount and the positive number base is so important in determining the amount of this growth or decrease. Understanding exponential numbers means that understanding the relation between the geometric patterns and exponents by making firstly quantitative reasoning then the numerical reasoning.

Figure 2

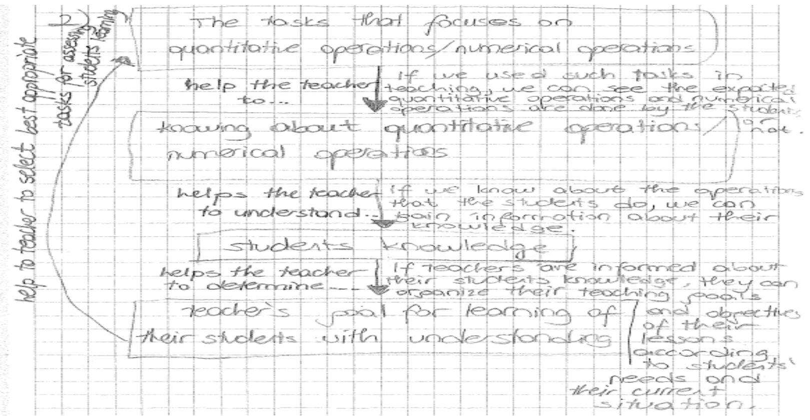

Figure 3: Denise's answer during within-class activity

whether these were cognitively high demand tasks. They concluded that the first task, which focused on finding equivalent fractions from the fraction chart, writing number sentences showing equivalences, and looking for patterns in the number sentences, concerned a task on empirical-learning processes. On the other hand, the task focusing on finding equivalent fractions based on re-drawing (re-partitioning) the given shaded rectangles focused on logico-mathematical learning processes. Then, in her weekly journal, Denise stated 'I think high cognitive demand tasks are tasks that require quantitative reasoning ability...' This suggests that Denise constructed a relationship between the quality of thinking in cognitively high demand tasks and quantitative operations.

Section 3 – Conceptual analysis: Data in this section showed how conceptual analysis might contribute to prospective teachers' awareness of the cyclic nature of effective mathematics teaching. We provide data from one week later after the discussion on conceptual analysis, pointing to the robustness of prospective teachers' knowledge of conceptual analysis.

R: Do you remember what we have talked about conceptual analysis last week?

N: I think you asked about the process of it. Who does it?

R: Yes. Can somebody say one more time what was it, what was the nature of it?

Q: It was like, while choosing the task, if she is choosing or if she is constructing, then we were doing the conceptual analysis. Like, we were thinking where the students might have difficulties, or might make mistakes, as teachers we were thinking how we can overcome those, help our students. Then, while the students are doing the task, the teachers were getting feedback from them. So, she would know how her students think. Also, she was getting feedback about how she could change the task the next time. So, it was like recursively going on this way.

Denise: She is looking at how much they know conceptually before the lesson too.

Strikingly, student Q stated that conceptual analysis can be done before, during, and after the lesson for different purposes, and Denise agreed. Also, the statement "So, it was like recursively going on this way" suggests that student Q is aware of the *cyclic* nature of the teaching. In addition, Denise's statement suggests that she is aware of a teacher's focusing on *what students know* prior to the teaching.

Section 4 – Clinical interviewing: In this section, data from Denise in the Clinical Interviewing Project was shown. Denise and her two group members chose radian, degree and the relationship between them as their topic to interview their classmates. We show Denise's analysis of her classmate, Veli, on the 4th question (see next page).

Our contention here is not to point to Denise's understanding of angle or radian; rather our emphasis here is *what she focuses on*. Denise's focus is *not just* on what her students do not know (he does not know what radian is). Rather, Denise focuses on *how Veli understands* it (he understands it as a length measure rather than openness, from her point of view), a characteristic of a PIP on mathematics teaching.

Then, prospective teachers did the Post-Assessment-2. We include the data to show that Denise's model for

Question 4: What is 1 degree? What is 1 radian?

When I asked him our fourth question, I saw that he could think better than a typical student might think. He thought 1 degree as the measure of the central angle which sees the arc length of the one of the 360 pieces when we divide the circumference of a circle into 360 equal pieces and making a similar connection with 2π radians and 1 radian, he said that 1 radian is the central angle which sees the $\frac{1}{2\pi}$ of the circumference, but he did not understand what 1 radian means. He had a misconception here, he thought that the measure of the central angle of a circle, which is 360 degrees or 2π radians, is equal to the length of the circumference of the circle and when he partitioned the circumference into 360 pieces or 2π pieces, 1 piece would be seen by the central angle of 1 degree or 1 radian. …the circumference of a circle could not be defined as degree, since degree is not a real number or is not a length measurement unit.

Figure 4

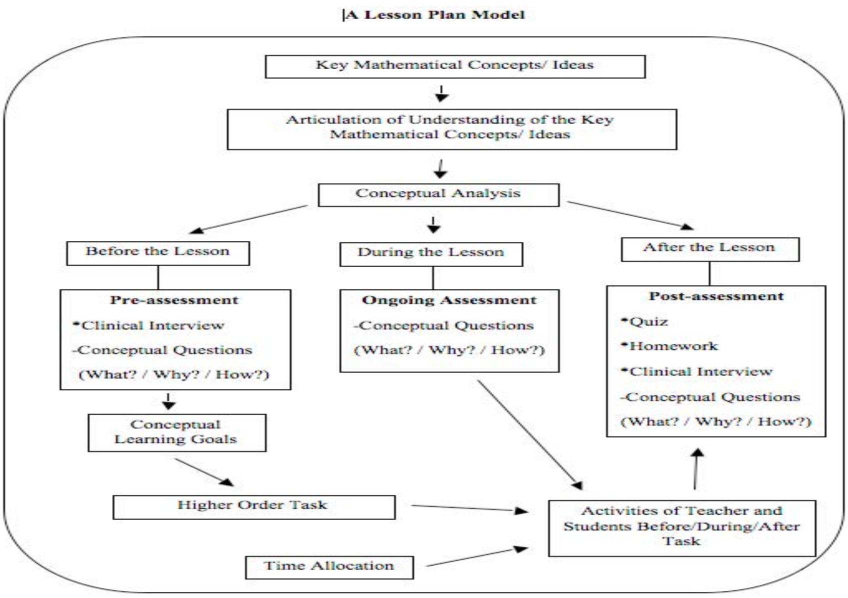

Figure 5

effective mathematics teaching changed at the end of the study. For the second question, Denise drew her model of a lesson plan for effective mathematics teaching.

For this model, Denise also provided her explanation as to why and how this figure models a lesson plan. For lack of space, we are not able to share her analysis. What is important is that Denise started her model with the key mathematical ideas that would yield her to learning goals for her students prior to the teaching. This would also allow her to choose higher order tasks she would engage her students in during the lesson through conceptual questions. This suggested a shift on her part towards a PIP since she was aware of the relationships between the components of teaching.

DISCUSSION

At the beginning of the methods course, Denise viewed mathematics, mathematics learning and mathematics teaching from a traditional perspective although she stated using representations and thought of some mathematical concepts as interconnected. After engaging in the quantitative and numerical operations her thinking has changed such that she was able to articulate a concept, exponential numbers, through her own mind activities. This suggested that she started viewing mathematics and mathematics learning as dependent on the knower. This suggested a shift from a traditional perspective towards a PIP. Also, working on the tasks focusing on logico-mathematical activities of mind, Denise came to know that cognitively high demand tasks require quantitative reasoning on the students' part. Also, Denise was able to think of tasks from a student's point of view. This indicated that she realized the differentiation of her reasoning from her students' reasoning. This was evident in her analysis of one of her classmates' reasoning on radian from the clinical interview project, in which she both focused on what her classmate did not think and how he thought. Denise was also able to realize the cyclic nature of the teaching process and showed it in her lesson model, given that she engaged in conceptual analysis, suggesting that awareness of the quantitative-numerical operations, logico-mathematical / empirical learning processes, the conceptual analysis and the clinical interviewing might afford changes in perspectives on the prospective secondary mathematics teachers' part. Empirical evidence showing the effect of engaging in aforesaid practices on a prospective teacher's perspective from a traditional approach towards a PIP represents a contribution to teacher development in terms of the design of methods and practice- teaching courses.

Dimensions of mathematics teaching and their implications for mathematics teacher education

Andrea Hoffkamp and Elke Warmuth

Humboldt-Universität zu Berlin, Department of Mathematics, Berlin, Germany, hoffkamp@math.hu-berlin.de

Developing the professional competence of mathematics teachers we need to consider different dimensions, for example, the content knowledge, the pedagogical content knowledge, and the pedagogical knowledge. Empirical studies in this area seem to provoke certain "trends" regarding the conclusions about "most effective" characteristics of a good (mathematics) teacher. Our findings with future mathematics teachers show that our students over-emphasize the pedagogical dimension while almost neglecting the importance of content knowledge. We analyse how the different dimensions interdepend and present exemplary learning scenarios for the education of future mathematics teachers focussing on the content knowledge dimension but, at the same time, combining it with pedagogical intentions derived from the special nature of our subject.

Keywords: Dimensions of competency, role of content knowledge, learning scenarios.

INTRODUCTION AND RATIONALE

The professionalization of mathematics teachers is still in the focus of politics and empirical studies like the international TEDS-M study (König & Blömeke 2012). In order to investigate and develop the professional competence of mathematics teachers different dimensions need to be considered. Describing the professional competence of teachers, Bromme (1997) distinguishes between *general pedagogical knowledge, content knowledge, curricular knowledge, the philosophy of the subject*, and *pedagogical content knowledge*. However the description of the complex structure of interweaving conditions between these dimensions is often missing or not addressed.

Especially since the study of Hattie (2009) there is a strong focus on the teacher personality:

> [..] the differences between high-effect and low-effect teachers are primarily related to the attitudes and expectations that teachers have when they decide on the key issues of teaching – that is, what they teach and at what level of difficulty, and their understandings of progress and of the effects of their teaching. This brings me to the first set of attributes [..]: passionate and inspired teachers. (Hattie, 2009, p. 26)

This led to a certain trend: the attempt to promote the pedagogical dimension within the teacher personality by describing and recommending only certain factors. For example, Anthony and Walshaw (2009) describe "characteristics of effective teaching of mathematics". In our opinion some of the descriptions are too little connected to the subject mathematics. Also the special (complex) relationship between the characteristics is not a subject of discussion, which implicitly implies that they can be treated independently.

Hattie also stated that the *content knowledge* dimension seems to have little effect on the quality of student outcomes. This can be similarly found in the study of Bromme (1997). By misinterpreting these results one might underestimate the dimension of content knowledge. Indeed Hattie concluded that "experts possess knowledge that is more integrated" and – of course – the content knowledge is an integral part of it (Hattie, 2009, p. 28). In fact Hattie (ibid) emphasizes the importance of formative assessment and feedback. Of course this requires a strong mathematical background of the teachers since the effect size of feedback referring to the subject or content appears to be high.

An opposite standpoint to the over-emphasis of pedagogical dimensions is the contribution of Wu (2005) – a professor of mathematics in Berkeley. He criticizes a "mathematics avoidance syndrome" at school and analyses how content "opens up the world of pedagogy and offers many more effective pedagogical possibilities".

Helmke (2012) criticizes that there are hardly any empirical studies investigating the professional quality concerning the content knowledge dimension of teaching at schools. Two very important works in this context originate from Ball and colleagues (2008) and Wittmann and colleagues (2001). Both refer to primary school mathematics. Based on Shulman's (1987) categories of teacher knowledge Ball and colleagues (2008) analyse the *content-specific dimension* detached from the *general dimensions* (like the pedagogical one). They characterise the subject matter knowledge, which is specific for mathematics teaching and differentiate it from the pedagogical content knowledge. With a different focus we find a similar approach in the work of Wittmann and colleagues (2001). They describe the *content knowledge as the core of mathematics teaching*. Moreover they develop the pedagogical dimension and the teaching methodology on the basis of mathematical ideas or content. In contrast to Ball et al. they particularly emphasize the role of metacognition ("consciousness"): teachers need to encourage the children to perceive the specifics of mathematics as a subject. This helps children to establish self-regulation mechanisms with regard to the subject.

In a deep theoretical analysis the educational scientist Gruschka (2008) also underlines the importance of content knowledge for teaching processes: "Teaching at school suffers by the shrinkage of content" (Gruschka, 2008, p. 73). In his work Gruschka often refers to mathematics teaching and reflects the role of content in a systemic way. According to Gruschka the professional competence concerning the content knowledge needs to be regarded within the complex of curriculum, pedagogy and philosophy of the subject. In more sophisticated words Gruschka (2008, p. 49) states that the unity of content knowledge and philosophy of the subject manifests itself in convictions about the pedagogical content dimension; whereas the pedagogical content dimension is determined by the anthropology of the students (as the core of pedagogical knowledge) and the attitude of the teacher towards the curriculum.

In our contribution we adopt the positions of Wittmann and colleagues (2001) and Gruschka (2008) for secondary mathematics teachers. We consider the whole complex of dimensions based on the specifics of our subject mathematics in an integrated way. By presenting examples we illustrate that the general dimensions, like the pedagogical or educational ones, are strongly connected to the content knowledge and philosophy of our subject mathematics. Our article is meant as a theoretical contribution to this topic containing illustrating examples. We also draw conclusions for the design of learning scenarios for mathematics teacher education at university. Following the above theoretical considerations we start with an analysis of some statements of future mathematics teachers in this context. These statements show that the beliefs about the dimensions of teacher competence have been shifted in a disadvantageous way.

DIMENSIONS OF TEACHER COMPETENCE FROM THE STUDENTS' POINT OF VIEW

To understand the context we shortly describe the situation of teacher education at Humboldt-Universität zu Berlin. At this university the future mathematics teachers learn their subject mathematics by attending mathematics lectures given by the mathematicians of the institute. Although these lectures are established for the future mathematics teachers only they are usually not practically oriented with regard to their future profession. As we will see later this is a dilemma. The pedagogical knowledge is acquired separately at the department of educational sciences. The pedagogical content knowledge is taught in seminars and lectures of the mathematics education group. The only courses in which the dimensions mentioned in the rationale are explicitly combined are some courses of the mathematics education group called "Stochastics and its pedagogy" or "Algebra and number theory and its pedagogy". Within these courses the content knowledge and pedagogical content knowledge dimensions are combined. Apart from these courses the dimensions are *not* taught in an integrated way. Especially the pedagogical dimension is nearly completely separated from the content knowledge.

The following statements and reflections originate from future mathematics teachers within a seminar in 2014 preparing the educational practical training phase (a 4-weeks period at school) in the master study program. Our students have to complete two practical training phases – one for each studied subject. Most of the students of this course will become secondary school teachers.

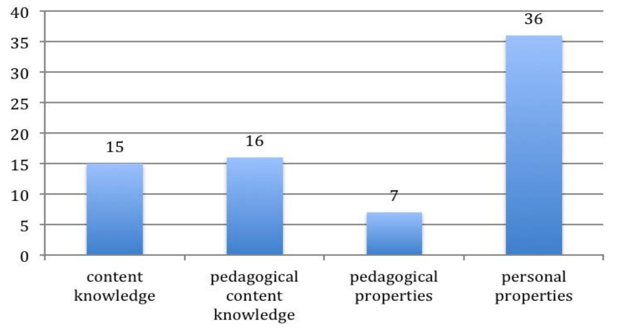

Figure 1: Students' answers to „Name the three most important characteristics of a math teacher": Absolute frequencies sorted by four categories

In the second session of the seminar we asked the students to write down the three most important characteristics of a good mathematics teacher. In the written answers of 24 students four categories could be identified: *content knowledge, pedagogical content knowledge, pedagogical properties and abilities,* and *personal properties*. The absolute frequencies of the answers are presented in Figure 1. Unexpectedly half of the students' answers could be attributed to the personal dimension. These were answers like *personality, fairness, patience, empathy, being not unforgiving, authenticity,* or *spontaneity*. Since the personal dimension is closely related to the pedagogical dimension, we were wondering about the students' beliefs about the connections and interrelationships between the categories.

Students' reflections about mathematics and pedagogy

Considering the mathematical content as the core of teaching we tried to find out which interrelations the students describe between the pedagogical and the content knowledge dimension. We were especially interested if the students deduce any pedagogical or personal factors from the content dimension. Therefore the students were faced with the results of the first questioning in the following way:

> "Comparing and clustering the characteristics named by the students of the course we see that most of the characteristics refer to personal and pedagogical abilities resp. qualities (see list of characteristics attached). On the other hand certain educational goals could be deduced from the list of characteristics.
>
> Please draw up your opinion to the following statements and write it down:
>
> 1) Without a firm mastery of the mathematical content, good pedagogy is impossible.
>
> 2) A firm mastery of the mathematical content opens up the scope for pedagogical actions and reinforces the pedagogical effectiveness."

The statements are adapted from Wu (2005, p. 7). Different from Wu the term "pedagogy" addresses mainly the pedagogical and personal dimension ("Pädagogik" in German) and not (only) the pedagogical content dimension.

The results of this questioning lead to more differentiated categories and allow a deeper insight. The following categories are specified by typical formulations of the students.

— *Content knowledge as the core of teaching:*

A firm mastery of the mathematical content leads to charisma, respect, self-consciousness and self-confidence of the teacher. Without a strong mathematical background a teacher cannot manage a class or will provoke discipline problems. Credibility and authenticity need a high level of mathematical competence.

> "Without a firm mastery in mathematics good pedagogy does not make sense, because the mathematical content and its mediation is the core of teaching and it has to be mediated by using pedagogical abilities."

In the statements within this category the students connect personal properties (self-confidence, charisma) and pedagogical factors (discipline, classroom management) directly with a high competence in the content knowledge dimension. In the students' view a strong mathematical background seems to strengthen personal and pedagogical skills that are important for teaching at school. However none of the students deduced personal or pedagogical properties or goals that are specific for the subject mathematics.

— *Mathematical content and pedagogy are separated areas:*

> "No, a firm mastery of the mathematical content and the scope for pedagogical actions are two totally disconnected 'construction sites'."

— Good Pedagogy is possible with low or no content knowledge:

"I am convinced of the thesis that a teacher with low professional content knowledge can cope well or better than teachers with high mathematical competence. I compare this with the study where an actor without any mathematical content knowledge gives a convincing talk about game theory in front of experts in this field."

This illustrates the dilemma mentioned at the beginning of this section. Mathematics lectures at university are not considered to be relevant for the teaching at school.

— High mathematical competence could hinder good teaching and pedagogy.

"I observed cases in which a high competence in mathematics hindered the establishment of empathy for the children, because these teachers were not able to imagine why and wherewith the children have problems."

The statements in these categories reflect the students' strong need for the human and emotional component of their profession. The implicitly mentioned aim of the students is: They want to be well received and appear likeable when teaching at school. In this sense the pedagogical dimension is over-emphasized by separating it from the content knowledge. Usually the students refer to their own experienced mathematics classes and want to do better. Therefore the students need to build their own pedagogical framework and system of values. We are confident that by considering the subject mathematics as the core for education in an integrated way, we could and have to support the development of the students in the above sense.

Analysis of a teaching professional's introduction of a new mathematics concept

With the following example we want to show how a teacher loses pedagogical effectiveness because of insufficient mathematical competence. We chose this example because it illustrates in an impressive way the interrelationships between the different dimensions concerning the professionalism of mathematics teachers. Besides the discussion of the interrelations we also show that examples like the following offer a valuable pedagogical potential for the education of future mathematics teachers.

One of our master students completed her 4-weeks practical training phase in which she had to teach and observe mathematics classes at school and write a training report. These reports consist of different parts. Aside from two lesson protocols and their reflection, the students describe their own lesson planning and resource development. The planning section especially contains an analysis of the taught subject by the student – as part of the content knowledge. About 30% of our students do *not* succeed in this part in their first attempt.

In her training report, she documented the observation of a "basic math course" in grade 13 (last year of secondary school). In the following protocol of the lesson, the student focussed on the methods of the mathematics teacher to introduce a new concept to the class – the concept of "expected value" in the case of the binomial distribution.

The teacher started with an extrinsic motivation: "What I will do next, will also be important for the next written exam." Having said this the teacher immediately moderates his statement by "But it is not that hard." The teacher uses an inductive approach to the concept and solely uses examples of the following type: "If I throw a fair dice 720 times. What do you think, how often will I get a 4?" The pupils answer "120 times" together with the reasoning "Well, there are six possible results. Thus 720 divided by 6 is 120." is accepted by the teacher with the words "Good, now the example with the tetrahedron. Whose example was that?". After four more examples of exactly this kind the teacher explains "Let's write this down in a mathematical way. $\mu = E(X)$ denotes what we expect. The number we receive is not a probability any more. The number usually doesn't lie between 0 and 1. We can also receive integers, for example if n is very large." After another example, which does not really fit to the binomial distribution, the teacher writes down the formula for the standard deviation by saying: "That's not difficult, you can just learn the formula." After that the class ends after 45 minutes.

This example reveals several dimensions of our subject matter. First the *content knowledge dimension*: The teacher does not have a conceptual understanding of the concept of "expected value" (*low content* *knowledge*). Therefore he *cannot act didactically*. He is not able to address the previous knowledge of his students and cannot use it for the development of the new concept. Therefore the teacher is *methodologically restricted* to direct instruction, since the content is not presented logically coherent and does not allow for pupil-centred methods. Also the teacher does not refer to the relevance of the concept for everyday life. Therefore he *cannot act educationally resp. pedagogically*. *Education to critical use of reason* would mean to discuss the significance and the misinterpretation of mean values as well as random fluctuations specific for stochastic phenomena. Expected values are a mathematical means for structuring and communicating. Since they reduce information they are supplemented by standard deviations. Their legitimacy as a teaching subject is only given if their relevance and limits are experienced (*curriculum dimension*). This is the prerequisite to educate mature people in an intellectually honest way.

Coming back to the education of future mathematics teachers, we take a look at the student's reflection of her protocol: The student criticized some methodological details and the abrupt termination of the class. From a mathematical perspective she did not have any objections. This example and the fact that about 30% of our students fail when working out a subject analysis is of course an alarming feedback for our education at university. It shows that we have to put more emphasis on the linkage between the content, the pedagogical content, and the pedagogical knowledge dimensions, and enable the future mathematics teachers to reflect on these linkages.

LEARNING SCENARIOS INTEGRATING DIFFERENT DIMENSIONS

As we analysed in the last section the different dimensions of teaching and learning mathematics depend on each other in a complex way. Since we cannot assume that the students achieve this view on their own, we need to offer substantial learning scenarios at university that allow them to actively deal with the dimensions in an integrated way. We want to present two exemplary learning scenarios following our theoretical considerations.

Using authentic material to educate reflective practitioners

As Gruschka (2008, p. 59 & 49) writes "if you want to understand teaching you have to understand the content dimension of the subject", and the core of pedagogical knowledge lies in the anthropology of the pupils. Therefore we start from the subject mathematics and use authentic material for the design of the learning scenario. The basis of the following activity is the protocol (presented in the last section) which is used as authentic material. The students receive the whole protocol as working material. The tasks should be worked out in small groups and afterwards discussed and reflected with the whole group.

Give-your-opinion!-task

a) Work out the definition of the "expected value E(X)" of a discrete random variable X with finite range of values. Which information of the distribution of X contains E(X), which information gets lost? Illustrate three different examples by using a graphical representation of the distribution of X.

b) Let E(X)=3. Interpret this value by switching from the level of mathematical model to the real world level. To which previous knowledge do you have to connect to?

c) Assess the approach of the teacher to introduce the new concept of "expected value". Do you agree with the teacher's given view of mathematics? Give reasons for your answer.

d) Give a sketch of your ideas for the introduction of the concept of "expected value".

e) How is the concept of "expected value" connected to the education to the critical use of reason? Where are the limits of the concept and its necessity to complement it by further concepts?

The above task combines the content knowledge dimension (a) as a necessary condition and basis for the following subtasks containing the pedagogical content and learning psychological dimension (b and d). Afterwards (c) the reflection of the situation and of the own view of the subject mathematics is required (philosophical dimension). The last subtask (e) refers to the pedagogical dimension and its connection to the mathematical subject matter. Particularly the pedagogical dimension in this scenario has the potential to develop – by *criticising the authority* of the teacher – *autonomy* and *critical faculties*, which are worthwhile pedagogical aims when teaching mathematics.

Including the metacognitive dimension

With the next scenario the content knowledge is combined with the philosophical dimension. This activity aims at the reflection of the special nature of the subject, since – as we analysed in the rationale – metacognition does play an important role when teaching mathematics and acting pedagogically. In a sense the following can be seen as a continuation of the first scenario, as it makes the *role of definitions within mathematics* a subject of metacognitive and philosophical discussion. The next scenario builds on the work of Hoffkamp and colleagues (2013). We already integrated it in a university course at Humboldt University and will briefly refer to our experiences.

> *Task 1:* (An exercise in defining in number theory.) Define the concept "even number". Also consider how you would define this concept at school and at university on different levels: primary school, secondary level and at the transition from school to university. Discuss the validity of the given definitions.

This seemingly simple task led the students to definitions like "the number 0,2,4,6 and so on", "all twosome numbers" (primary level), "all numbers that can be divided by two without remainder" (secondary level), or "the definition of divisibility leads to the description of the set 2Z" (university level). Then a lively discussion about the validity of the different definitions arose. Especially the definitions at primary level were not accepted by everybody as "being mathematical". With this task the students realized, that a definition is not necessarily unique, but depends on the mathematical context and purpose.

> *Input phase:* The students are confronted with the definitions and propositions of Euclid in the "Elements" (Book VII and IX): *An even number is that which is divisible into two equal parts. An odd number is that which is not divisible into two equal parts, or that which differs by a unit from an even number.*
>
> Using these definitions the following (simple) propositions of Euclid were deduced together with the students: *If as many odd numbers as we please are added together, and their multitude is even, then the sum is even. If an odd number is subtracted from an odd number, then the remainder is even.*

What the students experience in this part of the activity is that definitions change under historical conditions. They perceive the work of Euclid as the beginning of the axiomatic method and realize that Euclid's definitions are descriptive. They also realize that the proofs of the propositions "differ" from each other when using different definitions (like Euclid's or the modern university definition).

> *Task 2:* (An example from geometry.) Is it possible to decompose a square in two congruent parts? (from Fischer & Malle, 1985)

By discussing this task the students realize that the answer to the above question depends on our predefined concepts of "square", "decomposition" and "congruency". One can show that it is actually impossible to decompose a square into two congruent (and disjoint) parts. In fact a square could be mathematically described as a set of points in the plane. Then we have to ask: If we "cut" the square at the "center line", to which part do the "dots of the line" or the midpoint belong? Certainly mathematical definitions abstract from reality (of course we can cut a quadratic sheet of paper with a pair of paper scissors into two equal parts) and create ideal (mathematical) objects. Because of the idealization we need to proof our statements within our theory. The first two tasks lead to a sort of cognitive conflict: Both mathematical objects (even number and square) are familiar terms and the above difficulties are unexpected. This opens the way to discuss the nature and role of definitions from a metatheoretical point of view.

> *Task 3:* Give your opinion to the following statement: *Definitions are abstractions from reality following certain interests/purposes and change under historical conditions.*

Based on the previously made experiences the students discussed this statement philosophically in an explicit way. They started to emancipate from absolute truths and to reveal convictions about their subject.

They especially realized that – if each definition follows a certain purpose – this purpose has to be made explicit at school. This is strongly connected with the pedagogical dimension: as teachers we should take the pupils seriously as partners in a dialogue about mathematics and enable them to decide reasonably in a self-determined way.

CONCLUSION

In our article we analysed the dependency of the different professional dimensions of teaching mathematics forming an integrative entity. Based on our findings with future mathematics teachers we reasoned that the content knowledge dimension should be the core of mathematics teaching. We also derived pedagogical aims connected to our subject and its philosophy: a serious and genuine dialogue with the students and the education of the students at school (and university) to act and reason autonomously and rationally. In other words we developed the dimensions of the teacher competence based on the content and philosophy of mathematics – which defines the special nature of our subject. We claim that by offering learning scenarios (like the described ones) at university we help the students to create their professional system of values concerning educational aims. This could enable the students to build their own pedagogical framework based on the specifics of the subject mathematics. In this sense this is a very important point in the professionalization of future mathematics teachers.

Our present and future work is and will be guided by this approach and more learning scenarios will be developed and evaluated.

Training primary school teachers through research in mathematics' didactics

Julie Horoks and Brigitte Grugeon-Allys

University of Paris-Est Creteil, Laboratoire de Didactique Andre Revuz, Paris, France, julie.horoks@u-pec.fr

In order to become school teachers, since the last reforms in teacher education in France, the student teachers have to obtain a master's degree, including a research report in a field linked to education, or to the disciplines taught in school. In this study, we analyse the content and methods of an initial course in research in mathematics education, building some tools to assess how such a course can influence the beginner teachers' practices in class during the first years after their training.

Keywords: Teacher education, research initiation, practices, primary school.

In France, teacher training has gone through many changes during the last five years. The main result is that, since 2010, teacher training became part of a university master's degree, including some periods of internship in classrooms, the preparation for the competitive examination which serves to recruit teachers, and, what is new, a research course that leads to a research report on a field linked to education or a discipline taught in school. This initiation into research is supposed to help the prospective teachers in their professional development, reading and understanding results from research articles. Adapting findings for teaching should allow the teachers to reflect on their own practices.

Each university makes its own choices for the contents of the master's program for teachers, within the national guideline for the number of hours for the 2-year training. In the University of Créteil, near Paris, where the researchers of this report are also school-teacher educators, the time allowed for the research part of the training is rather important (120 hours out of 770 hours in total, spread over 2 years), compared to the training programs of the other French universities, but also compared to the time allowed for the rest of the training (professional and disciplinary content). The report requested from the student teachers after 2 years can be considered to be a research report, as it has to follow the same rules as any research report in our research field (a research question and hypothesis, an experiment in class, citation and bibliography norms) even though we probably are less demanding than with students following a research program. This part of the master's represents 34 ECTS out of the 120 needed for the diploma, including 10 ECTS for the report itself.

We are teacher educators for school teacher training (for teaching pupils from 3 to 11 years old) and particularly we run the course for research in mathematics education, which we designed a few years ago, after the reform. As researchers (Nadine Grapin, Brigitte Grugeon-Allys, Julie Horoks, Eric Mounier, Cécile Ouvrier-Buffet, Monique Pézard-Charles and Julia Pilet, all from the LDAR) we are also trying to assess how this course affects the professional development of our students, and find ways to pinpoint the effects of this initiation into research in mathematics education on their practices while teaching mathematics during the early years after the end of their training.

In order to study the effects of the training, we need theoretical and methodological tools to analyse both the content of our research course and the practices of the beginner teachers who were our former students. We present here the different sets of tools that we have developed for this purpose.

RESEARCH QUESTIONS AND THEORETICAL FRAMEWORK

To study teacher training

Some studies in France have already tried to assess the effects of initial training, for school teachers (Butlen et al., 2003) or high-school teachers (Grugeon-Allys, 2008; 2010). But these studies were carried out before the many reforms of teacher training and the introduction of research in the training program. Since 2010, the content for the training has changed in various ways depending on the universities (Grugeon-Allys, 2010). Note that we refer mostly to studies that were carried out in France, as we believe that the institutional and cultural context has an influence on teacher training and teacher practices.

We are trying to build tools to assess the effects of teacher training on professional development, and, in particular, the (potential and real) effects of training teachers through an initiation into research. We define some reference grids, linking the content of the training to the teachers' practices that are aimed for, and being able to relate the evolution in the teachers' practices at the beginning of their career to the dynamics of the training program. We are also looking for consistency among our former students' professional practices that we could link *a priori* to the training that we provided, in terms of knowledge as well as in terms of strategies used to share this knowledge.

The general question that we are asking is: does a course offering an initiation into research in mathematics education allow the students to enter a process of reflection upon their own practices, on the mathematical content taught in class and on their didactics, reflection which could promote their professional development as teachers? In this paper, we will focus on the tools that we are building to witness potential similarities between our former students' practices when they begin teaching in class, and link them to what was aimed for during the training.

Initiation into research in mathematics education, inside a teacher training program

The content of the course "initiation into research in mathematics education", in the Master's program for school teachers in the University of Créteil, is inspired by research results from the French field of *Didactique des Mathématiques*, and particularly results about the content taught in nursery and primary school (pupils aged 3 to 5 and 6 to 10 years old respectively), and about the related teaching and learning (and of course the content offered in this part of the training is influenced by the interests of the researchers participating as educators in this part of the training as well as in other courses). Our priorities are to prepare the students for their 50-page research report but also to bring them knowledge and tools that we consider useful and essential for their practice as future school teachers (for example, the ability to analyse and criticise a textbook on a mathematical topic, which is both a research and a teaching tool). The main theory that we talk about and use for analysis is the Theory of Didactical Situations (Brousseau, 1997), which can also be found among the objects and vocabulary used in other courses in the rest of the training, through some of its conceptual notions (such as *didactical contract* (a system of reciprocal obligation between the teacher and the students that sets their responsibilities, mainly implicitly, in class, during a didactical situation); *didactical variables* (parameters of the situation, with values that affect solution strategies. The effects can be of three kinds: (i) a change in the validity of a strategy, where a strategy that produces a correct answer with a certain value of a didactical variable will produce an incorrect answer with another value; (ii) a change in the cost of the strategy, for example, counting elements one by one is efficient for a small number but much more costly for a larger number; and (iii) the impossibility of using the strategy. (Mackrell et al., 2013); or, *devolution* ("the act by which the teacher makes the student accept the responsibility for an (adidactical) learning situation or for a problem, and accepts the consequences of this transfer of this responsibility" (Brousseau, 1997)) and *institutionalization* (which can take place after a series of activities where a piece of knowledge has been useful in the class to act on, communicate, or validate something, and is then linked by the teacher to a more general and shared knowledge)). Some of the sessions deal with particular mathematical content, its learning (pupils' errors) and its teaching (didactical strategies). Other sessions are more focused on the work with tools for the researcher, depending on the data to be analysed (textbooks, pupils' papers, videotaped sessions) or around the research literature (database, critical review). There are also many sessions dedicated to helping the student teachers with their research report.

Theoretical frameworks: Many levels of analysis

When trying to build some tools to try to assess the effects of the training on professional development, we have to be able first to analyse every stage of the training process, from the analysis of our goals and choices as teacher educators, to the analysis of the practices and choices of the teachers that we trained, during the first two years of their teaching when we are in their classes. This is a complex process, with many sides and points of view (the researcher's, the teacher educator's, the student's, the teacher's), and with many pieces of knowledge (on mathematics, on pupils, on teachers) (Shulman, 1986, although note that we do not use this framework in this research because we do not use the same categorisation of knowledge), some transmitted through the training, and some only influencing our choices without being visible to the students.

Different frameworks are thought to be useful for this study at different levels: to guide our choices for teacher training; to implement this training; and to analyse both its setting and its effects on students. We propose a multi-dimensional approach.

The Theory of Didactical Situations (Brousseau, 1997) is useful to us when we analyse sessions in class, in terms of *didactical variables* and *a priori analysis* of a task or situation. These are among the tools that we are presenting to our students during the initiation into research in mathematics education. They can be used to build and/or analyse situations for the classroom, to teach or to experiment in class with a research question. We also use the concepts of *chronogenesis* (progress of didactic time: description of the evolution of the knowledge proposed by the teacher and studied by the students) and *topogenesis* (change of positions of students and teacher with regard to knowledge (cf., for example, Laborde & Perrin Glorian, 2006).

To analyse and interpret teachers' practices, as well as our own as educators, we use the Theory of the Double Approach (Robert & Rogalski, 2005) defining five components in teachers' practices: cognitive and mediative components (what happens in class in terms of content and teaching/training strategies), but also personal, institutional and social (the curricula, the background, the institution, the colleagues ...). This theory allows us to take into account some constraints, which can explain teaching and training choices (for example, the fact that the content that we teach is linked to our own research can be explained through the personal component of our practice as educators).

Our hypotheses about teacher training also come from the Double Approach: being willing to take into account the constraints of training (not everything is possible for any teacher on any classroom) and the actual practices and needs of the teachers while training them. Regularity observed among teachers' practices might then be linked to their training, and variability of their practices linked to the particular constraints of the profession applied to each teacher.

To refine our analysis of teachers' practices, we use the concept of *didactical vigilance* (Charles-Pézard, 2010): we consider the permanent didactical adjustment made by the teacher in class and outside of class at different levels (local, global, micro practices), mobilising knowledge on mathematics as well as the way they are taught to analyse situations *a priori* and *a posteriori*, using tools from the Theory of Didactical Situations to detect phenomena in the classroom and take decisions regarding them.

To take into account the complexity of the teaching practices, we need to develop a multi-dimensional study, intertwining several frameworks, depending on what we focus on (teachers' or educators' practices), with a more or less wide focus.

METHODOLOGY

Based upon the rich theoretical material that we presented in the previous section, we built several grids of analysis to link the teachers' training and the teachers' practices potentially achieved through training (and later compared to the practice that we actually observed in class):

- a list of the types of tasks actually proposed during the training through the initiation into research in mathematics education;
- a list *a priori* of the expected teachers' practices that could be shaped by the work done during the training, the ones we might expect, based on research results of practices and on the national list of competences for teachers;
- a scale *a priori* of professional development of the school teachers, linked with the activities of the teachers in class.

We will show these grids and how we put them into use to assess and interpret teachers' professional development linked with their training.

The list of the categories of tasks that we proposed during the initiation into research in mathematics education

We analysed the content of the two-year course organised for the initiation into research in mathematics education in the Master's training program of the university of Créteil between 2011 and 2013. This content was not chosen with this research in mind, given that the research only started in 2013, two years after the beginning of the course. We considered the tasks given to the student teachers during the sessions and drew a list of types to characterise what our student teachers might have worked on: different kinds of analysis (mathematical tasks, pupils' productions, textbooks, mathematics sessions) as well as bibliographical work or the construction of the research questions and the methodology to test them. Some of these tasks can be found in the rest of the training but probably dealt with in a different way and with other aims: for example, mathematics sessions' analysis *a priori / a posteriori* are probably also proposed in the professional blocks of the program, but without a research question in mind. Tasks such as selecting, reading and analysing research articles might only be found in the research part of the training.

We consider that answering a research question and answering a professional (teacher) question does not require the same tools and resources. The data analysed might be the same (pupils' productions, textbooks) but with a different question in mind (testing research hypothesis). We believe that the resources used for the initiation into research are different from the ones the student encounters in the rest of the training (research articles / institutional documents). We also think that doing an experiment in class and teaching are not the same activities, even if they both usually involve building and implementing a session. The analyses involved are not the same and will not produce the same effects in the classroom.

The list of expected teachers' practices

The list of expected practices of the teachers when teaching mathematics was drawn up *a priori*, not considering what might or might not have been addressed during the training, but using the French reference of competences for teachers and some results in mathematics education research on teachers' practices that have been linked to potential learning for the pupils in mathematics. This helped us focus on particular activities of the teachers when they teach, or prepare their class, taking into account the mathematical content aimed at by the teaching:

- Choose or build a pertinent situation regarding the learning goals and the progression in learning;
- Know the mathematical content to be taught and their didactics;
- Manage different types of sessions (introduction, institutionalization, training, assessment, ...) and the different moments of a session (devolution, research, comparison of the procedures, validation, ...);
- Evaluate the pupils' learning and manage their heterogeneity;
- Reflect on one's own session afterwards, keep training and innovating.

We can see, in particular, considering the types of tasks proposed during the initiation, which practices we did not train at all (build an entire sequence of sessions on a subject for example) and the ones on which we spent much time (analysing tasks and sessions in class), but of course we cannot isolate the particular effects of the initiation into the global training.

The levels of achievement for every teacher activity

To analyse the evolution of every teacher's practices and compare it with other teachers, we built three levels of achievement for the practices (see Table 1). It takes into account what happens in the classroom, in terms of tasks and management, as in Butlen *et al.*, (2011), but also, on a more global focus, the preparation of the class by the teacher, and the reflection that he or she can have upon his or her own sessions. To illustrate this scale, we give an example, to assess the competence of a teacher for "managing different moments in a session" (see Table 1): level A is the highest one, and includes elements of analysis from the Theory of the Didactical Situations, to characterize the different phases of the session (from the *devolution* to the *institutionalization*).

Level C	Level B	Level A
*The different moments are not clearly identified (collective + individual research, no comparing of the procedures) *Not many initiatives for the pupils, the teacher is in charge of the validation *No moment of recollection of previous knowledge	*Some moments are organized during the session but they do not allow the pupils to engage actively in research or to compare procedures *Shared initiatives but the teacher is still in charge of the validation *The moments of recollection are about tasks and not knowledge, and taken in charge by the teacher	*The "launching" of the activity is organized (re-wording) *There is potential for active research for pupils *Procedures are gathered and compared with a hierarchy in the order in which they are presented, with shared initiatives for their validation, and construction of mathematical meaning *a summarization is made, leading to an institutionalization (*dépersonnalisation*, *décontextualisation*) linking it with the previous activity *Some moments of recollection of previous knowledge are promoted by the teacher

Table 1: An example of the three levels of achievements of teacher activity (managing different moments in a session)

EXPERIMENT AND FIRST RESULTS

To analyse the practices of our former student teacher with as much objectivity as we could, we built the categorization of the teacher practices and defined three levels of achievement for each of them, based upon some *a priori* result from mathematics education, and from national standards. We confronted these grids with the actual practices of our students, once they had started teaching full time in school, after the end of their initial training.

Data collected

We followed 13 students out of the 16 who took part in the initiation into research in Mathematics Education course between 2011 and 2012, who agreed to participate in the study, in order to assess the effect of their training:

— 7 out of 13 answered a questionnaire at the end of their Master's program, about their opinion of their training, with questions on their background before the training, but also on the interest they had taken in each of the subjects proposed in the initiation into research course, and the use they made (or thought they could make in the future) of the content of their training for their teaching.

The answers of our students to the questionnaire filled in at the end of the training showed a certain lack of interest for the theoretical content of the research initiation. The reasons why they chose our initiation into research in the first place vary from: "good in math" to "fear of teaching math", which means that we do not only have the best scientific students in our study. We asked them also to point out links between the research initiation course and the rest of the training, and they did not seem to see much common ground between research and the professional part of the training, not even with the same tasks proposed in both cases. We still have to pursue this study, but the small number of answers does not allow us to draw on the results of this questionnaire much.

— We followed our 13 former students (the ones who volunteered out of the 16) through observations in class and individual interviews by one of the researchers, during their first years as teachers.

We did not record the sessions (as it would have been difficult in this context) but the researcher who did the observation filled in a grid that we all had built before the observations, about the context of the school and the class, the phases organized by the teacher and the mathematical content and tasks proposed during the session, according to the tools we have set in place to analyse teachers' practices in mathematics. The interview allowed us to know if the teacher explicitly used some tools from the research training (through his or her vocabulary for example, or when describing his or her activity with other words than the ones used with us during the training), and to ask questions about how they would describe now the contribution of the training to their practices.

We also followed in class 8 student teachers who did not choose our initiation into mathematics education (but followed an initiation into research in another field). This part of the data has been collected but not analysed yet. It should allow us to pinpoint specificities of our former students, but we will not have as

Expected practices	C	B	A
Choose or build a pertinent situation regarding the learning goals and the progression in learning	1	5	6
Choose a textbook or other resources and use them with a critical view	1	6	5
Know the mathematical content to be taught and their didactics	1	8	3
Manage different types of sessions	1	8	3
Manage the different moments of a session	1	9	2
Evaluate pupils' learning	1	7	4
Manage the heterogeneity of the pupils	1	4	7
Reflect on one's own session afterwards	1	8	3
Keep training and innovating	1	9	2

Table 2: Levels of achievement of our former students at the end of their 1st year in class

much information on these eight students' training, which will be an important limitation.

First results in class

Trainers have to visit teachers twice in their classroom during their first year after training, to assess their work, and the two observations took place in this context. The evidence assessing the level of achievement for each element of the practices comes from the two observations, a few months apart, of half a day of class, including, each time, a session in mathematics, and from the interview that took place at the end of the second visit. The results for our 13 former students can be seen in Table 2.

We can see here that the global level of achievement of the 13 beginner teachers is between B and A, except for one student (who obtained a level C for each activity; it was a student who was in great difficulty, and did not succeed in becoming a teacher at the end of her first year in class). They built rather meaningful and pertinent situations for their class in mathematics, with an *a priori* analysis that allowed them to anticipate the pupils' difficulties in most cases.

They seem particularly efficient in managing the different phases of the session, with long phases of research for the pupils in certain classes. This is a type of task that has been often proposed to the student during the initiation into research course, while analysing videos, or experimenting in class for the research report. Validation of the tasks is still performed by the teacher rather than letting the pupils take the initiative.

Their opinion on the content of their training through the initiation into research has often evolved (from "too much work, too much theory" to "useful for preparing the session and reflecting on it afterwards"). Though they do not use concepts from the didactical theories in their discourse, they still seem to enact them in their practice (*didactical variables*, comparison and *organisation of a hierarchy in the* pupils' procedures, *a priori* analysis). For example, even if almost none of them used the term "*a priori* analysis" during the interview afterwards, they showed some capacity to analyse the content of their sessions, and the potential gaps between what was planned and what actually happened during the session. Incidentally, in the questionnaire at the end of the training, the majority of the students said that some content of the initiation was helpful to anticipate pupils' procedures, and that some of the content also gave them means to analyse their own sessions afterwards.

They seemed to us very reactive when reflecting on their sessions (changing things from their original plan immediately to take into account our remarks) and giving themselves means to keep improving their practices; which could confirm our hypotheses about the value of training through research to help the teacher enter a reflexive attitude for their teaching. Of course we still have to analyse the data collected in the other classes to confirm these results.

CONCLUSION

Even if the first results on teachers' practices during their first year teaching are very encouraging to us, we obviously have to underline the many limitations of our research:

— the small number of students, that does not allow us to generalise our findings;

- the impossibility to totally differentiate the effects of the research training from the effects of the rest of the program (but the questionnaire gave us an idea about the originality of the tasks proposed in our initiation, compared to the rest of the training, in which we also take part);
- conflicting roles of researchers, at the same time teacher educators and evaluators of the students whose practices they are trying to assess (even if we tried to separate the research from the assessment by giving clear protocols to the students) in a training context that was not built as an experiment on teachers' development.

As teacher educators, this study helped us build tools to organize the training, and gave us a clearer view of what we can potentially offer to the prospective primary school teachers through an initiation into research. We already made changes in our initiation program to take into account the needs of our students and address the question of the development of their practices more efficiently.

But we still have a lot of research to do to assess the real effects of training in general and through research in particular.

Tasks analysis as a mean to reflect and (re)think the pedagogical practice of teachers who teach mathematics

This study discusses how the analysis of mathematical tasks, within a teachers' in-service education study group, can help teachers who teach mathematics in the early years of Elementary School to reflect and (re)think their pedagogical practice. This research was carried out in a Brazilian public school, with the participation of 14 teachers. Within the in-service study group, the recognized importance of the tasks and their classification according to levels of cognitive demand by the teachers is discussed. The reflections and discussions in this study group allowed the identification of some changes in the teachers' perspectives in regard to tasks choice/preparation, the role of the teacher in the classroom and the recognition of students' capacities.

Keywords: Mathematical tasks, levels of cognitive demand, teacher education.

INTRODUCTION

The tasks proposed to students influence what and how they learn (Doyle, 1983; Stein, Smith, Henningsen, & Silver, 2009); therefore, it is essential for teachers to be prepared to select, in an informed way, the tasks to be proposed to their students and to support them in their work without reducing their complexity.

Several researchers have developed studies in which tasks are the focus of investigation, indicating that there is a relationship between the type of the proposed tasks and type of thinking developed by students (Doyle, 1983; Christiansen & Walter, 1986; Shimizu, Kaur, Huang, & Clark, 2010; Stein & Smith, 1998; Stein, Smith, Henningsen, & Silver, 2009). Thus, it is important to provide teachers with professional development opportunities to help them reflect on the role and relevance of the task for the teaching and learning processes and make them realize that not only tasks play a significant role in these processes but also that the way they are explored by the teacher in the classroom is fundamental.

In this article, we present the results of a research whose objective was to investigate how tasks analysis in a context of in-service education can help teachers who teach mathematics in the early years of Elementary School to reflect and (re)think their pedagogical practice and, more specifically, to understand these teachers' perspectives in regard to the tasks' choice and preparation, proposition and implementation, based on the levels of cognitive demand of each task (Stein, Smith, Henningsen, & Silver, 2009).

THE IMPORTANCE OF TASKS AND THE LEVELS OF COGNITIVE DEMAND

Tasks are used by teachers for different teaching purposes and they may appear in different moments of the lesson as exercises and problems, for instance. In this study, task is viewed as a proposition made by the teacher in the classroom with the objective to focus the student's attention in a determined mathematical idea which implies an activity from his part (Stein, Smith, Henningsen, & Silver, 2009).

When planning their lessons, many teachers are not used to think about the reasons behind their task choices and many times this action is supported merely by the mathematics contents which they are working or those included in the textbook. According to Pepin and Haggarty (2007), tasks can and must be seen as "[...] a process that can potentially help to enhance mathematical understanding rather than simply a vehicle for content" (p. 13). Next, three significant arguments related to the role of the task are presented to help teachers understand the importance of having a set of task selection criteria.

Firstly, "tasks with which students engage constitute, to a great extent, the domain of students' opportunities to learn mathematics" (Stein, Smith, Henningsen, & Silver, 2009, p. 131). The student's work is defined by tasks carried out by him/her, daily; however, some have the potential to mobilize complex forms of thought while others do not. Therefore,

> tasks that ask students to perform a memorized procedure in a routine manner lead to one type of opportunity for student thinking; tasks that require students to think conceptually and that stimulate students to make connections lead to a different set of opportunities for students thinking (Stein & Smith, 1998, p. 68).

A second argument is that tasks are instruments used to connect the students' learning objectives (Stein, Smith, Henningsen, & Silver, 2009). When choosing or preparing a task, it is important for the teacher to have a clear objective to propose to students. To think about the tasks' objectives prior to implement them can help teachers create a classroom environment that motivates the student to get involved in the solving of the proposed tasks.

A third argument is that tasks affect significantly the reasoning process students develop in order to solve them (Stein & Smith, 1998). Therefore, teachers should prioritize cognitively challenging tasks with the potential to engage students in complex thinking forms. This type of task can help students develop reasoning forms and strategies that allow them to go beyond the memorization of facts and procedures. However, the teacher must be aware of the fact that to select or prepare this type of task does not guarantee students' engagement since there are several classroom factors that can contribute to the maintenance or decline of the task's cognitive demand (Stein, Smith, Henningsen, & Silver, 2009).

Tasks can be analyzed from several perspectives such as nature, characteristics, number of strategies used to solve them, levels of cognitive demand among others. In this study, tasks are analyzed based on their levels of cognitive demand since, according to Stein, Smith, Henningsen and Silver (2009) "the cognitive demands of mathematical instructional tasks are related to the level and kind of student learning" (p. 17).

For Stein and Smith (1998), tasks can be grouped in four levels of cognitive demand: memorization; procedures without connections; procedures with connections, and doing mathematics. The first two categories involve tasks with lower-level of cognitive demand and the last two refer to high-level of cognitive demand tasks. With the purpose to provide support to teachers during task analysis according to their levels of cognitive demands, in a context of teachers continuing education, these researchers prepared a Guide to Tasks Analysis (Appendix 1), which includes a list of tasks characteristics in each one of the four levels of cognitive demand that can be used as a parameter for their classification.

The teacher can still use this guide "as lens for reflecting on their own instruction and as a shared language for discussing instruction with their colleagues" (Stein, Smith, Henningsen, & Silver, 2009, p. 2). Thus, by selecting/preparing tasks based on their cognitive demand allows the teacher to look into what the students learn and how they work with the tasks; their actions at the moment of proposing and implementing the tasks; the factors that affect the proposition and implementation of the tasks, which may contribute to their maintenance or decline.

However, in order to choose or prepare tasks based on the levels of cognitive demand, the teacher must not only be informed by some principles for tasks analysis but also know their students deeply and pay attention to aspects such as age, learning pace, level of education, mathematical knowledge and prior experiences so that those tasks constitute a real challenge for students (Stein, Smith, Henningsen, & Silver, 2009).

RESEARCH CONTEXT AND METHODOLOGICAL PROCEDURES

This research was developed within an in-service education program, in a study group context, with the participation of 14 teachers working with the early years of a public Elementary School in Brazil. The teachers had more than eight years of experience and played different functions in their schools.

The study group was coordinated by two researchers, one of them is the first author of this article, from the Mathematics Education and Sciences Teaching Graduate Program– PECEM[1], and was part of an in-service education project outlined by the school within the City Education Department annual planning. One of the goals of this study group was to motivate participants to learn about the levels of cognitive demand of the tasks and how to analyze tasks based on some principles. The study group met weekly, for one hour, for a period of six months and it focused on tasks analysis based on the categories proposed by Stein and Smith (1998).

The group discussions were organized in four phases. In the first, we discussed the tasks brought by the teachers and, they presented and explained the reasons that guided the selection of these tasks and how they worked with the tasks in the classroom. In the second, the teachers studied and discussed the features of tasks in each level of cognitive demand and later they conducted a new analysis of these tasks, classifying them according to the level of cognitive demand. In a third moment, the teachers worked on tasks with different levels of demand cognitive proposed by the coordinator of the study group, they analyzed and classified these new tasks and some teachers have expressed interest to apply them in the classroom (due to space limitations, it is not possible present the tasks in this paper). After this implementation, in the fourth phase, the study group discussed the relevant points and the difficulties faced by the teachers in the classroom, as well as evaluated the importance of task analysis and cognitive demand levels.

The instruments adopted for data collection included transcriptions of the audio recordings of the meetings so that the participants' speeches could be registered in their original form, keeping the integrity of the dialogues; written productions, with comments and reflections of teachers on discussions that occurred in group (free writing) and semi-structured interviews with some teachers. To identify the instrument from which the information was obtained, we use the fictitious name of the participant followed by the first letter of the instrument. So, the letter G was used for group meeting followed by the number of meeting, P for written productions, and I for interviews. For example, the identification of an information given by Cintia in the first meeting, is registered as "(Cintia, G1)". Due to space limitations, in general, only one excerpt was presented as an example of each analysis unit. Analysis units were constructed after several readings of the meetings' transcriptions, written productions and interviews, highlighting relevant excerpts for our study. Data analysis uses the Tasks Analysis Guide as reference (Stein & Smith, 1998).

1 This program is being developed at State University of Londrina, Brazil.

Reasons given by the teachers for their choice of tasks	Tasks allow teachers to approach mathematical content	I choose a task to work with content. If I want to work with the operations, the multiplication table, I choose tasks that allow me to work with them. If the content is measures, for instance, I choose a task that explores this content (Isadora, G1)
	Tasks allow to verify whether the mathematical content was "assimilated".	When I propose tasks to my students it is always with the intent to check whether they have learned the content and also to verify which contents still need more work to be done [...] (Fabiane, P1)
	Tasks allow to work with non- mathematical aspects	I never choose a task which deals exclusively with Mathematics. I choose a problem that involves several areas such as Sciences, Portuguese, Geography, several disciplines, a task that does not involve only calculations. (Carla, G1)
	Tasks allow to relate mathematics with the student's reality	[...] Tasks must always be connected with the child's reality. Children learn mathematics for their life. [...] They are more motivated (it's more pleasurable) when they have to solve real problems. (Mariana, G1)
	Tasks allow to develop reasoning skills	The objective of the tasks must be to contribute with the development of the student's reasoning skills. (Cintia, P1)

Table 1: Summary of the initial reasons given by teachers for their tasks choices

Reasons given by the teachers for choosing tasks

One of the actions developed in the beginning of the study group was a discussion over the tasks teachers had brought upon request of the teacher educators. They were asked to explain the reasons behind their tasks choices which included: to approach mathematical content; to verify whether the mathematical content was assimilated; to work with non-mathematical aspects; relate mathematics to the student's reality and to develop reasoning (Table 1). Some teachers gave more than one reason for their choices of the tasks.

The reasons presented by the teachers show that most of the tasks they selected are based on memorization or on procedures without connections (Stein, Smith, Henningsen, & Silver, 2009), i.e., they require only the reproduction and memorization of contents, rules and formulas learned previously, without establishing connection with concepts or meanings that give support to the contents given, and being more focused on correct answers than on the student's understanding.

Tasks analysis and the levels of cognitive demand relevance

The study of the levels of cognitive demand, the reflection on the tasks' role in the teaching and learning processes and of the high-level of cognitive demand tasks led teachers to think about their initial reasons to choose tasks and develop another view in relation their selection or preparation. Next, we present a table with some points provided by the teachers on the relevance of tasks and levels of cognitive demand (Table 2) during the study group work.

Teachers started to notice that tasks have different characteristics and that this difference can be interpreted through their levels of cognitive demand, bringing implications to the student's activity and to the complexity of the mathematical processes involved. They also became aware that their tasks selection criteria were focused almost exclusively on the coverage or verification of mathematical content.

Signs of changes triggered by discussions, reflections and task analysis

The actions developed by the study group on the reasons for choosing tasks, levels of cognitive demand as a tool to classify them and on tasks analysis allowed us to identify signs of changes in regard to tasks choice, role of the teacher in the classroom and student's capacity (Table 3).

During our first meeting, teachers had difficulty in justifying their choices to the group, considering that the habit of thinking about *why the tasks were selected*; *for they serve*; *what contents they cover, their level of complexity* and *whether the objectives were met*, it was not common practice of most teachers who participated in the study group. *"I never stopped to think why I chose the tasks. Today I become to realize how important it is to think about it". (Ana Lívia, G1). "Great! You know, when I gave the task to my students I did not think about the objective, about the reason behind it; so, I'll pay more attention to it from now on"(Ana Júlia, G1).*

During the group sessions, some teachers started to become more aware of the importance of selecting tasks and aggregating levels of cognitive demand to their criteria, reducing the number of tasks proposi-

Reflections on tasks analysis and levels of cognitive demand	Tasks relevance for the teaching and learning processes	I had never stopped to think about the importance of tasks for the student's learning process; but, now, here with this group, with these discussions and being aware of the difficulties some teachers had to justify their choices I realized how important it is to reflect on it. I realized that we have chosen tasks haphazardly. (Vitória, P1)
	The relevance of learning about the levels of cognitive demand of the tasks	[...] knowing about levels of cognitive demand changed my way of thinking and choosing tasks and helped me think better about how and which task to use and whether it is going to be useful to the public at hand [...]. (Ana Júlia, I)
	The relevance of high-level of cognitive demand tasks	It is extremely important to work with high-level of cognitive demand tasks, since they promote the development of autonomy, self-confidence and critical thinking, argumentation and therefore to think mathematically and to search for solutions to problems. (Denise, P19)

Table 2: Reflections on tasks and levels of cognitive demand

Change signs	Sentences that show the signs of change
Tasks selection by the teacher	These reflections have contributed a lot to my mathematical tasks selection criteria and also to tasks from other subjects. We are becoming more careful, thinking not only on the objectives of the tasks but also on their levels of complexity and the students, trying to imagine how they will react to the task and which are their possible answers. (Cintia, P6) The reasons I had before remain, but now I also select high level tasks which involve reasoning and not only formulas. But, I look for a balance among the tasks. Students still have lots of difficulty, so it is impossible to work only with high level tasks, that's why I stick to my old set of criteria (Fernanda, I) Today I look for tasks that make my students think; not only tasks that focus on the correct answer but on how the student will carry it out, on the process. But, I continue choosing tasks for verification, which are also important (...) I think that the other criteria came up due to my participation in the study group otherwise I would not have learned about them and become aware of their existence (Ana Júlia, I).
The role of the teacher	My posture in the classroom has also changed. Now I try to question the student more to know about his reasoning process (Ana Júlia,G17) [...] This group work not only helped us know the task but also to try to work with tasks in a different way. For example, I never gave the opportunity for my student to explain their work. Now, I always ask them to explain their work process to me and their classmates. (Fabiane, G17)
The students'capacity	I learned to value my students and their capabilities. Before I saw them as individuals coming from a poor neighborhood, with whom I was supposed to teach some mechanical skills and I would be very happy if they were able to learn them. However, I learned that they can achieve more; I did not know their potentials so, when I gave them the task you suggested I saw how wrong I was and that I could go beyond mere mechanical tasks. (Mariana, I) I was surprised by some students who many times have difficulty in carrying out simple mathematical operations, an algorithm; however, they solved very fast the sequence's problem they did very fast without questioning [me] much. Other students, who were always the first to finish a routine task, had difficulty solving this problem. (Denise,G13)

Table 3: Sentences that show signs of change by the teachers

tions focused on memorization or on the realization of a procedure without connections.

In regards to their role, discussions and tasks analysis allowed teachers to understand the impact of their actions on some teaching and learning processes, especially in relation to tasks choice and to promote a change in the way to implement tasks in the classroom. This way, they started to promote teaching and learning processes focused on the students' understanding.

As for the student's capacity, tasks implementation and solution helped teachers to realize that, many times, they underestimate the cognitive capacity of their students, their specific learning pace and difficulties and that the role of the teacher is to help them think on how to solve the task without removing its challenges (National of Council of Teachers of Mathematics, 2000).

FINAL CONSIDERATIONS

To think about the tasks they propose was not a usual practice for most teachers in the study group. Consequently, in the phase of the study group, some of them had difficulty justifying their choice of the tasks to be used in the classroom. However, despite these difficulties, some teachers were able to voice their reasons for choosing the tasks such as to use a task to approach mathematical content or verify whether the mathematical content was assimilated, and these practices are strongly present in the pedagogical practice of these teachers.

To learn about the levels of cognitive demand and analyze tasks was highly significant for most teachers, since they were able to realize the importance of thinking about the tasks and the way to work with them in the classroom. Thus familiarity with the levels of cognitive demand has also helped teachers to understand that tasks with a high-level of cognitive demand have the potential to involve the student in a work focused on reasoning and on understanding, making them choose and propose this kind of tasks.

Teachers became more critical regarding their choices of tasks which became an action based on a lot of thinking. They become more attentive to the objectives of the task, trying to anticipate how students would react to it and their possible solutions.

In addition, the teachers had the opportunity to reflect on their role in the classroom, since they realized that their attitudes and decisions influence their students' learning. Therefore, some teachers considered that they changed the way they teach by questioning more the students during the lessons, to know about their line of thought rather than being only concerned with the correct answers and mainly giving them more opportunities to justify their reasoning processes. Consequently, this change in the teacher's attitude shed a new light on the way they regard the students, since some of them used to underestimate their students' capabilities.

Thus, according to Stein, Smith, Henningsen and Silver (2009), to know about the levels of cognitive demand allowed teachers to differentiate mathematical tasks in order to identify those that offer opportunities for students to think without being led by their superficial characteristics.

However, even acknowledging the potential of tasks with high-level of cognitive demand, teachers have only aggregated them to their previous reasons. The lack of confidence in dealing with these tasks, the fear of not being able to meet the objectives of the lesson and at the same time demotivate students due to their difficulties and the justification that memorization and verification tasks are also relevant, are some of the arguments presented by teachers to justify the low frequency of high-level of cognitive demand tasks in their work. Such resistance must be understood within the context of an instituted professional practice, considering that the knowledge of levels of cognitive demand can help teachers to reflect on their teaching style and focus more on what students learn and how they work on a task as well as on their actions and attitudes when proposing and implementing a task.

APPENDIX 1. GUIDE TO TASKS ANALYSIS (STEIN & SMITH 1998)

Tasks Characteristics that involve low-level of cognitive demand	Memorization	Procedures without connections
	- Involve either the reproduction of facts, rules, formulas learned previously or memorization; - They cannot be solved by using procedures because they are either not necessary or the time is short to use them; - They are not ambiguous and involve the exact reproduction of the subject studied previously and what is to be reproduced is clear and directly stated; - No connection with concepts or meanings underlying the facts, rules, formulas or definitions taught or reproduced.	- They are algorithms. The use of one procedure or is specifically indicated or evident due to a previous instruction, experience or question location; - Require limited cognitive demand to resolve it successfully. There is little ambiguity on what needs to be done and how to do it; - There is no connection with concepts or meanings underlying procedures used initially; - They are focused on the production of correct answers instead of on the development of Math comprehension; - Do not demand explanations or whenever needed, they are explanations focused only on the description of the procedure used.
Tasks Characteristics that involve high-level of cognitive demand	Procedures with connections	Doing Math
	- Focus the students' attention on the use of procedures to develop an in-depth knowledge of concepts comprehension levels and Math ideas; - Suggest ways to be followed (explicitly or implicitly), which are general, common procedures which have intimate connection with conceptual ideas; - Usually represented by several ways (such as diagrams, manipulatives, symbols and problem-situations). They make connections among multiple representations that help develop meanings; - Demand some degree of cognitive effort. Although general procedures can be followed, they cannot be followed without being fully understood. Students need to get involved with the conceptual ideas underlying the procedures to be followed in order to fulfill the task successfully and develop comprehension.	- Demand complex thinking skills rather than algorithmic skills, and the tasks do not suggest, explicitly, a predictable way to be followed, instructions for its solution, or an example, which, when well-trained, could lead to their resolution; - Demand that students explore and understand the nature of Math concepts, procedures or relations; - Demand high monitoring or high regulation of the student's own cognitive process; - Require students to mobilize relevant knowledge and experiences make appropriate use of them during the task; - Require students to analyze and examine the task actively and whether it has limited resolutions and solutions limitations; - Demand considerable cognitive effort and may involve some levels of anxiety from the students' part for not having a previous natural list of the processes demanded by the problem.

Video-based peer discussions as sources for knowledge growth of secondary teachers

Ronnie Karsenty, Abraham Arcavi and Yael Nurick

Weizmann Institute of Science, Rehovot, Israel, yael.nurick@weizmann.ac.il

This paper reports on a study conducted as part of a larger project, named VIDEO-LM, which centres on video-based professional development for secondary mathematics teachers. The project aims to facilitate the reflective skills and the Mathematical Knowledge for Teaching (MKT) of secondary school teachers, in particular those teaching advanced mathematics courses. At the core of the project is a 6-component framework developed for analysing videotaped lessons in collaborative discussions with teachers. We describe the rationale and novelty of the project and the framework. Then, we focus on a study which examines the MKT growth of a group of teachers who participated in VIDEO-LM peer discussions, and present some preliminary findings.

Keywords: Video-based professional development, peer discussions, mathematical knowledge for teaching (MKT), secondary mathematics teachers.

INTRODUCTION

The power of videotaped teaching episodes as a vehicle for stimulating discussion and reflection among mathematics teachers has been discussed in recent years from various angles (Borko et al., 2011; Coles, 2013; Sherin & van Es, 2009). Although video has been used as a tool for teachers' professional development for the past 50 years (Sherin, 2004), the rapid advancements of digital video documentation has allowed for significant amplification in this field, which manifests in a host of professional development programs in various countries that include video as a major resource (e.g., KIRA and Mathe sicher können in Germany; the Problem-Solving Cycle and the Learning and Teaching Geometry programs in the US; WMCS in South Africa). Online video resources are now largely available to educators (MET in the US and Teachers Media in UK are prominent examples) and at least two international symposia were dedicated recently to the use of video in mathematics teacher education (see http://www.weizmann.ac.il/conferences/video-lm2014).

The following citations distil the main feature of video that can explain why it is regarded as a valuable tool for teacher development. Sherin and van Es (2009, p. 21) claim that "Teachers benefit from opportunities to reflect on teaching with authentic representations of practice"; Brophy (2004, p. 287) argues that video can introduce "the complexity and subtlety of classroom teaching as it occurs in real time"; and Nemirovsky and Galvis (2004, p. 68) suggest that "because of the unique power of video to convey the complexity and atmosphere of human interactions, video case studies provide powerful opportunities for deep reflection". All these scholars emphasize the role of video as a window to the authentic practice of teaching, which allows teachers to focus on complex issues that may be unpacked through observing, re-observing and reflecting on specific occurrences.

Generally speaking, there are three main trends in using videotaped episodes from mathematics lessons as resources for teacher development. First, video is utilized for introducing new curricula, activities, pedagogical strategies, etc. This target is mainly implemented through supplying teachers with video cases that model how teaching the new curricula, or using the pedagogical strategies, may be enacted (e.g., Seago et al., 2010). A second trend, becoming more and more prevalent (particularly in the US), is using videotaped lessons as a source for feedback and evaluation. Teachers watch videos from their own classrooms and discusses them with colleagues or instructors, often with the use of a pre-constructed standard-based rubric such as the one developed by Hill and colleagues (2008). The third trend is using videotaped episodes to enhance teachers' proficiency to notice, understand and discuss students' mathematical thinking (Sherin et al., 2011), usually in the form of "video clubs" (Sherin & van Es, 2009).

This paper brings forward a different direction for using video as a major resource for professional development of mathematics teachers, as emerges from a new project in Israel, named VIDEO-LM (Karsenty & Arcavi, 2014). In what follows, we describe the project and introduce the framework of analysis which lies at its core. We then report on a study conducted as part of the project, investigating the development of new Mathematical Knowledge for Teaching (MKT) in a group of teachers who participated in VIDEO-LM sessions.

THE VIDEO-LM PROJECT

VIDEO-LM (Viewing, Investigating and Discussing Environments of Learning Mathematics), is a project launched on 2012 at the Weizmann Institute of Science. Its over-arching goal is to improve mathematics teaching, with particular emphasis on the advanced tracks in secondary schools, through enhancing the reflective skills and the mathematical knowledge of teachers. The means to achieve this goal is by creating a pool of videotaped mathematics lessons, which serve as a basis for guided peer discussions with teachers. We use the lessons as "vicarious experiences" for teachers, centering on how the filmed teacher displays multifaceted elements of practice. The videos we use do not necessarily display 'exemplary teaching'; rather, we pick lessons that can potentially trigger fruitful conversations. As opposed to the first trend noted above, teachers are not presented with demonstrative videos focused around new materials or strategies, nor do they engage in evaluative discourses, as in the second trend. They may relate to students' thinking, the aspect centralized in the third trend, but only as part of the whole "teaching picture" revealed on the screen. In other words, the discussions are intentionally *teacher-centered,* and not *student-centered*.

Rationale

It is well known that teaching can be a lonely profession. Despite participation in professional communities, online forums and other forms of communication and collaboration with other teachers, the reality is that the vast majority of teachers are the "solo adult actors" in their classrooms, where they spend the lion's share of their professional life. In many countries teachers seldom get the chance to watch their peers in action once the pre-service period is over. This is not merely a social deficit, but also a barrier to certain processes of professional evolutions embedded in peer learning *in situ*. For instance, watching peers may expose teachers to alternative instructional strategies, which makes it possible to change routine thinking and actions (Santagata et al., 2005; Sherin, 2004). Thus, the VIDEO-LM project aims at creating opportunities for teachers to watch whole lessons given by others. Moreover, we seek to enhance the potential gains from these opportunities, by directing teachers to collectively analyse these vicarious experiences through a systematic use of a 6-component framework.

The framework for analysing videotaped lessons in teachers' discussions

We have developed a unique framework for analyzing videotaped lessons, inspired by the work of Schoenfeld (1998) and Arcavi and Schoenfeld (2008). Schoenfeld's theoretical model of "teaching in context" describes and predicts how teachers' goals, knowledge and beliefs affect their in-the-moment decision-making during lessons. Arcavi and Schoenfeld have taken this model as a basis for creating analytical tools with which mathematics teachers can reflect upon their own practice while watching videotaped lessons of other teachers. In the VIDEO-LM project, we have modified and extended these analytical tools to include six components, which are the building blocks of the framework we use. In the following, we briefly describe these six components.

1) *Mathematical and meta-mathematical ideas*. Given the topic of the lesson, there is a range of relevant concepts, procedures and ideas that may be associated with this topic. For instance, the topic of the square root function may involve the following ideas: the non-negativity of the function's domain; its monotonously increasing graph; continuity and derivability of the function; its relation to the function $y=x^2$; and so forth. Topics may also evoke meta-mathematical ideas, such as what makes a proof legitimate, why is one counter example sufficient to refute a conjecture, the arbitrariness of certain mathematical definitions, etc. Before watching a videotaped lesson, teachers are requested to elicit ideas, in an attempt to gauge the boundaries of this range. Then, once the tape is screened, they can refer to questions such as: Which of these ideas, or oth-

ers, did the teacher bring forward in the lesson? Which ideas were left out? How can this decision be explained? Which meta-mathematical notions were evident in the lesson?

2) *Explicit and implicit goals*. The rich span of mathematical ideas around a given topic enables choices of the goals teachers wish to pursue within a lesson. One of the reasons that lessons of different teachers on the same topic do not resemble one another is that teachers derive different goals from the range of relevant mathematical ideas. While watching a video, teachers try to identify the goals they think the filmed teacher was attempting to achieve, whether explicitly or implicitly. In other words, they ascribe goals to the teacher, just as one would ascribe meaning to a poem or some other piece of art. In this context, our aim is not to scientifically verify any "true situation" (i.e., what were the teacher's "real" intentions); Rather, we encourage the mental exercise of ascribing goals, targeted at (a) promoting the skill of articulating goals; and (b) enhancing awareness to the fact that alternative (sometimes even competing) goals to teaching a certain mathematical subject may exist.

3) *Tasks and activities selected by the teacher*. The tasks, problems and activities presented by the teacher during the lesson are the means by which the teacher's goals are fulfilled, hence reflecting the mathematical ideas chosen by the teacher. The video enables teachers to watch a "task in action"; how it is implemented, the nuances in introducing it and how the teacher addresses students' reactions. This enables quite a different exploration than the one teachers may preform when presented with the task in its written form (i.e., as it appears in textbooks or other written resources). We refer to such an exploration as an *a posteriori task analysis*, which can potentially enrich the discussion, giving an additional angle to that of the *a priory task analysis*.

4) *Interactions with students*. The implementation of the tasks and activities selected by the teacher is carried out through classroom interactions. This component includes generic elements such as positive and negative feedbacks given by the teacher, listening to students, wait time, etc., but also considerations that are more related to the subject matter, for instance how the teacher navigates the students' responses during the mathematical activity and poses subsequent questions. Following Clarke (2014), questions of equity, authority and knowledge construction are also valuable as triggers of productive conversations: Who gets permission to speak? Who is responsible for the flow of ideas? Is the mandate to produce new knowledge distributed or centralized?

5) *Dilemmas and decision-making*. The mathematics education community has learned much about teachers' decision making processes, from the work of Schoenfeld (1998; 2008) and others. However, for many teachers the "diving" into another teacher's decisions is a novel experience. The exercise offered to teachers participating in the discussion is to focus on the filmed teacher's dilemmas as they may be uncovered in the lesson, the decisions taken in order to resolve these dilemmas, and their consequent tradeoffs. The risk is drifting into criticism and judgmental talk, a problem pointed out in the literature on video sessions (e.g., Coles, 2013; Jaworski, 1990). To avoid this, teachers are guided to consider the choices made by the teacher under the assumption that she acts in the best interest of her students (Arcavi & Schoenfeld, 2008). Taking this as a starting point, the constraints and affordances of the teacher's choices can then be examined, and alternative paths can be elicited and explored.

6) *Beliefs about mathematics teaching*. The issue of how teachers' beliefs shape their practice has been widely studied (e.g., Li & Moschkovich, 2013; Schoenfeld, 1998). In fact, all the components (1) through (5) above are likely to be guided by the set of beliefs the teacher brings into the classroom. Facilitating discussion about beliefs is a highly complicated and delicate matter. However, we suggest that such a conversation can be valuable. Teachers are not always aware of messages they convey during mathematics lessons, through direct or latent communications, nor of their considerable influence on how students perceive the domain of mathematics and how they function during the lesson. Thus there is a potential gain in the exposure to explicit and implicit attitudes reflected in another teacher's actions. The discussion focuses on questions such as: What

may be the filmed teacher's views about the nature of mathematics as a discipline? How does the teacher perceive her role? What may be her ideas about what "good mathematics teaching" is? What does she think about the students' role as learners?

THE STUDY

The framework of analysis described above was implemented by the VIDEO-LM team in several courses with in-service teachers. As described earlier, and in line with Sherin's review (2004), different video-based programs set different learning goals for discussions with teachers. Ours was a two-folded goal, strongly linked to two agendas that we found valuable. One is the need to promote teachers mathematical knowledge for teaching (MKT), as defined by Ball and colleagues (2008). The other is the important move from a judgmental or evaluative discourse about the mathematics teaching profession towards a reflective and more constructive discourse, as advocated for instance by Jaworski (1990). In this paper, we limit our focus to the first goal only. We report on an exploration conducted on a group of teachers, who experienced peer discussions using the VIDEO-LM framework. The research question was defined as follows:

— What may be the gains of video-based peer discussions around the VIDEO-LM framework, in terms of the teachers' MKT?

Design, data collection and data analysis

During 2013–2014, a group of teachers participated in VIDEO-LM workshops, as a pilot for a professional development program conducted later on with other groups. The group met once a month throughout the 2013 academic year, and continued to meet monthly, with some change in members, during 2014. Each session lasted about 4–5 hours, a total of 60 workshop hours. For every session we used one videotaped lesson (45 minutes on average) with various modes of watching implemented (e.g., watching together or in small groups, focusing on different components of the framework, watching the whole lesson uninterruptedly vs. breaking it to selected episodes). About half the lessons used were filmed in high track high school classes (grades 10–12), and the others were junior high school lessons (grades 7–9). Data collection means included field notes taken during workshops, video-documentations of all discussions, documentation of e-mail correspondences initiated by the teachers after some of the sessions, and questionnaires administered at the end of the course, focusing on the participants' views about the 6-componant framework used in workshops. The content analysis preformed on the collected data included (a) tracing all of the participants' utterances associated with MKT (i.e., unpacking mathematical concepts or relating to teaching these concepts); (b) grouping utterances into units of analysis that share similar ideas; (c) using the units to form "utterances maps" that convey the development of mathematical, meta-mathematical and pedagogical ideas throughout different parts of the sessions. This process is still ongoing; therefore the results reported herein are preliminary.

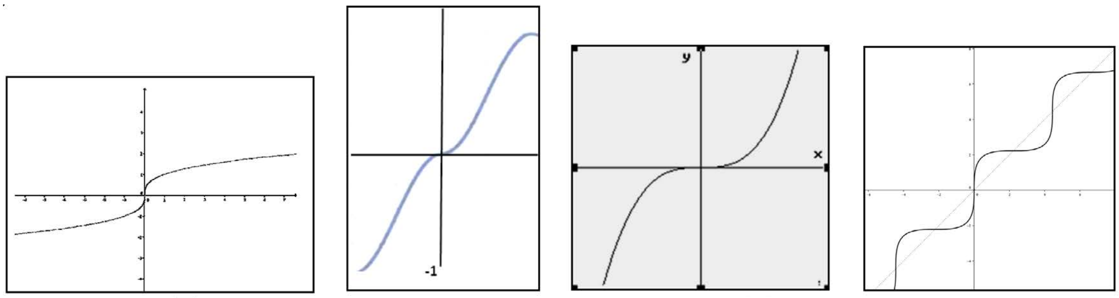
Subjects

The 2013 group comprised of 10 teachers, of which 7 continued to the second year in 2014, with 5 new members joining in. All participants were secondary school mathematics teachers with a teaching record of over ten years, and were well acquainted with the mathematics curriculum of grades 7–12. Nine of them were lead teachers, i.e., holding additional positions such as heads of mathematics departments in their schools, instructors, or principals. The group was diverse in terms of gender and sector (i.e., included religious and secular Jews, Israeli and Palestinian Arabs). None of the subjects had a prior significant experience with watching videotaped lessons.

Preliminary results

The data analysis revealed that discussions focused around the six components of the framework were rich in examples, insights and suggestions brought up by participants. The deep mathematical conversations during sessions and in subsequent e-mail correspondences, although not fully analyzed yet, point to the joint development of new mathematical knowledge for teaching, triggered by the videotaped lesson. We chose to present here two detailed examples, demonstrating processes of collective knowledge growth.

Example I: How do we define an inflection point? The videotaped lesson in this case was given in an 11th grade high track calculus class. The teacher explored with her students the concept of concavity of functions, leading to the definition of inflection points as points where the graph changes from concavity



$f(x)=\sqrt[3]{x}$ $\quad$ $f(x)=(\cos x-1)\cdot \operatorname{sgn}(x)$ $\quad$ $f(x)=x\cdot|x|$ $\quad$ $f(x)=\sin x$ ‘turned’ by 45°

Figure 1: Teachers’ generated examples

upwards to concavity downwards, or vice versa. This was then translated into a “working tool”, associating inflection points of $f(x)$ with the extreme points of $f'(x)$, or the zeros of $f''(x)$. Discussing the mathematical ideas introduced in this video, participants raised the following question: What about an inflection point where the first or the second derivatives do not exist? The group became motivated to find counterexamples where $f(x)$ has an inflection point in x_0 but $f'(x_0)$ or $f''(x_0)$ do not exist, and found a graphic example but not an algebraic representation of such a function. Following the session, in an intense and rich e-mail conversation, teachers found and shared different counter- examples, as described in Figure 1.

In all these examples, $f(x)$ has an inflection point in 0, but $f'(0)$ and/or $f''(0)$ do not exist. Furthermore, one teacher generalized that the product of *sgn(x)* and any even function in which $f'(0)=0$ and $f''(0)\neq 0$ would be a suitable counterexample (e.g., $g(x)=(\cos x-1)\times \operatorname{sgn}(x)$).

As a result, the group reached a consensus about the accuracy of definitions of inflection points that are customarily presented in advanced calculus classrooms. This new collectively generated MKT was explicitly articulated by one of the teachers, as follows: “I think that everything we have seen so far shows that the correct definition of an inflection point is a point where the second derivative changes its sign, that is, there is an opposite sign in the neighborhoods before and after the point. The ‘usual’ definitions are incorrect – (1) a point where the second derivative is zero, and (2) a point where the first derivative has an extremum”.

The process of knowledge development also included valuable pedagogical ideas offered by participants, such as the idea to have students find on their own counter- examples to the “rule” that identifies inflection points with $f''(x)=0$. Another component of the process evolved during the session, when the goals of the videotaped teacher were discussed. Participants attempted to justify the choice of the teacher to present an inaccurate working definition, by ascribing to her two major considerations: firstly, students may not be ready to grasp the correct definition, which requires advanced thinking, and secondly, left/right derivatives and functions such as $x\cdot|x|$ are not included in the curriculum and in the final exams. This part of the discussion opened a debate on a more general question, i.e., when is it legitimate to “sacrifice” mathematical accuracy for the sake of our students’ best interests?

Example II: Are the commutative and associative properties interdependant? In this case, the teachers watched an episode from a lesson on the commutative and associative laws, given in a 7th grade heterogeneous class. Prior to watching the video, they were asked to elicit any mathematical ideas that may be associated with this topic. They suggested a fairly wide range of ideas, from the simple fact that addition and multiplication satisfy both laws, while subtraction and division do not, through various models that demonstrate the laws, to efficient solutions of multi-term exercises using the laws. It appeared that most teachers perceived the topic as natural and intuitive for students, at least in the numerical level. Thus, the lion’s share of the discussion was dedicated to considering the general algebraic forms of these properties (e.g., $a+b=b+a$), and suggesting why and how they should be taught. Some teachers viewed the teaching of the algebraic generalizations as necessary for consolidating students’ intuitive knowledge, while others perceived it as a difficult goal to achieve in 7th grade.

In the video episode screened, the teacher asked the class whether operations that satisfy the commutative law necessarily satisfy the associative law as well, and vice versa. The students’ spontaneous collective

Verbal description:	**Operation #1:** The operation on a given pair of numbers returns the *first* number in the pair.	**Operation #2:** The operation on a given pair of numbers returns the *larger* number in the pair.	**Operation #3:** None
Operation Table presented:	$\begin{array}{|c|c|c|c|c|} \hline \triangle & 0 & 1 & 2 & 3 \\ \hline 0 & 0 & 0 & 0 & 0 \\ \hline 1 & 1 & 1 & 1 & 1 \\ \hline 2 & 2 & 2 & 2 & 2 \\ \hline 3 & 3 & 3 & 3 & 3 \\ \hline \end{array}$	None	$\begin{array}{|c|c|c|c|} \hline * & a & b & c \\ \hline a & a & a & b \\ \hline b & a & c & b \\ \hline c & b & b & a \\ \hline \end{array}$
Commutative law	✗	✓	✓
Associative law	✓	✓	✗

Figure 2: The operations discussed in the 'commutative and associative laws' episode

answer was "yes". The teacher then introduced three examples of mathematical operations (see Figure 2), and led a discussion about which property exists in each example, resulting in the conclusion that the properties are not interdependent.

Each pair of teachers was requested to focus, while watching the episode, on one of the components of the analysis framework. Then, in the plenary, findings were described by the teams and discussed by all participants. According to our goal, we focus herein on the mathematical ideas which were elicited and discussed. It should be noted, however, that these ideas were triggered not only by the first component ('mathematical and meta-mathematical ideas'), but also when discussing the videotaped teacher's goals, choice of tasks, interactions with students and beliefs.

On the whole, teachers were surprised by the episode, since the main mathematical idea they have noticed was not included in the span of ideas constructed by the group earlier: they described it as "undermining the perception that an operation can either satisfy both the associative and commutative laws, or none of them". The teachers used representations from set theory to express this idea (see Figure 3), noting that addition and multiplication are in the intersection of the commutative operations and the associative operations sets, while subtraction and division are in the complement of the union of these sets. While students might hold the misconception that the other possible two sets are empty, the lesson demonstrates that operations exist in all possible sets.

A major discussion evolved around the use of operation tables to exemplify operations that satisfy only one of the two properties. Some teachers asserted that operations on small finite groups are not equivalent, both mathematically and pedagogically, to operations defined on the real numbers. The discussion facilitator asked the teachers to consider the advantages and disadvantages of the teacher's choice of operations. The advantages offered by participants were that (a) these examples clearly serve the teacher's apparent goal – challenging what students erroneously perceive as obvious; (b) the process of considering these operations and checking which properties they hold may contribute to the development of critical thinking, which is another goal that can be ascribed to the teacher; (c) using such examples conveys that operations

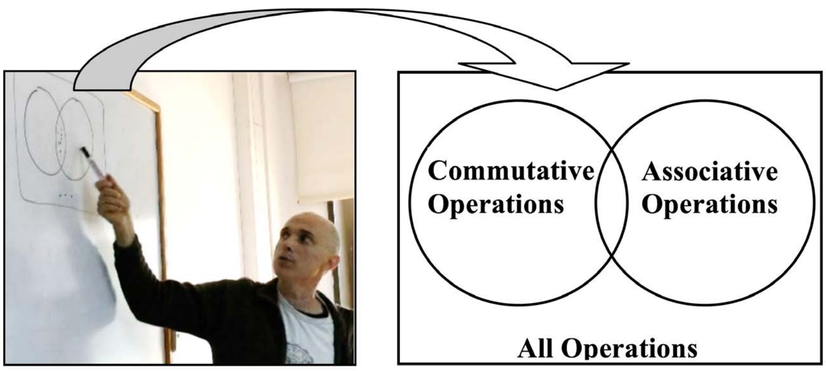


Figure 3: A teacher presenting the mathematical idea of the episode using set theory

can appear in different contexts, for example, real numbers, finite groups, or height of students (which was one way the teacher used to illustrate operation #2), and furthermore, demonstrate that operations can be defined for one's needs. On the other hand, the disadvantages mentioned concerned the same fact that the operations were "made up", i.e., somewhat artificial, and in 2 of the 3 examples were defined only on 3–4 objects. This was viewed by some teachers as limiting, irrelevant to the students' prior or subsequent knowledge and therefore unconvincing; they opined it was problematic to generalize from these examples that the laws are not interdependent. Thus, the teachers were challenged to find an operation, defined on the real numbers and relevant to students' school learning, for which only one of the properties holds. They have eventually found such examples: $a \square b = (a+b)^n$, $a \square b = \sin(a+b)$ and $a \square b = |a+b|$. In all these cases the operation satisfies the commutative law but not the associative law.

CONCLUDING WORDS

The instructional practice for using video with teachers is still underdeveloped (Ball, 2014). Despite a notable progress in this field, essential questions such as how to design and facilitate effective discussions need further exploration (Coles, 2013). This paper reports on a pilot work that may contribute to the development of such practice, by using a unique framework of analysis in video-based teacher discussions. The framework is deeply rooted in the subject matter of mathematics, thus discussions are perceived, alongside their role as promoters of reflective skills, as opportunities to deepen mathematical knowledge. The collaborative discussions support teachers' attempts to unpack the practice observed on the screen, through the implementation of mechanisms such as ascribing goals and weighing alternatives. The two examples presented clearly demonstrate the potential contribution of such video-based discussions to the evolution of a rich and multifaceted mathematical knowledge for teaching. We hope that the continuation of our studies, exploring teachers' use of this framework, will amplify the understanding about the nature and impact of this process.

Pre-service mathematics teachers' scaffolding practices

Hulya Kilic

Yeditepe University, İstanbul, Turkey, kilichul@yahoo.com

The aim of this study was to investigate pre-service mathematics teachers' scaffolding practices occurred during one-to-one interactions with students. Seven pre-service teachers worked with a pair of sixth grade students for 12 weeks. Their interactions with students were videotaped and they were used the main data source for the analysis. Their interactions with students were analysed according to Anghileri's (2006) scaffolding practices framework. The findings revealed that the pre-service teachers' scaffolding practices were mostly based on reviewing what students did by using prompting and probing type of questions and asking for explanation and justification.

Keywords: Scaffolding, pre-service teachers, mathematics, one-to-one interactions.

INTRODUCTION

Student-centered teaching strategies are accepted to be an effective way of enhancing students' understanding and learning by constructivist theorists (Moore, 2009). In a constructivist teaching environment, teachers scaffold students' learning by arranging classroom settings, supplying appropriate materials, giving meaningful tasks or using effective questioning (Anghileri, 2006; Bliss, Askew, & Macrae, 1996; Hobsbaum, Peters, & Sylva, 1996; Wood, Bruner, & Ross, 1976). The effectiveness of such scaffolding practices depends on how effectively the teacher leads the student-teacher interactions for the sake of students' learning. To promote students' understanding, teachers should encourage students to explore, think and practice rather than simply telling and explaining (McCosker & Diezmann, 2009). As teachers gain experiences in teaching, specifically if they know how students learn, what is difficult or confusing for them and what misconceptions they have, better they begin to manage scaffolding practices (Goos, 2004).

For effective teaching, teachers should know how to teach the given topic to the particular group of students by using appropriate strategies, examples and representations, in other words, they should possess strong pedagogical content knowledge (PCK) (An, Kulm, & Wu, 2004; Ball, Thames, & Phelps, 2008; Shulman, 1986). An and colleagues (2004) defined knowledge of students' thinking is one of the components of PCK such that teachers should build on students' mathematical ideas, address to their misconceptions, engage them in mathematics learning and promote their mathematical thinking. Because scaffolding practices entails direct interactions with students aiming to contribute their understanding and learning, those practices are naturally counted as the signs of teachers' PCK (Appleton, 2008; Rosiek, 2003). In other words, teachers' scaffolding practices reflect their PCK. Furthermore, because the mission of teacher training programs is to prepare pre-service teachers (PSTs) to the profession, they should enable PSTs to begin to build up their PCK through experiences. Therefore, in order to contribute to the development of PSTs' PCK in a teacher training program, they might be given opportunities to experience some scaffolding practices with a small or large group of students and then reflect on their practices.

The aim of this study was to investigate how one-to-one interactions with a pair of students contribute to PSTs' PCK, in particular, their knowledge about how students think and how to scaffold students' understanding and learning. However, in this paper, PSTs' scaffolding practices occurred in three of twelve interactions are discussed in terms of the frequency of using those particular practices because overall analysis of data has not been completed yet.

THEORETICAL FRAMEWORK

Since the constructivist learning theory is the essence of many reformed school curricula and teaching practices, there are more studies on how to train PSTs to address the requirements of such reforms and practices. Although recent studies revealed that PSTs are lack of PCK (e.g., Morris, Hiebert, & Spitzer, 2009), engaging in one-to-one interactions with students aiming to understand their mathematical thinking or analysing videos of such interactions with the same purpose contributes to PSTs' PCK (e.g., Llinares & Valls, 2010; Stockero, 2008). During the interactions with students, PSTs need to provide necessary scaffolding through guidance and effective questioning. There are different scaffolding practices varying in terms of the effectiveness of students' conceptual understanding and learning. Anghileri (2006) defined 3 hierarchical levels of scaffolding practices to enhance mathematical learning (see Anghileri, 2006 for details). In this paper, her classification of scaffolding practices will be used to analyse PSTs' interactions with students.

Anghileri (2006) named the first level of scaffolding practices as *environmental provisions* such that teacher organize the classroom, provide necessary artefacts (manipulatives, tools) and tasks and follow a sequence during the instruction to help students understand the subject matter. At this level student-teacher interaction is not so direct with respect to the other levels. The second level is *explaining, reviewing and restructuring* and it involves direct student-teacher interactions. Explaining involves *showing and telling* and *teacher explaining* where the teacher has the control of the interaction. Reviewing involves five types of interactions: "1) getting students to *look, touch and verbalise* what they see and think, 2) getting students to *explain and justify*, 3) *interpreting students' actions* and talk, 4) using *prompting and probing questions*, and 5) *parallel modelling*" (p. 41). In the first type, the teacher encourages students to tell what they did, repeat the instructions or use manipulatives and reflect on what they observe. In the second type, the teacher asks students to explain their ideas by providing their reasoning so that the teacher gets opportunity to understand students' thinking and catch possible gaps in their reasoning. In the third type, the teacher attempts to make students' actions explicit for other students as well as for that particular student. In the fourth type, either the teacher directs the students to the predetermined solution or the solution in her mind through prompting questions or she attempts to encourage students to think deeply through probing questions. In the last type, the teacher provides a task similar to the one that the students have difficulty to understand and then she solves it. Anghileri (2006) defined four interactions for Restructuring: "1) provision of *meaningful contexts* to abstract situations, 2) *simplifying the problem* by constraining and limiting the degrees of freedom, 3) *rephrasing students' talk*, and 4) *negotiating meanings*" (p. 43). In the first type, the teacher provides real life problems for abstract calculations to help students to understand the meaning of the calculations. In the second type, the teacher gives a simpler problem or decreases the complexity of the problem to make it understandable for the students. In the third type, as different from *interpreting students' actions and talk*, the teacher provides appropriate terminology and encourages students to use appropriate mathematical language. In the fourth type, the teacher attempts to understand whether students have some misunderstandings or they are able to derive correct meanings from the interaction. The third level of scaffolding practices identified by Anghileri (2006) is *developing conceptual thinking*. She described those practices as to be "teaching interactions that explicitly addresses developing conceptual thinking by creating opportunities to reveal understandings to pupils and teachers together" (p. 47). She defined three types of such practices: 1) *making connections*, 2) *developing representational tools*, and 3) *generating conceptual discourse*. Making connections refers to showing how mathematical concepts are related to each other and encouraging students to use those relationships when necessary. In the second type, the teacher uses various representations (symbolic, numeric, graphical, etc.) to promote students understanding and facilitate making meaningful connections. In the third type, the teacher initiates a discussion to revise what have been said so far and what the students get from it eventually.

METHODOLOGY

Sample

Seven female pre-service mathematics teachers and 14 sixth-grade students participated in this study. Two of the PSTs were junior students and the rest were seniors. The PSTs voluntarily participated in the study. The sixth grade students were from the middle school that Faculty of Education had a *university-school col-*

laboration agreement. Those students were determined by their own mathematics teachers amongst the students who volunteered to participate in. The teachers informed us that it was a heterogeneous group in terms of mathematical achievement. The PSTs were randomly matched with a pair of students and they worked with those students during the whole semester.

Data collection

In this study, data was collected through the videos of interactions of PSTs with a pair of students, videos of group discussions before and after the intervention sessions, and PSTs' written reflections about the sessions. The data was collected for 14 weeks of 2014 spring semester but the PSTs worked with students for 12 weeks because the first week was used to introduce the aim of the study and the expectations from the PSTs and the last week was used for PSTs' evaluative feedbacks about the study.

At the beginning of the study, PSTs were told about how to scaffold students' understanding and learning by referring to the related literature (e.g., Anghileri, 2006; Moyer & Milewicz, 2002). They were given examples (in the form of video clips and vignettes) of what to notice during the interactions, how to use effective questioning and how to use representations and manipulatives to enhance students' mathematical thinking and understanding. As they worked with the students, some episodes were selected from their own interactions as an example to discuss in the following weeks.

The researcher prepared the tasks that PSTs would work with students. Those tasks were aligned the sixth grade math curriculum and they involved the topics that had already been covered in the school. The PSTs were asked to work on the task before the pre-group discussion. Each week the researcher and the PSTs discussed the tasks in terms of the expected students' performance. PSTs shared their ideas about possible misconceptions and misunderstandings and how to eliminate them. In some cases they suggested to make some revisions on the tasks and the revised versions were used during the intervention sessions. After 10 weeks, the PSTs were asked to prepare and implement two tasks for their own groups and give a rationale for preparing those tasks.

The intervention sessions took place in a classroom provided by the middle school administration. During the intervention sessions, the students firstly worked on the given tasks individually for 10–12 minutes and then they discussed their answers with each other for 5–10 minutes. During this period, the PSTs did not interact with the students, they just observed and videotaped what students did or said. Then she began to interact with them by asking what they did and why they did so. At the end of each intervention session, whole class discussion was carried out by the researcher to summarize the solutions of the given tasks. After then, the PSTs came back to the Faculty of Education which is located 10-minutes apart from the middle school to discuss how the session went. In this post-group discussion the PSTs talked about whether the students performed in a way that they expected, whether they were able to address students' difficulties or misconceptions effectively, whether that particular difficulty or misconception was common for the majority of the students. Then the PSTs were asked to watch their own intervention videos and write about what happened during the sessions, what they noticed, what questions they asked, etc. In the following week, the researcher gave feedbacks to the PSTs at the beginning of the pre-group discussion after reading their reflections and watching their videos. This procedure was followed for 12 weeks.

Data analysis

The videos of each intervention session of each PST and all written reflections will be analysed to understand how the setting of this study contributed to PSTs' PCK. However, the data analysis has not been completed yet. In this paper, three of intervention sessions were selected and analysed according to Anghileri's (2006) scaffolding practices framework. Three intervention sessions were determined according to the date of occurrence in order to discuss whether the type of scaffolding practices changed over time or not. Therefore, the videos of the third, the sixth and the tenth week were analysed. Each session was analysed in terms of whether the PST used that particular scaffolding practice or not. This analysis did not involve the evaluation of whether they used them effectively or whether it eventually helped students' understanding. Two researchers watched the videos together and determined what scaffolding practices occurred during the interactions. Therefore, the coding according to the framework based on the full agreement of the raters.

FINDINGS

The third, the sixth and the tenth weeks were selected for the analysis of PSTs' scaffolding practices. All scaffolding practices were coded at Level 2. None of them was at Level 1 or Level 3.

In the third week, the task was about divisibility rules. There were two questions in the task such that in the first question the students were asked to construct the smallest or the largest number that is divisible by 3, 4 or 6 by using the given digits. In the second question they were asked to figure out divisibility rule for 15 by filling out the given table. As shown in Table 1, PSTs mostly used *prompting and probing*, *looking, touching and verbalizing* and *students' explaining and justifying* type of scaffolding practices.

In the third week, the majority of the PSTs began discussion by asking to tell what the students did (*verbalisation*). They usually asked for *justification* of students' answers such as "Why do you think that 96 is the largest number that is divisible by 3?" Some of them used *prompting questions* to help students figure out the divisibility rule for 15. For instance, they said "Look at the numbers divisible by 15. Are there any other common numbers that they are divisible by?" Thus, the students were able to notice that those particular numbers were divisible by 3 and 5 at the same time. In some cases to make sure that students understood the divisibility rules, they repeatedly asked for them. For instance, after asking why 96 is divisible by 3 in the first item, they asked how 45 is divisible by 3 or why 80 is not divisible by 3 in the following items (*probing*).

In the sixth week, the task was about equations, inequalities and solving simple equations. There were three questions in the task such that in the first question the students were asked to determine the heaviest or the lightest object by looking at the given system of pan balances. In the second question, they were asked to figure out what to put on the left side of the pan balance by using the relationships in given two other balances. In the third question, they were given a system of balances involving different solids and asked to determine the height of each. As shown in Table 2, again PSTs mostly used prompting and probing, looking, touching and verbalizing and students' explaining and justifying type of scaffolding practices. The majority of the PSTs preferred to begin the interaction by asking what the students did. After listening to their answers if they did something wrong they

	Explaining		Reviewing					Restructuring

Table 2: The frequency of PSTs' scaffolding practices during the sixth week

either encouraged them to *explain their reasoning* or asked *probing questions* to make them realize their mistakes. For instance, PST_F's one of the students thought that if three cubes are in balance with one sphere in a pan balance then the cube is heavier than the sphere. When she asked him to explain his reasoning he said that the amount of cubes is more than the amount of the sphere. Then she said that "numerically 3 is greater than 1 but what characteristics of the objects you need to pay attention when comparing them in a pan balance? That is, when they are in balance... The amount of the objects?" He thought for a while and told that he needs to compare the weight because there is inverse relation between the amount and the weight. That is, if there are more cubes than spheres it means that single cube is not enough to hold one sphere, that is, it is lighter.

In the tenth week, the task was about fractions. There were two questions in the task such that in the first question the students were asked to share the given amount fairly among the given number of people. In the second question, they were expected to solve a problem involving two-step partitioning. As shown in Table 3, PSTs mostly used looking, touching and verbalizing and prompting and probing type of scaffolding practices.

In this task, the PSTs asked students to represent the problems by using fraction tiles (*looking and touching*). Because most of the students failed to solve the problems correctly, such manipulatives helped them to understand their mistakes. Then, the PSTs helped students to find the answers by asking *prompting and probing* questions. For instance, some students thought that when they share 3 sandwiches among 6 kids, each gets 1/6 of the sandwich because when they divide each sandwich into two, they get 6 pieces totally and each kid gets one of the pieces. The PSTs asked students what 1/6 represents as a fraction and what the "whole" is in the given problem. The students realized that one sandwich is the "whole" and each kid is getting the half of a sandwich. That is, each kid is getting one of the six pieces but each piece is half of a sandwich.

DISCUSSION

The findings revealed that the PSTs' scaffolding practices were at Level 2 according to Anghileri's framework. Other studies also support this finding (e.g.,

	Explaining		Reviewing					Restructuring				
	Showing and telling	Teacher explaining	Looking, touching and verbalizing	Prompting and probing	Students' explaining and justifying	Interpreting students' actions and talk	Parallel modelling	Providing meaningful context	Rephrasing students' talk	Negotiating meanings	Simplifying the problem	**Total**
PST_A	0	1	2	1	1	2	0	0	1	1	0	**9**
PST_B	0	1	2	2	1	1	0	0	1	0	0	**8**
PST_C	0	1	1	2	1	1	0	0	0	1	0	**7**

PST_F	0	2	2	2	0	1	0	0	0	0	0	**7**
PST_G	0	1	2	1	0	1	0	0	0	1	0	**6**
Total	**1**	**7**	**13**	**12**	**7**	**7**	**0**	**0**	**3**	**3**	**0**	

Table 3: The frequency of PSTs' scaffolding practices during the tenth week

Kaldrimidou, Sakonidis, & Tzekaki, 2011). Probably because the setting was not an actual classroom environment and the PSTs worked with just a pair of students, many of the scaffolding practices at Level 1 (*environmental provisions*) were not observed. However, the setting allows the usage of Level 3 scaffolding practices but none was observed in those three weeks.

A similar pattern in terms of the frequency of scaffolding practices was observed in those three weeks. The PSTs mostly used *reviewing* type of practices. The *parallel modelling* and *simplifying the problem* practices were not observed in any of three weeks. Because the PSTs were told not "to teach" but "to help" students, they might avoid using modelling practice to support their learning. Furthermore, because the tasks were clear and simple for the sixth grade students, they might not need to simplify the problems.

Having similar pattern in scaffolding practices was not surprising because the PSTs were encouraged to try to understand students' mathematics and their thinking. Therefore, they mostly used prompting and probing questions and asked for students' explanations and justifications. Although the discussion of how effectively they used those questions is not the scope of this paper, such questioning seemingly contributed to their PCK in terms of knowledge of students and teaching strategies as noted in the studies of other scholars (e.g., Llinares & Valls, 2010; Stockero, 2008). For instance, as time passed, the PSTs began to estimate the students' performances more accurately. Before the implementation of the task in the tenth week, some of the PSTs claimed that their students would answer the sharing question as 1/6 because they would count the pieces rather than using the definition of fraction and those students did so. However, a further analysis needs to be done to claim how this setting helped the development of PSTs' PCK.

Although it is expected that PSTs would use higher level of scaffolding practices over time, it was not the case for those three weeks. For each session the PSTs inclined to explain some facts, review the discussed concepts or tell what to do. The PSTs mostly used *teacher explanation* towards to the end of the sessions. The reasoning behind this might be to make sure that everything is clear in students' mind and there are no misunderstandings. The PSTs used *showing and telling* when they realized that the students' did not possess/remember prior knowledge to solve the given problems. When the students did not remember the mathematical concepts involve in the tasks, they did not do anything with the task. This "showing and telling" practice commonly occurs whenever the teacher notice that the students are not able to engage in task because of lack of knowledge (Kim & Hannafin, 2011; Stylianides & Stylianides, 2011). Therefore, this tendency of PSTs is understandable.

Advice and guidance for students enrolled in teaching mathematics at primary level

Nicole Koppitz and Christof Schreiber

Justus Liebig University Gießen, Gießen, Germany, nicole.koppitz@math.uni-giessen.de

In the winter semester 2013/14, the department of Mathematics Education at the Justus Liebig University of Gießen launched a two-year-project offering assistance to students aspiring to become primary school teachers. The aim is to identify and rectify deficits pertaining to core mathematics. Moreover, the objective is to develop a positive attitude towards mathematics. This project applies to all but particularly to students, who have a weak mathematical foundation and require a boost in motivation. Data from the student's initial standard is used to develop practical modules such as tutorials, reflections, learning portfolios, consultations as well as systems that help manage individual learning.

Keywords: MKT, primary school preservice teacher education, reflection, learning opportunities, education support programme.

INTRODUCTION

Various studies have shown that a teacher's mathematical foundation plays a key role in good teaching (Döhrmann, Blömeke, & Kaiser 2010). As such, the German state of Hesse has made German and mathematics mandatory subjects for teacher-students, who are studying to become primary school teachers (Grade 1 to 6). Hence, passing these two subjects is a prerequisite to becoming a primary school teacher. Our investigation is about the skills, beliefs, self-concepts and motivations of teacher-students in the first year of their studies. In this paper, we focus solely on the students' skills and the various support-offers for students.

According to our surveys, only about half of the students, who enrolled into the course of becoming a primary teacher, would have opted to study mathematics by choice (see Table 1). The study groups have heterogeneous motivation and foundation levels. Among students who pass mathematics with ease, there are also struggling students that attend math lectures. Therefore, weaker students need to overcome their deficits. Fears, which may have developed and accumulated over time, are also covered in this project. If the deficits in math are not eliminated, the path of becoming a primary teacher cannot continue despite the level of motivation or performance in German and their third subject of choice. Should this be the case, students would be forced to change to secondary teaching or transfer to a university located in another state of Germany.

PROJECT IDEA

Due to the pressing issue mentioned above, the department of Mathematics Education of the Justus Liebig University of Gießen has launched a two-year-long project since the winter semester 2013/14. The aim of this project is to identify potential deficits of students' with regard to their skills, problems, attitude as well as their self-concepts pertaining to mathematics. Thereupon, supportive arrangements should be developed and evaluated.

All students, including those with weak mathematical foundations and low motivational drive, are supported throughout their course of study. In an attempt to overcome learning difficulties, students learn to reflect and develop a positive attitude towards mathematics through consultation sessions and additional training programmes provided by the department. This is done based on retrieved data from the analyses of the students. The level of math expertise and motivation as well as self-concepts of one's own abilities are to be inquired. In addition, the attitude towards mathematics needs to be identified. The results from these steps are used to customise consultations and training programmes for students in need of assistance.

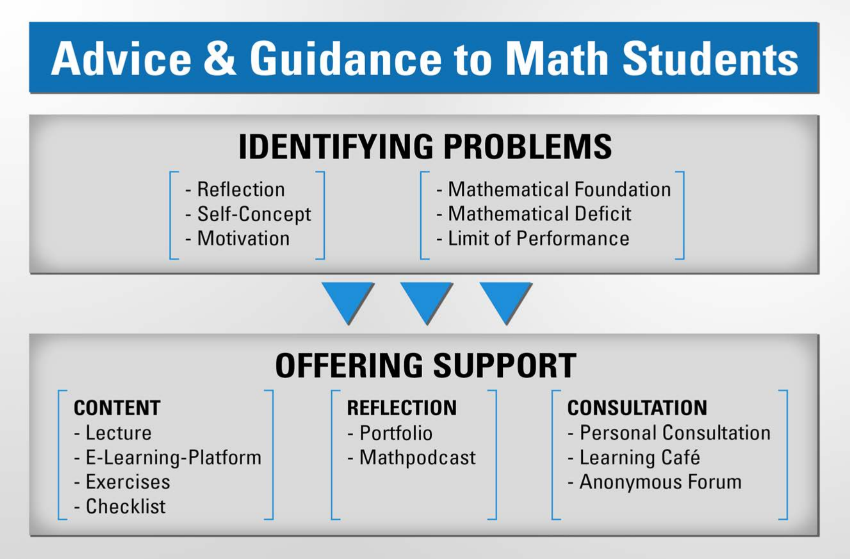

Figure 1: An overview of the project idea

INVESTIGATION

This investigation focuses on primary school teacher-students, who are in their first two semesters of academic study and may experience a drastic change: changing from school to university life. They are now confronted with having to be responsible for their own attendance of lectures and tutorials. Their whole academic study period is made of 7 semesters (3 ½ years) including a semester of examination. It has a total of 180 credit-points (ECTS). In the department of Mathematics Education they have to earn 26 or 38 credit-points, depending on whether they choose to do an internship for German or mathematics. The lecture, pertaining to this project, deals with 'subject matter knowledge' (Ball, Thames, & Phelps, 2008), together with the tutorials constitutes of about 330 hours of work, which are equivalent to 11 credit-points (ECTS). The module consists of two main lectures that run over two semesters and are accompanied by tutorials. A final exam will round up the second semester. The lecture's content covers in particular the basics of arithmetic, stochastic and geometry. Around 190 students attend the first academic year. In the first year, the dropout rate, usually before the second semester's final exam, is about 10%. We gathered data of all these students in order to get a good overview about their skills, their motivation and their beliefs. In future, we hope to continue to evaluate individual students to investigate different cases in greater detail.

At the beginning of their first semester, students completed a mathematical proficiency test and filled out a questionnaire anonymously with regard to their personal attitude towards mathematics (Grigutsch, Raatz, & Törner, 1998), their self-concepts (Dickhäuser, Schöne, Spinath, & Stiensmeier-Pelster, 2000) and level of motivation (Brandstätter, Schüler, Puca, & Lozo, 2013) towards their tertiary studies. The mathematical problems that had to be solved in the test were mostly from junior high school. The math problems were selected according to their mathematical relevance at university level, so as to identify the student's mathematical knowledge boundaries. These results are explicitly of a pilot-study and they are still preliminary in nature. Therefore, we will only describe observed trends and provide a few examples from the tests of October 2014 in the following (n=155):

Pertaining to individual personal assessment, we observed that a majority of students started their studies with overall low levels of motivation. Only about 32% of the students have indicated to be of the opinion that they are good enough to meet the demands of their mathematics course. However, 93% of them believe that they will become great math teachers.

Item	Strongly Agree (%)	Agree (%)	Agree Less (%)	Disagree (%)	No Decla-ration (%)
Having been given the freedom of choosing a subject, I chose mathematics.	18	31	15	33	3

Table 1: Choosing Mathematics freely

Item	Strongly Agree (%)	Agree (%)	Agree Less (%)	Disagree (%)	No Decla-ration (%)
I believe I can meet the demands of the subject mathematics.	32	38	23	7	0
I believe that I can be a good mathematics teachers.	18	75	6	0	1

Table 2: Excerpt of the questionnaire concerning students' self-concepts

We have to consider that these results are based on the students' self-assessments. 70% of the students feel, that they are able to study the math they need for becoming a primary school teacher. Interestingly, the percentage of students who believe they already have the required knowledge, does not match the results of the mathematical proficiency test.

The evaluation of the mathematical proficiency test shows that 80–95% of the students were able to solve questions of the German 'Abitur' (general qualification for university entrance) standard. In particular, applying Pythagoras theorem and mathematical equations. Moreover, commonly used units such as length or currency were converted correctly with ease.

The following results show that one third or even half of the math students cannot apply their knowledge learnt in school. This correlates with our assumption that there is a need to provide support options for the weaker students. Thus, these problem areas are indeed important and relevant to the educational path of studying to become a primary school teacher.

In the following year, we will try to achieve a greater participation of students for the questionnaire, so as to optimise the foundation of our support options. Furthermore, we will evaluate the initial approaches that started in the first year of the project in the following paragraphs.

After having gathered the data mentioned above, we have chosen a broad sample of students to be interviewed. The interviews adopted the problem-centred approach by Witzel (2000). Each student is interviewed 4–5 times. It should be noted, that the focus lies not on the interviews nor on the questionnaires, but rather on the upcoming project approaches.

PROJECT APPROACH

As the project launched in the winter semester 2013/14, only a few approaches to address the identified deficits could be outlined. We have conducted another inquiry, although still ongoing, dealing with the initial circumstances that the students begin their studies with. By the means of this data, measures are customised to fit the needs of the students. The measures, which have already been implemented and those that have yet to be, will be described in the following. We have to consider, that it is an alternating iterative process: There are existing measures and some that have yet to be implemented, but the problems are not yet sufficiently identified in detail. At the same time we have to support the student's learning, we have to identify problems, prevent them from occurring and evaluate measures.

Exercises

Besides lectures, exercises play the most important role in learning. Students may even feel that exercises

Item	Tested skills	Answered Correctly (%)	Answered Wrongly (%)	No Attempt (%)
Solve the following problem: 9475:25=	Basic Arithmetic Operations	65	27	8
In a square, draw all the axes of symmetry.	Concepts of Plane Figures, Symmetry	76	16	8
In a parallelogram, draw all the axes of symmetry.	Concepts of Plane Figures, Symmetry	48	44	8
How many results can be produced by rolling a dice four times consecutively.	Combinatorics, Concepts of Multiplication	47	36	17

Table 3: Examples of the mathematical part of the questionnaire

go before lectures. As the feeling is mutual, this paper will focus on the importance of exercises. As the project began upon the commencement of the winter semester lectures, the already prepared math exercises received only minor adjustments. Just like in previous semesters, students were assigned exercises to deepen their understanding of the lecture content. These exercises were discussed in weekly tutorials lead by students of higher semesters, supervised by a research associate. The exercises can be categorised into five types, namely arithmetic problems, application questions, problem solving and modelling tasks as well as justifying mathematical concepts.

In the following semester, the exercises will be restructured to take the form of "productive practicing" (Leuders, 2014). The exercises should help sustain knowledge and be retrievable at any given point in time. During these exercises, automated calculations should be prevented, as they tend to be forgotten easily. Nevertheless, it is important to strengthen and link mathematical understanding to arithmetic technique. In each series of exercises, the following competences should be covered: 'Securing factual content', 'automation of skills', 'broadening and deepening of perception', 'reflection of concepts and their application', 'applying knowledge pertaining to problem-solving' as well as 'creating an appropriate impression of mathematics' (Leuders, 2014, p. 253; translation by the authors). As such, the homework of the following semester will comprise of three parts:

- The first part deals with tasks in which students are taught to solve problems on a syntax level. This skill should be integrated into structure and problem-solving tasks. Either a structure is investigated to practice applying skills or simple forms of problem-solving tasks can be used. As each student approaches the task on his own terms, they develop a personal heuristic to solving problems using the given arithmetic rules. The tasks remain at a standard that allows students to check if they have understood their calculation method and the arithmetic rules used. Two days before the tutorial, students receive a suggestion sheet providing a solving method for the task. If necessary, the students can receive help using the online-forum or bring their query to the tutorials.

- The second part covers mathematical problems that are in line with the competences mentioned above. These tasks should meet the demands of the math lecture. The students are given one week to solve the problems. These problems aim to teach the students mathematical understanding, justification, problem-solving and derivational skills. After the given week, the suggested answers are only handed out if they have been compared and discussed within the tutorial. The tutorials actively incorporate the student's input and provide a platform for communication to take place.

- The third part occurs during the tutorials, where math problems are done in class. These tasks can cover various types of the targeted competences. Due to the broad spectrum of lecture topics available, various types of questions can be chosen for discussion in the tutorial. Moreover, mathematical topics can be explored and nurture comprehension by using the resources provided by the Math Learning Lab to create practical situations.

Personal consultation

After the mathematical proficiency test had been evaluated in the first part of the project, students were given the opportunity to seek advice and support through consultation sessions. Consultations were visited on a voluntarily basis, in light of having to remove a student's anonymity in order to discuss his test results.

First, the students were asked about their own expectations. The idea was to observe if the students were able to assess themselves and reflect on their performance. Thereafter, the students received feedback pertaining to the test. Having identified their strengths and weaknesses, they were given advice on what topics to focus and brush up on. These suggestions were supposed to help the students to cope with the expectations of the syllabus. If deemed necessary, a follow-up consultation could be arranged to discuss topics of the first session in greater depth.

As the project continues, we plan on implementing consultation sessions addressing topics beyond the proficiency test, so that students are able to receive advice and support anytime. In order to make these consultation sessions more sustainable in the long run, consultation sheets have been introduced to secure results and progress as well as to give students a way to prepare for the sessions (Macke, Hanke, & Viehmann, 2012).

E-learning platform

The University provided an online learning platform called 'Ilias' for the students. Based on this platform we provide tasks, which enable students to practice additional math problems at their own time, while being able to instantly monitor their learning progress. The following types of math problems were incorporated into this system.

- Some problems merely recapped mathematics of secondary education. Algebra, geometry, arithmetic and stochastic theory make up the foundation and prerequisites of studying mathematics at tertiary level.
- The majority of problems were similar to the above-described homework. The tasks are derived from lecture content and serve as additional practice. These tasks are especially relevant for the examination at the end of the lecture-period.
- Some tasks go beyond basics and covered lecture content. This is done, so that students receive a broader spectrum of topics and greater understanding through exploring other topics on their own.

In future, more features will be added to this platform in order to break down complex lecture topics and to be able to tackle them with a variety of methods. For example, relevant Internet links and teaching videos can be useful for post-preparation of lecture content. In addition, the learning platform is undergoing developments to enable the upload of mock exams for additional exam preparation. As a result, students receive a first glance and what might face them during an exam.

Portfolio

Different forms of e-Portfolios used in teacher education are described by Vogel and Schneider (2012). Our paper exclusively refers to a 'reflection-portfolio' (Vogel & Schneider, 2012, p. 136, translation by the authors). Nearly every exercise worksheet has questions incorporated that trigger self-reflection. These are supposed to be worked on individually and filed, so that each student has a portfolio that documents their learning progress over the first year of their studies. Up to now, the students were required to reflect on the following:

- Personal experiences of primary and secondary school
- Their opinion of certain lecture topics being relevant for teaching in primary school
- The importance of mathematics and certain lecture topics to society
- Their factors which motivate them to become a teacher

At the end of the summer semester 2014, the portfolios were collected, looked through and given feedback by the lecturers. On one hand, the portfolios shed light on personal attitudes and each learning progress. On the other hand, they revealed that several students did not take the reflections seriously as they were written rather superficially. Bräuer (2014) experienced the same scenario and demonstrates how students could be supported.

Hence, the next round of portfolios will be integrated into the platform's server. The lecturers can not only monitor entries and strategically upload additional exercises and revision material but also address problems and difficulties in the lecture itself once voiced out in the reflections. If necessary, the lecturer can also leave comments immediately and encourage the student to reflect deeper (Bräuer, 2014). The portfolios can also serve as personal learning diaries or be published on a blog to help others too.

Anonymous forum

From the winter semester 2014/15 onwards, students have the opportunity to post questions onto a second forum. Previously, students had the tendency of asking questions directly to their tutors via email. Thus, interactive discussions on the forum were non-existent and there was no need for other kinds of support. Furthermore, many questions were asked repeatedly. It was not clear if they were general problems or isolated incidents. We assumed that the reason students had refrained from using the non-anonymous forum was due to the fear of humiliating themselves when posting their question. Therefore, the anonymous forum aims to promote the asking of questions through the means of an open and safe platform. As the students are generally familiar with the social-media platform 'Facebook', Kempen (2014) refers to it as an appropriate tool for exchanges between the students. We however, chose 'Ilias' (s. above), an e-learning platform that is more secure and ensures more privacy.

Learning Café

Students can come to the Learning Café located at the institute's Math Learning Lab. They will be given a room in which they can meet to discuss math problems. Additionally, a staff member of the lecture will be present to provide answers to questions students might have. Some math concepts can be visualized through the ready-available resources found in the Math Learning Lab. Over time, study groups may develop, as the Learning Café serves as a conducive meeting point. Students can create "learning communities" (Gunnarsdottir & Palsdottir, 2013, p. 3085) to acquire and develop a professional jargon as well as collaborative competences. This suits reserved students, who may now have the courage to clarify concepts with lecturers, tutors or even students directly. A similar project is described by Zimmermann (2012), in which though, these opportunities are offered on a daily basis and for students of different ages.

MathPodcast

Students can volunteer to participate in a podcast project that runs alongside the lectures. Audio podcasts are created within small groups. They are based on math lectures and trigger students to reflect on mathematical content and their standard of math skills. They need to explain a lecture topic verbally without the use of gestures or other materials. The podcast production starts with the recording of a spontaneous attempt of trying to explain the topic using basic knowledge. This recording will then be fine-tuned through collective research. Thereafter, a script will be designed which will be used to create a podcast ready to publish (Schreiber, 2013). This process is suitable to allow students to reflect on a particular math topic. Tutors will accompany the podcast productions throughout, while the students will receive feedback on their correct and wrong understanding of concepts (Klose, Tebaartz, Schreiber, & Lengnink, 2014).

FURTHER PROSPECTS

In the second part of the project it is important to get data of all the students, not only of 110 out of 160 like we did this semester. The E-Learning-Platform will be available once the lecture-period begins. As such, the students can benefit from its content throughout the semester and we receive access to evaluate the platform's success. Furthermore, the Learning Café and tutorials will be offered from the first week onwards throughout the lecture-period. Hence, we can evaluate the students' reception of both support options and optimize them further.

The project's running time is limited to two years. It serves to develop and implement measures that nurture and foster mathematical understanding. Once the project is over, the measures have to be continued without any additional financial support. Many points mentioned above are easily implemented and complemented in terms of materials. Specific assistance can only be given if the evaluation of a student's learning process requires minimal effort. Therefore, it is vital to carry out an online evaluation, so that lecturers receive an overview by the means of simple statistical data on the current learning standard of the students.

ACKNOWLEDGEMENT

This study is supported by HMWK (Hessisches Ministerium für Wissenschaft und Kunst) titled "Weiterentwicklung von Beratungs- und Begleitangeboten für Studienanfänger/innen im Studiengang L1 (Primarstufe)".

A protocol for analysing mathematics teacher educators' practices

Ana Kuzle[1,2] and Rolf Biehler[2]

1 University of Osnabrück, Osnabrück, Germany

2 University of Paderborn, Paderborn, Germany, biehler@math.upb.de

Studying practices in a teaching-learning environment, such as professional development programmes, is a complex and multi-faceted endeavour. While several frameworks exist to help researchers analyse teaching practices, none exist to analyse practices of those who organize professional development programmes, namely mathematics teacher educators. In this paper, based on theoretical as well as empirical results, we present a protocol for capturing different aspects of mathematics teacher educators' practices in a professional development setting. Implications for professional development programmes' planning, implementation and evaluations are given at the end of the paper.

Keywords: Mathematics teacher educators, professional development, training practices.

PROFESSIONAL DEVELOPERS OF MATHEMATICS TEACHERS

The teaching-learning quality in schools and, with it, teacher professionalisation has long been a concern of educational organisations, schools, governments and researchers and continues to grow in importance. Many countries, such as England (National Centre for Excellence in the Teaching of Mathematics (NCETM)), Sweden (National Centre for Mathematics Education), Austria (Austrian Centre for Instructional and School Development), set their focus to improve education, and in that effort, are investing vast resources in teacher professional development. These countries established so called CPD institutions, which offer a systematic approach to large scale and sustainable CPD, establishing standards for high quality CPDs. This has been recognised as one driving force to allow reform of school mathematics. Germany is not an exception to this phenomenon. For years already, the German educational system is being challenged with many difficulties, such as considerable shortage of specialised secondary subject teachers, high quota of at-risk students, more and more out-of-field teachers, and a high variability between different federal states (Kramer & Lange, 2014). In 2010, the German Center for Mathematics Teacher Education (DZLM) was founded as a cooperation of seven universities, and is oriented at improving and innovating the German mathematics classroom. The core objectives of the centre are to promote continuous professional development, set nationwide standards for it, and develop quality needs-based CPD programmes.

However, do we have the capacity to reach plethora of mathematics teachers? Gal (2013) in his PME plenary talk in Kiel discussed this issue in a sense of *2.5% rule*. The 2.5% rule denotes the fact that only 2.5% of teachers are novice teachers coming from the university. Thus, this small group might receive "up to date" quality teaching and learning ideas as advocated by current professional organisations and new curricula. Gal further warned that, when we train as many inservice as preservice teachers, a quota of barely 5% can be achieved. This fact raises the need to develop new structures within the professional development institutions to reach the big masses. Along these ideas, DZLM's key mission is to develop comprehensive training programs to educate mathematics teacher educators (MTEs), sometimes shortly called "multipliers", as it would allow for a large scale dissemination of the centre's initiative. Depending on the country, MTEs take upon different roles (e.g., coach, mentor, specialist). They are responsible for strengthening classroom teachers' understanding of mathematics content, and helping teachers develop more effective mathematics teaching practices, and by doing that to better student learning. Hence, MTEs are central for providing opportunities for teachers' professional development.

Elliot and colleagues (2009) contend that this area has been understudied – we know very little as to what MTEs need to know and be able to do – but is growing in its importance (e.g., Kuzle & Biehler, 2015; Rösken-Winter et al., 2015). Understanding MTE's practices is essential for attending their diverse needs – during planning, implementation, and evaluation of the professional development programmes. The more we know about how to support them, the more mathematics teachers can benefit. In order to fill in this gap, we present here a protocol for analysing MTEs' training practices, which was developed on the basis of effective CPD practices. We contend that such protocol may allow scholars with lenses for evaluating MTEs' PD courses and at the same time supporting their further development.

THEORETICAL CONSIDERATIONS WITH RESPECT TO EFFECTIVE CPD FACTORS

In this section, we give a succinct overview of descriptors for effective professional development from the literature (e.g., Cochran-Smith & Lytle, 1999; Garet et al., 2001; Lipowsky, 2004; Lipowsky & Rzejak, 2012; Putnam & Borko, 2000). These are elaborated by outlining DZLM's (2013) six PD design principles, which were used as a theoretical frame in this paper as well as in Kuzle and Biehler (2015). There is a small overlap between the two papers, however, without literal quoting.

Learner-orientation

Effective professional development links directly to teachers' job, namely teachers' curriculum, and their specific needs and concerns. In other words, the training courses focus on the individual, heterogeneous prerequisites and needs of the participants. They encourage and demand active and responsible participation of the participants in design and implementation of the PD. Hence, the participants are not informed, but involved as active learners in this process through which they develop their professional knowledge (Garet et al., 2001). However, PDs that are based solely on this knowledge do not suffice for influencing their actions. They need to, however, address the individual circumstances of the participants, account for participants' daily activities, and capitalise on teacher's prior knowledge and experiences. Ensuring and amplifying learner-orientation can be achieved through designing and administering preliminary inquiry regarding participants' experiences, expectations, and needs (Kuzle & Biehler, 2015).

Case-based learning

Relating CPD practices to the participant, his or her experiences, teaching and/or student learning supports teacher motivation and commitment to the learning process. In other words, the reference to teachers' everyday situations, so called "cases" or "training cases" serve both as a starting point and as a field of application for teaching and learning in the context of the PD. To intensify case-relatedness the MTEs can incorporate their student work or use participants' practical experiences (Kuzle & Biehler, 2015). In either case, subject-specific learning processes and learning outcomes of learners (e.g., pupils) should be diagnosed, interpreted, and direct consequences for the teaching practices should be extracted (e.g., Lipowsky & Rzejak, 2012; Timperley, 2011). Combining individual needs with overreaching goals of the professional development initiative, strengthens teacher commitment to the PD and increases motivation to learn (Timperley, 2011).

Competence development

Effective professional development is coherent; competence and goal orientation are a crucial prerequisite for a didactical and organisational design of PD that satisfy "depth and breadth of impact" (e.g., Garet et al., 2001; Lipowsky & Rzejak, 2012). This construct is multi-faceted and encompasses all resources teachers need to create quality teaching-learning environments. Among others, competence development should address teachers' professional knowledge, including also orientation towards students' learning (Lipowsky & Rzejak, 2012). This competence and goal orientation should be transparent for all concerned parties (Kuzle & Biehler, 2015). Only then can the references to one's own teaching practices become clear and the implementation tangible (Elliot et al., 2009).

Application of various instructional formats

To ensure interactive learning experiences, various instruction formats should be combined in collaboration with the leader(s) and other teachers. A diverse variety of working methods (e.g., blended learning seminars, practice- and collaborative based work, self-study) supports participants in their skill acquisition, and helps accommodate different learning styles and preferences. The participants must also be given time to engage in different activities at different levels and in different settings in order to learn or consolidate their knowledge (Putnam & Borko, 2000). In addition, an intertwinement of input, active learning and reflection phases (so called "sandwich model") in crucial for connection between theory and practice.

Stimulating collaboration

Another essential CPD design aspect is to stimulate cooperation among the participants, and between the participants and the professional developer. This fosters exchange of experiences. Whereas using various instructional formats begins at fostering collaboration (short-term collaboration), these could be used as a starting point for a collaboration going beyond the CPD course itself (long-term collaboration). Thus, beyond just sharing ideas, and reflecting on the learning process, the participants, for instance, work together towards a common goal, jointly plan lesson, and organise mutual classroom visits (Lipowsky & Rzejak, 2012). In that manner, community building and networking can take place, which is together with professional developer-teacher structure, important for sustainability of PDs (Zehetmeier & Krainer, 2011). The extent of effect is dependent on the PD format.

Fostering (self-)reflection

Relevance of a PD and the sustainability of the professional learning can also be attained through reflective activities (Ingvarson, Meiers, & Beavis, 2005). Participants are encouraged to engage in collaborative and self-reflection on covered topics/material as well as on their own teaching, student work, attitudes, conceptions, and other. Through reflective practices the teachers can consolidate their skills and knowledge, and better understand teaching and learning in the classroom (e.g., Cochran-Smith & Lytle, 1999; Putnam & Borko, 2000). Reflective practices are most effective when reviewed throughout the PD (Ingvarson et al., 2005).

PROTOCOL FOR ANALYSING TRAINING PRACTICES

In the previous section and in Kuzle and Biehler (2015) we outlined effective professional development design principles. As seen above each design principle is composed of many different attributes. These were used to create a protocol for analysing what different attributes of each design principle can get implemented (see Table 1). In addition, we assigned to what extent these practices can be addressed in a PD with "yes", "no", and "partly".

This instrument was tested on a sample of PDs, that took place as a part of five month long DZLM's CPD "Competence-oriented teaching and learning of data analysis" for MTEs (Biehler, Kuzle, & Wassong, submitted; Kuzle & Biehler, 2015), which was developed by a team of researchers from the University of Paderborn (Biehler, Kuzle, Oesterhaus, Wassong). The CPD program focused on deepening MTEs' professional knowledge of teaching statistics using digital tools, and developing MTEs' competencies and knowledge for developing and implementing PD in statistics. As a part of that CPD, five MTEs' teams developed and implemented five 4-hour long PDs on teaching data analysis with statistical software. The general structure was prescribed by the course designers and was composed of 4 thematic blocks: (1) introductory block (ca. 1 hour), (2) block 1 (1¼ hours), (3) block 2 (1¼ hours), and (4) reflection and closure (ca. ½ hour). While the general function of the first and last block was clear, the mentors were free to organize and implement blocks 1 and 2, however, they had to select content and activities from the CPD for them and implement DZLM design principles. These were video-taped and then analysed using content method analysis as suggested by Miles and Huberman (1994).

For filling in the protocol, we used a five-step procedure for analysing the MTEs' practices exhibited in each PD. First we divided the first short PD into blocks. Secondly, for each block in the PD 1 we identified whether different design principles occurred at all. Thirdly, after having determined the six design principles and its accompanying attributes for each block, we looked at their quality in each block. For each block, we assigned the three categories, yes, partly, no, to each of the characteristic attributes for each design principle based on the following algorithm:

- A statement got categorised as "yes" when it was thoroughly and thoughtfully addressed within the block.
- A statement got categorised as "partly" when it was either not thoroughly or thoughtfully addressed within the block.
- A statement got categorised as "no" when it was not addressed whatsoever within the block.

DESIGN PRINCIPLES	Addressed level		
	Yes	Partly	No
Learner-orientation			
MTEs' focus of the PD is of relevance to MTs.			
MTE provides opportunities for MTs to share experiences with respect to the PD topic.			
MTE designs the PD in a manner that allows MTs to be integrated into the learning process as active learns through hands-on activities.			
MTE designs the PD in a manner that allows MTs to be integrated into the learning process as active learners through hands-on technology use.			
MTE provides MTs opportunities to actively build their content knowledge on the basis of their existing knowledge and experiences.			
MTE provides MTs opportunities to actively build their pedagogical content knowledge on the basis of their existing knowledge and experiences.			
MTE provides MTs opportunities to actively build their technological knowledge on the basis of their existing knowledge and experiences.			
MTE provides MTs with opportunities to actively build their technological pedagogical content knowledge on the basis of their existing knowledge and experiences.			
MTE provides MTs with opportunities to build an understanding of student's thinking in a specific area.			
Case-based learning			
PD connects to MTs' teaching practices.			
PD combines the MTs' needs with the goals of educational initiative.			
MTE integrates MTs' input with respect to the topic of the PD.			
MTE addresses explicitly specific needs and concerns of MTs with respect to their teaching experiences and daily concerns.			
MTE allows MTs to apply newly learned knowledge into follow-up activities.			
MTE allows MTs to discuss newly learned knowledge with respect to their teaching practices.			
The content of the PD is illustrated on real student work (artefacts).			
MTs analyse student work, interpret it and reflect on their student learning in their own classroom or in the classroom of other MTs.			
Competence development			
MTE's focus of the PD connects to specific curricula and learning standards.			
MTE has a well-defined image of effective classroom learning and teaching.			
MTE makes/describes clearly fostered competencies and/or goals are transparent.			
MTE focuses on developing MTs' content knowledge.			
MTE focuses on developing MTs' pedagogical content knowledge.			
MTE focuses on developing MTs' technological knowledge.			
MTE focuses on developing MTs' technological pedagogical content knowledge.			
MTE engages MTs as adult learners in the learning approaches.			
MTE models pedagogy and various instructional strategies for the whole sequence of lessons designed to support development of conceptual understanding.			
MTE provides MTs with concrete ideas for implementing new materials and/or ideas in own classroom.			
MTE supports MTs in understanding student thinking with respect to the topic.			
MTE emphasises how to improve student learning.			
MTE helps MTs anticipate possible student learning difficulties and/or misconceptions.			
Application of various instructional formats			
MTE accommodates individual learning styles and preferences.			

MTE engages MTs in different learning formats such as sharing and discussion, reflection, solving problems.			
In a PD, input, active learning and reflection phases are intertwined.			
MTE relates different parts of the PD one to another.			
Stimulating collaboration			
MTE provides MTs with opportunities to collaborate with other MTs (share ideas, viewpoints, work together).			
MTE supports MTs to develop their professional expertise and to serve in leadership roles.			
MTE supports MTs to plan together instruction and/or analyse student work with respect to a common goal.			
MTE offers MTs support beyond the PD course itself.			
Fostering (self-)reflection			
MTE provides MTs with opportunities to reflect throughout the PD.			
MTE provides MTs with opportunities to reflect critically on their teaching practices.			
MTE provides MTs with opportunities to reflect critically on the new ideas particularly with regards to their teaching practices, and experiences.			

Table 1: Protocol for analysing MTEs' training practices

In the fourth step, on the basis of step 3 we assigned the three categories, yes, partly, no, to each of the characteristic attributes for each design principle for the PD as a whole. The categorisation was based on the following algorithm:

— A statement got categorised as "yes" when it was overall always or not once thoroughly and thoughtfully addressed (2 points).

— A statement got categorised as "no" when it was never addressed (0 points).

— A statement got categorised as "partly" for all other cases (1 point).

Lastly, we visualised a profile of the PD in a table (see Table 2) on the basis of the sum of the scores of characteristic attributes for each design principle. This process was used for all other short PDs. In addition, Table 2 allows for insights what design principles were more prevalent, and how the PDs differed in their focus and goals.

In addition, another rater coded the data. We checked the inter-rater reliability by using the formula recommended by Miles and Hubermann (1994), in which the coder reliability is calculated in the following manner: coder reliability = number of agreements/total number of agreements + disagreements. The inter-rater reliability was calculated at 96.6%.

DISCUSSION: A 4-DIMENSIONAL MODEL OF TRAINING PRACTICES

Reform of mathematics classroom is an ambitious and very much needed cause. Understanding MTEs' practices is an essential mean to achieving this goal.

PD	Design principles					
	Learner -orientation	Case-based learning	Competence development	Application of various instructional formats	Stimulating collaboration	Fostering (self-) reflection
PD 1	13 (72.2%)	10 (62.5%)	17 (65.4%)	8 (100%)	4 (50%)	6 (100%)
PD 2	9 (50%)	5 (31.3%)	12 (46.2%)	6 (75%)	3 (37.5%)	1 (16.7%)
PD 3	16 (88.9%)	15 (93.8%)	23 (88.5%)	8 (100%)	5 (62.5%)	5 (83.3%)
PD 4	10 (55.6%)	4 (25%)	10 (38.5%)	6 (75%)	2 (25%)	1 (16.7%)
PD 5	11 (61.1%)	7 (43.8%)	15 (57.7%)	5 (62.5%)	4 (50%)	2 (33.3%)
Total	18 (100%)	16 (100%)	26 (100%)	8 (100%)	8 (100%)	6 (100%)

Table 2: Descriptive statistics of protocols for analysing MTEs' practices

The developed protocol for analysing MTEs' practices proved to be a reliable instrument for measuring what different effective CPD design principles and to which extent these got implemented in the PD courses. More particularly, the above presented protocol offers means to evaluating MTEs' PD practices with respect to effective CPD factors. Hence, it offers lenses for insights into their training practices and challenges that seem to impact the quality of their professional development programmes. On this basis needs-based professional development programmes can be developed to support MTEs' diverse needs in the professional development system. On the other hand, it may provide MTEs' with lenses for capturing different aspects of their training practices when planning and implementing their PD courses.

While DZLM principles (2013) and the work of other researchers (e.g., Cochran-Smith & Lytle, 1999; Garet et al., 2001; Lipowsky & Rzejak, 2012; Putnam & Borko, 2000) focus on practices for effective PD and the activities of its participants, in the instrument we focused explicitly on the MTE itself, that is, on their actions to achieve the prescribed practices. No matter the situation, the professional developer (here MTE) is a critical protagonist, as he/she is the one who sets goals for a professional development. For that reason, we contend that their doing – as it is when focusing on teachers – should be made the central focus of theoretical frameworks.

With these considerations in mind, we propose here a model in which four interrelated professional development dimensions with respect to MTE's doing stand in focus (see Table 3). This model focuses on 4 dimensions: (1) general MTE's role, (2) nature of selected materials/tasks and its quality (3) role of the MTE when using manipulatives, and (4) established socio-mathematical norms. The first dimension entails practices aligned with learner-orientation. The second dimension focuses on activities in which MTs engage to make the new ideas problematic, connect

MODEL DIMENSIONS AND ITS FACETS
(1) General role of the MTE
— Engages MTs as adult learners in the learning process (e.g., time on tasks, building on existing knowledge, practices, and experiences)
— Integrates in depth knowledge about assessment, curriculum and how to teach it
— MTE and MTs work together on a specific concern about student engagement, learning, etc.
— Makes target goals transparent (e.g., emphasises the important content to know and understand, and why)
— Uses ample opportunities for an on-going assessment of learning
— Integrates MTs' knowledge into an active learning process
(2) Nature of activities and materials
— Allows MTs to build and/or consolidate their professional knowledge
— Challenges MTs existing practices
— Helps MTs focus on student learning
— Helps MTs understand their students' learning, misconceptions
— Allows integration of theory and practice
— Connects with teacher current knowledge and/or practices
(3) Role of the MTE when using manipulatives
— Allows MTs to construct meaning for the tool with respect to the topic
— Supports MTs to use the tool for a purpose (e.g., to better their teaching practices, to consolidate their knowledge and skills)
— Connects the use of tool with MTs' teaching practices
— Connects the use of tool to the topic(s) of interest
(4) Socio-mathematical norms (professional exchange, collaboration)
— MTE uses various instructional format allowing MTs to engage in a variety of continuous teaching-learning scenarios
— MTs have opportunities for discussions (professional exchange) with the MTE and other MTs in professional learning
— Professional learning focuses on MTs' problems in teaching and learning
— MTs can choose issues of interest and share those
— MTs have ample opportunities to share their results, concerns, etc. and to reflect on those
— Continuous learning and learning opportunities are a part of the PD

Table 3: A 4-dimensional model for analysing MTEs' practices with some descriptors

to where the MTs are with respect to their knowledge or practices, and leave behind a mathematical value. Thus, this dimension entails practise aligned with competence development and case-based learning. The third dimensions focuses on manipulatives used to achieve mentioned dimensions. The fourth dimension entails practices aligned with application of various instructional formats, stimulating collaboration and fostering (self-)reflection. Thus, its focuses on normative aspects of professional development discussions that are specific to MTE's mathematical activity.

In our future work we plan to continue developing instruments for examining MTEs' PD programmes. Our goal is to define and develop a descriptive model – on the basis of the above presented protocol and the 4-dimensional model – that would allow us to assign different quality levels (level 1 to level 5) to the five PDs, and PD programmes in general. This would allow giving MTEs a detailed feedback on their practices, and target those facets of professional knowledge that may be either lacking or need to be further developed.

Principles and tools for teachers' education and the assessment of their professional growth

Nicolina A. Malara and Giancarlo Navarra

University of Modena and Reggio Emilia, Modena, Italy

We describe here the training model, developed within the ArAl project and characterized by the tight interrelation between contents to be taught (didactics of arithmetic and algebra in the perspective of early algebra) and teacher-educational processes, meant for teachers of the K-8 levels. We show how teachers, tutors and mathematics educators, by reflecting onto the Multi-commented Transcriptions (MTs), attain a shared development of the theoretical frame, of the methodologies and of the teaching materials that shall create the basis for the teachers' professional evolution. Finally, we tackle the question of how to assess teachers' professional growth by showing that MTs contain precious evaluation indicators.

Keywords: Teacher education, professional growth of teachers, assessment.

INTRODUCTION

In the last years, many studies have been devoted to teachers' professional growth. Most of them underline that the teachers' change depends on the intertwining of different teachers 'inner' factors: mathematical knowledge for teaching, beliefs, emotions and awareness at different levels (Jaworski, 2012, Mason, 2008, Schoenfeld, 2013). In particular, Sowder (2007) states that many of a teacher's core beliefs need to be challenged before change can occur. Schoenfeld stresses that the point is not what a teacher knows, believes or says, but rather how his/her knowledge and beliefs play out in the classroom. The change needed to traditional teachers to become non-traditional, inquiry-oriented teachers is not simple to achieve: it is very difficult to deeply affect the complex structures that constitute the basis for teachers' practices and strictly influence what they do, and their way of interpreting everything what happens. Our studies consider these aspects together: they aim at the renewal of the arithmetic and algebra teaching, they take into account both cultural and affective factors influencing teachers' action and develop the implementation of teachers' educational paths that are linked with the class activity and the students learning.

TEACHERS' EDUCATION: OUR APPROACH

As mathematics educators we are involved in activities for pre-service/temporary teachers or in-service teachers. In both cases, we develop studies on teachers' education with the aims: a) to validate our hypotheses about the effectiveness of our approach to favour changes in arithmetic/algebraic teaching; b) to individuate relationships between educational processes enacted and new teachers' awareness, attitudes and behaviours; c) to confirm, extend and generalize results highlighting the essential conditions which determine them. Our research studies are essentially qualitative and develop through a methodology framed in the Italian research model for teaching innovations which is based on a sharp interaction with the teachers and a constant practice of shared reflections on the experimental paths jointly planned and enacted by the teachers about the mathematical content in play, the quality of their behavior, attitudes, knowledge, ways of thinking promoted in the students. Our interventions with/for the teachers are centered on the following key points.

Fostering teachers' reflection on their knowledge and on the coherence between their expressed beliefs and their teaching practice

The teachers involved in our educational programs (K-8 segment) have different cultural backgrounds, due to their different educational paths. Their beliefs about arithmetic and algebra are based on their knowledge but mainly on their emotions and beliefs, fruit of their previous experience (as student and teacher). These aspects constitute an often fragmented and fragile net of reference which underpin their teaching orientations. Most of the teachers believe that the teaching of arithmetic precedes the teaching of algebra; therefore, the procedural point of view prevails over the relational one, the manipulation of mathematical objects prevails over the reflection upon them, products prevail over processes, in problem solving the operational aspect prevails over the representation and interpretation leaving in shadow the control of meanings. As to the teachers' vision of their role in the classroom, the most widespread one is that of a ('soft') director, deriving from the belief that teaching means mainly conveying pieces of knowledge. Trying to make teachers overcome such beliefs through training means, first of all, leading them – through the *practice of the reflection* – towards a deep analysis of their knowledge and beliefs, which makes them call into question and gradually re-formulate their personal epistemology in a new frame oriented towards early algebra.

Developing open and redefined educational paths

Teachers' educational programs often present a structure having a mono-directional motion within work-groups: mathematics educators limit themselves to giving teachers indications on how to improve their teaching, together with a set of tasks to be presented in the classrooms. In such a structure, teachers are basically users of a framework vision that they receive in top-down mode. On the contrary, our model suggests a multidirectional motion, characterized by a synergic network of relationships among teachers, tutors and mathematics educators, aimed at obtaining results that a single teacher would hardly achieve on his/her own. This synergy of relationships allows a continuous development of theory, methodologies and tools. We can therefore define this framework as being built in a bottom-up mode, within a tight interrelation between teaching contents and educational processes. A glossary shared with the teachers supports the educational process. It is a dynamic tool, to which teachers constantly refer. With the aim of constituting a real sharing of these theoretical elements, the glossary is progressively integrated according to the teachers' declared needs. Thus, a real 'formative communication' develops among teachers, tutors and mathematics educators in the inquiry community [1] (Cusi et al., 2011).

Planning teachers educational paths and designing tools for data detection

The teachers addressed by our project are distributed in almost all Italian regions but they are subject to a frequent turn-over (funding decreasing, retirements, change of school directors and teachers etc.) and are fluctuating in duration. For this reason, the educational paths we develop for pre-service/temporary teachers are different from those developed for in-service teachers. In the first case more space is given to the study of classroom processes of *others* teachers with the aim of educating trainee-teachers to develop a good sensitiveness about constructive teaching (Malara & Navarra, 2009; Cusi & Malara, 2011). In the second case the educational paths are focused on the study of the teachers' *own* teaching processes and on the comparison between the attitudes and behaviors of the teachers involved in the same experimentations. This kind of activities are developed with the aim of making the teachers become aware of their own ways of acting and of the possible strategies to adopt in order to refine problematic didactical approaches. These activities also enable to deduce general results and to identify new research problems.

Collecting narratives and discursive data meaningful to teachers' growth

Our results are generated by different kinds of data: *notes about the meetings* during which the teachers and the researchers discuss the potentiality of the activities to be presented in the classes or, a posteriori, analyse the effectiveness of the teachers' ways of proposing the activities; *in-progress didactical materials* (tasks, students protocols, short excerpts of micro didactical situations, terms of the glossary, etc), selected by the teachers for the sharing of experimental results; *teachers interviews or discussions,* where aspects linked with their knowledge or methodological and emotional aspects are highlighted; *multi-commented transcripts* (MTs) [2] of audio (sometime video) recordings of classroom processes. Teachers' meta-reflections are encouraged, since they are asked to analyse the transcripts of class discussions commenting not only on students' interventions but also on their own interventions, trying to refer to the different constructs of the wide theoretical frame (see forward the point 'Methodology of Multi-commented Transcripts'). The collected data are studied to identify categories of teachers' behavior, characterized by set of actions modeling a metacognitive and effective teaching (Cusi et al., 2011).

THE CONTENTS: EARLY ALGEBRA AND THE ARAL PROJECT

Early algebra arises from the need to favour the pupils' construction of meanings in arithmetic in a pre-algebraic perspective across K-8 school levels. Its approach to arithmetic is based on specific principles: the anticipation of generational activities at the beginning of primary school; the social construction of knowledge, i.e. the shared construction of new meanings, negotiated on the basis of the cultural instruments available at the moment to both pupils and teacher; a focus on natural language as main didactical mediator for the slow construction of syntactic and semantic aspects of the algebraic language; identifying and making explicit algebraic relationships and structures within concepts and representations in arithmetic. In this context, our *ArAl Project: arithmetic pathways towards favouring pre-algebraic thinking* (Malara & Navarra, 2003) counters the traditional sequence of arithmetic/algebra teaching and suggests that their teaching is based on the intermingling between two disciplines, in the perspective of a continuity between primary and secondary school (see Figure 1).

We claim that the main cognitive obstacles to the learning of algebra arise in unsuspected ways in arithmetic contexts and may impact on the development of mathematical thinking, mostly owing to the fact that many students have a weak conceptual control over the meanings of algebraic objects and processes, seen as translations of verbal sentences and in their mathematical status. Our hypothesis is that algebra should be taught as a new language from the beginning of primary school, so that one gets to master – through a set of shared social practices (collective discussion, verbalization, argumentation)– modalities that are analogous to the learning of a natural language: gradually appropriating its semantic aspects and putting them in their syntactic structure. For this reason, it is necessary to build up an experimental and continuously redefined environment, capable of informally stimulating the autonomous elaboration of a formal coding for verbal sentences by discussing them with the whole class. This process of construction/interpretation/refinement of 'draft' formulas is what we call *algebraic babbling*.

This approach leads to a sort of Copernican revolution in the teachers' beliefs. It brings about awareness for the meaningfulness of their role, with reference to their position within the educational process. The teaching of arithmetic in an algebraic perspective is fostered by making teachers shift their attention from procedures towards relationships in arithmetic. Let us clear up this point by presenting four key-issues that exemplify our framework.

The equal sign and the duality process-product

The usual reading of 5 + 6 = 11 is '5 plus 6 *is* 11': what's on the left to the equal sign is seen as an *operation,* whereas on the right it is seen a *result*. The two sides of the equal sign are interpreted as *ontologically different entities*. But the algebraic meaning is different: it indicates the equivalence between two representations of the same quantities, i.e. between two entities that are *ontologically equal*. We usually introduce this alternative perspective by discussing with teachers the words of an 8-year-old pupil: "It is correct to say that 5 plus 6 makes 11, but you cannot say that 11 'makes' 5 plus 6; so, it is better to say that 5 plus 6 'is equal' to 11, because in this case, the other way round is also true."

Canonical and non-canonical representations of a number

Similarly to what happens with the equal sign, writings such as $[(3 + 2) \times 4]^2$ are seen as *operations* waiting for a *result*. In order to promote a reflection upon them in an algebraic perspective, we use the strategy of writing on the blackboard a list of facts concerning a specific pupil: name..., daughter of..., owner of a dog called..., and so on. We then explain that the situation is similar with numbers: each number can be represented in many different ways, through any odd equivalent expression. Among these representations, only one (e.g., 12) is its *name* – the so-called *canonical* form, whereas the others (3 × 4, 3 × (2 + 2), 48/4, ...) are its *non-canonical* forms, each of which makes sense with reference to the context and the underlying process. This experience enables to understand that $[(3 + 2) \times 4]^2$ is one of the many non canonical forms

	Arithmetics

									Algebra				

Early algebra (EA)													
K	1	2	3	4	5	6	7	8	9	10	11	12	13
EA						EA-AT			AT				
						Algebraic Thinking (AT)							

Figure 1: Towards a new perspective of the teaching/learning of arithmetic and algebra

of the number 400. Being able to recognize and interpret these forms builds up the semantic basis for the understanding of algebraic expressions like $-4p$, ab, x^2y, $k/3$. The concepts of canonical/non-canonical form also allows to reflect upon the possible meanings associated with the equality sign; in $[(3 + 2) \times 4]^2 = 400$ we don't see the operations and results anymore, but rather the equivalence between two representations (non- canonical and canonical) of the same quantity.

The duality 'representing vs. solving'

It is a widespread belief that solving a problem means identifying its *result*; this perspective focuses the attention on the *operations*. In order to bring about a change of perspective, it is necessary to move from the cognitive to the metacognitive level, where the solver *interprets the structure of the problem and represents it through algebraic language.* In the traditional perspective, solving a problem means separating the entities that are known from the entity to be found, then spot out the necessary operations. In the perspective of early algebra, the attention is concentrated on the (known or unknown) *entities*, and on the *relationships* among them. In a 'classical' problem for level 4, 'The sides of a rectangle are 3cm and 4cm long. find the perimeter', *the explicit entities are two* (3 and 4), the implicit one is the 'double' operator applied to each side and *the operations are two*; we obtain the writing $(3 + 4) \times 2$ which gives the result 14. But if the task is expressed as follows: '*Represent* in mathematical language the situation so that you can find the perimeter', *the entities are four*: the length of the two sides, the 'double' operator, the length of the perimeter (p), the *operations are two* but there is also a *relationship*: the equality between p and the representation of the process through which it is obtained. The sentence $p = (3 + 4) \times 2$ expresses all this is. This shift of perspective amplifies comprehension; in order to foster it, we use the principle '*first represent, then solve*'.

The duality transparent-opaque

A representation in mathematical language is made of symbols that convey meanings, the comprehension of which depends both on the representation in itself and on the ability of those who interpret it. One could say that the canonical form of a number is poorer of meanings than its infinite possible non-canonical forms, for example: the tendency of immediately carrying out the calculation $5^2 \times 5^1 \times 5^3$ leads to a result, represented by its canonic form (15 625), but the efficacy produced by the 'intermediate' representation 5^{2+1+3} gets lost, whereas it would allow to build the comprehension of why, in algebraic realm, $ab^2 \times a^2b = a^3b^3$. We can therefore talk of a higher *opacity* for writings such as 15 625, of a higher *transparency* for those like $5^2 \times 5^1 \times 5^3$ and 5^{2+1+3}. Generally speaking, the transparency of the process favours the control of meanings, highlighting the underlying properties; it allows to understand possible errors and to clear up possible misconceptions which may arise.

THE EDUCATIONAL PROCESS: TEACHERS' PROFESSIONAL GROWTH IN THE PERSPECTIVE OF EARLY ALGEBRA

The methodology of multicommented transcripts

In order to fulfil these, and others, key-issues, we involve teachers in an activity of critical analysis, and consequent reflections, of the transcripts of audio and video-recordings of classroom processes, which we call Multi-commented Transcripts Methodology (MTM). It has the aim of highlighting the interrelation between the students' construction of knowledge and the teacher's behaviours in guiding them to perform this construction. The Multi-commented classroom Transcripts (MTs) are sent by teachers, together with their own comments, to e-tutors who make their own comments and send them back to the authors and other members of the team. The e-tutor highlight not only the positive aspects, but also the possible stereotypes, beliefs and behaviour that are often mistaken, and comment them with reference to the theoretical framework that is shared in the community of inquiry and, for some key-elements, also with the pupils. The joint reflection on the MTs strongly influences the development of theoretical, methodological, instrumental, material aspects (Units of the ArAl Series,

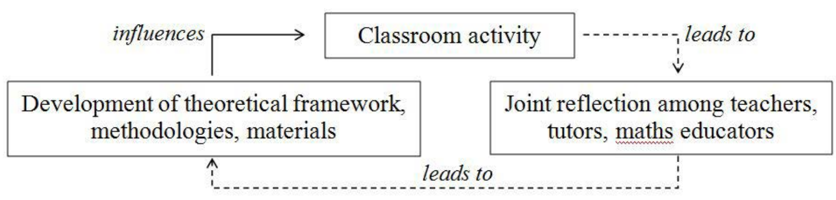

Figure 2: The cycle of teachers' mathematics education

papers, articles, learning objects) and supporting elements (website, blog, Facebook Group) aimed at offering teachers a cultural background that can help them act differently in the classroom (see Figure 2).

HOW TO ASSESS

The problem of how to assess the teachers' change is an open research question. The strategy we adopt is to assess in an indirect and articulated way, through the MTs, the way in which the teacher's classroom action evolves during the training path. The factors we observe are: (a) the pupils' interventions; (b) the modalities in which the teacher interacts with the pupils; (c) the comments expressed by a teacher in the MTs and his/her reflections received in the sharing of his/her MTs within the community of inquiry. With this goal, the intersection of experience between both typologies of teachers (pre-service/temporary and in-service) becomes relevant in the strategies of the project, for example: meaningful excerpts from MTs produced by in-service teachers give vent to tasks for future teachers, aimed at assessing their ability to face specific classroom situations by hypothesizing contingent actions and foresee their development (Malara and Navarra, 2009). Some examples (teachers in service):

How pupils express themselves

One can infer from pupils' sentences whether the teacher works in a pre-algebraic perspective, i.e. fostering the development of algebraic babbling and therefore inducing a 'metacognitive' attitude.

Episode 1(9 years old, grade 4)

Pupils are asked to represent in mathematical language the total number of sweets contained in six bags (each of which contains four chocolates and three candies).

Alessandro: I have written 7×6.
Miriam: I have written $(3 + 4) \times 6$: it is more *transparent*, Alessandro's writing is *opaque*. It means that it is not clear, whereas transparent means that you understand.

Miriam refers to the dichotomy *opaque/transparent* to express *how the non-canonical form of a number helps to illustrate the structure of a problematic situation*. This awareness in the pupil testifies to the fact that the teacher has acquired the ArAl theoretical framework and shares it with the pupils.

How teachers interact with pupils

The way in which a teacher interacts with the pupils, and the role that he/she takes up have a strategic importance, because they influence the quality of the teaching.

Episode 2 (8 years old, grade 3)

The pupils have represented this situation in the mathematical language and reflect on the suggestions made by Alice $n = 5 + 2 \times 8$, Martina $5 + 2 \times 8 = n$ and Ada $n = (2 + 5) \times 8$.

Francesco: I think they are right because 5 +2 represents the marbles that are in a box, by 8 which is the number of the boxes.
Maria: They are the same as Ada's but they don't have parentheses.
Teacher: Let's reflect on the presence of the parentheses. Do they change anything?
Andrea: I think they do, because $5+2\times8$ is equal to 21, while $(2+5)\times8$ is equal to 56.
Bruno: It's true: the teacher said once that in a chain of operations you solve multiplications first.
Maria: This means they are not the same!
Francesco: That's right, the translation with the parentheses is the more correct one.

There are many elements here that let us assess positively, at different levels, the teacher's action: (a) *mathematically*: she has introduced the pupils to the use of letters, to the priority of operations within expressions, to the use of parentheses; (b) *linguistically*: she has fostered the organization of meaningful, complete sentences; (c) *metalinguistically*: she has promoted the reflection on the mathematical writings and their comparison; (d) *socially*: by inviting pupils into discussion, she has let them interact without her influence, listening to each other and having spontaneous dialogues; (e) *methodologically*: she has shared the theoretical framework with the class, by spreading words such as 'represent' and 'translate'. On the other hand, we make the teacher notice and reflect on the fact that (2) Francesco has referred '5 + 2' *to the marbles* and not *to their number*; (2) Andrea speaks of *result*, and pupils should be guided from the level of *calculations* to the level of *representations*.

The teacher's self-reflection and the suggestions offered by other comments

The way in which a teacher interacts with the pupils, and the role that he/she takes up have a strategic importance, because they influence the quality of the teaching.

The comments written by the e-tutor and other experts – even in several diaries by the same teacher – allow to ascertain whether the classroom-leading strategies have changed (and *how*) during the educational project. Among the factors that influence the assessment there are, for example, the following issues: Does the teacher develop a wide range of roles in order to promote a refection onto mathematical processes or objects? Does he/she foster linguistic interactions by encouraging verbalization, argumentation, and collective discussion? Does he/she negotiate and share with the pupils the theoretical framework? Does he/she modify their initial points of view or does he/she seem unsensitive towards meaningful changes in his/her initial attitude?

Example 3 (12 years old, grade 7)

The class is tackling with the teacher the mathematization of a situation that requires the translation of the sentence 'for each 4 sage plants there are 6 rosemary plants'. The pupils attain first the formula $s = (6/4) \times r$, then $s = 3/2 \times$ r. The teacher shifts to the level of interpretation and asks the pupils to determine the number of rosemary plants corresponding to 66 sage plants. Some pupils offer a solution by substituting the value 66 and s in the second formula. Then, another pupil speaks:

Mario: I have done it in a different way: 66:4=16 and the remainder is 2. Then I have done 16×6=96 because for 4 sage plants I have 6 rosemary plants. Then, since 4s=6r, I have divided by two that is 6:2=3 and after that I have added 3 to 96. The result is then 99.

Teacher: Bravo, now let's draw a graph by using the relationships that we know.

To this point, the teacher's reflection and the tutor's comment in the MT are:

Teacher: Here I should have lingered on what the pupil was trying to say, because I think that his reasoning is very interesting and it could have helped his classmates to see the same situation from different points of view.

Tutor: Ok. But before that, one should have underlined the improper use of letters as labels and the argumentation should have been interpreted at relational level, so as to show that his procedure is based on the non-canonical representation of 66 as 4×16+2, on recognizing the multiplicative relationship between 2 and 4 (2 is the half of 4) and on the implicit assumption of the distributive property. The pupil is referring to the non-simplified formula r=(6/4)s and transforms the calculation (6/4)×66 into (6/4)×(4×16+2) = = (6/4)16+(6/4)2=6×16+3=96+3.

CONCLUSIONS

The question of teachers' evaluation is complex also because what we want to evaluate is a process which, in its nature, is continuously becoming and reflects daily changes of mood, energy, personal interest in the topic being dealt with, relationship with the pupils. All these factors interfere with the quality of the classroom activity management and therefore influence what one would like to evaluate: the effect of participating in the training on the strategies of leading a lesson. Our studies concentrate therefore on a formative evaluation of what arises in the MTs, a dynamic evaluation, which pays attention to nuances, apparently unimportant details, to micro-decisions that the teacher makes in just as many micro-situations, in which he/she often shows the co-existence of pre-existing beliefs and possibly hesitating opening attitudes, induced by the training. We hold this way promising, particularly if it is embedded in a educational context that constantly involves teachers and broadens the sharing of the MTs and of their reflections (along with their possible evaluation) to other actors of the community of inquiry, fostering a system of crossed evaluations.

These aims could be reached in a medium/long-term (two/three years or more) under these conditions: (i) enacting an educational project with several supporting tools; (ii) avoiding separation between theory and practice; (iii) building an environment in which effective circular relationship occurs between what happens in the classroom, the joint reflection of teachers-tutors-mathematics educators on classroom events, the shared effort of refining practices by relating it to the theoretical frame and developing materials, tools, as well as the assessment of the progressive change of the teaching through further classroom activity.

ENDNOTES

1. We use the term 'community of inquiry' in the sense of Jaworski (2012). It involves mathematics educators (in the double role of didacticians and researchers), tutors (in the double role of mentors and teachers/researchers) and teachers.

2. The MTs are shared by e-mail and after critically analyzed during the periodical meetings of the ArAl community. Currently about 300 MTs have been put on the website <http://www.progettoaral.wordpress.com>. Together with other theoretical or practical materials, they constitute an integrated set of tools for teacher professional development".

Development of teachers' mathematical and didactic competencies by means of problem posing

Uldarico Malaspina[1], Albert Mallart[2] and Vicenç Font[2]

2 Universitat de Barcelona in Barcelona, Faculty of Education, Barcelona, Spain

This paper presents a didactic experience with problem posing carried out with in-service secondary teachers. We propose a strategy specifically designed to modify a given problem and enrich its mathematical and didactic potential. The starting point is a teacher's class episode, which includes a previously designed problem as well as the reactions of the teacher's students when solving it. We ask the participating teachers to pose 'pre-problems' and 'post-problems', working individually at first and then in groups. The experience shows that problem posing contributes to the development of teachers' didactic and mathematical competencies.

Keywords: Problem posing, problem solving, teacher competencies, teacher training.

INTRODUCTION

In 1989 the National Council of Teachers of Mathematics (NCTM) recommended providing opportunities for students to think mathematically and develop knowledge by creating problems: "Students in grade 9–12 should also have some experience recognizing and formulating their own problems, an activity that is at the heart of doing mathematics" (p. 138). In addition to this, the NCTM recommended offering opportunities to formulate problems from a given situation as well as opportunities to create new problems by modifying the conditions of a given problem (NCTM, 1991, p. 95). In this sense, teachers must obviously develop their problem posing skills in order to work in this way with their students; they should not be limited to using the problems found in books or online (Ellerton, 2013; Singer & Voica, 2013; Malaspina, 2013b; Bonotto, 2013). The cited authors also emphasize the importance of the relationship between problem solving and problem posing. In Bonotto's words (2013): "There is a certain degree of agreement in recommending problem-posing and problem-solving activities to promote creative thinking in the students and assess it." (p. 40).

Some research on problem posing and its relation to the problem solving process has led to new research on the benefits of incorporating problem posing in teacher training programs (Ellerton, 2013; Tichá & Hošpesová, 2013; Malaspina, Gaita, Flores, & Font, 2012; Malaspina, 2013b). We agree with Ellerton (2013) when she says: "For too long, successful problem solving has been lauded as the goal; the time has come for problem posing to be given a prominent but natural place in mathematics curricula and classrooms" (pp. 100–101) and our research shares this idea. We have designed activities with the purpose of motivating pre-service teachers and current teachers to create math problems and reflect on their didactic aspects. The problems were posed starting from a given problem or from a given situation. In this paper, we describe some cases of the first type.

FRAMEWORK

Mathematics teacher's competencies

At the international level we have observed a tendency for convergence among university curricula design. Some countries have opted for a curriculum model organized by professional competencies that differentiates general (or transversal) competencies from specific ones.

Many of the tasks proposed in order to develop and evaluate students' mathematical competencies are problem-based. A teacher must not only be good at solving problems, but also needs to know how to choose, modify and create them with a didactic purpose. A teacher also needs to be able to critically evaluate the quality of the mathematical activity required to solve the problem proposed and, if necessary, to be able to modify the problem in order to facilitate a richer mathematical activity.

Teachers should already have mathematical competence to solve problems, but if they want to select, modify or create them with a didactic purpose, they need to be competent in didactic analysis of the mathematic activity (Rubio, 2012). The first competence is common in many of the professions developed by mathematicians. The second one is, however, more specific to the mathematics teacher.

According to Giménez, Font and Vanegas (2013) and Rubio (2013), we understand the competence of didactic analysis as the ability to design, apply and evaluate learning sequences by means of didactic analysis techniques and quality criteria. In teacher training, this competence has to be developed by proposing tasks to the future and current teachers that require them to carry out didactic analysis. One of these tasks consists of creating problems and thinking about them didactically.

Problem posing

Stoyanova and Ellerton (1996) summarize the meaning of creating mathematical problems from different points of view:

> Problem posing has been viewed as the generation of a new problem or reformulation of a given problem (Duncer, 1945); as the formulation of a sequence of mathematical problems from a given situation (Shukkwan, 1993); or as a resultant activity when a problem is inviting the generation of other problems (Mamona Downs, 1993). Dillon (1982) conceptualized „problem finding as a process resulting in a problem to solve." Silver (1993, 1995) referred to problem posing as involving the creation of a new problem from a situation or experience, or the reformulation of given problems. (p. 518)

As Silver, we consider that posing mathematical problems is a process through which one produces a new problem from a given one (problem's variation) or a new problem from a situation (problem's elaboration), whether it is real or imagined.

In order to develop this perspective of problem posing, it is necessary to identify the four key elements of a problem: Information, Requirement, Context and Mathematical Environment (Malaspina, 2013c). The Information consists of the quantitative or relational data that are given in the problem. The Requirement is what is asked to be found, examined or concluded; it can be quantitative or qualitative, and it can include graphics and demonstrations. With respect to Context, a "contextualized problem" usually relates to any real situation, to everyday life; but we consider that the Context can also be strictly formal or mathematical. In this sense, we affirm that the Context can be intra mathematical or extra mathematical. In the first case, as its name implies, the problem is more linked to an abstract situation and, in the second case, the problem is more linked to a real situation. Finally, the Mathematical Environment refers to the mathematical concepts needed to solve the problem.

Therefore, we understand the problem's variation as a process that builds a new problem by modifying one or more of the four key problem elements.

OBJECTIVES AND METHODOLOGY

We have two objectives:

- To show that an appropriate strategy helps stimulate the ability to create mathematical problems by modifying a given problem and considering its mathematical and didactic aspects.
- To show that problem posing is a means of contributing to the development of teachers' didactic and mathematical competences.

Regarding the methodology, since the research relates to creativity, we have chosen a qualitative methodology that includes a strategy, observations and case studies.

The first step was choosing a topic and designing some easy and motivating problems as starting points to pose new problems.

At the beginning, the problem posing experiences were performed with pre-service primary school teachers as part of the mathematics course in the Faculty of Education of the Pontificia Universidad Católica del Perú. These did not have a context of a specially designed strategy. The positive experiences of both the individual and group works were the basis for designing problem posing workshops, which are summarized below.

A PROBLEM POSING STRATEGY

We give a short presentation on problem posing, including some examples of problems created in previous workshops, in which we emphasize the importance of creating problems that favour learning and mathematical thinking. We present a previously elaborated problem to the workshop participants considering the context of a concrete class episode of Teacher P. In this episode, some of the students' reactions when solving the problem are described briefly. We ask participants to: i) solve the given problem; ii) pose problems by modifying the given problem to make the solution easier and to help clarify students' reactions (these problems are called 'pre-problems'); iii) pose problems by modifying the given problem so as to challenge Teacher P's students beyond correctly solving the given problem (these problems are called 'post-problems'). The problem posing must be carried out individually at first and then in groups with the help of the instructor of the workshop. Moreover, the problems created by a group are also solved by other groups. There is also a socialization phase with all the participants. In this phase, the participants share the rationale behind the individually or collaboratively created problems. In addition, the problem solved by a group (which is not the author group of the problem) is exposed and commented critically. The purpose of this is that the discussion with the authors of the problem as well as the participants' and instructor's comments help to enhance the capacity of posing problems with mathematical and didactic potentialities.

This is the strategy we have followed in several workshops, especially with current secondary teachers. It should be mentioned that the experiences we show and examine in this article are about percentages.

CASES OBSERVED

After explaining and exemplifying some ways for varying a given problem, we applied the described strategy in a workshop with 15 current secondary school teachers. We proposed the following class episode and we asked the teachers to do the tasks (i)–(iii) related to the episode problem. Both, the interaction of the teachers with the instructor and the socialization phase, were very important for obtaining information about the rationale behind the created problems.

The episode

In a class of mathematics, teacher Sánchez asks his students to solve the following problem:

The first week of July, a store called ALFA sold all products at full price; the second week, the store discounted all items 20%; and the third week, the store applied an additional discount of 15% that was announced as the "GREAT DISCOUNT OF 20%+15% ON ALL THE PRODUCTS".

You have to decide whether or not during the third week of July ALFA sold its products at prices 35% less than during the first week of July.

After a few minutes:

— Most of the pupils say "Yes, they did."

— Juan and Carla say "No, because in the third week the discount was less than 35%."

— Maria says that in the third week the discount was 68%.

Some pre-problems posed by teachers in the workshop

Pre-problem 1 (Individual work)

Rosa bought a $100 blouse that was discounted 20% because of end of season sale and with an additional discount of 10% for having the store credit card. What was the total percentage discount that Rosa received?

The author's idea when she posed the problem was to set a price with percentages that are easy to calculate in order to help students focus their attention on the total discount.

Pre-problem 2 (Individual work)

In a clearance sale, a shop applies a 50% discount on all its textiles during a week, and the following week it applies an additional discount of 50%. What is the total percentage discount applied during the second week?

The author of this problem was interested in showing the students that the total discount is not a simple sum of percentages. In order to achieve this objective, the author had chosen discounts of 50% because a total discount of 100% is not intuitive.

Pre-problem 3 (Group work)
(The author of Pre-problem 1 joined this group)

Rosa bought a $100 blouse that was discounted 20% because of end of season sale and with an additional discount of 10% for having the store credit card.

a) How much did Rosa pay for the blouse?

b) What percentage of the blouse´s original price did Rosa pay for the blouse?

c) What is the blouse's total percentage discount?

The author group thought this problem would help students distinguish between the amount paid and the discount. This seemed to be the confusion of student Maria in the episode. Apparently she had done the calculations well, but she did not distinguish between the amount paid (68% of the initial price) and the total discount (100%–68% = 32%). Some of the participants commented that considering $100 as the initial price should be used as a counterexample for illustrating the wrong answers, and they said to be careful because it could reinforce a simplified and not deeply reasoned way of generalizing a particular case.

Some post-problems posed by teachers in the workshop

At the beginning of creating post-problems, the participating teachers created problems that were very similar to the given problem, some with other prices and, in other cases, considering three successive discounts; essentially, they were the same problems as the original, but with quantitative modifications in the information. However, little by little they carried out more creative modifications when they formulated post-problems:

Post-problem 1 (Group work)
Pedro and Juan each bought a shirt. Pedro bought a shirt with a discount of 20% plus an additional discount of 20%. Juan bought one with a discount of 30% plus an additional discount of 10%. Who received a greater discount?

The author group thought this problem would reinforce the fact that the total discount is not a simple sum. When it was solved by other group and socialized, the participating teachers appreciated that there were no specific initial prices for the shirts.

One of the teachers said that he created a similar post-problem considering percentage wage increments: for worker A, 5% in 2011 and 4% in 2012; and for worker B, 6% in 2011 and 3% in 2012. The problem was to determine which of the workers received a better percentage increment in the two years; or did they receive the same percentage increment? In his group, this problem was considered easier than the episode problem and, for that reason, it was not used as a group post-problem.

Post-problem 2 (Group work)
There is a store where you can pay 30 days later, but there is a 10% surcharge. And if you want to pay after 31 days but before 35 days, there is an additional 5% surcharge. If Julio bought something on August 20th and paid on September 23rd, what total percentage surcharge did he pay?

The author group thought it was interesting to pose situations about cumulative percentage, considering surcharges and not only discounts. As in Post-problem 1, initial amounts are not specified in this problem and its solution requires a better understanding of the percentage concept. In the socialization it was commented that this problem was easier than the problem of the percentage wage increments.

Post-problem 3 (Group work)
Celia bought a dress for $ 125.46. If the dress was 15% off with an additional discount of 18%, what was the original price of the dress?

The author group said its intention was to motivate students to use algebra to solve percentage problems. Indeed, the group that solved the problem used the equation:

$$(0{,}82)(0{,}85)x = 125.46$$

One of the comments during the discussion was that all problems maintained an extra mathematical context. However, we also need to create problems with an intra- mathematical context. Generalization allows us to work in this context. The following problem was created with this idea.

Post-problem 4 (Group work)

If the shop called BETA has an end of season discount of p%, plus an additional discount of q%, what is the total percentage discount in relation to the original price?

The problem allowed us to illustrate the total discount using a composition of linear functions that express the sale price of a product whose original price is x and has a discount of r%. That means, functions of the form $f(x) = (1 - \frac{r}{100})$.

COMMENTS

The studied cases show that the proposed strategy contributes to the development of the competency of problem posing and to thinking about problems didactically (e.g., Pre-problem 2, the comments about Pre-problem 3 and Post-problem 1).

In most cases, the primary modification of the initial problem is about its information and its requirement. Post-problem 4 did not arise spontaneously. However, the alterations are not only quantitative (e.g., different percentages), but also qualitative (e.g., the problem deals not only with discounts, but also with increases), relational (e.g., the information is given in a way that it makes it easier to reflect on possible wrong answers, as in Pre-problem 2) and, in some cases, a piece of information is added or a requirement is extended (e.g., Pre-problem 3)

The percentage theme favours the creation of problems in an extra mathematical context and we highlight the great diversity of imagined situations in problem posing workshops. The problems exposed in this paper are only a part of those imagined by the participants in this workshop and there are many others created in other workshops. The processes of reflecting on these diverse new problems – individually, in a small group and with all the workshop participants – contribute to the teachers' advances in knowledge of the mathematical object, in the observation of their reality and in elaborating tasks to go deeper into the subject to solve the problem created. We underscore the importance of working individually at first and the richness of working in groups later. All work is strongly enriched with socialization, in which arguments, opinions and comments that reflect involvement in creating problems arise.

Problem posing has to be designed to promote students' learning or to develop their mathematical thinking. We have studied (Malaspina & Vallejo, 2014) that problem-posing workshops related to one concrete theme allow participants to go deeper into the subject matter and to make mathematical connections. In the present research, Post-problem 4 shows the connection between percentages and linear functions, which was unknown for most of the participating teachers.

Examining the quality of the created problems is not the intention of this article, but we can appreciate that problems created by groups have a higher mathematical and didactic potential – above all if they have been created from episodes in classes. Certainly, the better the teachers' mathematics background and teaching experience, the higher the quality of the problems they create.

FINAL CONSIDERATIONS

We have developed problem posing activities with pre service teachers and current ones. We have considered individual work and group work in dealing with a given problem during an episode, which happens under certain characteristics. The analysis of these activities – in particular the cases considered in this paper, with current secondary teachers – show that they contribute to the development of didactic and mathematical competencies. Problem posing provides opportunities in which the two competencies have the possibility to interact in a creative way. The results are didactically valuable suggestions for their students as well as advances in teacher training.

It is important to break the "enculturation process of accepting problems that others create as those which need to be solved" (Ellerton, 2013, p. 87). We will contribute to this breaking by giving pre-service and in-service teachers good opportunities and orientations for creating problems. When teachers have experiences with didactic analysis and mathematical connections through processes of creating new problems, they improve their mathematical and didactic competencies, and they could induce their pupils to create their own problems.

This article is part of a wider area of research in which problem posing is also considered from a given situation. The corresponding activities have been considered in a next phase. We have interesting didactic experiences, some of which are explained in Malaspina and colleagues (2012) and Malaspina (2013a).

The problem posing strategy exposed and commented in this paper could be a good methodological tool for teacher training. Certainly, from a research point of view, it would be interesting to test it in relation to different mathematics topics at various teaching levels and in different countries.

As a part of the challenges posed by this research on creating math problems in mathematics education contexts, we invite readers to consider the following questions:

How do we measure the influence of the problem posing competency development for teachers on their performance in class with students?

How do we verify or reject the conjecture that assuming the challenge of creating math problems on a given topic activates new learning processes that favour intra mathematical connections with other fields of knowledge and reality?

A development over time of the researchers' meta-didactical praxeologies

Francesca Martignone

Università del Piemonte Orientale, Vercelli, Italy, francesca.martignone@unipmn.it

This paper shows how the study of the meta-didactical praxeologies can highlight different features of tasks, actions and theories that a researcher can develop working also as a teacher educator. The theoretical tools presented are part of the Meta-Didactical Transposition model: a model based on the Anthropological Theory of Didactics adapted to the analysis of teacher education processes. These tools are useful to identify and describe when and how some different components of the researchers' praxeologies changed during the dynamic processes, which involved researchers and teachers in a teacher education project.

Keywords: Teacher education program, Meta-Didactical Transposition model, meta-didactical praxeologies, teacher educators.

INTRODUCTION

The study presented in this paper is part of an ongoing larger research that involves Italian and French researchers (Aldon et al., 2013; Arzarello et al., 2014). It aims at developing theoretical tools in order to describe and analyse the peculiar features of different teacher education programs. The first result was the elaboration of a model that takes into consideration the complexity of the processes evolving in a teacher education program. This model is based on the Anthropological Theory of Didactics (Chevallard, 1992, 1999) adapted to teacher education, and is named Meta-Didactical Transposition model (MDT).

This paper deals with the first step of a fresh study that focuses on one of the aspects that MDT model can investigate: how to study the development over time of researchers' praxeologies during a teacher education program. At first we present MDT model and then we analyse the praxeologies of the researchers, who worked as teacher educators in a particular teacher education program (the MMLab-ER project). The paper shows how the theoretical lenses given by the MDT model can be useful to identify and then to analyse the development of a specific type of praxeologies: the meta-didactical praxeologies.

THEORETICAL LENSES

The knowledge needed for an effective teaching of mathematics is a crucial issue faced by the international research on math education. Drawing from Schulman's categories of knowledge (Shulman, 1986) and using examples from the practice of teaching, Ball and colleagues (Ball & Bass, 2003; Ball, Thames, & Phelps, 2008) identified a special Subject Matter Knowledge that they labelled as Specialized Content Knowledge (SCK): i.e., "the Mathematical knowledge and skills unique to teaching" (Ball et al., 2008, p. 400). This is a set of knowledge and skills that cannot be reduced only to the knowledge of the discipline or to the pedagogical knowledge: for instance, to look for patterns in student errors or to size up whether a nonstandard approach would work in general, require a specialized mathematical work not needed in other settings. The identification of the SKC is useful for analysing the knowledge involved in specific activities, but in order to describe the processes developed over time during a teacher education program, other theoretical tools are necessary. Therefore this paper presents some suitable interpretative tools that can be useful to describe and analyse the actions developed to face particular tasks in a teacher education program. In our research (Aldon et al., 2013; Arzarello et al., 2014), we adapted the Anthropological Theory of Didactics – ADT- (Chevallard, 1992, 1999) to teacher education, and we constructed the Meta-Didactical Transposition model – MDT – (Aldon et al., 2013). The ADT is a model of mathematical knowledge, conceived as a human activity developed for the purpose of addressing specific families of tasks. Its main theoretical tool is the notion of praxeology, which is structured into two levels: the "know-how" (*praxis*) and the "knowledge" (*logos*). The *praxis* includes different kinds of problems to be studied as well as techniques available to solve them. The *logos* includes the "discourses" that describe, explain and justify the techniques used. This theoretical discourse is called technology whose etymology derives from "discourse (logos) on the technique (technè)". The formal argument, which justifies such technology, is called theory. (Garcìa et al., 2006). As already underlined by Huillet (2009), the ADT can also give strong interpretative tools to analyse the mathematical knowledge and competencies needed by a mathematics teacher to teach mathematics in a given institution.

The MDT model gives the lenses for studying the different praxeologies developed during a teacher education program. These praxeologies develop by means of the interaction between the community of researchers and teachers, who can develop both new awareness at a cultural level and new skills in teaching.

This paper argues the researchers' meta-didactical praxeologies development by means of an explanatory example of a teacher education program carried out in Italy, the MMLab-ER project (see next paragraph). The paper focuses on the meta-didactical praxeologies, analysing their development over time at *praxis* level and at *logos* level. The term "meta-didactical" denotes that these praxeologies deal with the actions and the reflections of researchers about the educational activities. The analysis of these praxeologies is useful to show when and how researchers' actions and theories develop by reflecting upon the nature of and reasons for the changes that occur. The study of the meta-didactical praxeology is a fresh way to analyse the processes involved in a teacher education program because it doesn't focus only on PCK (Schulman, 1986), or on SCK (Ball et al., 2008) or on the relationship between researchers and teachers, or on the actions carried out to orchestrate the working group sessions.

This paper shows a germinal study about the developing interlacement of the praxeologies linked to researchers' work as teacher educators, and to the praxeologies developed when they study theories, plan, observe and analyse classroom activities, or construct theoretical lenses to describe and interpret students' difficulties and successes.

THE MMLAB-ER PROJECT

The MMLab-ER project, framed in the Italian research for innovation (Arzarello & Bartolini, 1998), responded to national and international standards about Inquiry Based Science Education (Rochard et al., 2007). The researchers involved in the projects are also the teacher educators. The project aimed at the construction of a network of well-prepared in-service teachers (primary and secondary school teachers) about mathematical laboratory and about the semiotic mediation processes (Bartolini Bussi & Mariotti, 2008). In this project, ancient and new tools were involved: i.e. working reconstructions of ancient mathematical machine and ICT (Bartolini Bussi et al., 2011; Martignone, 2011, Bartolini Bussi & Martignone, 2013). The focuses of the MMLab-ER laboratory approach were the analysis of exploration and argumentation processes (Boero, 2007) and the study of the cultural aspects involved (Bartolini Bussi & Martignone, 2014). During the MMLab-ER activities, the teachers carried out a Cultural Analysis of Content (Boero & Guala, 2008) that consists of working on what they know about a specific content and, above all, on their capacity of analysing the historical, cultural and epistemological aspects of the mathematical content involved. During the project, teachers were engaged in laboratory activities designed and orchestrated by the teacher educators; afterword, the teachers designed and carried out several teaching experiments with their classes. During the meetings, and also by means to e-learning platform, the teachers and the teacher educators shared and discussed the teaching experiments plans and results. Over a period of four years (2008–2012), the project was carried out for the first two years, followed by one year break in which the researchers analysed the project results, and resumed and completed on the fourth year. This development makes the MMLab-ER project a suitable example for studying the development of the meta-didactical praxeologies over time.

THE RESEARCHERS' PRAXEOLOGIES DEVELOPMENT

In this paper, the focus is on the researchers' meta-didactical praxeologies. Some of the researchers involved in the MMLab-ER project (in particular, over the whole four years, the researchers involved were Rossella Garuti and myself) analysed their actions using the MDT model lenses. We analysed our meta-didactical praxeologies (both as teacher educators and as researchers) in three different phases of the MMLab-ER project: at the beginning, during the first two years, and in the last year of the project. The MDT model gives us some interpretative tools to control the overall development of researchers' meta-didactical praxeologies, identifying how these praxeologies changed at different levels: *praxis* level and *logos* level.

At the beginning of the MMLab-ER project

When the MMLab-ER teacher education program started, the researchers had their own meta-didactical praxeologies linked to: 1) their studies on students' activities in the classroom, and 2) their experiences and studies on teacher education. In the former ones, the problem is to study the educational potential of the laboratory activities with mathematical machines. In the second ones, the researchers' praxeologies are linked to their work as teacher educators. These praxeologies are strictly intertwined but the *tasks*, *techniques* and the *theoretical discourses* are different. According to the aims of the MMLab-ER project, the researchers designed the activities to foster teachers' attention on the exploration processes, on the conjecture productions, and on the proof constructions. The *techniques* concerned the development of *tasks for teachers* (Watson & Sullivan, 2008) that include, for example, the selection and the analysis of some teaching experiments (Martignone, 2011). The following tables contain the answers to the questions: which tasks did the researchers face? Which techniques did they use? Which theoretical tools were in the background?

Table 1 describes the different aspects of researchers' meta-didactical praxeologies (P_{R1}), where the *task* is to think over the educational potential of the laboratory activities with mathematical machines. These praxeologies are meta-didactical because they reflect on educational activities. They are developed when the researchers study theories, plan, observe, analyse classroom activities, and construct theoretical lenses to describe and interpret students' difficulties and successes. Table 1 details the techniques and the theoretical discourses involved in these praxeologies.

Table 2 describes the researchers' praxeologies linked to the researchers' work as teacher educators and their studies on teacher education processes (P_{R2}). Also in this case, the praxeologies are meta-didactical, because the *task* is about the reflection on educational activities that involved in-service or pre-service teachers.

In the MMLab-ER project the researchers were also the teacher educators, therefore they directly observed and then reflected on the activities carried out during the teacher education program. The theoretical background was grounded on the research on teacher education (see Table 2).

Tables 1 and 2 show how the praxeologies components developed by the researchers are different when they reflect on classroom activities or on their work as teacher educators. The actions and the theoretical

background are coherent. The study of the *praxis* and *logos* levels of these meta-didactical praxeologies allows us to underline the different features of the work of the researcher, who is also a teacher educator during a teacher education program. As already underlined, the *praxis and logos le*vels of the different praxeologies identified are strictly linked but we can distinguish, according to the different *tasks* faced, the specific *techniques* and *theoretical discourses* involved. The next paragraphs describe how these praxeologies change over time.

During and at the end of the MMLab-ER project

During the MMLab-ER project new praxeologies are generated by the intertwining and sharing of praxeologies developed by researchers and teachers. The teachers and the researchers analysed together the laboratory sessions: in particular focusing on the exploration processes, the conjectures productions, and the proof constructions in the activities with mathematical machines. By means of this work, in which theory and practice are strictly intertwined, new shared praxeologies developed, and also the previous teachers' and researchers' praxeologies improved. The analysis of praxeologies is useful to show when and how researchers' actions and theories develop, by reflecting upon the nature of and the reasons for the changes that occur. Focusing on researchers' meta-didactical praxeologies, we have identified the aspects that do not change and how the *praxis* and *logos* levels of the initial researchers' praxeologies (Tables 1–2) are modified over time. We face these questions: How do the researchers meta-didactical praxeologies change? At what level? Why do they change?

During the first two years of the MMLab-ER project some *techniques* of the researchers' praxeologies were improved by introducing new activities elaborated with the teachers, and by modifying some *tasks for teachers* and classroom tasks. We took into account what was discussed during the teacher education program, and we refined the tools for analysing teachers' and students' worksheets, logbooks, videos, etc. (Martignone, 2011). Also the *theoretical discourse* was improved by refining some interpretative tools: for example, the cognitive studies about mathematical machines were developed by analysing and identifying the argumentation processes involved (Antonini & Martignone, 2011).

During 2011, while waiting for new funds for a new start of the project, the researchers had the possibility to analyse all of the documentation collected: in particular, videos and worksheets about the laboratory activities carried out by teachers and students, the teachers' reflections collected in the logbooks, and the final reports of the teaching experiments, all stored in the MMLab-ER e-learning platform. In the last year of the project, the materials produced in the previous teaching experiments (educational paths, worksheets, final reports [6], logbooks, etc.) became the starting point for new teaching experiments designed and carried out in the classrooms by the teachers. The reflection on the previous activities influenced the design of the tasks and the development of the researchers/teacher educators' *techniques*: for example, some activities were modified, others were removed. Through the lenses of praxeologies development (P_{R2}) we can see that an improvement of meta-didactical praxeologies *techniques* occurred: modifying some *task for teachers*, removing others, introducing new tasks elaborated with the teachers involved in the previous years of the project. Researchers worked with the new teachers in analysing many logbooks, used as tools for reflection, and in sharing the analysis carried out with the previous teachers. There was also an improvement in the *logos* level: developing new studies on cultural and educational aspects involved (Bartolini Bussi & Martignone, 2014).

Thanks to the project, the researchers had the possibility to work with teachers for many years, developing long term collaboration. They carried out design and fine grain analysis of their teaching experiments. Therefore the researchers improved also their praxeologies about the reflection on students' activities with mathematical machines (P_{R1}). They shared reflections and theoretical tools with teachers in order to interpret students' difficulties and successes (Banchelli & Martignone, 2013), and to design new activities to overcome the found obstacles and to investigate new aspects about the educational goals of the activities.

CONCLUDING REMARKS

The paper describes how the identification of the meta-didactical praxeologies can be used to analyse the researchers' actions and reflections developed during a teacher education program. The development over time is described as a sequence of frames where the researchers' praxeologies change. In particular, the overall development of researchers' praxeologies can be checked by studying how the praxeologies changed at different levels: practical-technical and theoretical. The identification of these different levels, the *praxis* level (or "know how") and the *logos* level (or "knowledge"), gave us a fine grain tool to analyse how the praxeologies change over time. We would like to answer the questions: Which are the researchers' meta-didactical praxeologies? How do the researchers' meta-didactical praxeologies change? At what level? Why do they change?

In the paper, the different features of the work of the researchers, who work also as teacher educators, are identified by distinguishing the different *tasks*, *techniques* and *theoretical discourses* developed. The new key (explained by the word "meta") is the identification of reflective actions about the activities carried out by the researchers/teacher educators in a teacher education program. The analysis of the meta-didactical praxeologies is useful at first to identify and then to think about the evolution over time of important aspects linked to the work of researchers involved in a teacher education project. The next step of the research will consist in an improvement of the theoretical tools used to study the praxeologies development: in particular, we will carry out a fine grain analysis of the praxeologies by classifying them as specific, local, regional and global (Chevallard, 1999). These further interpretative tools could be useful to describe the complexity of the meta-didactical praxeologies developed in the teacher education programs.

As a final remark, it is important to stress that this paper deals with a little part of the research that used the MDT model: as a matter of fact, MDT model can give also useful tools to compare the components of meta-didactical praxeologies involved in different teacher education programs carried out in the same country or in different ones (Aldon et al., 2014). Moreover, the research group will work on further developing of the MDT theoretical tools, in order to make them suitable also for planning and designing new teacher education programs.

Mathematics educator transformation(s) by reflecting on students' non-standard reasoning

Maria Mellone[1], Arne Jakobsen[2] and C. Miguel Ribeiro[3]

2 University of Stavanger, Stavanger, Norway

3 Norwegian University of Science and Technology, Trondheim, Norway

In this study, we present some results stemming from a research work exploring the way in which prospective teachers develop their interpretative knowledge and awareness by discussing students' errors and non-standard reasoning. For this purpose, we designed a particular kind of task that was administrated and discussed in our own lectures. The discussions and reflections associated with this experience allowed us, as educators, to expand our own mathematical knowledge and awareness. Based on the analysis of video-recorded lessons delivered as a part of a course based in Italy, we will argue that work grounded in discussing students' naive ideas/non-standard reasoning represents a core aspect of the mathematics teachers' education field, whereby educators are also viewed as learners.

Keywords: Teacher's knowledge, educator's knowledge, interpretation, pupils' productions.

INTRODUCTION

This work is a part of a wider research project aimed at accessing and developing the knowledge mathematic teachers require for effective instruction. Part of this work pertains to designing and implementing contexts and tasks suitable for promoting the development of such knowledge. In our previous work, the focus was mainly on prospective teachers' answers and reasoning when solving a specific task. In this paper, we expand on this early work and promote a discussion on our own reflections upon the implementation and analysis of this particular task and the way of managing it. This particular task is essentially rooted in asking the (prospective) teachers to provide sense to students' productions, some of which can be considered incomplete, containing errors, or simply being grounded on nonstandard reasoning (e.g., Jakobsen, Ribeiro, & Mellone, 2014; Ribeiro, Mellone, & Jakobsen, 2013b). Our aim is to provide reflection on how this kind of task can promote mathematical knowledge development among (prospective) teachers and teacher educators.

Several historical examples show that the growth of mathematical knowledge often occurs through a dialectic process of "proofs and refutations," where initial, and often partially incorrect, hypotheses are progressively refined through a critical analysis of their consequences (Lakatos, 1976). Moving from a phylogeny to an ontogeny level, we can argue that this is similar to the learning process experienced by an individual. Adopting this perspective, a learner that makes an error can be compared to a person that got lost on his/her journey. Thus, if (s)he had an important meeting, (s)he will likely arrive late and agitated. On the other hand, if (s)he is a tourist who is visiting new places, getting lost may be perceived as an opportunity to discover new places that (s)he wouldn't have known otherwise (Borasi, 1994).

Grounded in some of our previous work (mentioned above), and starting from these reflections, we argue that the work on errors, incomplete answers, or non-standard reasoning should represent a core aspect in and for developing mathematics teacher education. Agreeing with Tulis (2013), we claim that teachers must be sensitive to students' errors and nonstandard reasoning. We also point to the fact that, in everyday classroom, a learning climate in which errors are perceived in a positive way should be established, allowing students to learn from their mistakes. The development of positive attitudes towards errors should be pursued from the beginning of mathematics teachers' professional development (assuming that it starts in teachers' initial training). With this aim, we worked in our own courses with prospective teachers (and in other professional development contexts) using the previously mentioned particular type of task. This task has been used in our lessons as a prompt to orchestrate a mathematical discussion (Bussi, 1996). We used mathematical discussion as main tool to develop, together with our students, mathematical knowledge and new awareness of the opportunities and richness of learning experience that can come from the work on nonstandard reasoning. Such use is thus also aimed at building a co-learning community, throughout an inquiry community perspective (e.g., Jaworski & Goodchild, 2006).

THEORETICAL FRAMEWORK

In mathematics teacher education, only a few approaches are using mistakes and nonstandard reasoning as a resource in Mathematics Education (Tulis, 2013). From our perspective, one of the core aspects of teaching practice should focus on developing teachers' knowledge that can assist them in giving sense to students' productions and perceiving errors as a learning opportunity (e.g., Ribeiro et al., 2013b). Such knowledge would allow teachers to develop and implement ways to support students in building knowledge that is founded in their own reasoning, even when such reasoning differs from that expected by the teacher. Aiming at accessing and developing such knowledge and ability, we have been developing tasks for teacher training that require them to solve problems before trying to give sense to students' productions aimed at answering such problems. Thus far, these tasks have been used as a tool for both observing and deepening the access to prospective teachers' mathematical knowledge for teaching (MKT) (Ball, Thames, & Phelps, 2008). Driven by this prompt, we also aim to support, in our lectures, the development of prospective teachers' MKT. During this research work, we have been focusing on a particular kind of knowledge we refer to as *interpretative knowledge* (Jakobsen et al., 2014). It is essential for teachers to possess, as it entails the knowledge in and for making sense of students' solutions and helps teachers provide productive feedback to them (in the sense discussed by Bruno & Santos, 2010).

In particular, we recognize the peculiar and specific nature of this knowledge and thus consider it a part of the Specialized Content Knowledge (SCK) domain of the MKT model, while also recognizing its links to the Pedagogical Content Knowledge (PCK). Findings of our previous studies indicated that a poor Common Content Knowledge (CCK) compromised the prospective teachers' ability to give sense to students' solutions that differed from their own. Indeed, we found evidence in support of our hypothesis that a lack of common knowledge on a particular mathematical topic hinders the prospective teachers in forming a flexible perception of that topic, making it difficult to move to different visions and their potential use in teaching (Ribeiro et al., 2013b; Jakobsen et al., 2014).

At this time, our research work is moving to another aspect we consider intrinsically involved in the kind of mathematical activity developed in teacher training—our growth and development as mathematics teacher educators. For this reason, we are complementing the previous focus on MKT and on the interpretative knowledge with the Inquiry community perspective (see, for example, Jaworski & Goodchild, 2006). According to this approach,

> Didacticians have designed activity to create opportunity to work with teachers, to ask questions and to see common purposes in using inquiry approaches that bring both groups closer in thinking about and improving mathematics teaching and learning . . . . This design process is generative and transformative. (Jaworski & Goodchild, 2006, p. 354)

The principal aim of this approach is to work with teachers as co-learning professionals, with didacticians and teachers each contributing with their specialist knowledge in order to collaboratively develop new knowledge in practice (e.g., Schön, 1987; Wagner, 1997). By using this type of tasks in our lectures, and paying attention to the response we receive from the attendees, we, as educators, are living a transformative experience, derived from participating in what we consider a co-learning community with our students. The idea of Inquiry Community is rooted in the Activity Theory Framework (Vygotsky, 1978), comprising of a subject, an object, and a mediation between them. In our case, the subjects involved are the community of prospective teachers and teacher educators. The mediation corresponds to the task, whereby the prospective teachers are asked to give sense and feedback to students' solutions. Finally, the outcome is the MKT development of both prospective teachers and mathematics teacher educators. The considered perspective for professional development of teacher educators is grounded, from one side, in reflecting and discussing upon our own practices (e.g., Avalos, 2011). On other side, complementarily, we also assume that being a teacher educator involves much more than applying the skills of school teaching to a different context (e.g., Loughran, 2014). In our view, it requires a specialized type of (complementary) knowledge that the teachers need (e.g., Superfine & Li, 2014) in order to expand teacher trainers' vision of teaching. At this stage, working with students must be different from working with teachers, and should focus on deepening the "hows," the "whys" and the connections among and within topics.

METHOD

The context of this study is the mathematics courses in teacher education, in particular some courses where we (the authors) were the lectures. In this paper, for brevity, we limit our focus to the data pertaining to two classes of the course held in Italy. This course is taught in the third year of a five-year program of the master degree in education, and can be taken upon passing the Foundation of Mathematics exam.

In the course, different tasks were explored, focusing on problem solving aimed at exploring particular mathematics education issues in depth (e.g., arithmetical, algebraic, and geometrical thinking) and the students' MKT pertinent to such issues. Complementarily, the course also focused on more general mathematics education approaches (e.g., sociocultural nature of learning, semiotic mediation process), among other goals. The entire course was conceptualized assuming the Inquiry Community Perspective, with the aim of promoting the development of a co-learning community. Around 100 prospective primary teachers participated in these classes. In addition, one educator/researcher was responsible for delivering the course, while one researcher took responsibility for the data collection (gathering the prospective teachers' written answers, as well as audio and video recording the classes). This was the second course in which this task was implemented and pertinent data gathered.

During the first lesson of the activity, a questionnaire containing the task was given to prospective teachers, asking them to answer it individually within one hour. The task required them to solve a very "simple" problem. They were given the following instructions: *Teacher Maria wants to explore with her students some notions concerning fractions. For this purpose, she has prepared a sequence of tasks involving five chocolate bars. Let us look at one of them: What amount of chocolate would each child get if we divide five chocolate bars equally among six children?*

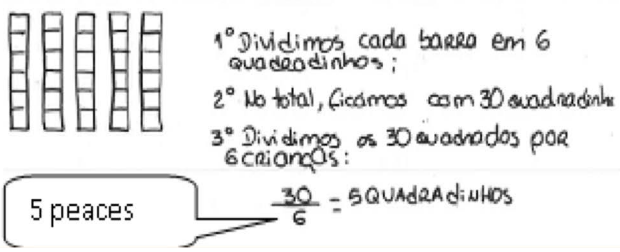

Figure 1: Ricardo's solution "1° We divide each bar in six squares; 2° In total, we have 30 squares; 3° We divide 30 squares among the 6 children. 30/6=5 squares"

After completing the task (i.e., providing their own answer to the aforementioned problem), we asked the participants to consider some students' solutions to the same problem. Some responses contained errors while others were incomplete, and some involved a nonstandard approach to problem-solving. Figure 1 and 2 present two of those responses, while a broader discussion of the productions included in the questionnaire is given in Ribeiro, Mellone, and Jakobsen (2013a). In particular, we asked prospective teachers to give sense to a set of pupils' productions, while following specific requirements: (i) For each pupil's production, decide if you consider it mathematically correct (adequate) or not, and justify the (in)adequacy of the mathematical rationality shown; (ii) Give a constructive feedback to pupils, especially to students whose answers you consider inadequate, and create a set of possible questions in order to promote their mathematical knowledge development.Data from the questionnaire was analyzed in terms of prospective teachers' own solutions to the problem, taking into consideration the different types of answers given,

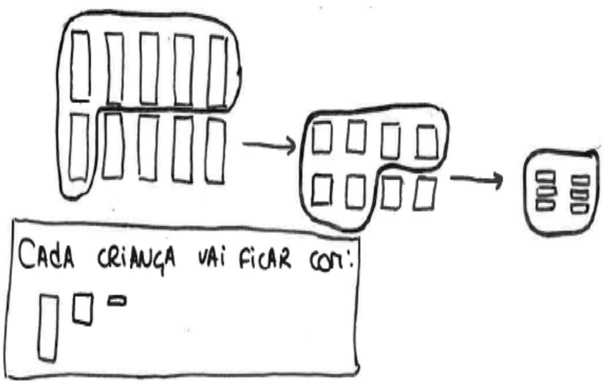

Figure 2: Mariana's solution "Each child will get"

the number of representations used, and their evaluations of the pupils' solutions (for further details, see Ribeiro et al., 2013b). The subsequent lesson, grounded in the collective mathematical discussion (Bussi, 1996) of the task was video recorded and analyzed in terms of prospective teachers' and educators' own reflections, discoveries, and points of turn in the MKT development. The fact that we, as educators, are considered an integral part of the inquiry community, in particular community of learners, is the key point of this paper. Nonetheless, this same fact represents a sensitive point of the method we chose for our analysis, since we analyzed "ourselves." However, in this case, we analyze the Italian experience. Thus, at the beginning of the lesson, the Italian researcher was chosen to provide her point of view on some crucial points of the mathematical discussion that took place. In the next stage, we conducted a joint analysis, followed by joint discussion and reflection.

SOME EVIDENCE OF THE TRANSFORMATIVE EXPERIENCE

The transformative experience is a complex process and there are several considerations to take into account. Here, we will focus on two examples of the kind of reflections that are driving our experience, as well as our reflections and discussions. These examples were chosen because they are perceived as constituting crucial and critical points of the mathematical discussion undertaken. In particular, we focus on some of the mathematical discussion that took place when commenting on Mariana's solution (Figure 2). It should be noted that prospective teachers' answers to the questionnaire revealed that some found interpretation of this solution particularly difficult. This finding is in line with the reports of Norwegian (Jakobsen et al., 2014) and Portuguese experiences. Among the prospective teachers' comments to this solution, the following answers were particularly interesting:

> Mariana's solution is not understandable, so the first question would be: what does this representation mean? After I have listened to her answer, I will try to show her my own representation and we will reach the solution together"; or "She does not understand fractions – she is just dividing the pieces.

Comments such as these reveal the difficulty these prospective teachers had in leaving their own space of solutions. In particular, when this space consists of a single element (Jakobsen et al., 2014), it seems impossible for prospective teachers to appreciate and understand different solution strategies students adopt. As a result, they are unable to exploit them to support children's deeper knowledge development on the subject. Many of the prospective teachers responded in a similar way. A particular case concerns those that provided answers using only natural numbers, similar to Ricardo's solution (Figure 1), or saying "*each will get 5/6 of each chocolate bar.*"

The collective discussion promoted some changes in reasoning and argumentation. Here, it is worth noting the difficulties in orchestrating a mathematical discussion within a community of about 100 individuals. Thus, in order to facilitate constructive discussion, Mariana's production was projected on the wall and was thus clearly visible to all participants, while the educator focused on identifying prospective teachers that wanted to comment on the solution (using a microphone). After some minutes of discussion, in which most prospective teachers expressed their difficulties in understanding Mariana's reasoning (including how she obtained 10 bars), something changed. This is evident in Miriam's contribution to the discussion.

> Miriam: She basically takes the five bars and divides them in half and so she has ten pieces, so she gives six, while four remain. Then she divides the others in half again, and then there are eight and she assigns six, so two remain. The other two are divided into three parts, so six more pieces. Then finally, she says: every child will have a half of bar, plus the half of the half of a bar and a third of a bar (she stopped)
>
> –voices of students who want to intervene–
>
> Educator: Wait a moment, give her time...
>
> Miriam: mmm ... it's as if ... a third of the half of the half.

It is worth pointing out that Miriam, along with the majority of the prospective teachers that took part in the discussion, did not previously understand Mariana's solution. However, by building her own reflections on those of her colleagues, she was able not only to understand something that was not clear during the individual work, but also to recognize in the pieces of Mariana's representation the particular fractions representing parts of the unit (the chocolate bar) involved. In the next step, the educator proposed to all participants to write down the explanation Miriam provided. The aim of this task was to prompt the prospective teachers to understand and verify the equivalence between 5/6 and the sum of these particular fractions. The amazement most prospective teachers felt upon discovering the meaning of Mariana's solution was the prompt to build an interesting discussion about the fact that, just because one does not understand something, it does not mean that it is incorrect. Such prompt also facilitated exploring links between teachers' specialized and pedagogical content knowledge, as well as understanding its importance/role in practice (e.g., Ribeiro & Carrillo, 2011). One of the focal points of the task conceptualization and implementation is on exploring and developing students' awareness on the knowledge involved (nature and type) in and for elaborating constructive feedback. In taking this approach, we were deepening some aspects of Bruno and Santos's (2010) work on written feedback.

While discussing and reflecting upon Mariana's production, prospective teachers experienced some contingency moments (Rowland, Huckstep, & Thwaites, 2005), allowing us to reflect and discuss upon the work we had done thus far. Such reflection is linked to the development of a mathematical knowledge we, as mathematics teacher educators, experienced by sustaining our own professional development. The situation presented here was driven by a comment made by Francesca, another prospective teacher. Indeed, after recognizing the correctness of the subdivision of the bars presented in Mariana's solution, most prospective teachers also saw the possibility to create numerical representations of the quantities indicated within the drawings. However, another issue was raised by Francesca.

Francesca: Yes, I think it is mathematically correct, because there are six children. But, if I had seven children, for example, I don't know if this division into equal parts could work. However, it was a trial and error process and this time it succeeded; but I do not know if, with other numbers, it could work.

Educator: So . . . you are saying that this procedure does not seem to be applicable to other numbers ...

Francesca: I do not know, it amazes me, but perhaps it could not work with other numbers.

At that moment, the educator was not prepared for such a comment and did not prompt a discussion that would explore this issue further. However, Francesca's comment was a focus of discussion and reflection in the scope of the research group, and served as a starting point for developing a new mathematical awareness. Indeed, on one hand, according to Empson, Junk, Dominguez, and Turner (2006), Mariana's solution can be seen as a *progressive parts strategy* considering it without any anticipatory organization of the subdivision. Yet, on the other hand, such solution reflects a peculiar management of subdivisions, with the potential for being generative of a precious mathematical insight. One can argue that Ricardo's solution (Figure 1) is grounded in the understanding/assumption that, in order to equally share five chocolate bars, each bar can be partitioned into 6 parts, thus perceiving $\frac{5}{6}$ as equivalent to $\frac{1}{6}+\frac{1}{6}+\frac{1}{6}+\frac{1}{6}+\frac{1}{6}$. Linked to this strategy, in which it is possible to recognize a kind of anticipatory thinking (Empson et al., 2006), there is the view of a fraction $\frac{n}{m}$ as equivalent to the sum of n unitary fractions $\frac{1}{m}$. In contrast, Mariana's progressive partitions strategy suggests an interpretation of $\frac{5}{6}$ as equivalent to $\frac{1}{2}+\frac{1}{4}+\frac{1}{12}$. Thus, it is impressive to see how this particular representation of a fraction as the sum of unitary fractions appears naturally in her reasoning. Her approach reveals the possibility to represent uniquely any fraction as a finite sum of decreasing rational numbers, such that the first element is the integer part of the fraction and each subsequent one is the greatest unitary fraction that is contained in the remaining part, which can be represented as $\frac{n}{m}=i+\frac{1}{q_0}+\frac{1}{q_1}+\ldots+\frac{1}{q_k}$. Such a representation has the strong advantage of showing clearly a sequence of rational numbers, simpler than the one assigned, that are, in a sense, the best lower approximations of it. Thus, after developing these reflections, during the following class, the educator had the opportunity to discuss the findings with the prospective teachers. The aim was to allow them to develop complementary elements to be included in their own space of solutions (e.g., Jakobsen et al., 2014).

SOME FINAL COMMENTS

In this paper, some insights and reflections pertaining to a particular task were presented. The discussions prompted by Mariana's production have provided the opportunity to reflect on prospective teachers' knowledge elaboration on a particular aspect of fractions, as well as on our own role in the development of such knowledge and of our own awareness. However, we want to stress that, although such reflections were grounded in a task on fractions, the mathematical topic itself and the particular mathematical fact of "discovering" the possible link between Mariana's solution and the representation of a fraction as the sum of unitary fractions, are not the focus here. Indeed, as a meta-discourse, we are arguing something more general. The experience, and the way in which we presented it, is perceived as a contribution to the discussions and the associated reflections that highlight the need for a more focused work (and research) on the interpretative knowledge needed by (prospective) teachers and their educators, and the way(s) to promote it. Moreover, assuming that teachers and teacher educators need different "ways of hearing," we argue that different aspects and different natures of professional knowledge need to be taken into account when designing and implementing teacher training. The ultimate aim of this initiative is a joint and intertwined development of all the constituents of the inquiry community (Jaworski & Goodchild, 2006).

A significant number of diverse possibilities and paths for discussion were anticipated when we discussed and prepared the task and its implementation. Fortunately, some unforeseen situations emerged, leading to improvisations, some of which corresponded to contingency moments (Rowland et al., 2005). The reflections upon these situations, and the associated discussions on our own practice, have enabled us to develop a broader perspective on the process of teaching teachers, providing us with a deeper insight into what it requires and entails. Indeed, as we listened to the prospective teachers' comments on the proposed students' solutions, we also had some difficulties in interpreting and giving sense to their reasoning. This has led to mathematical critical moments, allowing us to reflect upon them. In our view, this is an essential aspect in and for promoting professional development for teachers as well as teacher trainers. In this sense, collaboration among the authors was crucial. By reflecting upon the discussion with prospective teachers, we could appreciate the type and nature of possible connections, representations, and navigations that could be made (needed) between and within topics. This has been one triggering event, leading to the awareness of the need to help teachers develop a much deeper knowledge. The work of Superfine and Li (2014) is a good example of an effort aimed at deepening and evolving this knowledge further.

Finally, we want to call attention to inextricable links among the tasks we prepare and implement (type, nature, and focus), the role of research on (prospective) teachers' knowledge and practices, and the learning opportunities we, as facilitators, provide. In order to also bring together theory and practice, we must recognize the importance of the role teacher trainers play in developing teachers' knowledge and practices. Thus, we argue that, if we want to enable prospective teachers to give sense to students' solutions and provide constructive feedback, we, as educators, need to do the same, albeit with a different focus. We posit that the courses specifically designed for teachers must have aims differing from those classes for students are geared towards. In this sense, a practice-based approach, in which prospective teachers can experience similar situations to those we expect them to encounter with their students is essential. We also recommend that teacher training address the role and the attitude of the educator, as one of the key elements. In particular, we recognize the importance and the need for teacher educators to live/work in terms of transformative experience, being sensitive to growing opportunity it offers.

Characterizing one teacher's participation in a developmental research project

Hélia Oliveira and Ana Henriques

Universidade de Lisboa, Instituto de Educação, Lisbon, Portugal, hmoliveira@ie.ul.pt

This study was developed in the context of a developmental research project with eleven mathematics teachers and two university researchers working collaboratively during part of one school year. The paper analyses the participation of one teacher in the emergent inquiry community devoted to developmental research on tasks targeting students' statistical reasoning. Inquiry and modes of belonging to an inquiry community are present in the analysis of the data that were mainly collected in the collective meetings of the project. Preliminary results show that the teacher's participation is closely connected with an inquiry stance and critical alignment to her practice and in some instances to the project's goals.

Keywords: Inquiry community, statistical reasoning, developmental research.

INTRODUCTION

Assuming the important role of sound tasks and the use of technological tools to promote students' statistical reasoning, a developmental research project that seeks to deepen the understanding about the conditions for the development of that kind of reasoning in the classroom has been carried out by the two authors. Recognizing the teacher's central role in the classroom practice, the project assumed a collaborative nature, involving the authors, as researchers and a group of teachers who wanted to learn and share new ideas about the teaching of statistics in basic education.

The project was originally planned to be, simultaneously, a research and a teacher development project. Teachers had some previous contact with research in education and assumed the shared role of designers and researchers with the university researchers, as it happened in other developmental research projects (Goodchild, 2014). Our first reflections about the process, made us consider the teachers' participation in the group and its nature, as we observed that some teachers expressed doubts, resistance and delayed the implementation of the tasks in the classroom. Addressing this issue is seen by us as an opportunity to question the dynamics foresaw for the project, as well as to understand the conditions for professional development that were created. Preliminary analysis of the work carried out in the group made us conjecture if implicitly were we trying to promote an inquiry community (Jaworski, 2008) since we intended that all participants would assume a role in the tasks' design and in reflecting about their use in the classroom. We did not have readymade tasks for teachers to apply and we did not intend to include them in the action only (Jaworski, 2008). In fact, teachers got involved in designing the tasks, making punctual or important suggestions or proposing alternatives. We, as university researchers, had many questions and few answers and wanted to learn from this experience. However, since this was a funded project, there were certain constraints to the collaboration with the teachers, namely: the sessions should follow a predetermined time schedule and the teachers' written reflections had to fulfil some conditions. All this made us question how teachers would conceal the interests of their teaching practice and the compromise they had with the project.

In order to understand the nature of the teachers' participation in an emergent inquiry community committed to developmental research on tasks targeting students' statistical reasoning, we started by developing an exploratory study focusing on one teacher in the group. Thus, this study is oriented by the following research question: how did one mathematics teacher's participation in an emergent community of inquiry evolve? With this study we also intend to reflect about the conditions created by this developmental project for teachers' professional development.

THEORETICAL BACKGROUND

This study comes from a developmental research project that assumes the perspective of co-learning among teachers and researchers as they design tasks and environments and investigate their students' learning. This is in line with many recent studies that see this collaboration as a favourable setting for developing teachers' knowledge (Potari, Sakonidis, Chatzigoula, & Manaridis, 2010). Specially, when implementing new approaches in their classroom teachers may benefit from working in collaborative settings that involve other teachers and researchers (Ponte, Segurado, & Oliveira, 2003).

In a developmental research project based on collaboration, teachers and researchers both learn in the process since they come together to develop teaching with the goal of improving students' experience of mathematics (Goodchild, Fuglestad, & Jaworski, 2013). Concerning the practice that evolves when teachers and researchers are collaborating, learning occurs through inquiring into it (Potari et al., 2010). According to Jaworski (2008) inquiry is "a mediational tool in social settings enabling development of knowing between people and hence the participative individuals" (p. 327). When inquiry is used as a tool for learning and development, we can talk about an inquiry community (Jaworski, 2008).

According to Potari and colleagues (2010) the difference between a community of practice as conceived by Wenger (1998) and an inquiry community is that in the later inquiry is part of the norms of practice and so it attributes great importance to critical reflection on the practice, as a form of meta-knowing. Inquiry is assumed as a stance in those communities which "means to challenge regular practice when it is ineffective, to reflect on the reasons why an approach might not achieve the intended outcome and to propose alternative approaches" (Goodchild, 2014, p. 313).

Goodchild, Fuglestad, and Jaworski (2013) consider that inquiry can be used "as a tool to be a form of critical alignment, that is engagement in and alignment with the practices of the community while at the same time asking questions, trying out new approaches and reflecting critically" (p. 396), and therefore critical alignment is crucial for the developmental process. Jaworski (2008) contends that in opposition to communities of practice that are more stable, the inquiry community is emergent as "It does not avoid issues, tensions and contradictions, but deals with them as part of emergent recognition and understanding leading to possibilities for expansive learning" (p. 327).

In Wenger's work (1998), to belong to a community of practice involves three different modes: *engagement* – active involvement in mutual processes of negotiation of meaning; *imagination* – creating images of the world and seeing connections through time and space by extrapolating from our own experience; *alignment* – coordinating our energy and activities in order to fit within broader structures and contribute to broader enterprises. According to the author, when these modes work in combination in a community of practice, it can become a learning community. In terms of an inquiry community, critical alignment is also required as participants "engage in existing practices, aligning to some extent with those practices, but in a questioning or inquiry mode" (Jaworski, 2008, p. 314).

THE CONTEXT

The idea for the developmental project grew from our perception that statistics receives reduced attention from mathematics teachers in basic education in our country. They usually consider it an easy theme that does not require much time in its teaching. Recognizing the need to further understand how to develop students' reasoning using the technological tools at our disposal, specifically the *TinkerPlots* software, we envisioned that it would be more productive to involve teachers that are well informed and interested in this issue (Wells, 2007) in a joint enterprise of developing and testing specific statistical tasks in their basic education classrooms (5^{th} to 9^{th} grades), rather than to develop our theoretical ideas and then simply propose them to teachers. Previous experiences in collaborative research projects showed us that collaboration between teachers and researchers can produce important synergies (Ponte, Segurado, & Oliveira, 2003).

The proposal presented to the teachers concerned the participation in the developmental research project where two or three cycles of a sequence of task design, implementation in the classroom, analysis of results and refinement of the tasks would involve everyone in the group. To make collaboration possible in the multiple activities of the project we required that participant teachers were acquainted with research methods in education. Therefore the eleven mathematics teachers who accepted the invitation had diverse experiences in teaching statistics but all of them had a masters' degree in mathematics education or were attending such a course. However, the theme of statistical reasoning and the use of *TinkerPlots* software were new for the majority of the teachers in the group.

The work carried out was inspired in Design Based Research and followed a teaching experiment design (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). The university researchers were responsible for the overall plan of the project and for conducting the research and the teachers for developing small scale teaching experiments in pairs. The university researchers also assume the ultimate responsibility for the tasks to be implemented in the classroom and the guidelines for teachers to elaborate the reports of the teaching experiments.

The project had financial support that facilitated the support of one research assistance to collect data and extended itself for eight months (from November to June), in a total of 13 meetings (three to four hours each). The first three meetings were dedicated to discuss big ideas concerning statistics reasoning and the required conditions to its development and to explore the software's potentials. The perspective of Garfield and Ben-Zvi (2010) of Statistics Reasoning Learning Environment (SRLE) was discussed within the group and the basic principles of Cobb and McClain (2004) for the design of the sequences of tasks were adopted.

The first cycle in the design research took place in the subsequent meetings. The tasks' characteristics were informed by the principles of SRLE, and they were designed with the intention of providing meaningful contexts in which students would be challenged to formulate questions based on real data, analyse data with the *TinkerPlots* and to make data based informal inferences. Teachers generally worked in pairs, planning the lessons, collecting data and reflecting about them. One or both teachers in the pair implemented the sequence of tasks in one's class, and were supported by the other in the classroom management and data collection. After finishing the sequence, the teachers elaborated a short written report about each task and shared their experience in the group meetings. The materials produced and the joint reflection in the group informed the tasks' reformulation and the conditions for their implementation in the subsequent cycle by other teachers. In the last two meetings the teachers presented, in pairs, the reports of the teaching experiments, and discussed them with the group. Finally, they produced a written report that extended their oral presentation and presented the main ideas on the experiment.

Retrospectively looking at this group, we start conceiving it as an emergent inquiry community, where co-learning inquiry occurs as researchers and teachers are learning together through inquiry (Jaworski, 2008) about challenging tasks, the students' activity with technology and the opportunities for promoting their statistical reasoning. We share Jaworski's perspective that in this group "teachers and didacticians are both practitioners and researchers" (p. 312). The collaborative engagement of all members, even though they assumed different roles and identities, made possible the development of insider and outsider research (Goodchild, Fuglestad, & Jaworski, 2013). The projects' extended live period also contributed to emergent relationships among the participants, mainly among the pairs, and among university researchers and teachers.

METHODOLOGY

This study represents our first attempt to analyse teachers' participation and their professional development in the project. Among the eleven teachers in the group, we choose to start by studying Maira's participation as an exploratory case study (Cohen, Manion, & Morrison, 2007), since we were surprised by her reluctance in applying the tasks that were being designed in the project in her class. She was one of the two teachers who had previous experience with the software, and showed more enthusiasm in getting involved with the project from the beginning. Nevertheless, for several weeks we doubted she would apply the tasks in her classroom. Finally, Maira decided to apply two tasks with one 5th grade class that she considered very problematic, and this gave us the motive for trying to understand how her participation in the inquiry community evolved throughout the project, which is our research question.

All group meetings with the teachers were audio-recorded and the teachers' written reports from their teaching experiments were collected which allows us to understand the teachers' participation in the emergent community of practice. In a case study research, the identification of critical incidents or events is crucial for understanding the case (Cohen, Manion, & Morrison, 2007). Hence, after a careful reading of transcripts of all meetings, we looked for key moments in the project where Maira's discourse expressed more or less sense of belonging to the emergent community, and we used the notions of engagement, imagination and (critical) alignment (Jaworski, 2008; Wenger, 1998) to characterize her changing participation. According to the adopted methodology, the results are presented as a chronological narrative of events and combine description and analysis (Cohen, Manion, & Morrison, 2007).

RESULTS: THE CASE OF MAIRA

We identified four key moments related to Maira's participation in the project which define the four sections in the data analysis.

Discussing the theory

In the third meeting, the group discussed some theoretical principles concerning SRLE, based on one paper from Garfield and Ben-Zvi (2010). Maira connected the overall perspective about teaching of those authors with an episode from her classroom, which occurred a few days earlier. She expressed her difficulties in dealing with students' lack of interest in school, learning difficulties and disruptive behaviour in the classroom. Her decision to develop group work with these students produces evidence of her motivation to try new methods.

> ... this paper dates from 2010, but almost 20 years after my initial training course, we still debate the issue of the traditional teaching (...) Therefore there is a high resistance and I think it has to do with us ... I have been resisting but this week I promoted small group work [in that class]. I imagined it would be chaotic and this and that ... And again, I must admit: it didn't happen. The mistake is ours, because, perhaps, this was my best lesson since the beginning of the school year.

Conceiving her usual practice as different from the one reflected theoretically in the paper, Maira recognizes that there is a personal and general resistance to change, expressing *critical alignment* with it. The results gave her more confidence in assuming some risks with those students: "We have to belief and take a chance even in [the perspective of] a chaotic lesson (...) and then, maybe, we really have surprises".

In this meeting, Maira also attempts to give meaning to some theoretical ideas by trying to think about their connections with the statistical knowledge she considers possible to develop with 5th graders. Speaking about possible tasks for promoting students' statistical reasoning, the main goal of the project, she considers that:

> This kind of tasks that nurtures relationships is important, at least to develop their vocabulary and bring them close to this kind of argumentation, to the discourse that is used in statistical reasoning.

In the project's initial phase, Maira shows *critical alignment* to her practice, disposition to *engage* in the project, and motivation to *imagine* to do things differently. However, she is permanently thinking on the characteristics of the students and conjecturing about how those theoretical ideas (that the project seem to adhere to) might be adapted for her classroom (critical alignment with the project).

Thinking about the tasks

During the 5th meeting where one of the tasks for the 8th grade was designed, several discussions about the situations that could be adapted for the 5th grade occurred. In the next transcript, we observe that Maira shares her opinion about the tasks that she considers more suitable for her 5th grade class and the sequence in which they should be integrated.

> They [the students] need to have data that are very close to them, so they can recognize them ... Because... this is a completely different representation from the ones that they are acquainted with. They are used to see graphic, pie graphics, bar graphics, at least in the press, isn't it? (...) But if we want them to manipulate those data with a deep understanding, what each one represents, I think that is has to be something closer to them, as in the first task [discussed] where they insert the data.

In this moment, the teacher expresses engagement with the project, making suggestions that reflect what she knows the students' needs in this school level, and the kind of work they will do with the software.

Later on, Maira begins to question the opportunity for implementing the tasks in her classroom. In the 7th meeting, she speaks again about the students' misbehaviour, lack of interest in school, resistance to learning and lack of autonomy. She rehearsed many strategies but none seems to succeed:

> And also already tried to have a small text explaining what they have to do, [and asked them] "Let us read!" and "Let us do!", "No"! It's no use. (...) I really have to be by their side, even if it is only to read and to follow. So it will be an experience, perhaps... very difficult. (...) I have not been able to solve this.

It seems that in face of the circumstances, Maira starts questioning the possibility of developing the tasks as foreseen. It is still possible to identify her will to be engaged with the project, making part of the joint enterprise, but she also reveals a strong disbelief in obtaining any positive outcome from the implementation of the designed tasks with her students.

Discussing the lessons

Close to the end of the project, when teachers were presenting the results from their teaching experiments, Maira reacts to one comment of one of the two university researchers that she interprets as one of surprise for the lack of involvement of the students from a different teacher in the first lesson they used the software *TinkerPlots*.

> I know it is hard to hear when we have software which we, as teachers, find fantastic, that "with this the students became more restless". But we have to think in a different way ... It is obvious that the software has great potential, and it would be great that this was a magic formula that when entering the classroom the kids would be attached and involved ... but that is not going to happen... However, I think we should not lose this enthusiasm!

It seems that Maira is interpreting the project expectations in a simplistic way: we presume to have excellent results with these tasks. Maybe she has assumed some disappointment in university researchers concerning the effort made in producing the materials for the classroom and having the students not so involved has they expected. It appears that she is also manifesting her frustration by what she says next: "We have to consider that we have many obstacles".

Later in the same meeting, Maira reflects on the nature of tasks that have been designed and the difficulties her students had in dealing with their openness. She considers that such situation makes her reflect on the lack of opportunities their students previously had for working with such kind of proposals:

> [Students say]: "I don't know how to do! What shall I do?". And they were a bit lost. And that is also due to the fact, maybe, that her teacher ... didn't work certain kind of situations that can be explored and not the traditional "Calculate ... Determine", isn't it? Hence, there is a lot to do, really. I consider that this make us [think].

In this meeting, Maira expresses her lack of engagement with what she considers to be one motivation in the project, as she interprets the expectation of the university researchers. However, the difficulties faced by her students in understanding the questions in the tasks made Maira question her own practice and therefore exhibiting also critical alignment with it.

Inquiry on the students' activity

In the subsequent meeting, when presenting the results of her teaching experiment, Maira shows a small video from one moment of the collective discussion in the class, to share with the group of teachers something she valued positively:

> ... I thought this is interesting because, if you notice, they are really discussing this issue. And this issue of being probable or not is not so obvious (...) Carlos seems to be surprised "How come you did not understand?!" (...) But to her [another student] it was still confusing. And I think that the example given by Bianca was excellent and it was also very good that the other girl questioned that it was not the same thing, because in her representation a big difference was visible.

The interactions among the students are highly valued by Maira, as she identifies that they are discussing important statistical ideas, especially because this kind of social practice never occurred before in this class. In her final report about this experiment, Maira argues that the students' interactions that took place had "a noteworthy impact on improving the students' argumentative discourse", as well, allowed her to have "a clearer understanding of the informal inferences [that] emerged in groups and nurture a discussion of statistical ideas".

However, Maira also questions her role in those moments, considering that she could have explored more deeply some statistical concepts:

> ... when he spoke about "more than 50%" ... I could have taken that situation but then I left it because, in the meanwhile, the other girl was trying to speak ... It might seem ease but that [discussion] was a bit confusing, and sometimes we cannot grasp all.

Another important remark concerning Maira and her colleague's reflection about the teaching experiments was their proposal of a new category to analyse students' statistical reasoning, because they felt they had interesting results which did not fit the framework it was provided by the university researchers (by Makar & Rubin, 2009). Maira explained that the category appeared as they observed that students made generalisations that rely on the context: "which are statements that they do that come from their personal experiences and beliefs". In the final report, she refers explicitly the activity of her class and identifies different difficulties and limitations concerning students' statistical reasoning.

DISCUSSION

In this teacher's case it is possible to see elements connected with belonging to an emergent inquiry community. Maira engaged with the project in noteworthy ways since she expressed her ideas in the meetings, made an effort to understand the theoretical ideas conveyed, and was highly involved in reasoning about task design. Imagination was also present in her participation since she started to conceive the possibility of developing new approaches with the class even if this represented a big challenge for her. In an initial moment she appeared to believe that students could accomplish the project's expectations regarding the work with the designed tasks but as the project unfolds many doubts arise. We observe that Maira experienced a tension between the adherence to the joint enterprise of the group, with critical alignment to her established practice, and the non-participation in the implementation of the tasks, assuming that those can only be applied in certain favourable circumstances.

Close to the end of the project, through her inquiry about the taught lessons with the tasks designed in the group, she came to express her critical alignment: there were difficulties and the results were not in line with what she had imagined according to the project's goal – developing students' statistical reasoning. From her point of view, the conditions for developing the lessons according to the adopted model were not adequate. It was her further inquiry on data from those lesson supported by some theoretical ideas that helped her to notice some positive results and to evaluate what happened in some instances of the teaching experiment in a different way. This made her question her attitude and role in the classroom, and the mathematical situations she usually proposes in the class. The critical alignment with her practice, presents "possibilities to develop and change normal states" (Jaworski, 2008, p. 314).

The analysis of Maira's participation in the project shows that some characteristics of an inquiry community were present in the practices of the group, being inquiry an important aspect to consider. The developmental research project created many opportunities for discussing ideas among the group, and stimulated the teachers to negotiate changes to practice. Therefore, inquiry emerges in the participation of this teacher as an attitude that informs her practice and that it is not reduced to a technique applied in some situations (Goodchild, 2014). The results concerning just one teacher reveal the project's potentiality for promoting teacher development through a cycle of collectively planning demanding tasks, experiment them in the classroom and reflecting collaboratively about the outcomes using one analytical framework.

However, when we analyse the tensions Maira experienced concerning her engagement with the project, it appears that her active involvement in the mutual process of negotiation of meaning about the joint enterprise and its purposes was absent in some instances. This requires further research to understand how this was experienced by the other participants, and the implications of this participation to their professional development.

ACKNOWLEDGENT

This work is supported by national funds through FCT – Fundação para a Ciência e Tecnologia, Project *Developing statistical literacy: Student learning and teacher education* (PTDC/CPE-CED/117933/2010). We thank Ana Isabel Mota, research assistant in the project, for her extensive work in data collection for this study.

A model of theory-practice relations in mathematics teacher education

Kaj Østergaard

Roskilde University, Roskilde, Denmark
VIA University College, Horsens, Denmark, kost@via.dk

The paper presents and discusses an ATD based (Chevallard, 2012) model of theory-practice relations in mathematics teacher education. The notions of didactic transposition and praxeology are combined and concretized in order to form a comprehensive model for analysing the theory-practice problematique. It is illustrated how the model can be used both as a descriptive tool to analyse interactions between and interviews with student teachers and teachers and as a normative tool to design and redesign learning environments in teacher education, in this case a lesson study context.

Keywords: Anthropological theory of the didactic, teacher education, lesson study.

THE THEORY-PRACTIC PROBLEMATIQUE

Establishing coherence between theory and practice is one of the main challenges in mathematics teacher education (e.g., Bergsten, Grevholm, & Favilli, 2009). In Denmark more than four out of ten student teachers experience a lack of coherence between the teaching of general educational science and didactics taking place at the university college and the practice of teaching in schools (Jensen et al., 2008). Throughout the last decades teacher education has become increasingly academic – which can be seen as positive – but concurrently, the practices at schools have become much more challenging due to increasing social and ethnic segregation, which affect schools particularly in disadvantaged neighborhoods. Therefore, many student teachers tend to focus on practical teaching tools rather than academic theories. This development causes a risk of a widening of the gap between theory and practice in teacher education.

The theory-practice divide can be regarded from (1) theory to practice or (2) from practice to theory. Ad (1) the questions are: How can theoretical knowledge be utilized to analyze and develop teaching practice in schools and how do we create a shared frame of reference from teaching practice to interpret the theory? Subject matter knowledge, pedagogical knowledge and pedagogical content knowledge are taught separately at university colleges but are in reality inextricably entwined with each other. The challenge is how to create interplay between the academic theories of mathematics and pedagogy and teaching practice in teacher education. It is crucial to create this interplay in order to legitimize the theoretical education and to place school knowledge in a wider context.

Ad (2) the teaching practice must be made visible and handled as the main object of discussion and theorization in the teacher education. This is necessary in order to ensure that student teachers' learning in and from teaching practice is connected to the theoretical education and brings about a critical view on the theories and research from a practical point of view.

These complex theory-practice relations in teacher education calls for a model, which can be used to describe and analyze the interplay between mathematical and didactical knowledge; teaching practice and learning in both teacher education and mathematics teaching in school. In particular, it is important that such a model can help differentiating between the different kinds of theory-practice relations in teacher education.

The aim of the research project behind this paper is to answer the following two research questions:

1) What different kinds of theory-practice problems appear in mathematics teacher education – according to the student teachers?

2) How can these theory-practice problems be conceptualized and analyzed within a model based on *The Anthropological Theory of the Didactic* (ATD)?

In this paper, the focus is on how the model can be used as a tool for analyzing empirical data from a lesson study project with teachers and student teachers. However, at first, the model evolved will be presented and discussed. The paper is round off with discussion of the benefit of the model in analyzing theory-practice relations in mathematics teacher education and on how such analyses can inform the design and use of lesson studies in teacher education.

A MODEL OF MATHEMATICAL TEACHER EDUCATION

ATD (Chevallard, 2012) provides an epistemological framework for mathematical knowledge. In ATD mathematical knowledge, regarded as a human activity including teaching and learning mathematics, is modelled by mathematical and didactical *praxeologies* (Winsløw & Madsen, 2008). Praxeologies consist of a practice block (*praxis*) regarding the questions *what to do* and *how to do it* (know-how) and a theory block (*logos*) regarding *why to do it* (know why). In addition to this, ATD models the *didactical transposition* of mathematical knowledge from *scholar mathematics* mainly evolving at universities to *knowledge actually taught* and *learnt* in schools (Bosch & Gascón, 2006, p. 56). The didactical transposition is divided into two steps. The first step is the *external didactical transposition* from *scholar mathematics* to *knowledge meant to be taught* – the mathematical knowledge as it is described, for example, in curriculum and textbooks. This step is often performed by people outside the school. The second step is the *internal didactical transposition* from *knowledge meant to be taught* to *knowledge actually taught* – this step is every day work for teachers.

The two concepts, praxeology and didactic transposition, both bring central theory-practice relations into focus – the first one inside an institutional frame (e.g., the school) and the second in a broader context between institutions. Together they provide a comprehensive picture of teacher education in mathematics, which can be usable to point out and analyse problems and constraints as the theory-practice problematique.

In the model below the two concepts are combined to form a model for analyzing the theory-practice problematique in teacher education (Figure 1). In my research the model is intended to be a tool for both descriptive and normative analyses. At first, the model is used descriptively to analyze different kinds of empirical data from two lesson study projects in connection with teacher education. On this basis, the model will be used normative to propose new ways to organize teaching practice, preparatory education and the theoretical education at the university college to improve the coherence between theory and practice in teacher education.

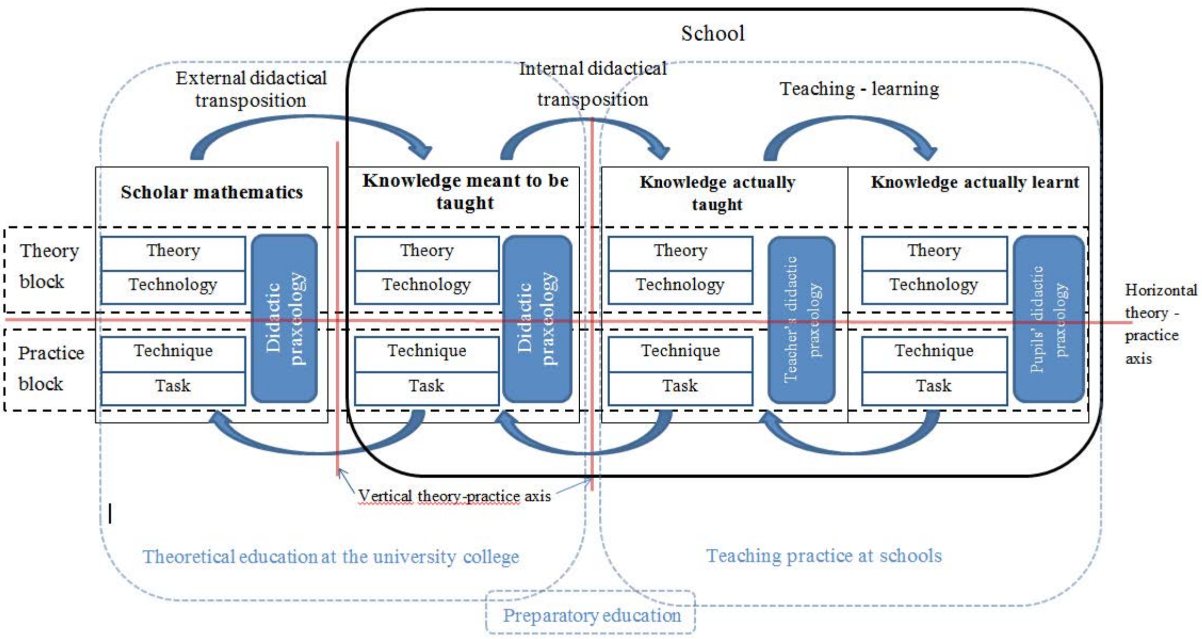

Figure 1: Teacher education model

The model consists of four columns containing the four kinds of knowledge in the didactic transposition. Each kind of knowledge is described by a mathematical praxeology with theory, technology, technique and task (see Winsløw & Madsen, 2008, for further details) depict with white boxes and a didactic praxeology, also with a theory and practice block, depict as blue boxes in Figure 1. By collocating the model and teacher education practice three different, pivotal theory-practice problems can be located – occurring in different forms. These are emphasized by red axes – two vertical and one horizontal axis.

The horizontal axis is dividing the practice blocks and the theory blocks. This axis stresses the divide between practical, procedural mathematics with emphasis on techniques to carry out tasks and theoretically *doing mathematics* by combining techniques and concepts, arguing, proving etc. The transcendence of this barrier is a crucial point for mathematical education – the higher level of abstraction in the theoretical block is a necessity but also a very difficult barrier to almost all pupils. Consequently, this axis is a significant problem area for teacher education both with regard to student teachers learning scholar mathematics and pupils learning mathematics at school and the relation between practice and theory block is an appropriate model in both cases.

The two vertical theory-practice axes are dividing, respectively, the scholar mathematics and knowledge meant to be taught and knowledge meant to be taught and knowledge actually taught. The divide in the first axis is treated at the university college. Comparison of scholar mathematics and knowledge meant to be taught is again highly relevant in teacher education to analyze what and why specific content is or is not selected for curriculum. It is pivotal for student teachers to be critical to this selection and to question the decisions in curriculum or textbooks. The arrows at the base of the model pointing "back", for example, from knowledge meant to be taught to scholar mathematics stresses that knowledge meant to be taught or actually learned can be taken as a starting point for analyzing the mathematical knowledge on the previous levels in the system. The latter of the vertical axes is dividing the theoretical education taking place at the university college and teaching practice at schools. To combine these two, university colleges often organize preparatory education as a special forum, depict as a small box in the bottom of the model.

The *internal didactical transposition* from knowledge meant to be taught to knowledge actually taught is everyday work for teachers and thus obvious content in mathematical teacher education.

The two columns to the right are a little different compared to the other kinds of knowledge. The relation between knowledge actually taught and knowledge actually learnt cannot offhand be described as a theory-practice problem because both are a part of the teaching practice at schools – the knowledge *actually* taught and learnt. Of course, teaching and learning can be described and analyzed by theoretical tools but the interplay at schools is a practice matter. As the transposition takes place inside school it is a part of the internal transposition but knowledge actually taught and knowledge actually learnt are closer connected and appears in a more direct interrelationship than the other kinds of knowledge. Student teachers are supposed to react to pupils' communication and learning, for example, during a dialogue in the classroom and adapt the teaching to the individual pupil or the specific class. Knowledge actually taught and knowledge actually learnt can be theoretically analyzed separately but are intertwined in practice. Therefore, the two kinds of knowledge are not separated in the model, but have a common borderline regarded as the interplay between the pupil's knowledge and the knowledge presented by the teacher in the form of the teaching environment presented.

THE LESSON STUDY PROJECT

The next section is an analysis of a group of two teachers and three student teachers' learning outcome from a lesson study project on the basis of the ATD-model. The lesson study was conducted in autumn 2013 in two classes grade 6 and 7 and the title was *"Similar – what does it mean?"* It was a part of a bigger lesson study project with the title *Trigonometry and inquiry based learning* involving 29 student teachers and 17 teachers conducted by a colleague and me. The empirical data from the lesson study consists of a lesson plan, video recordings of the two completions of the lesson, two 45 minutes interviews with one of the teachers and one of the student teachers and an article written by the student teachers. After the lesson study project I formulated an interview guide and accomplished the following data analysis on the basis of the ATD-model with a special focus on the three theory-practice axes.

Lesson study

Lesson Study is a Japanese form of action based development of teaching and teachers' and student teachers' teacher knowledge. In Japan, Lesson Study is an integrated part of both teacher education and teaching development in elementary school (Stiegler & Hiebert, 1999).

The ingenious and yet simple idea of Lesson Study is that the participants – student teachers and/or teachers – consider substantial didactical questions through mutual preparation, completion, analysis and reflections on one single lesson. Participants' observations and subsequent reflections on the pupils' learning and from this the didactical theme are crucial elements in the format. In the concrete project the student teachers studied trigonometry and inquiry based education at the University College before the project to be well-prepared to cooperate with the teachers. Together with the teachers, they prepared the lesson and formulate focus points for the observations to ensure that the observations are targeted at the didactical theme. A central element in Lesson study is the written *Lesson Plan* encompassing i.a. deliberations on mathematical, didactical and pedagogical aims of the lesson and hypothesis on pupils' strategies to solve the problems they are faced with. After a minimum of four hours of preparation one of the student teachers taught the lesson while the rest of the participants observed on the basis of the focus points. The lesson was evaluated immediately after the completion on the basis of the observers and the teacher's observations after a carefully worked-out plan. The evaluation resulted in suggestions to change the lesson and improvement of the lesson plan. Afterwards, the lesson was taught by a new student teacher in a new class immediately followed by an evaluation meeting where the second completion and the entire lesson study process was evaluated. The lesson plan was edited and the gained experience was described and discussed. At last, the student teachers wrote an article for *Matematik* – the Danish journal of mathematics teacher. It must be emphasized that the learning outcome from the lesson study not only – and not even mainly – relates to the lesson in question. On the contrary, lesson study is suitable to work with pedagogical and didactical problems on a generally level. The concrete and empirical basis opens up new possibilities to confront didactical and pedagogical principles with teaching practice at schools (for further details see, e.g., Lewis, 2002).

Data analysis: The lesson plan

The lesson plan is divided into three sections: First, some practical information concerning the participants, who taught the lessons, the name of the school, dates for completion of the lesson and the classes involved. The second part encompasses the tittle and aims of the lesson, competencies involved and working method. The last section is a detailed plan of the lesson containing mathematical focus point and learning goals of the lesson, a timetable, key question, teaching resources and useful tips for the teacher.

The lesson starts with a 10 minutes introduction to *geometric similarity* on the basis of every day examples of similar and not similar objects like a golf ball and a football, different sizes of Toblerone packaging (chocolate), enlarging/reducing in a photocopier and a pony and an Arab horse (not similar). After the introduction, the pupils receive a right-angled triangle cut of cardboard and the teacher asks the key question: *"You shall pretend that you are a photocopier and draw an enlarged and a reduced copy of the triangle".* This is the main mathematical task *t* of the *knowledge actually taught*. When the pupils have drawn the two triangles they must contact the teacher. The teacher then asks them two questions: *"How did you construct the triangles?"* and *"How can you convince me that the two triangles are similar to the one cut of cardboard?"* The two questions encompass the transcending of the horizontal theory-practice axis from the practice block to the theory block in knowledge meant to be taught. The teacher's didactic praxeology in connection to this mathematical praxeology is therefore a key issue of the lesson.

The crucial mathematical praxeology to be developed in the lesson study is based on the type of task T: *Given a right-angled triangle, how can you reduce/enlarge the size without changing the form?* A possible, predictable – and desirable – technique τ is to copy two or three angles from the cardboard triangle for instance by putting it on top of the paper and draw the angles and then reduce/enlarge the length of the sides. The technology θ to be realized by the pupils is firstly, that equiangular triangles are similar and secondary; the ratios between the lengths of equivalent sides are constant. Theory Θ – in this case the mathematical definition of similarity – is framing and justifying technology.

The lesson plan also points out some pivotal didactic praxeologies. One substantial didactical praxeology is concerning the inquiry based education mentioned in the category *mathematical working methods: "working in pairs – inquiry based education*" (IBE). IBE is concerned with the teaching-learning relation in the model – a theoretical idea about how pupils learn and from this how to teach. The example shows the delicate interplay between the pupil's and the teacher's didactic praxeology. The appertaining type of task in the teacher's didactic praxeology is how to set up a learning environment that makes the pupils investigate the mathematical task. The task is not explicitly mentioned in the lesson plan but two different techniques to solve the task appear in the following quotes: *"The pupils work inquiring with concrete materials and get the opportunity to reason on their own"* and *"Tips for the teacher: Be careful not to unveil the points".* So, the two main didactical techniques are to use concrete materials and to give the pupils opportunity to work out their own solutions (in pairs) without a standard procedure presented by the teacher.

The example shows how the model captures underlying mathematical and didactical considerations and the relations between these. In this case, the model is primarily used descriptively to analyse the lesson plan but it can as well be used normatively for instance to improve the design of the lesson plan template in the example about the ratios between the lengths of the sides by stressing the connections between mathematical and didactical praxeologies or type of task, technique and technology.

Video recordings of the lessons

The video recordings show that the student teachers to a great extent conduct the lesson as it is described in the lesson plan. They have experience with lesson study and know that this is important to focus the attention on the teaching instead of the teacher. During the section of the lesson where the pupils work with the problem in pairs they stick to the manuscript of the lesson, for example, *"Be careful not to unveil the points"*, and pose the planned question. For instance, in the following situation in grade 6:

Pupil 1: This one is double size
ST: How can you convince me, that it is the same triangle? Can you argue that they are similar?
Pupil 1: It has the same shape – and it has three sides
Pupil 2: And it is right-angled
ST: Yes. But so is this triangle (the teacher shows a triangle from another group). And your triangles are not similar to this one?
Pupil 1: No
ST: No, but they both have a right angle and three sides. Try to find out what the similar triangles have in common but these have not. Think about it... (The student teacher leaves)

The student teacher's first question is almost exactly quotation from the lesson plan. This question is difficult to answer to the pupils. Nevertheless, Pupil 1 refers to "same shape" as a colloquialism but unfortunately, the teacher do not respond to the suggestion and so the pupil do not get the opportunity to create a link to the mathematical concept – equal angles. This is the task of the didactic praxeology – to extend their understanding of the everyday word similar to a more exact mathematical interpretation. The example (and others alike) shows that the question does not encourage the pupils to investigate mathematical properties about the similar triangles and thereby get an opportunity to become acquainted with the theory block of the mathematical praxeology. The technique to solve the didactical task seems to fail. Maybe as a consequence of this, the student teacher improvises and reformulates the question: *"Try to find out what the similar triangles have in common but these have not."* This question is not mentioned in the lesson plan but it leads the pupils to examine mathematical properties because the question is posed in mathematics. An obvious answer to the question is that similar triangles have angles in common but ratios of the length of sides are not in the same way immediate obvious for pupils at this age. A new didactical task is therefore how the teacher can pose questions to lead the pupils to examine the ratios of the length of sides without "unveiling the point"? Analyzing the situation by means of the model could for example lead to a question like *"What will happen if you multiply the length of the three sides with the same number – 2 for example?"* The example shows that a problem concerning the didactic praxeology requires an analysis in details of the appertaining mathematical praxeology.

The video recordings show that the student teachers are very determined to follow the lesson plan as it is planned by the participants. The comprehensive preparation of the lesson and the very close connection to the theoretical education gives the student teachers an opportunity to try out their theoretical knowledge – both didactical and mathematical – in practice. Because they stick very carefully to the lesson plan there is a close connection between knowledge meant to be taught and knowledge actually taught and between the mathematical and the didactical praxeology – this is a crucial challenge in teacher education. Obviously, this challenge should be taken up in teaching practice but student teachers often find this very isolated from the theoretical education at the university college. In teaching practice the student teachers are "forced to act" – they have to teach a fixed number of lessons each week. Therefore, they often experience teaching practice as complex and stressful and fall into short-lived performance without coherence to their learning outcome from the theoretical education.

Interviews

Dialogue and working relationship between teachers and student teachers are – off course – important learning resources about school practice for student teachers. The interviews show that both teachers and student teachers experience significant differences between the dialogue involving teachers and student teachers in the lesson study compared to the usual teaching practice situation:

> Teacher (about teaching practice): Usual, when you have student teachers, it is vulnerable. Very often, you tell them what they did wrong or what they shall be aware of next time in the class instead of sticking to the point, the lesson, the content. (...)
>
> Teacher (about lesson study): Focus is on the lesson and not on the student teachers. We are not supposed to supervise them. We discuss what is working and what is not working about the lesson. We share a common responsibility to make the lesson work. We don't evaluate the student teachers but the lesson.
>
> Student teacher: In teaching practice, the teacher watches you when you teach, whereas in lesson study we are equal. We should all participate in the preparation of the lesson and we could all contribute to the lesson.

In teaching practice the student teacher usually prepare the teaching and teach a single lesson, while 1–3 of his or her fellow students and the teacher observe the lesson. Afterwards, the teacher supervises the student teacher in very close connection to the student teacher's presentations and interactions with the pupils in the lesson. The student teacher then tries to *"correct the mistakes"* before the next performance – some descriptions by student teachers and teachers indicates an inappropriate "trial and error" method. The strong focus on the student teacher's performance emphasizes the practice block of the teacher's didactic praxeology and – to a lesser extend – the teaching-learning relation in the ATD-model. According to both teachers and student teachers, it is unusual to discuss didactical and mathematical theory, curriculum and other topics in connection with the teaching on a general level – the two columns to the left in the model are almost absent in the dialogue. The interviews show that the teacher's didactical praxeology in knowledge actually taught is most often disconnected from both the appertaining mathematical praxeology and the mathematical and didactical praxeologies in the other columns. This is evident in many of the dialogs between teachers and student teachers in connection with teaching practice. Such practice off course implies a risk of widening the gap between student teacher's experience of theory and practice during their teacher education.

The interviews show two main differences between the dialogue between teachers and student teachers in connection with usual teaching practice and lesson study. Firstly, the dialogue in lesson study take place both before and after the teaching and especially the very long time spent preparing the lesson was emphasized as fruitful. The common preparing together with the lesson plan template makes the participants discuss and consider knowledge meant to be taught, the internal didactical transposition and the interplay between mathematical and didactical praxeologies. Secondly – as stressed by the teacher in the quote above – focus is on *teaching* and not the *teacher* in lesson study. This implicates for instance that knowledge actually learnt to a much higher degree is included in the dialogue in connection with lesson study than it is in the dialogue in connection with teaching practice and thus, the interplay between knowledge actually learnt and knowledge actually taught can be examined, discussed and related to knowledge meant to be taught.

There is a very clear consensus between teachers and student teachers that the dialogue in connection with lesson study to a much higher degree than the dialogue in connection with teaching practice includes a broader range of pivotal problems in teaching and learning mathematics. As a consequence, theory-practice axis in the model are treated and transcended more often.

CONCLUSION

The ATD model points out three different theory-practice problems in mathematics teacher education. It is crucial to put focus on all three axes and give student teachers opportunities to establish coherence between theory and practice in connection to the three axes.

Through different examples from a lesson study it is shown, that the model can be a fruitful tool to analyse teaching and learning contexts. Firstly, the model can be used as a descriptive tool to analyse and criticize planned teaching (lesson plan), actually completed teaching and the participants' experiences of the teaching with a special focus on theory-practice problems. Secondly, the model can be used as a normative, prescriptive tool for making adjustments to or changes in didactical designs for teacher education.

Uncovering facets of interpreting in diagnostic strategies pre-service teachers use in one-on-one interviews with first-graders

Simone Reinhold

Leipzig University, Faculty of Education, Leipzig, Germany, simone.reinhold@uni-leipzig.de

The research presented in this paper focuses on prospective elementary teachers' proceeding in one-on-one diagnostic mathematics interviews. It goes beyond measuring the accuracy of teachers' judgments of students' achievements and analyses qualitative facets of diagnostic competence. Participants of mathematics methods courses were asked to prepare and conduct diagnostic interviews with children in grade one and reflect on their diagnostic proceeding afterwards. Findings of the research affiliated to this university teaching project lead to a model of strategic elements in PTs diagnostic proceeding and suggest types of diagnostic strategies. These may be realized or deliberately used to foster a sensitive qualitative diagnostic attitude.

Keywords: Prospective teachers, teacher education, analyses in one-on-one interviews, children in grade one, diagnostic strategies.

INTRODUCTION

Shulman (1986) or Ball and colleagues (2008) suggest distinct domains of teacher knowledge and point out *pedagogical content knowledge* (PCK) to be an integral element of teacher knowledge. PCK includes knowledge about *common* mathematical conceptions or misconceptions that are frequently encountered in the classroom. An interesting option to gain this kind of knowledge arises from teacher education settings where teachers examine *individual* cases: Analyzing a student's error to understand the underlying misconception refers to *knowledge of content and students* (KCS), which is regarded as a sub-domain of PCK by Ball and colleagues (2008, p. 403). Thus, the capability of "eliciting and interpreting individual students' thinking" can be found among the set of "high-leverage practices" (University of Michigan, 2015; Cummings Hlas & Hlas, 2012).

In this sense, identifying unique facets of the specific individual situation may contribute to a better understanding of widespread (mis)conceptions and provide an improvement of KCS (e.g., Peter-Koop & Wollring, 2001; Hunting, 1997). Dealing with individual cases may thereby foster the development of a teacher's diagnostic attitude and improve his or her teaching practices: If a teacher has detailed information on a student's individual mathematical concepts at his or her disposal, he or she gets the chance to design appropriate learning opportunities for this student. In this sense, diagnostic competence is an important element of adaptive teaching competence (Wang, 1992).

Recent studies concerning teachers' diagnostic competences mainly focus on measuring the accuracy of teachers' judgments (e.g., regarding a rank order within classes; cf. Südkamp et al., 2012). In these studies, diagnostic competence is "operationalized as the correlation between a teacher's predicted scores for his or her students and those students' actual scores" (Helmke & Schrader, 1987, p. 94). Individual mathematical learning processes which teachers try to capture during phases of concrete diagnostic activities are scarcely touched upon this understanding of the concept of diagnostic competence. But, focusing on high-leverage practices and on approaches of informal formative assessment (cf. Ginsburg, 2009), *how* do teachers arrive at a diagnosis of a student's conception via oral questioning or observation? As differences in accuracy might be due to teachers' different ways of diagnosing and analyzing, *how* do they get to an appropriate interpretation of a child`s utterances or how can they be helped to achieve appropriate diagnoses?

THEORETICAL FRAMEWORK

Diagnostic interviews in research, in the classroom and in teacher education

One-on-one diagnostic mathematics interviews stem back to the clinical method of interviewing developed by Jean Piaget. For educational research, one-on-one interviews provide a powerful method to gain insight into children's mathematical conceptions. Following a qualitative research paradigm, these conceptions can be interpreted from the children's utterances and activities they show while working on a problem. (cf. Hunting, 1997; Ginsburg, 2009).

To cope with the challenges of every-day classroom situations, teachers need a sensitive, constructivist views of their students' individual mathematical thinking and their progress in developing mathematical concepts. Thus, diagnostic interviews not only serve as a research method, but have also reached the classroom and may appear as little talks between teacher and student during a phase of individual working. In addition, research-based frameworks (e.g., concerning learning trajectories) resulted in the design of standardized task-based interviews to assess the range and depth of children's thinking in the context of mathematics learning in school. In these task-based interviews, in-service teachers actively explore facets of children's approaches to mathematics tasks. Prepared interview tools and empirically based growth points for the analysis guide teachers through these one-on-one diagnostic interviews and provide them with weighty arguments for their diagnoses. This may not only foster children's mathematical learning but also serve teachers' professional development (e.g., ENRP task-based assessment interview/CMIT/EMBI; cf. Clarke, 2013; Bobis et al., 2005; Peter-Koop et al., 2007).

High-quality programs for prospective teachers (PTs) engage them in concrete tasks which also include tasks of assessment or observation and focus on students' learning processes (e.g., Borko et al., 2010). Thus, studying students' mathematical conceptions in one-on-one interviews (which the PTs *themselves* prepare, conduct and analyze) offers substantial learning opportunities (cf. Prediger, 2010; Sleep & Boerst, 2012). Being involved in research projects that include interview assessments may also support the development of a sensitive diagnostic attitude (cf. Jungwirth et al., 2001; Peter-Koop & Wollring, 2001).

A process-oriented approach to diagnostic competence

Expertise in the area of diagnosing children's mathematical conceptions must not be restricted to teachers' accuracy in measuring children's achievements. It should additionally include rather vague aspects like diagnostic sensitivity, curiosity, an interest in children's emerging understanding and learning or the aptitude to gather and interpret relevant data in non-standardized settings (e.g., Prediger, 2010). Aiming at a framework to analyze processes and facets of diagnosing, it seems helpful to take a model into account which points out phases of the diagnostic process. In this sense, acting within a diagnostic situation in a one-on-one interview which intends to enlighten students' (mathematical) thinking can be regarded as an integral element of a circular process consisting of three dimensions, each including several components (Klug, 2011; Klug et al., 2013): Before trying to sum up information for a substantial diagnosis, it is crucial that the teacher sets the aim of the diagnosis in a preparatory *pre-actional phase*. This includes that the teacher should intentionally aim to watch the individual student's learning processes and therefore choose appropriate tasks and methods. The following *actional phase* includes data collection and data interpretation. Finally, the *post-actional phase* implies taking the necessary action from the data collection and interpretation in the actional phase (e.g., giving feedback, planning actions to foster). Activities in this phase also serve to prepare a repeated run through the diagnostic macro-process.

Cognitive elements in the micro-processes of the actional phase of diagnosing

Researchers in mathematics education have partially specified the challenges that in-service or prospective teachers face within such diagnostic macro-processes: Obviously, teachers actively do "construct knowledge by observation, experience, transfer and interrelation." (Bräuning & Nührenbörger, 2009, p. 945). Furthermore, there is a strong interest in the field of noticing and interpreting which can be analyzed when PTs face students' mathematical solutions. In this field, Ribeiro and colleagues (2013) investigate prospective teachers' *interpretative knowledge* which they regard to be part of SCK (*specialized content knowledge*, specified as sub-domain of content knowledge by Ball and colleagues (2008)). In these studies, the concept of interpretative knowledge is related to the ability of noticing and the authors point out that many PTs "find difficulties in interpreting children's solutions different from their own solution". Crespo (2000) and Kuhlemann (2013) offer similar results.

Focusing on *micro-processes within the actional phase in a one-on-one mathematics interview*; *collecting* data, *interpreting* and drawing *conclusions* have a major impact on the diagnosis which is derived from an interview and are likely based on different kinds of knowledge (e.g., KCS or SCK, see Figure 1). Here, proceeding in a one-on-one diagnostic interview is vitally influenced by cognitive processes and a person's (verbal) articulation (e.g., ways of questioning, confirming). Intentional decisions (e.g., switching between tasks) may reveal facets of the ongoing internal considerations.

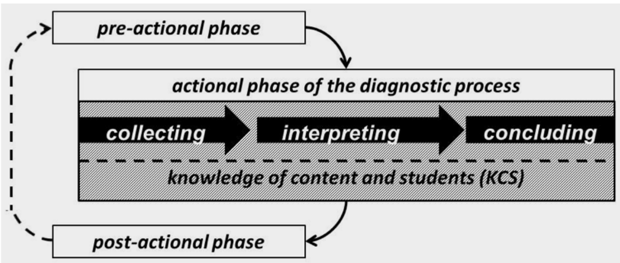

Figure 1: Differentiating the micro-process in the actional phase of diagnosing

Moyer and Milewicz (2002) identified general questioning categories (check-listing/instructing/probing and follow-up questions) used by PTs while collecting data in one-on-on diagnostic interviews. As there is no direct access to students' conceptions in these interviews, they "must be reconstructed by interpreting their utterances" (Prediger, 2010, p. 76) as "the interviewer attempts to construct a model of the student's mathematical knowledge" (Hunting, 1997, p. 149). Consequently, it is also important to reach a substantial perception of the diagnostic situation while interpreting. According to Barth and Henninger (2012, p. 51), this "includes the ability to structure the situation cognitively, the ability to change the focus of attention and the willingness and ability to adopt other perspectives" which leads to the generation and testing of hypothesis. Moreover, there is a demand "to know which information or knowledge sources play the most important role during the process of diagnosing students' learning prerequisites" (Barth & Henninger, 2012, p. 50). Yet, the implications of "gathering information, acting systematically" (Klug et al., 2013, p. 39) within the *actional phase* are not entirely clear for one-on-one interviews in mathematics education, so far.

RESEARCH QUESTIONS

The project *diagnose:pro* which is setting the frame for the study presented here emphasizes the need to sensitize prospective elementary mathematics teachers (PTs) to varieties, ranges and depth of young children's mathematical thinking. Therefore, graduate students (Master of Education) prepare, conduct and analyze one-on-one interviews about arithmetic problems with first-graders. These activities were part of a specific teacher education project at the University of Braunschweig (2011–2014) which is, due to space limitations, not presented in detail here. One part of the affiliated research project focuses on cognitive diagnostic strategies PTs use in their reflection and during the analysis of those interviews. To reach an empirically grounded theoretical framework for a qualitative view of PTs' cognitive activities in one-on-one interviews with children, the main purpose is to detect traits of these diagnostic strategies:

- What cognitive elements characterize the PTs' diagnostic strategies when diagnosing individual arithmetic approaches in one-on-one mathematics interviews with children at the beginning of grade one?
- Which types of (flexibly used) diagnostic strategies can be reconstructed from interviews they or others have been conducting?
- What kind of (pedagogical content) knowledge is included during the diagnostic proceeding?

METHODS

Making use of various approaches, data collection has been ongoing since 2011 and started with explorative studies via video-vignettes which led to written (mostly open) diagnostic comments of 31 PTs on diagnostic scenes. As analyzing these "diagnostic products" was not sufficient to answer the posed research questions, the following data-collection was shifted to video- and audiotaped peer-talks about mathematic diagnostic interviews: Here, students of two university courses (Master of Education, 28 participants in 2012) were asked to discuss about diagnostic scenes in video-vignettes. Finally, seven PTs (who had conducted a diagnostic mathematics interview with a first-grade child themselves) agreed to take part in retrospective interviews which complemented data collection in 2013. These interviews resembled methods used by Moyer and Mielewicz (2002). All PTs attended a mathematics methods course in the last year of their university studies which provided the opportunity to conduct individual diagnostic interviews with up to six first-graders per PT in cooperation with an elementary school. First drafts of these interviews were prepared at the beginning of the course where the PTs could refer to previous theoretical work on concepts of arithmetic learning trajectories and the method of task-based mathematics interviews (e.g., EMBI; Peter-Koop et al., 2007).

With only general advice at the beginning of the retrospective interviews, the PTs were asked to "analyze the interview" while watching the video-recording of an interview they had conducted. The PT was requested to stop the video at any scene in order to comment on the diagnosis he or she would derive from this specific situation or related observations. If comments were rather short or pure in detail, the PT was asked to explain what knowledge, information or evidence warranted his or her hypothesis. In addition to this concrete task (diagnosis of the child's conception or knowledge), the PT reflected on his or her proceeding in a more general way: Referring to the preliminary design of the interview, the PT was asked to comment on the choice of tasks selected, the wording of questions, on their own gestures or on deviations from the sketch. All re-interviews' analyses are based on Grounded Theory methodology and methods including open, axial and selective coding (cf. Corbin & Strauss, 1990). The interpretation, coding and contrasting comparison of the data are supported by ATLAS.ti which enables the research team to directly code video-data.

FIRST RESULTS

Analyses of the study's data support the notion that cognitive elements of PTs' approaches to diagnosis in one-on-one interviews often resemble basic processes in qualitative data analysis. This includes acts like *collecting*, *interpreting* and *concluding* within diagnostic micro-processes (see Figure 1). Furthermore, the findings contribute to the identification of sub-categories of collecting, interpreting or concluding and to interrelations among these sub-categories (see Figure 3). Excerpts from re-interviews with Ann and Sue, Master students in their last year of studies, exemplify facets of *interpreting* within the diagnostic micro-process of the actional phase.

Facets of interpreting: Comparing and contrasting

In her interview with six-year old Tom, Ann offers empty boxes for ten eggs and some chestnuts. The boxes of ten are partitioned in four fields (see Figure 2) since Ann intends to find out how children use these structures for counting. She assumes the children to use abbreviated enumeration, i.e, counting strategies including subitizing parts of an amount (cf. Besuden, 2003). Ann stops the video and comments on a scene where she has just put five chestnuts into the box (forming a row). Tom is asked to add further chestnuts in order to get a result of eight and fills two, then one more into the box. Answering Ann, he remarks "Because I left two free, one more'd be nine, then ten."

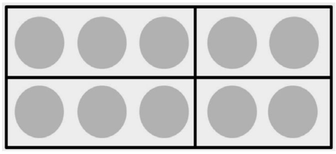

Figure 2: Structured box

Ann (07:08): And there I noticed that he, eh, always took ten as a starting point for the higher numbers, well, for eight and a moment ago for nine. He remembers, okay there are ten in the package, and then he always counts backwards.

In her comment, Ann compares and refers to Tom's previous work ("a moment ago"). *Comparing* details to a child's previous utterances or actions, to that of others or to the PTs own concept may also occur in terms of *contrasting* different scenarios:

Ann (08:30): Here, he saw, okay, there are four in one box and there are another four in the second box, well, four plus four equals eight, but he didn't do it that way in the next task. There he'd count single ones, it was done quite differently.

Facets of interpreting in a diagnostic micro-process: Coding

Sue uses the same kind of tasks in her interview with six-year old Ben. She wants him to find out how many chestnuts have to be added to four chestnuts (which are presented in the "square" on the right side of the box) to get a result of seven. Ben replies by first adding two (forming a "rectangle"), then one more to reach seven (Ben: "These are six, then seven."). Sue codes these activities by creating and applying the new term "auxiliary calculation":

> Sue (05:40): Responding to my enquiry, how he'd done this, now, how many he'd add, actually, I only wanted to hear three, well, he would seize on his, let's say "auxiliary calculation", six plus one equals seven.

PTs are similarly coding observed phenomena as they try to grasp unfamiliar, but obviously central aspects. Codes are often referred to later in the interviews (e.g., Sue's reference to the code "auxiliary calculation", 22:30) and also include substitutions for established terms (e.g., "shortcut" instead of "subitizing").

Facets of interpreting in a diagnostic micro-process: References to knowledge of content and students (KCS)

To describe the children's performances in the re-interview, PTs also try to make use of standardized terms that refer to previously acquired KCS and seize on theoretical concepts that were studied in the methods course before conducting the interviews:

> Sue (04:50): Well, at the beginning, Ben definitely used counting strategies. He saw those four and went on counting from that summand. He noticed, okay, if I add two then I'll get six, thus, he didn't go like "five...six", but he said, okay, two, that's six.

Although details of the counting strategy "counting on by steps of two" are not reflected here, referring to mathematical KCS tends to be an important element of PTs' diagnostic strategies: PTs do use information from their teacher preparation courses. They retain general knowledge of children's development of mathematical conceptions (e.g., "understanding of quantities"), but then remain unfocused in supporting their interpretation with this knowledge:

> Ann (15:17): But, Tom doesn't have, eh, a complete understanding of quantities at his disposal, partly he did, partly he didn't. It's when a child notices that a number is now, eh, bigger than the number before, or that one can draw conclusions from one equation to the next, that is connected to the first one.

Types of diagnostic strategies

Following Grounded Theory methodology, distinct types of diagnostic strategies with a stress on different elements of diagnostic proceeding (i.e., on the exemplified (sub-) categories) are detected. As indicated by the arrows in Figure 3, PTs' diagnostic strategies are far from a linear process and may be driven by general dimensions of diagnostic strategies (e.g., topographic or symptomatic search; Cegara & Hoc, 2006).

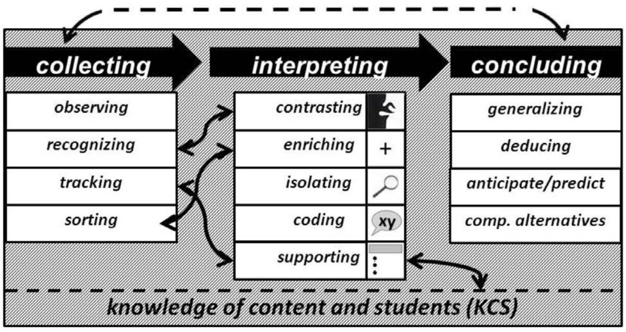

Figure 3: Sub-categories of collecting, interpreting and concluding

Following the strategy *descriptive collector*, the PT focuses on collecting and describing the actions, neglects both interpreting and concluding, and searches rather typographically. A *concluding collector* strategy is characterized by skipping elements of interpretation as collecting leads directly to conclusions which resembles findings of Crespo (2000). Symptomatic searches occur when elements of interpreting prevail in a *branched interpretation*. Here, interpreting, collecting and concluding are intertwined and frequently linked to KCS.

DISCUSSION

The findings of the study provide evidence of sub-categories of collecting, interpreting and concluding within micro-processes of the actional phase of diagnosing. They point at KCS within these processes and hint at a variety of strategy types. Thus, results enrich, for example, the idea of "interpreting" in the actional phase of diagnosing suggested by Prediger (2010) or Barth and Henninger (2012).

Bearing in mind that the findings are restricted to a particular type of tasks (arithmetic issues) and that they refer to a rather small number of participants (n=28 in peer-talks; n=7 individual interviews), the study outlines new topics in the field of teachers' professional development: It raises the hypothesis that reflecting on facets of interpreting in one-on-one interviews enhances PTs diagnostic sensitivity. This may increase their knowledge of assessing children's mathematical abilities and contribute to the consideration and implementation of "high-leverage practices": An awareness of "strategic diagnostic tools" might help to master diagnostic challenges in the classroom. Thus, further activities of the project *diagnose:pro* will explore how the findings (elements of diagnostic strategies/types of strategies) can be taken up in university courses and contribute to appropriate diagnoses of children's concepts in one-on-one interviews. Further steps also include using the developed model to qualitatively evaluate changes of PTs' interpretations over the duration of university courses and to analyze what leads to changes in PTs' diagnostic strategies.

Teacher empowerment and Socioepistemology: An alternative for the professional development of teachers

Daniela Reyes-Gasperini, Ricardo Cantoral and Gisela Montiel

Cinvestav, Mathematics Education Department, Ciudad de México, Mexico, dreyes@cinvestav.mx

Teacher empowerment is an alternative proposal from Socioepistemology that postulates it as a tool for the professional development of teachers. The concept of empowerment is accompanied by the "problematization of knowledge" in both senses: mathematical knowledge and school mathematical knowledge. We assume that teachers will be better able to transform their educational reality, since they will have taken possession of the teaching knowledge. This new relationship to knowledge is not based more on mnemonics, but on what we consider to be the essence and "raison d'être" of knowledge that will allow the teacher to develop various strategies considering his group of students. In this paper, we will discuss "proportionality" for its high cultural value and its transversality in education.

Keywords: Socioepistemological Theory, teacher empowerment, problematization of knowledge, proportionality.

POSITIONING THEORY

While "the best-selling question" of the 90's was *how* to teach using various teaching strategies in order to make the understanding of certain mathematical knowledge more accessible to students at different educational levels, the Socioepistemological Theory posed a somewhat different question: *What* is it that we are teaching? *What* is it that our students are learning? That is to say, lets study and discuss the *nature of mathematical knowledge*, and thence, "reflect on" the *school mathematical knowledge*. Studying its nature does not implies just making an epistemological study, but getting a systemic perspective of the epistemological, didactical, social and cognitive dimensions of mathematical knowledge, it means, looking at them as a whole.

In terms of teaching practice, while the classical currents analyzed the tasks that teachers use in the classroom, the teacher-student interactions, the competition brought into play to solve math problems, the teacher's knowledge on how students think, know or learn a specific mathematical content, among many others, Socioepistemology wondered what and how is the professor's relationship to knowledge in a specified didactic relationship? It is for this reason that our line of research considers a necessary articulation between two theoretical elements: the functionality of the mathematical knowledge of proportionality (transversal notion in the educational system with high practical value in everyday life) and the theoretical construct of teacher empowerment (Reyes-Gasperini & Cantoral, 2014). On the basis of such an articulation we wove a conceptual framework in order to show that the *teacher empowerment, from a socioepistomological vision,* is a little known alternative to study the professional development of teachers *problematizing* mathematical knowledge.

Socioespistemological theory studies the social construction of mathematical knowledge. The education problem is not that of the constitution of abstract objects, but *their shared significance by its culturally situated use*. It is assumed that since this knowledge is socially constituted in non-school settings, its diffusion to and from the educational system forces it to a number of changes that directly affect their structure and functioning, so that also affects relationships established between students and their teacher. The socioepistemological research promotes a *decentration of the object*, that is, to pay attention to the *practices* from which it emerges and not just on the mathematical object per se. Socioepistemology delimits the role of historical, cultural and institutional setting in human activity, so the problem that motivates the research can be student's difficulties in learning a particular concept; however, studying it seeks to contribute to an alternative vision that includes the associated social practices and, to that extent, provide a social and cultural look of mathematical knowledge (Cantoral, 2013, Cantoral, Reyes-Gasperini, & Montiel, 2014).

SOME LINKS TO TEACHER EMPOWERMENT WITH MATHEMATICAL KNOWLEDGE

Empowerment is a *social phenomenon* typically studied in various disciplines and approaches, from social (Martínez Guzmán Dreyer & Silva, 2007), feminist (Camacho, 2003), from the Psychology Community (Montero, 2006), or from an educational point of view (Howe & Stubbs, 1998, 2003; Stolk, de Jong, Pilot, & Bulte, 2011). While each of the disciplines has a particular focus on the phenomenon, they all concur in their main characteristics that we have synthesized in the following way: empowerment is understood as a process of the individual in collective work (interaction is required in collective work), which parts from the reflection to be consolidated in action, which is produced by the individual without the possibility of being granted (collaborative work will be necessary but not sufficient to promote empowerment) and, above all things, *transforms the reality of the individual and his context.*

In particular the projects that aim to promote teacher empowerment (Howe & Stubbs, 1998, 2003; Stolk, de Jong, Bulte, & Pilot, 2011) provide teachers with tools to design new situations emphasizing contextualization, either by knowledge of new research related to the topic, as well as by the sample of situations that provide a context to what they already know. All with the aim of obtaining an attitude of leadership, confidence and improvement in their practices towards education, emphasizing the fact that they may acquire the power to take the reins of their own growth. While we may coincide with the results that are expected to be achieved, we believe that this type of analysis is reduced to only a pedagogical interpretation.

Our proposal, given the socioepistemological character that is added to this phenomenon, incorporates the notions of *problematization of mathematical knowledge (PMK) and problematization of school mathematical knowledge (PSMK)* keys to boost teacher empowerment. The action of *problematizing* the school mathematical knowledge is done with the knowledge that teachers use in the educational system. Now, why do we differentiate *PMK* from *PSMK*? The *PMK* refers to the fact of "making a problem out of knowledge", an object of training analysis, locating and analyzing its use and its *raison d'être*, namely refers to the study of the nature of said mathematical knowledge, for example related to the proportionality, on the basis of questions like: What problem did the *notion of proportion* come to resolve that could not be resolved without them? Are the problems more difficult when the magnitudes are heterogeneous than when they are homogeneous? Why are problems on the fourth missing value worked on if the comparison is not represented there? Where do the proportions appear in the civilization? What characterizes the relation of proportionality? Among many others. The socioepistemological study based on teaching, epistemological, social and cognitive dimensions of knowledge can make up a *unit of socioepistemic analysis* (*USeA, UASE in spanish*) that causes a singular symbiosis between, and from, the four dimensions, in order to generate a theoretical framework that challenges mathematical knowledge, and subsequently, school mathematical knowledge.

In contrast, when we work with the *PSMK*, we draw on the knowledge that is fundamental to the educational system. Based on the *USeA* an activity guide is designed which confronts the typical educational activities in order to put the teacher in a learning situation and thus generate spaces for the *PSMK* to be performed (Reyes-Gasperini, Cantoral, & Montiel, 2014). We understand the *PSMK* as the action part of the introspection, the gaze of the learner and uses available in their everyday life.

It is necessary to mention at this point that the socioepistemological theory rests on four fundamental principles (Cantoral, 2013): the regulatory principle of *social practice*, the principle of *contextualized rationality*, the principle of *epistemological relativism* and the principle of *progressive resignification* or *appropriation*. These four principles underlie the *PSMK*, well this problematization will allow the teacher to consider that social practices are the foundation of the construction of knowledge (regulation of social practices), and that the context will determine the type of rationality with which an individual or group – as a member of a culture – builds knowledge whilst he/she can express it and put it to use (rationality contextualized). Once this knowledge is put to use, that is to say, it is consolidated as knowledge, its validity will be relative to the individual or the group, as it emerged from their construction and their arguments, which gives that knowledge *epistemological relativism* Thus, because of the evolution of the life of the individual or group and its interaction with various contexts, such enriching knowledge of new meanings will be redefined constructed to this moment (progressive redefinition).

Therefore, the links between empowerment and mathematical knowledge are given by the articulation of the typically social phenomenon with the socioepistemologic character that underlies its main action: the *PSMK*.

PROBLEMATIZATION OF MATHEMATICAL KNOWLEDGE (PMK) AND PROBLEMATIZATION OF SCHOOL MATHEMATICAL KNOWLEDGE (PSMK): THE CASE OF PROPORTIONALITY

In our current research, we take the proportionality, as a mathematical notion, to work the *PMK* and the subsequent *PSMK* with teachers. In order to give some guidelines for what leads to the construction of the USeA, we part from an idea rooted in the educational system and society in general, however, we should make it plain that here there will only be presented some examples of what the USeA is in its entirety. If we asked in a generic way, "What is proportionality?" most would answer that it is a form of variation: "When *more is more* or *less is less*", or, "when using the rule of three". In these responses, we find two aspects to consider, first, the memory of a "recipe" to identify a problem of proportionality; on the other, an algorithm with which to solve said problem. Some typical examples given in this respect are: the price in buying tortillas in kilos, the distance traveled in a certain time, among others; but they all have the same prototype. The use of colloquial language allows the fluidity of a set mathematical thought, but will inevitably redefined subsequently, for example, at a formal level, it should be reflected in written form at a level of symbolic object and consider "the notion of constants proportionality" as the product or the reason for the magnitudes. Piaget's theory (1958, quoted in Noelting, 1980) considers proportionality as the hallmark in the development of formal operations, therefore, we ask, have students (or teachers in our case), developed this type of reasoning? The idea of spending an additive relationship to a multiplicative relationship seems to be the fundamental idea that has been pursued in studies concerning proportionality.

In problems of proportionality, usually, it is asked, "How many hours it take to travel 25 miles?", for us it is important to reflect on the notion of speed, considering it as relation between distance and time, rather than solely the notion of "missing value". Perhaps this is an obstacle that so far may not have been considered as an issue that cuts across the colloquial and has to do with a germinal idea of what the notion of reason is. To do this we ask, what is the nature of proportionality? Is it a continuous or a discrete nature?

Given this situation, we question whether it is possible that the question "how many" can generate a centered answer among students in the quantification rather than the relationship. Well, if we asked what is or what are the relationships that can be established between the magnitudes, perhaps we would be giving the students a relationship beyond the concentration in number and quantity to think about. That is, if from a psychologist point of view the research reports that proportional reasoning is related to the development of formal operations and is complex, if not impossible, to achieve such reasoning, it would seem that we should think that the way that said knowledge is addressed is alien to the reality of the student and teacher in our case.

We conducted a formal analysis of the theory of proportions addressed by Elements of Euclid in his Book V, we work on par with the idea of incommensurability. Hence we affirm: if there is no such thing as a common measure, how can these quantities be measured? The problem of measuring, was replaced by Euclid as the problem of comparing. This is the fundamental question that gave rise to the theory of proportions between magnitudes. So, is the condition caused by the inability to measure what has led to the need to compare? Just as the inability to advance time which has led us to predict (Cantoral, 2013).

In this respect it is stated that this theory emerges to address two specific problems of the time. On the one hand, before the conflict that had suffered the Pythagorean theory regarding the impossibility of assigning a number to the ratio of two quantities, theory of proportion was redesigned in such a way that "you could talk about reasons and proportions, without specifying whether or not they were considered commensurable magnitudes" (Guacaneme, 2012, p. 104), where the greatest merit of the theory described in Book V is the possibility of comparing incommensurable magnitudes (Corry, 1994, quoted in Guacaneme, 2012). On the other hand, the elements are intended to present the mathematical theories under a deductive axiomatic scheme. Now, if the theory of proportionality arises as the possibility of comparing incommensurable magnitudes, it is logical to think that if most of the problems encountered in the literature that are to do with the missing fourth, these kind of problems does not always require a proportionate reasoning (Lamon, 1999), for there will be nothing to compare because the amounts are given and you have to operate on them arithmetically, applying the rule of three most of the time. In addition, they can announce themselves with the structure of the missing fourth, without there being a proportional relationship between the magnitudes, however, the students will resolve it since the characteristic they believe to be enough to apply the simple rule of three is that both magnitudes increase (while the issue is to characterize the type of growth). So far, we conjecture that it is necessary to return to emphasize the relationship between the magnitudes by *comparing* them.

During the process of research on proportionality, we have studied the famous "Cauchy functional" that gave light to analyze the difference between the additive and multiplicative thinking in depth, creating a new look at the nature of the proportionality. There are four functional Cauchy equations (Roa, 2010), in a later study we related each of the four functional equations at school-level with four functions that are of significant importance: Exponential function: $f(x + y) = f(x) \cdot f(y)$; $x, y \geq 0$; Logarithmic function: $f(x \cdot y) = f(x) + f(y)$; $x, y \geq 0$; Power function: $f(x \cdot y) = f(x) \cdot f(y)$; $x, y \geq 0$; Proportional function: $f(x + y) = f(x) + f(y)$; $x, y \geq 0$.

The Cauchy's functional served as sustenance to give evidence, in an analytical and graphical way, for the differences between a proportional linear function and a non-proportional linear function, since that function is only true in the first case. This allows us to analyse the proportional function from a particular property and not just from the classical ownership "double receives double" or from "the rule of three".

In our case, we study in depth the related with the proportional function, which, based on the USeA of Reyes-Gasperini (2011), it was stated with the models of proportional thinking reported in the literature. Let's start now by thought patterns, there is a qualitative thought that is the first to appear in individuals (Inhelder & Piaget, 1972) and is exemplified by the idea of the chorus "more is more; less is less".Godino and Batanero (2002) conducted a study based on (Noelting, 1980) where they report the following types of reasoning used by students to decide between two jugs of juice which is the one with the "stronger" taste. Their arguments are based on the comparison of the number of glasses of water and juice placed. The question posed is: "My mother has prepared two jugs of lemonade. In jug A she has mixed two glasses of water and one glass of lemon juice. In jug B she has mixed three glasses of water and one glass of lemon juice. In which of the two jugs is the lemon flavor is more intense?"

Even if the amounts are in play, the answer is not a quantity, but a relationship between them: which is more intense? As the authors say "the additive strategy would be to compare the difference between the glasses of water and the lemon juice in each jar" (Godino & Batanero, 2002, p. 439), but they ensure that this strategy will not be sufficient to address problems of greater complexity. Regarding the above, Carretero

$$¿f(x) + f(y) = f(x+y)?$$

$$\begin{gathered} f(x) = mx + b, b \neq 0; f(y) = my + b, b \neq 0 \\ (mx + b) + (my + b) = m(x + y) + b \\ mx + my + b + b = m(x + y) + b \\ m(x + y) + 2b \neq m(x + y) + b \\ \text{So, } f(x) + f(y) \neq f(x + y) \end{gathered}$$

$$\begin{gathered} f(x) = mx; f(y) = my \\ mx + my = m(x + y) \\ m(x + y) = m(x + y) \\ \text{So, } f(x) + f(y) = f(x + y) \end{gathered}$$

Figure 1

(1989) distinguishes two types of structures. On the one hand, those having a given relationship between homogeneous magnitudes (also called extensive by other authors) to those called scalar multiplicative models; and on the other hand, those having a relationship between heterogeneous magnitudes (also called intensive), to those called functional multiplicative models. Subsequently Lamon (1993) also makes a distinction as strategies for students to find the missing value in a proportion. He calls them inter models (corresponding to the multiplicative model scalar) and intra models (corresponding to the functional multiplicative model). The work with the different types of multiplicative structures around the acquisition of the notion of proportionality allowed Carretero to conclude that "the division is evidently a more difficult operation than multiplication, despite the underlying multiplicative structure" (Carter, 1989, p. 95). Thus, we conclude that the additive model precedes the scalar multiplicative model, which is less complex than the functional multiplicative model, however, they are all thoughts that underlie the idea of proportionality.

Moreover, G. Vergnaud works on the theory of conceptual fields considering them a set of situations that can be "analyzed as a combination of tasks of which are important to know their own nature and difficulty" (Vergnaud, 1990, p. 140). Regarding proportionality, he compares the conceptual fields of additive structures (those that require an addition, subtraction, or a combination of the two) and the multiplicative structures (those that require multiplication, division or a combination of the two). This allows him to generate a classification and an analysis of cognitive tasks and in procedures that are potentially at stake in each. This allows her to generate a classification and an analysis of cognitive tasks and in procedures that are potentially at stake in each.

He concludes by stating that "it is not superfluous, on the contrary, to emphasize that the analysis of the multiplicative structures is profoundly different from the additive structures." (Vergnaud, 1990, p. 144). This is to say, we can ensure that there will be tasks that demand a multiplicative structure, and others, an additive structure.

Therefore, not all problems deserve to postulate a proportional reasoning in terms of Lamon (1993), but as Vergnaud (1990) says, there are problems that can be solved by additive structures or pre-proportional reasoning, for example: "If one coconut costs 35, how much do 10 coconuts cost?".

This example is tackled by Carraher, Carraher and Schiemann (1991), where they see how a child solves "on the street a sales situation": <u>Client:</u> How much does one coconut cost?; <u>M</u>: Thirty-five; <u>C</u>: I want ten coconuts; How much is it for ten coconuts ?; <u>M</u>: (Pause) Three are 105 plus three is 210. (Pause) we are four short. It is ... (pause) ... it seems to be 350.

An immediate question, at this level of analysis is: Has the child developed proportional thinking? Our answer is yes, because the situation does not require a multiplicative structure, but reaches an additive structure (additive model composed seen above), and behold, our assumptions about the mathematical knowledge of proportionality: proportional reasoning viewed as the relationship between two magnitudes that remain constant, should be assessed whether developed or not, whenever the situation warrants a comparison, that is, an analysis of relationship type between the magnitudes, and not the discovery of a missing value. Hence the need to draw up a learning situation that involves a sequence of activities where different thoughts are progressively and systematically put into play.

Proportionality arises to address the inability to measure incommensurable magnitudes; therefore, as it has already been shown as evident, the current school significance induces us to look at a math problem with a different rationality for offering its epistemological nature. This may explain the academic failure of students to proportionality.

Given the fundamental idea that the inability to measure generates the need to compare, let's see what happens with a purely mathematical problem to which the scales for working have been removed with the idea of the type of relationship between the magnitudes more than in the quantification of the values.

Activity: To the right of the graph of the function f is presented. Does this represent a direct or inverse proportional function? Justify your answer.

Most teachers with whom we have worked on this activity (both secondary school teachers and students) argue that it is inversely proportional because "a plus x, minus y" (qualitative thought). This was the trigger

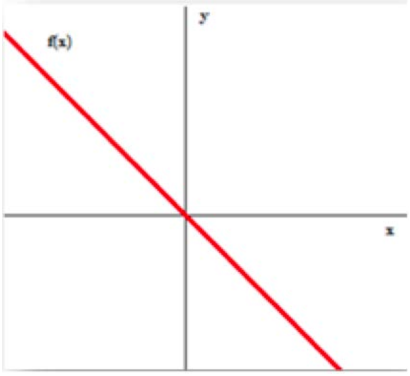

Figure 2

to replant the way we work proportionality in the education field, because it generates germinal mathematical errors supported by "rote simple recipes".

The work with teachers leads us to characterize "what it is proportional" (the proportional, as we use to say in our language of practices) as a relationship between two magnitudes whose ratio remains constant. First, is analyzed the constant rate of change, that characterizes all linear relationship () and then analyzes the constant ratio, that is maintained between its variables, which characterize directly proportional linear relations (). Thus, was worked on the relationship between the magnitudes as from different properties of proportional relationships. So rote recipes make sense and meaning.

Figure 3

To illustrate, we will show an activity we did with teachers, in order to address the idea that not every relationship which have the simultaneous increase or decrease characterizes a proportional relationship:

"Considers that the first figure is the original. Which of them could be considered an extension or reduction of it?"

After the teachers' discussions, where the notion of scale was at stake, we address them to reflect that it is not enough to consider the presence of an increase, we must emphasize the way this increase is done.

DEBATE AND FINAL CONDITIONS

The mathematical treatment of a transversal mathematical subject in all of mathematics education shows that you not only need to work with teachers on pedagogical issues of general teaching process, or only the contents as they are addressed in school. But to this type of study we add the need to problematize mathematical knowledge to then work with teachers posing questions of school mathematical knowledge and thus contribute to the professional development of teachers through the *change of relation to mathematical knowledge*, and not solely based in mnemonic rules or formulas with little meaning, but based on what we call "the reason for this mathematical knowledge and its frameworks that allow their use."

What we propose to be discussed in in the Group of Mathematics Teacher Education and Professional Development is how to generate, within the professional development of the teacher, areas in which the knowledge of the teacher is not classified, but through what the teacher has in its repertoire (background), deepen and challenge the school mathematical knowledge and change accordingly their relationship to knowledge. Thus we assume that teachers will be better able to transform their educational reality, since they will have taken possession of knowledge that teaches. This new way to relationship to knowledge no longer based on mnemonics, but on what we consider the essence of its purpose and allow the teacher to develop various strategies by the group of students he/she may work with. In short, we are studying the process of teacher empowerment, which we postulate as a tool that contributes to teacher development.

The line of research on teacher empowerment provided by socioepistemology brings a fresh, different look on dominant versions in the literature of professional development of the teacher in the field of school mathematics.

Instructional coherence as perceived by prospective mathematics teachers: A case study in Chilean universities

Francisco Rojas and Eugenio Chandía

Pontificia Universidad Católica de Chile, Faculty of Education, Santiago, Chile, frojass@uc.cl

One of the notions that future Chilean teachers hold about their educators is the lack of coherence between the latter's instructional practices and the ways in which they are expected to teach mathematics in school. Upon this basis, we sought to characterize the Instructional Coherence of teacher educators, and particularly the way in which it is perceived by students. By applying a questionnaire to prospective teachers from two Chilean universities, focused on their teaching models, the relevance of replicating certain instructional practices in the school classroom, and the types of modelling observed in their educators, we were able to establish that coherence is perceived when prospective teachers notice, in the practices of their teacher educators, the characteristics of the teaching model that they themselves profess.

Keywords: Mathematics teacher educators, instructional coherence, modelling, pre-service teacher education.

CONTEXT

In Chile, international evaluations of both Chilean educational policy (OECD, 2009) and mathematics teacher quality (TEDS-M; Ávalos & Matus, 2010) have shown that the pedagogical and disciplinary education of the country's newly graduated and practicing teachers is not good enough to result in good performance. Even though major efforts have been made to improve Pre-Service Teacher Education, little light has been shed on the education processes of teachers in university classrooms (the so-called "black box"). In addition to this, and despite the relevance of teacher educators in this process, fewer studies have been conducted in Chile about these participants than about prospective teachers (Cisternas, 2011). Conducting more in-depth research on this issue could help to understand a factor which we consider essential in pre-service teacher education: the instructional practices of teacher educators and the perception of prospective teachers about the coherence between their educators' discourse and such practices.

THEORETICAL FRAMEWORK

Rojas and Deulofeu (2013) have observed that the teacher educator's instructional practices (mathematical-didactic activities designed and its classrooms management) are strongly related with the construction of the teaching models of prospective teachers. This educational process should include at least two aspects to be constructed: on the one hand, that the body of teacher educators offer future teachers opportunities to learn mathematics in the way their students are expected to learn (didactic model transference) (Chapman, 2008; Deulofeu, Figueiras, & Pujol, 2011), thus generating processes that model teaching practices; on the other hand, that the teacher educator introduce activities which constitute opportunities to learn to teach mathematics, in the sense of planning one's teaching, analyzing classroom management through classroom episodes, and working upon the basis of the mathematical production of secondary school students, which should establish a strong theoretical-practical relationship (Boyd et al., 2009; Gellert, 2005). The general purpose of these activities, in terms of design and implementation, is to allow prospective teachers to construct the knowledge necessary to teach high school mathematics. A major part of these activities depends on how the teacher educator manages them, that is, how he/she uses them to display their underlying didactic-mathematical approaches (Zaslavsky, 2007).

Instructional coherence

However, it is not enough to study the teacher educator's practices. If we consider Chilean students' demands for greater coherence in their educators (MINEDUC, 2005), it is necessary to advance a notion of coherence that is functional within the educator's job. In the literature, coherence is defined as the degree to which the main goals associated to teaching and learning are shared by everyone involved in the education of teachers, and also considers the degree to which learning opportunities are organized, both conceptually and logistically, to achieve these goals (Tatto, 1996). Within this concept, two types of coherence can be identified: conceptual (between the professional perspectives of those who work with teachers) and structural (associated with the design of learning opportunities) (Hammerness, 2006). Beyond capturing the notion of consistency, these definitions stress the idea that coherence requires alignment between ideas and learning opportunities (Grossman, Hammerness, McDonald, & Ronfeldt, 2008). However, none of these conceptions emphasizes the instructional coherence of the teacher educator, understood as the degree of alignment between his/her instructional practice and the *didactic transfer models* that he/she promotes in it, including the theoretical models that support them.

The alignment between the theoretical and didactic models of the teacher educator and his/her instructional practices in the university classroom may provide information about how teacher educators can become models for future teachers. Therefore, a teacher educator will display Instructional Coherence when his/her practices model the didactic-mathematical actions that he/she expects prospective teachers to acquire.

Modelling

The teacher educator is always an example for teachers; thus, when considering the widespread idea that teachers teach in the way they were taught, the modelling role that the educator acquires becomes relevant. In this regard, Lunenberg, Korthagen and Swennen (2007) state that the ways in which the educator models certain views of learning can be more important than the content itself. For the authors, these "ways" are grouped under the notion of modelling, understood as "the practice of intentionally displaying certain teaching behaviour with the aim of promoting student teachers' professional learning" (p. 589). So, considering these ideas, we could study Instructional Coherence in order to understand the ways in which a teacher educator makes explicit the message that he/she wants to convey to his/her students.

The authors define four types of modelling based on their literature reviews and their own research. These forms of modelling are grouped into implicit and explicit, with the latter having several degrees of complexity.

Implicit modelling: Even though the educators recognize that they must be good examples of the conceptions of teaching that they attempt to transmit, students often do not see these conceptions in practice. In fact, many educators do not manage to make their teaching models explicit, and their students' preconceptions about teaching and learning do not change significantly.

Explicit modelling: teacher educators should make explicit which choices they make while teaching, and why. Some techniques to achieve this goal could be journal writing, "thinking aloud", or co-teaching. Although these ways of making educators' didactic decisions explicit may be useful, they are not naturally observed in their actions.

Explicit modelling and facilitating translation into student teachers' own practices: even if educators explicit their decisions, students should be able to transfer them to their own classroom practices. This requires reflection and an analysis of the educator's instructional practices, combined with an attempt to define what they mean in teaching terms. From this starting point, students will be able to make their own decisions.

Connecting exemplary behavior with theory: it is clear that the theory-practice connection is essential in teacher education. For this reason, it is necessary to go beyond making pedagogical decisions explicit and giving students the chance to analyze them; students should connect practice with theoretical structures that allow them to explain these decisions and characterize them to inform their decision-making.

In order to identify which of these characteristics of their educators' instructional practices were present in the lessons observed, the questionnaire included referred to the modelling that students observed in their educators when conducting certain actions aimed at developing their knowledge for teaching.

Questionnaire dimensions

Both for educators and students, mathematics teaching involves the consideration of several theories that make it possible to construct a didactic model (Steiner, 1990) which has stable foundations and which can be implemented flexibly (Godino, 1991). Therefore, to study said models at any educational level, it is necessary to break down the practice of the participants involved according to the fundamental characteristics of the model that they profess.

In order to do this, and on instrumental terms, our questionnaire was created considering a set of theoretical approaches which are currently observed in Mathematics Education research. In this regard, Furinghetti, Matos and Menghini (2013) distinguish certain dimensions that make it possible to study theoretical teaching models. The first dimension, which emerged from early 19th century mathematics, concerns the promotion of mathematical thinking. This dimension also involves the promotion of statistical thinking, which is distinguished from mathematical thinking in that the argumentation of the former is based on data (Ben Zvi & Garfield, 2004). The second dimension is associated with the psychological-cognitive theories of the teaching and learning of mathematics advanced by Piaget, Vygostky, Dehaene–Gingerenzer, Bruner, Ausubel, and Van Hiele, among others. The third dimension defined here groups cultural and social approaches together. The theories it concerns are those of Freudental, Kilpatrick, Polya, and Shoenfeld; social epistemology, socio-criticism, the Theory of Didactic Situations, and the Theory of Didactic Transposition, given their sociocultural nature. In addition, considering the latest results of Lesson Study, we added a fourth dimension which is associated with the hermeneutic processes that characterize the Japanese teaching model.

The following are the characterizations that we have constructed for each dimension in order to illustrate how indicators present them.

RESEARCH QUESTION

By singling out instructional coherence as a key element in teacher education, due to its role in the construction of the teaching-learning models of future teachers, our study is guided by a fundamental question: Which characteristics of teacher educators' practices make students regard them as coherent? More specifically, this article focuses on *student perceptions about the coherence displayed by their educators* which can be useful as issues for reflection.

METHODOLOGY

Given that the purpose of this research is to assess students' perceptions about the instructional coherence of their educators, we used techniques and instruments capable of measuring this qualitative variable. Thus, we employed Likert qualitative measurement scales, because they are capable of generating a discrete ordered continuum of the students' perception level.

Sample

In order to look into students' perceptions about the instructional coherence of their professors, students

Dimension	Theoretical Characterization
Mathematical Thinking	This dimension is expected to capture characteristics of the mathematics teaching model which revolve around mathematical work, considering key aspects of mathematical or statistical thinking.
Psychological-Cognitive	This dimension is expected to capture characteristics of the mathematics teaching model that focus on cognitive-structural aspects of mathematics learners. It should also identify aspects that shed light on the reasons behind learners' behaviors and actions concerning mathematics.
Socio-Cultural	This dimension is expected to capture characteristics of the mathematics teaching model associated with the relationships established by social and cultural groups when learn or create mathematical meaning.
Hermeneutic	This dimension is expected to capture characteristics of the mathematics teaching model which are aimed at creating expertise and command of mathematical knowledge via the thorough use of processes and strategies.

Table 1

and educators belonging to education programs for secondary school mathematics teachers at Chilean universities were invited to participate. In order for a university to be selected, the following requirements had to be met: (a) having a teacher education program accredited for 4 or more years[1], (b) having had a minimum admission score of 550 points in the mathematics part of the test for the last 4 years[2], (c) having 14 or more Mathematics classes, and (d) 3 or more didactics/method classes in the program curriculum[3]. These values were established after analyzing the data for the 36 secondary education programs in Chile, since it was necessary to set a minimum quality level according to the parameters used in the national context. Of all the teacher education programs studied, only two met these criteria.

Specifically, the classes chosen were those belonging to the didactic or methodological area, since they are where students' mathematics teaching knowledge is strengthened, regardless of their formal name in each teacher education program. Finally, a total of 42 students, 11 from one university and 31 from the other, answered the questionnaires.

Questionnaire structure

The coherence variable is complex to study; therefore, in order to collect information about it from the students' perspective, an instrument comprising three parts (A, B, and C) was used. In part A, the students were asked about their academic trajectory in the teacher education program they are part of (number and type of courses taken) and their perception about their preparation for teaching the syllabus contents at different educational levels. In part B, they were asked about their beliefs concerning the main characteristics of mathematical activity in schools through a Likert scale (Likert I) that presented several strategies or methodologies which they would regard as necessary for their pupils to generate mathematical knowledge. In part C, they were asked about the educational process that they had experienced in their programs via two Likert scales. The first of them (Likert II) presented instructional practices, which can be observed in courses of a didactic or methodological nature. Students were asked which of these practices they believed were useful to replicate in schools, in order to identify which instructional practices were making an impact on the construction of their teaching-learning models. The second scale (Likert III) aimed to identify the type of instructional modelling used by their professors. In order to achieve this, the same indicators present in the previous scale were presented, but identified as actions performed by the educator. For each of them, students were asked to classify the indicator according to the modelling types described above.

Analytic process

In order to evaluate perceived coherence, this study analyzes parts B and C of the instrument. Likert I (Part B), was coded binarily, assigning 1 to "Yes" and 0 to "No", and Likert II (Part C), was again coded binarily, assigning 1 to the option "Useful to replicate" and 0 to the option "Not useful to replicate". The second scale of part C (Likert III) was coded binarily for each instructional model. That is, the implicit model was first identified with number 1, while 0 represented the rest; then, number 1 was used for the explicit model and 0 for the rest, and so on. In this way, 4 dichotomous scales were obtained, which made it possible to compare and group the indicators for each of the models. Binary scales were used because, to perform hierarchical and event tree analyses on the indicators for determining concentration in categorical variables when N is small, it is necessary that data be binary or be arranged into a Likert scale, that no normality be observed, and that no relations be present among them.

To analyze the binarily-coded scales, a hierarchical cluster analysis was performed using the Jaccard index, which makes it possible to determine the homogeneity between two indicators. These indicators reflect each of the characteristics of the mathematics teaching models within the frameworks established and described above. Index I is defined as $I = x/(x + y - z)$, with "x" reflecting the number of prospective teachers who chose indicator X, "y" reflecting the number of

1 The accreditation of programs certifies their quality according to their declared purposes and the criteria established by each academic and professional community (see www.cnachile.cl).

2 The University Selection Test (Prueba de Selección Universitaria, PSU) is a standardized measurement with a mean of 500 points and a standard deviation of 110. The selection process for students who wish to become teachers requires that they obtain at least 500 points in the PSU.

3 Teacher education processes are heterogeneous in terms of the number and types of classes that they offer their students. The programs available are concurrent and consecutive, with 8 to 24 mathematics courses and 1 to 7 methods (didactics) courses.

prospective teachers who chose indicator Y, and "*z*" reflecting the number of prospective teachers who chose both X and Y.

RESULTS

In order to characterize the students' perception of their professors' instructional coherence, three key elements reported by the above Likert scales were considered: the students' teaching models (Likert I), the usefulness of replicating the instructional practices of their educators in their own teaching (Likert II), and the type of modelling under which they observe said practices (Likert III).

Students' teaching models (Likert I)

With respect to the predominant mathematics teaching and learning models among prospective teachers, when asked "For a student to generate mathematical knowledge, it is necessary to", the hierarchical cluster analysis revealed two clusters with Jaccard homogeneity indexes over 70%.

The first cluster grouped the next indicators: 3. *Consider the mental structures of students in terms of the concepts' abstraction level*, 4. *Consider the discussion between students to generate the concept, 5. Show examples and counterexamples*, 6. *Create a representation of the concept in the student*, 8. *Consider that students have a certain knowledge and that they will use it to understand concepts*, 9. *Consider the socio-cultural aspects of students in connection with the activity*, 14. *Transform pure mathematical knowledge into knowledge that can be taught*, 16. *Present situations which are significant to the student*.

This set of indicators shows that students attach great importance to their pupils' previous knowledge, both cognitive and sociocultural. This reveals that the socio-cultural dimension, as well as the psychological-cognitive dimension, are among the elements that characterize the model that prospective teachers use to teach mathematics.

The second cluster concentrated the following indicators: 9. *To formulate a problem for knowledge to emerge in response to it* and 13. *To face the student with a problematic situation*. Both of them are associated with problem-solving as a strategy to generate knowledge. Said indicators are included in the socio-cultural dimension of the theories about how mathematics should be taught; specifically, they are linked with the Theory of Didactic Situations and Polya's notion that mathematics should be learned by simulating the activity of a mathematician.

Usefulness of replicating their educators' instructional practices (Likert II)

Concerning the instruction provided by university professors, the actions which are part of or characterize their teaching model are those which students believe would be useful to replicate in schools. Specifically, the following clusters displayed a Jaccard homogeneity coefficient over 75%.

Cluster 1: 1. *The way in which mathematical problems were solved*, 3. *The way in which students were made to participate*, 4. *The way in which discussions were generated about the mathematical learning activities conducted*, 10. *The way in which students were made to reason*, 11. *The way in which complex didactic and/or mathematical activities were approached (breaking something down into smaller elements, giving examples and counterexamples, using analogies, etc.)*.

Cluster 2: 17. *The way in which students' comprehension was verified*, 18. *The way in which mathematics education theory was used*.

Both clusters are part of the social and cultural dimension of how mathematics is taught, which intersects with the elements that characterize the students' teaching model. It is noteworthy that, even though the indicators ask students to reflect on the aspects in which the educator's work–his/her way of conducting activities in the classroom, on the one hand, and his/her "mathematical-pedagogical" work, on the other–it is precisely the "form" of mathematical-pedagogical action that is relevant when generating an impact on the knowledge of prospective teachers.

Modelling type observed in the educators (Likert III)

Finally, regarding the forms of modelling observed by the students, only transfer modelling displayed an association with the indicators in the clusters that characterize the students' mathematics teaching-learning models. Although the Jaccard coefficient was lower than those of previous classifications, it never dropped below 45% in any of the clusters of the transfer model.

Cluster 1: 14. *To identify students' mathematical errors*, 15. *To tackle students' mathematical errors*.

Cluster 2: 10. *To make students reason*, 3. *To make students participate*

Cluster 3: 4. *To generate discussions about mathematical learning activities*, 17. *To verify students' comprehension*, 19. *To motivate or involve students in classroom tasks or activities*.

As can be observed, the three clusters again belong both to the social-cultural and the psychological-cognitive dimensions. In addition, it is interesting to note that the aspects or actions associated with evaluation, such as providing feedback to students about their work, were observed to have 50% of homogeneity, but in the implicit model of the educator.

CONCLUSIONS

When comparing the dimensions *students' teaching model*, *usefulness of replicating educators' instructional practices*, and *type of modelling observed*, three strong associations can be observed. First, comparing the students' teaching models with the usefulness of replicating certain instructional practices (Likert I & II) reveals that those deemed useful correspond to the same dimensions that characterize their own teaching models, and are associated with aspects of the socio-cultural and psychological-cognitive theories of mathematical education. Second, when comparing teaching models with the modelling types observed in instructional practices (Likert I & III), the students manifest the same traits (indicators) that characterize their teaching model only for a specific modelling type: the transfer model. This implies that students observe characteristics of their own teaching model when the educator connects instructional practices with the reality of schools. Third, comparing the usefulness of replicating certain instructional practices with the modelling type displayed by the teacher educator (Likert II & III) reveals that those deemed useful are precisely those that belong to the transfer model. These associations indicate that, when the educator manages his/her class in such a way that allows him/her to relate didactic-mathematical actions with the school classroom, the student regards such actions as relevant because they are the ones which belong to his/her teaching model. In terms of perceived instructional coherence, students regard their professors as coherent when their practice reflects their teaching model.

We believe that the results provide empirical evidence of a phenomenon that we knew, but which we had not characterized. In this regard, it is worrying for our national teacher education system, as well as for other systems, to know that students only consider their teaching to be effective in terms of coherence when instructional practices match their didactic models. This prompts a question: to which degree has the education received affected students' conceptions of teaching and learning? In the case of the education of secondary school teachers, one of the main characteristics of education programs is their strong disciplinary focus, which contrasts with a brief period of pedagogical instruction. So, how has disciplinary instruction helped to change the traditional teaching patterns of school mathematics? This and other questions lead us to consider the need to know the initial didactic models of students, that is, how they see the teaching and learning of mathematics when they enter university, and how their views change as they progress in their teacher education program.

Word problems of a given structure in the perspective of teacher training

Marie Tichá[1] and Alena Hošpesová[2]

1 Academy of Sciences, Institute of Mathematics, Prague, Czech Republic, ticha@math.cas.cz
2 University of South Bohemia in České Budějovice, České Budějovice, Czech Republic

The paper reports on the results of a research study focusing on how to train prospective teachers for guiding their pupils through the process of solving word problems. The teaching experiment involved prospective teachers' work with graphical representations called branched chains to solve and pose word problems. The paper shows the difficulties the students were facing, presents ideas from discussions during joint reflection, tries to describe the changes in the students' skills and attitudes. It also points at the differences between prospective primary and secondary mathematics teachers.

Keywords: Inquiry based mathematics education, prospective teacher training, subject matter knowledge, knowledge base for teaching.

INTRODUCTION

This contribution is a follow up to a presentation on CERME8 (Hošpesová & Tichá, 2013), which focused mainly on the quality of prospective teachers' content knowledge and their ability to apply their knowledge of mathematics in the solving process of problems leading to inquiry based mathematics education (Artique et al., 2011). This became the starting point of this paper in which we discuss one of the possibilities of developing pedagogical content knowledge (PCK) and prospective teachers' inquiry based approaches to word problems.

As has been pointed out repeatedly, students learn mathematics by problem solving. While solving a problem, they learn to instruct themselves, to make decisions which methods of solving to choose. It comes natural when solving problems to explore, discover and justify. The whole solving process can be regarded as *the solver's dialogue with the problem* (How to begin? How to carry on at a particular point?) The solver modifies his/her decision on the basis of information from the problem and confrontation with the goal (with the question to be answered in the problem). He/she alternately asks questions or poses problems and solves these problems. This implies that problem posing and problem solving are intertwined.

A mathematical (word) problem should have certain properties one of which is structure. When posing a problem we should always bear this in mid. That is why we started to include posing of problems of a given structure into teacher training. We are convinced that this activity helps (prospective teachers) (a) get rid of stereotypical nature of problems they pose (he/she grows aware of a structure of a problem and the much needed variety), (b) get insight into the structure of a problem when solving it and (c) overcome the tendency to focus only on the sequence of calculations that lead to the result.

What we find crucially important is the need to develop prospective teachers' skills and ability to create (mental) representations, to model phenomena with mathematical tools, to formulate questions and pose problems. In the past years we have shown the diagnostic, *educational and motivational benefit* of integrating activities connected to problem posing in teacher training (Tichá & Hošpesová, 2013). We have discovered that problems posed by the trainees are often stereotypical in context, quality of the environment, representation and structure. The trainees did not find it hard to diversify the context and environment. However, it is very difficult to start considering deliberate, conscious work with the structure of the problem; both in problem solving and particularly in problem posing. That is why we have shifted our attention to this area.

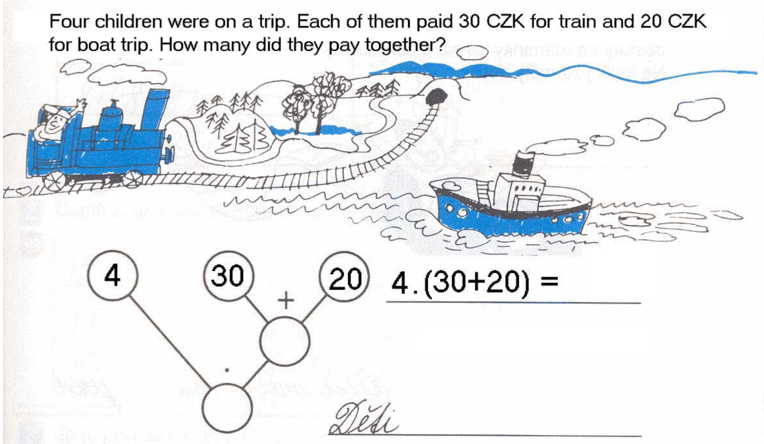

Figure 1

In the here referred study we would like to discuss how prospective teachers work with the structure of a word problem. With this aim we selected one part of Czech primary school curriculum, solving two-step word problems. In teacher training, we used specific graphical representations called branched chains (example in Figure 1 from the textbook for primary school level written by Kittler and Kuřina, 1994). Kittler and Kuřina understand branched chains as the model of the problem translated into the language of chains or as a record of the solution of the problem. We use these chains as the means of visualization, as graphical representation either of the problem structure or the problem solving procedure.

Similar graphical representations were used by Nesher and Hershkovitz (e.g., 1994). They refer to them as schemas for representation of two-step word problems.

Let us remark here that the concept of a schema is very frequent in mathematics education research and is used in various interpretations. These interpretations are often based on approaches and theories of cognitive psychologists such as Skemp (1971), Fischbein (1999), etc. A schema is habitually characterized as a mental structure with two main functions: it integrates the existing knowledge, and it is a mental tool for acquisition of new knowledge; a schema describes both the mental and physical actions involved in understanding and knowing. Also other characteristics are given: schema as internal representation of information, as a model of activity (action scheme), as a set of interrelated knowledge in a specific area, as representational structures that represent knowledge in the form of networks of connected concepts, as action structures, goal directed activity.

An analysis of the use of the concept of schema within different theoretical context of mathematics education is given for example by Davis and Tall (2002).

Hejný (2012) justifies that a schema, which in his opinion represents understanding, is the necessary condition for creation of a knowledge structure. Our approach to work with branched chains is analogical. We understand this work as the graphical means of visualization and a tool for grasping the structure of problems (data and relations between them) both when solving and posing problems. This means that we use these chains for deepening understanding of the problem solving process and the structure and/or construction of the problem.

TEACHING EXPERIMENT, ITS PARTICIPANTS AND METHODOLOGY

We tried to answer the following questions: What problems do prospective teachers pose when their structure is given by a branched chain? Are prospective teachers aware of the structure of the assigned problems? Whether and how do the students consider the structure of word problems?

It should be noted that in Czech schools it is a very common practice to solve word problems using various graphical representations. However, our experiment showed that most of the participants probably had no prior experience with branched chains.

Participants

We worked with two groups of participants – prospective teachers. The first group consisted of 36 prospective primary school teachers. Their undergraduate studies include courses in pedagogy, didactics and psychology, and also basics and didactics of all subjects taught at primary school level (mathematics, Czech language, arts, sciences, etc.). The other group consisted of 15 prospective secondary school mathematics teachers.

Teaching experiment

The participants solved a set of tasks in the seminar on didactics of mathematics. In the first stage the students (a) created branched chains to the assigned problems, (b) posed word problems of a specific structure represented by a branched chain, and (c) decided which branched chain represents a given word problem. In the second stage the students carried out joint reflection of posed problems.

Data analysis

The survey was planned and conducted as a qualitative study. We analyzed all students' written production as well as their verbal comments in the subsequent joint reflection. At the beginning we used open coding. After that we were looking for relationships between solutions and the students' subsequent discussions. What we could observe in our analysis was the gradual acceptance of branched chains and deepening of understanding. This could be observed both in the posed problems and in the students' contributions in the joint reflection. Our decision was to conceive this paper as an analytical story describing how students come to adopt branched chains and outline some of their misconceptions.

RESULTS AND DISCUSSION

We started by discussing branched chains (Figure 3) and asked prospective teachers how they understand and would call these "pictures". Their responses included: *"means of visualization, graphical representation, graphical record (of gradual addition), addition snake, alternative form of recording addition, a sequence of operations using brackets, analogy to addition "pyramids", family tree, tournament tree, mind map, Pascal triangle".*

Posing a problem of a given structure

In the beginning, participants were solving two tasks:

T1. Create a simple word problem to match Figure 2.

T2. Replace one piece of data in the simple problem you have just posed by a simple problem (e.g., as

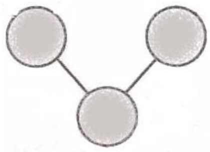

Figure 2

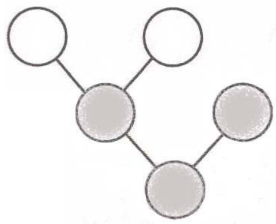

Figure 3

shown in Figure 3), thus you will pose a two-step word problem.

Most students were able to fulfil these tasks without difficulty and posed the required problems, e.g.:

> Problem 1 (Figure 2): Every school day, Matyáš gets pocket money from his mum and dad. He always gets 20 CZK from his mum and 30 CZK from his dad. How much money does Matyáš get every day?

> Problem 2 (Figure 3): Matyáš gets pocket money from his mum and dad. He always gets 20 CZK from his mum and three ten-crown coins from his dad. How much money does Matyáš get? (The author implicitly assumes commutativity.)

We could observe that in the beginnings some students (especially prospective primary school teachers) understood branched chains clearly as a representation of the solving procedure. Many students when solving T2 posed a problem which was set in the same context and which was a sequel to the story in T1, but they posed two separate simple one-step problems. As an example we present problems 3 and 4. Problem 4 is self-contained; it does not develop Problem 3. However, the follow-up discussion showed that the author had expected this pair of problems to be understood as connected, that the assignment of Problem 4 would be understood as a sequel to Problem 3.

> Problem 3 (Figure 2): Mum was baking biscuits. There were 6 lines of biscuits on a baking sheet. There were 3 biscuits in each line. How many biscuits were there on the baking sheet?

> Problem 4 (Figure 3): Mum divided baked biscuits among her two children equally. How many biscuits did each child get?

For some students it was hard to grasp "the language of chains". In the follow-up discussion the author realized that Problem 4 did not correspond to the figure from task T2 (Figure 3). That is why she visualized Problem 4 by a new branched chain (Figure 4); the words "divide between two children" was replaced by the sign for division ":" used in Czech schools. In fact she tried to make a kind of illustration of the problem; but Figure 4 made by her does not correspond to graphical representation using the language of chains, neither in the solving procedure, nor in the structure.

Another prospective primary school teacher posed two consequent simple problems 5 and 6. She also continued the story. When representing problem 6, she used representation which contains problem 5 and is a mere record of gradual addition.

> Problem 5 (Figure 5): We saw 3 giraffes and 6 sheep in the ZOO. How many animals did we see?
>
> Problem 6 (Figure 6): In the afternoon we continued our trip and we saw 1 hippo, 1 bear and 4 zebras. How many animals did we see during the whole day?

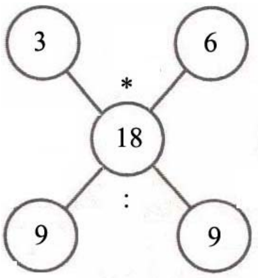

Figure 4

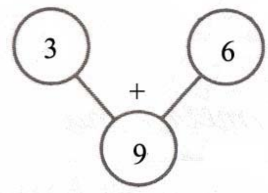

Figure 5

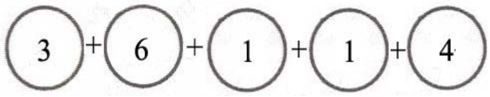

Figure 6

There were also inaccurate, ambiguous or even misleading formulations in various answers that could be interpreted in more ways in the posed problems. This became clear in the joint reflection on the posed problems which involved also solution of posed problems both by their creators and other participants.

Expanding the chain

Following the previous two tasks T1 and T2, the students were asked to work on modification of chains and structure of problems and solved the following task:

T3. Find other possibilities of "developing" the initial simple scheme (Figure 2) than shown in Figure 3.

In process of solving T3, the students proposed the expansion of a chain given for example in Figure 7 and returned to Figure 3 and reminded it. Doing that they formed for example a triplet of consequent problems 7–9:

> Problem 7 (Figure 2): I will buy 4 cakes at the price of 7 CZK each. How much will I pay?
>
> Problem 8 (Figure 7): I will buy 4 cakes at the price of 7 CZK each and bread for 19 CZK. How much will I pay altogether?
>
> Problem 9 (Figure 3): I will buy 1 poppy seed cake and 3 jam cakes. Each cake costs 7 CZK. How much will I pay?

This triplet of problems was then discussed by the students. After the discussion, one of the students expanded the original chain (Figure 2) into Figure 8. However, when posing Problem 10 she was not sure whether the chain corresponded to the assignment of the task T3 and to the text.

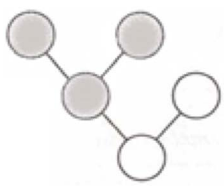

Figure 7

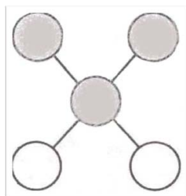

Figure 8

> Problem 10 (Figure 8): I will buy 4 cakes worth 7 CZK, i.e. (4 x 7) = 28. I will pay using a twenty-crown coin and add 8 CZK using two-crown coins, i.e. (20 + 8). Is this OK?

Other students proposed to visualize Problem 10 with the help of Figure 12. That is they realize that Problem 10 was not a problem with two operations.

Linkage of the problem to the chain

T4. Decide whether Jirka's (Figure 9) or Hana's (Figure 10) schemes "fit" the following assignment: *We were giving out notebooks. 15 were left in one package, 9 in another. I want to make packets of three from the remaining notebooks. How many packets will I make?* Justify your answer.

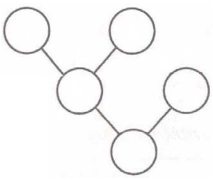

Figure 9

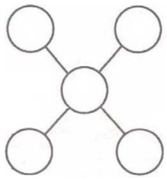

Figure 10

Within the frame of the joint reflection, one of the students suggested that the assignment of task T4 should be expanded and proposed the three chains in Figure 11 (i.e., Jirka's, Hana's, and Magda's).

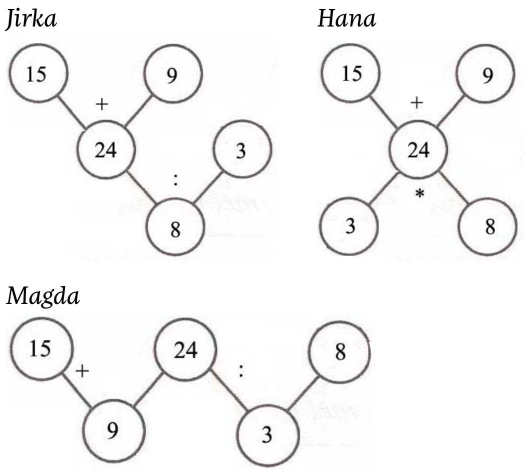

Figure 11

A very passionate discussion broke out in connection to the chain "Magda". One of the students proposed the chain should be "straightened". This idea launched a discussion on the meaning of numbers and symbols of operations in this chain. It was very useful and beneficial when students compared the chain "Magda" to a graphically seemingly very similar chain in Figure 14 (Problem 12).

Some other findings

We could also come across problems with more operations (multiple-step problems) that did not correspond to the assignments, which the students came to realize only in the joint reflection – for example, Problem 11 that was meant to represent chain in Figure 12.

> Problem 11 (Figure 12): I will buy 4 cakes at the price of 7 CZK. I have one twenty-crown coin and several two-crown coins. How can I pay?

Another student posed Problem 12 and created two chains to visualize it (Figures 13 and 14). This triggered a discussion on whether this is visualization of the solving procedure or the structure of the problem.

> Problem 12 (Figures 13 and 14): Honzik found 10 glass marbles on the pathway. He knew his brother was collecting glass marbles and that he would get 2 crowns for each. However there was a hole in his pocket and he lost 3 marbles on the way home. How much did he earn?

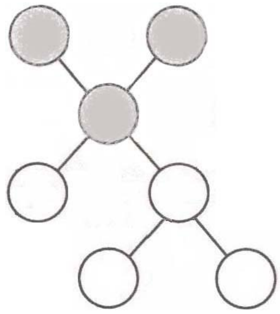

Figure 12

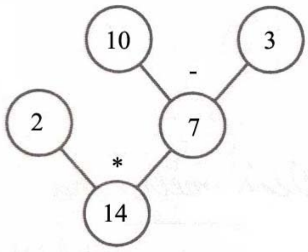

Figure 13

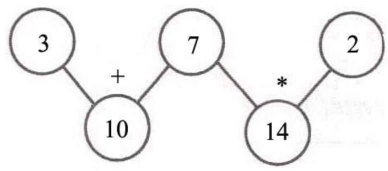

Figure 14

It is clear that students' opinions on the function, role of branched chains vary. However, most of the students agreed that a branched chain could help them solve problems.

We could also see that the effort to visualize required strenuous mental and intellectual effort. For some the will to use a chain at all costs may result in confusion. The chain stops being a benefit and becomes an obstacle. The student who had posed problem 13 was not able to decide whether it corresponded to the chains in Figures 15 or 16 and said: *"I am totally lost in this task."* and *"I think I first posed one problem and then a chain. When creating the problem I was already thinking about the model. Of course I could proceed the other way."*

> Problem 13 (Figures 15 and 16): The best basketball players were to be selected from three classes. Five were chosen from 2.A, they went to team A. 6 pupils were selected from 2.B, they were sent to team B. Eight pupils from 2.C were divided equally into both teams. How many players were in both teams?

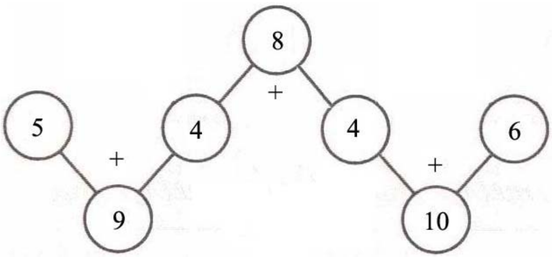

Figure 15

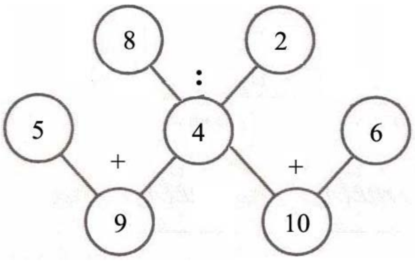

Figure 16

SUMMARY AND DISCUSSION

As we showed above some participants grasp branched chains as a representation of a problem structure, others as a representation of its solving procedure. This corresponds to the frequent view that a schema includes both a category of knowledge and the process of obtaining that knowledge. Both these perspectives could be come across. However, the conducted survey showed differences between the respondents: prospective primary school teachers usually understood branched chains as a record of the solving procedure (they did not mention the structure, the construction of the problem). In contrast, prospective secondary mathematics teachers were more likely to perceive a branched chain as a graphical representation of the structure of a problem. They stated that work with branched chains helped them "penetrate into the heart of the problem", grasp the problem. The following students' opinions could be come across:

> "… this is the first time I've seen visualization of word problems of this type … these schemas can help children who find it difficult to solve multiple-step problems to grasp the assignment."

> "I used to make an illustration of a problem only if everything else had failed. Now it's the other way round and I will teach my pupils to do the same …"

> "I can now get to know the structure of each problem. Thanks to this I can create also other types of problems than those they are usually assigned."

Both groups agreed that it was more difficult to pose a problem to match a model than to create a chain illustrating a problem. This regardless of whether the chain visualizes the problem solving procedure or its structure. This is documented by the following respondent's opinion: *"It's much harder for me to proceed from the chain to the problem … when posing a problem one must think very differently and this leads to better comprehension and in consequence to easier solution of problems."* However, we also came across a contrary opinion: *"I believe a branched chain helps us pose problems. It was easier for me first to construct the chain and then to come up with a story that fits it."* But some students refused the use of branched chains in teaching mathematics entirely.

Let us note here that joint reflection was a very important part of work in the seminar. Without this stage the students would have never grown aware of the fact that their problems did not meet the criteria from the assignment.

This makes us ask the following open questions: Why do some students understand branched chains as representation of the structure of a problem, what is its cause? Will this have impact on their understanding, on their competence to guide pupils while solving problems?

The relationship of this study to inquiry based mathematics education

We perceive work with branched chains for representation of word problems as (a) another substantial and stimulating activity leading to cultivation of PCK of prospective teachers and as (b) the field for application of inquiry based learning in teacher training (the concept is used in accordance with Artique et al. 2011). We are convinced that this approach is important in teacher training not only because of the fact that trainees get hands-on experience with inquiry based education but also because it develops creation of PCK. It is not insignificant that it brings other quality to the acquired knowledge, in this case focus on deliberate work with the structure of problems, which helps prospective teachers realize possible modifications of a problem and their effect on the cognitive difficulty of their solution, the potential of different problems. This should result in more deliberate and focused integration of word problems into their teaching.

When we study the issues related to problem solving, we build on the concepts of inquiry and discovery in mathematics education, i.e. on activities that are characteristic of inquiry based learning. The effort to improve mathematics education especially in the 1960s' resulted in bringing the issue of genetic teaching. This concept came out of the characteristics formulated by Bruner (1966) (who speaks of learning by discovery; to educate somebody means to teach him/her to get actively involved in the process of gaining, structuring and storing knowledge), Wittmann (1974) (genetic teaching is based on natural cognitive process in building and using mathematics), Freudenthal (1973) (genetic principle is characterized by guided rediscovery as a step in the learning process). These fruitful, powerful ideas are also as a rule present in the definition (indicated in the list) of the basic characteristics of inquiry based mathematics education and are reborn in a new form.

Benefit of posing problems of a given structure in teacher training

Some positive changes could be observed when the students were working with branched chains. We are well aware of the fact that the question how this change can be verified remains unanswered so far. Using a metaphor, similarly to force which is measured from its effects, the benefit of joint reflection and work with structure can be seen in changes, in a shift in certain aspects, as an indicator of these activities to development and refinement of PCK. We could observe the following changes:

— Change of climate (intentional work with structure when posing problems motivates students, improves their attitude to teaching mathematics and supports their self-confidence).

— Change of character of problems (from simple, easily solvable "textbook-like" problems that were often uninteresting, stereotypical and sometimes erroneously formulated, to problems that were challenging to pupils, were not common, whose assignment was varied (there were graphs, charts, tables ...), that allowed different solving procedures, whose solution often required reasoning.

— Deeper insight into a selected area, domain, deeper understanding of concepts and procedures (solving strategies and methods).

In our ongoing research we expand our database and we classify the posed problems and branches according to pinpointed characteristic properties.

Mathematical opportunities: Noticing and acting

Zelha Tunç-Pekkan[1] *and Hülya Kılıç*[2]

1 MEF University, İstanbul Turkey, tuncz@mef.edu.tr

2 Yeditepe University, İstanbul, Turkey

The aim of this study was to investigate how three pre-service teachers (PSTs) listen to students, notice Mathematical Opportunities (MO) and scaffold ideas based on MOs. There were 12 videos of three PSTs' interactions with a pair of 6th grade students respectively while studying fractions. We analysed videotapes and identified different number of MOs for each PST. The findings revealed that with the help of this research and teaching environment, all PSTs listen to the students to understand their mathematical thinking initially (meaning catching MOs) and try to follow-up on them in action in differing levels of sophistication. While most of the investigated MOs resulted in a mathematical solution, PSTs need to further develop appropriate scaffolding practices.

Keywords: Pre-service teacher education, mathematical opportunities, fractions, scaffolding, listening to children.

INTRODUCTION

Reform oriented teaching supported the idea that "all students should have the opportunity and the support necessary to learn significant mathematics with depth and understanding" (NCTM, 2000, p. 50). Reform-oriented teaching and its natural necessity, student-centred education, require teachers to attend to students' thinking both in planning and in action. Many researchers investigated how this mechanism work in terms of how teachers listen to, pay attention to students' mathematics and act accordingly (Franke, Webb, Chan, Ing, Freund, & Battey, 2009; Sherin, 2004). Giving importance to students' mathematics and using this construct in pre-service teacher education programs as component for quality teacher-education have been also argued in different research venues (D'Ambrosio & Campos, 1992; McDonough, Clarke, & Clarke, 2002; Philipp et al., 2007). While the research in pre- and in-service education of teachers helps us illuminate the issue of how to use students' thinking for practice, there is more to investigate for how this opportunity pre-service teachers become to notice children's mathematical thinking and act on such situations.

In this paper, we will report an intervention study that focused on three pre-service teachers and their interactions with three pairs of 6th grade students. The purpose of the study was to understand how pre-service teachers' (PSTs) notice children's mathematical solutions and steer their interactions using those notices i.e., how they use those constructs for the purpose of "scaffolding activities." In relation to this concern, we defined *Mathematical Opportunities (MOs)* occurred in the interactions and used those opportunities as basis for our web of analysis. Therefore, we had following research question:

To what extend do the pre-service teachers notice MOs and scaffold students' mathematical thinking during interactions (with the students)?

THEORETICAL FRAMEWORK

Mathematical opportunities

Our definition and use of mathematical opportunities for pre-service teachers might show parallelism with what Leatham et al. noted for teachers. It is that teachers should recognize such opportunities initiated from the students to build on the students' mathematical thinking (Leatham, Peterson, Stockero, & van Zeist, 2015). They called those opportunities as *Mathematically Significant Pedagogical Opportunities to Build on Student Thinking* (MOSTs) and described them as being observable student actions that enable teachers to make inferences about students' mathematical thinking, as being appropriate and important *mathematical point* to be focused on and as having potential to help students to understand the essence of the *mathematical point*. We build further on MOs for the purpose of understanding how they might provide opportunities for PSTs and what the affordances of those opportunities in action for the students.

Instruction based on students' thinking

A teacher-initiated or student-initiated conversation between the student and the teacher is valuable in terms of having a potential for creating teaching-learning opportunities. Van Es and Sherin (2002) stated that in reform-oriented teaching, teacher's noticing and interpreting students' actions are key components when adapting instruction in the moment. While many experienced teachers can learn how to notice and interpret over the years of practice, it is important that these concepts should be integrated in the teacher education programs as basis for reform-oriented teaching centered on students' thinking. From their research, van Es and Sherin (2002) identified the components of "noticing" as follows: "(a) identifying what is important and noteworthy about a classroom situation; (b) making connections between the specifics of classroom interactions and the broader principles of teaching and learning they represent; and (c) using what one knows about the context to reason about classroom interactions." (p. 573). For the purpose of providing learning opportunities for PSTs about "noticing," instead of the whole classroom interactions, we provided a setting where PSTs observed the two individual students solved mathematical problems. Then PSTs continued to observe when two students discussed about their solution of the particular problem and lastly we let them to interact with the students to understand, and extend students' thinking with their questioning and scaffolding activities. In this sense we think that providing such micro-classroom environment is important for PSTs to focus on "noticing" of a pair of students' mathematical thinking and provide in-action instruction around their observations of students' thinking.

Questioning and scaffolding

With the demands of reform-oriented teaching, the nature of the interactions between the students and the teachers has to change from traditional *show* and *tell* to more advanced interactions. Teacher's use of language, teacher's intentions, the use of representational and instructional tools, how an interaction is started, continued and ended are important for providing learning opportunities for the students. Anghileri (2006) discusses three levels of "scaffolding practices" (for further explanations, see Anghileri, 2006). The first level is basic and it is related to the environmental and physical materials in the classroom and their effect on orienting students for preparing learning. She defines Level 2 scaffolding as "explaining, reviewing and restructuring." Anghileri (2006) states that usually showing and telling had been an accepted explaining in traditional teacher initiated actions. However, she states that there are alternatives to showing and telling, such as reviewing and restructuring. Probing and prompting questioning types are mainly used in reviewing students' mathematical ideas. While probing questions are "to gain insight into students' thinking, prompting their autonomy and underpinning the mathematical understanding that is generated" (p. 42), prompting questions might "lock the teacher in the center stage" (p. 43) and might put the student into guessing mode of teacher's intentions behind the questions. Level 3 scaffolding is identified as the highest level of scaffolding such that we rarely observe this in classroom discourse, it is the scaffolding that helps students' extend their thinking and "specifically focused on making connections and generating conceptual discourse" (Anghileri, 2006, p. 47). While Anghileri's framework helped us to how to focus on scaffolding actions, we needed to develop a new framework, which helped us to explain PSTs' teaching practices in this study (see the Analysis part).

METHODS

Research setting and participants

Data collected for this analysis occurred in an after school program with the partnership of a university in Istanbul, Turkey and a local low SES middle school 6^{th} grade classroom. Participants included three senior PSTs specializing in teaching middle and high school mathematics (Anna, Betty, Carol; all names are pseudonyms) and three pairs of 6^{th} grade students (Pair A, Pair B, and Pair C; worked with Anna, Betty and Carol, respectively). PSTs and the students participated in this study voluntarily. All of PSTs had some informal teaching experiences such as tutoring mathematics, teaching in an after school programs voluntarily, however their teaching experiences were not homogenized.

Mathematics workshops

Mathematics workshops originally started with the idea to teach 20 local 6^{th} grade students difficult mathematics concepts using manipulative as an after school program. There were two university professors (authors) who did team-teaching in the workshops, five to seven PSTs who voluntarily came to workshops and helped the 6th graders whenever needed and one research assistant videotaped the whole class interactions. After each session, the professors and PSTs came together and discussed their observations related to what happened in the workshop and their observations related to students' understanding. About 11th week in the workshop program, we realized that PSTs were doing "show and tell" instead of paying attention to students' mathematical thinking and they were very directive in their questions. For the following eight weeks, we recruited three PSTs from the group, assigned them to particular three pairs of students, and focused on one mathematical topic, *fractions*. Sixth grade students were chosen based on the observations and performances they showed during the first 11 weeks. There were two mid-achieving pairs (Pairs A and B) and one-high achieving pair (Pair C).

In this paper, we will focus on smaller part of the data-4 weeks. During this 4-week period, each session was about 45 minutes and organized as follows: The first author introduced the activity and 6th graders individually worked on them. Later, 6th grade students worked in pairs and had chances to discuss their solutions with their partners. During this time period, PSTs only observed and video recorded students' individual work and their work in pairs. PSTs did not talk to students during this time period. This was on purpose since we wanted to have PSTs focus on students' activities while freeing themselves from the urge of teaching. This enabled them to observe the students' mathematical thinking process, how students communicated and negotiated their thinking to their partners. Later, PSTs were allowed to talk, interact and ask questions for 10–15 minutes. Finally, time permitting we had whole classroom discussions with 6th graders that the first author led.

ANALYSIS

We analyzed four sessions of three PSTs own-recorded videotapes. Data analysis consisted of analytic induction (Bogdan & Biklen, 2003). We reviewed all the videotapes one by one and identified MOs. We define MOs as 6th grade students initiated solutions and these solutions are usually interesting ways of mathematical thinking related to the fractions topic. For example, 6th grade students were asked to draw a number line and locate unit fractions such as 1/2, 1/3, 1/4, 1/5 on it. Betty's students treated the unit fractions as if they were whole numbers and they located them accord-

Identifier	Description	Coding
Opportunity	The mathematical situation that 6th grade students provide and overall how PSTs approached the situation	**Y:** Yes **N:** No
Opportunity in action	The interactions such that what kinds of questions PSTs asked to assess and advance students' thinking, what kinds of mathematical or mathematical pedagogical knowledge they used in their interactions, and how they proceeded and closed the conversations	**N/A:** If the PST missed the opportunity **Level 1:** If PST has surface level questioning. Conversation is mostly described as individual questions-answers. There is no big mathematical idea communicated in the conversation. Teacher mostly asks for explanation but does not take it to the further; she does not do anything with the explanation. **Level 2:** If PST asks probing and prompting questions. There is progressive conversation, which might include students' contribution, but it is mostly teacher-dominated conversation *with her mathematical goals in mind*. "Reviewing" and "show and tell" could be indicators of this level. In addition, PST might attempt to give examples and use materials to help students achieve her mathematical goal in mind but the students may/may not understand or make the teacher's intended connections. **Level 3:** If we saw evidences of PST's guiding students. Purpose of questioning is guiding towards a legitimate mathematical idea. The students also positively perceive questioning. Questioning might advance the students thinking. Students might have some ownership of the ideas developed during conversation. PST addresses misconception (if there were any) by providing mathematically valid examples to help the students to understand the teacher's mathematical goal.

Table 1: Coding scheme for analysing MOs

ingly with equal distances. This is an example of a MO that we investigated in detail. We made coding based on a grounded framework we developed ourselves (see Table 1) but it also shows some similarities to the focal points of van Es and Sherin's (2002) "learning to notice" and Anghileri's (2006) "questioning and scaffolding" frameworks.

We will introduce two examples from the common opportunities and discuss how the opportunity was used by two PSTs. In the third opportunity (see Table 2) the students were asked to find a fraction between 1/2 and 1/3, make a number line and place that fraction between 1/2 and 1/3.

Anna and Pair A

Anna's students' answer to the given problem is given in Figure 1. The students thought 1/2 and 1/3 as integers of 2 and 3 respectively. Therefore, a number which was bigger than 2 and smaller than 3 was 2.5 (In Turkey, comma is used to show decimals).

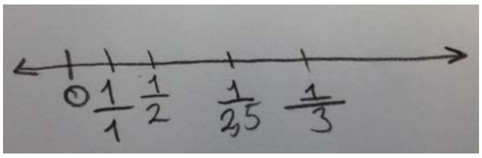

Figure 1: Anna's students' work

From their drawing we inferred that students probably thought that, except "0", the numerators of the fractions would be "1" and denominators would be "in order" starting from "1." Because they knew that 2.5 is between 2 and 3 then ½.5 would be the answer. Anna had the idea that fractions should be represented in a/b form where "a" and "b" are natural numbers but not decimals. In the following vignettes, Anna first wanted to discuss this point:

Vignette 1

Anna: How did you find two and a half? What kind of number is two and a half?
Pair A1: It has comma
Anna: Decimal
Pair A2: It is with comma, that is, it is not whole.
Anna: What kind of number system are we interested in? That is, how do we call the numbers [pointed to 1/2 and 1/3] in this system?
Pair A2: Proper fraction [it was supposed to be unit fraction].
Anna: Proper [Unit] fraction, right? Even it is improper, it is fraction. We show fraction like this [pointed to 1/2]. So, why did you write a decimal here [pointed to ½.5]?
Pair A2: We couldn't find anything else.
Anna: OK. How can you represent two and a half in other way?
Pair A2: 2/4
Pair A2: The half of 5. That is 1/2 of 5.
Anna: What do you do with 5, that is, how can you represent this as a fraction?
Pair A2: 1/5...
Anna: Your thinking is good but you are missing something. What did you do here? [Pointed to the previous number line] What did you do to show 1/4? What did you do 1?
Pair A2: We divided into 4 pieces.
Anna: What did you do with 5 and got 2.5?
Pair A2: 5, again we divided it into two.
Anna: OK. What kind of expression is that?
Pair A2: 1/2.
Anna: You are saying that 5 but then how did you divide it into 2.5? Where that division operation comes from?
Pair A2: Division operation...
Anna: Don't get confused by division. Here [pointed to previous drawing for 1/4] you divided into 4 because you have 1/4 at hand and to find it you divide one by four. Then, I am just talking about this 2.5. Because, why you wrote 2.5 here, it's interesting. Very interesting. I cannot think of it.

Then Anna drew a number line placing 1, 2 and 3 and then placing 2.5 between 2 and 3. The conversation continued with her questioning but because of the limited space we will not include it. Anna realized that students' thinking would lead to a correct answer if the problem statement asked a number between 2 and 3; an answer of 2.5 as a decimal would be acceptable. Her questioning shows us that she realizes students are not necessarily thinking in the same way that Anna thinking about conception of fractions. Anna's interaction with the students evolved around many topics. She first questioned students whether their answer was a fraction or decimal, then she wanted to have the students show 2.5 as a fraction (where she differed from the original answer of ½.5).

In our framework, PST notiaced the MO (coded as Y for Opportunity). Once she received answer of "one half of 5" from the students, she moved asking questions about how to represent it (students said 1/5 that Annaa did not investigate). She then asked them to relate to earlier example of 1/4 "where 1 was divided into four pieces" (as students verbalized). Anna then focused on centralizing the conversation on "division operation" and how students might have used "division" to get 2.5 from 5. For a while, the focus of the conversation and leading questions were unclear. Eventually, Anna asked how they thought ½.5 as in the same way they would give meaning to 1/4 (where students said it was one piece out of four pieces). Students did not give a definite answer to the question but they indicated that it seemed "illogical" after talking to Anna. The conversation ended without a satisfying situation neither for the students nor for Anna.

When we analysed the conversation, we observed that Anna controlled the conversation. Nature of her scaffolding and questioning changed throughout the conversation: she used some probing questions (e.g., how can you represent this as a fraction? So, why did you write a decimal here?) But interestingly the conversation did not lead to any productive ways of thinking on the students' part. The probing questions sometimes did not help the students and the teacher did not know how to use it to steer the conversation to help students gain some understanding. We coded these interactions as Level 2, for Opportunity in Action. We did coding for all three PSTs and on five common MOs (see Table 2 for the results).

Betty and Pair B

Betty's students' answer to the given problem is given in Figure 2. They thought a number between 1/2 and 1/3 could be found if the numbers are rewritten as 2/2 and 3/3. A number in between would be less than 3/3 and more than 2/2, so it would be 2/3.

Betty started the conversation by summarizing what the problem was asking. She wanted to make sure that students were also viewing the situation as she was. Then, students' answer was not an answer she expected. She asked "how" they found the answer. We coded whether teacher noticed this Opportunity as Yes. The conversation continued with teacher's questions focused on understanding how students came up with the answer of 2/3. Students introduced "wholes" and used number line as a conveying representation of their ideas. When Betty did not agree with students' answer of 2/3, she did not say this directly but asked them to locate 1/2 and 1/3 on the same number line. This was a good move in terms of reorienting students' thinking to what was asked in the original question situation. But she moved to using fraction strips, i.e., a tangible linear manipulative with colored parts and unit fraction symbols written on them. Betty first asked a general question, such as how to use the fraction strips to transfer that knowledge into the number line. Then the focus of the conversation moved to comparing 1/2 and 1/3 with the colored fraction strips. Even though with questioning, students were able to say, "1/2" is bigger than "1/3" they had hard time to understand what fraction might be in between those two numbers when fraction strips were used. Eventually, since the students were so immersed in the context, i.e., fraction strips, they were not able to look at all the other possibilities that included proper fractions such as 5/12 or 2/5. They were thinking that it should be a unit fraction that was overly written on the fraction strips. Betty indicated that she was surprised: "Now you say there is no fraction. But you were saying there was 2/3 before..." Betty's purpose of questioning evolved depending on what kinds of answers she received from the students. We coded Opportunity in Action as Level 2 since PST asked probing and prompting questions. There was a progressive conversation, which might include students' contribution, but it was mostly teacher-dominated conversation with her mathematical goals in mind.

FINDINGS

In the initial round of coding, two researchers (authors) checked all the videotapes that three PSTs recorded and identified different number of opportunities for each PST. We identified 9 opportunities for Anna and pair A (mid-level achieving), 10 opportunities for Betty and Pair B (mid-level achieving), and 15 opportunities for Carol and Pair C (high-level achiev-

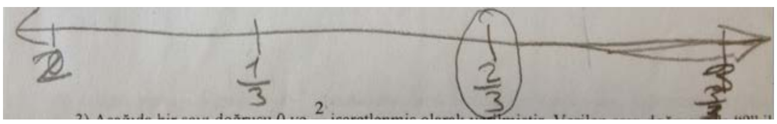

Figure 2: Betty's students' work

Pre-service Teacher	Description of the Opportunities	Opportunity	Opportunity in Action
Anna	Opportunity 1: Showing one fourth of an equilateral triangle Opportunity 2: Ordering unit fractions on a number line Opportunity 3: Placing a fraction in between two unit fractions (e.g., 1/2 and 1/3) Opportunity 4: Sharing an unknown amount, fraction multiplication and comparison Opportunity 5: Fraction division with manipulative and transferring to paper	Y: 5	Level 2: 5
Betty		Y: 5	Level 2: 4 Level 3: 1
Carol		Y: 3 N: 2	N/A: 1 Level 1: 2 Level 2: 2
Total		**Y: 13** **N: 2**	**N/A: 1** **Level 1: 2** **Level 2: 11** **Level 3: 1**

Table 2: Summary of the frequencies of the coding items

ing). This different number depended on the nature of the interactions PSTs and the pair of 6th graders had about the specific fraction problem. In the second round of coding, we overviewed all of the occasions and we identified 5 opportunities common for all the three PSTs (See Table 2). Based on the coding scheme we coded the PSTs interactions with students separately and achieved 0.88 consistency initially. Then we discussed the different coding and reached full consistency in coding.

With this experience, none of the three PSTs did "show and tell". They developed better questioning skills (Sleep & Boerst, 2012). Although, this was the case, as stated in other studies (e.g., Morris, Hiebert, & Spitzer, 2009; van Dooren, Verschaffel, & Onghena, 2002), one PST's lack of content and pedagogical content knowledge hindered to catch all MOs and address them effectively (see Carol's case, in Table 2). For Anna, while her interactions in defined MOs indicated as Level 2, her communication skills in Turkish deterred her from finding ways to use her content knowledge. This situation was directly related to her developing pedagogical knowledge for teaching fractions. Even though, PSTs listen to the children to figure out students' mathematical thinking, they need to further develop appropriate scaffolding activities. For instance, working with high-level achiever students who can argue their thinking more firmly might benefit PSTs growth more (see Carol's case). In addition, PSTs' own preparation, thinking ahead the necessary mathematical connections and planning towards some mathematical goal can improve their scaffolding actions (see Betty's case). Eventually, this might result in advancement of the conversations and 6th grade students' mathematical gains. In the working group, we will provide further evidences related to these claims and seek contributions from the group members.

Facebook and mathematics teachers' professional development: Informing our community

Jorryt van Bommel[1] and Yvonne Liljekvist[1,2]

1 Karlstad University, Karlstad, Sweden

2 Uppsala University, Uppsala, Sweden

Nowadays, communication and cooperation on social network sites, such as Facebook, have become common. These kinds of sites are also used within teachers' professional development, both in formal and informal ways, as they create and form new opportunities to communicate and cooperate. In this paper, our aim is to discuss how mathematics teachers' informal participation in social network sites can inform the mathematics education research community.

Keywords: Professional development, social network sites, Facebook, mathematics teacher.

INTRODUCTION

It is well known that the present evolution of social media and social network sites transforms how people communicate, interact, and work together. Teachers use these different forums, such as: web sites, personal blogs, twitter or Facebook as resources in terms of networking, give and take advice and lesson plans, etc., for mutual benefit in their professional development (Manca & Ranieri, 2014). This is an informal professional development initiated and formed by the teachers themselves (Bissessar, 2014; Liljekvist, 2014).

Each forum serves different purposes: websites are often one-way communication and serve to inform others and share ideas[1]. Such ideas can be lesson plans; hence websites where teachers upload their own planning documents to be shared with other teachers occur (e.g., www.lektion.se). There are websites initiated by a municipality (e.g., www.pedagogvarmland.se), where active teachers, for instance, comment on pedagogical debates, or notify on-going developmental work. Furthermore there are teachers' personal websites where they gather materials of interest, such as lesson plans, but even research articles or links to other interesting web sites. (e.g., mattefroken.wordpress.com). Another form is the blog; some teachers have started blogs merely focused on their personal reflection in relation to their profession. 'Blogging' can be incorporated within a teaching position; for instance, one of the head teachers in a municipality can be responsible to share pedagogical ideas, etc. through a blog (e.g., http://pedagogstockholmblogg.se/vara-bloggar/).

All of these media are mostly a one-way communication – a monolog. However, other media offer the possibility for (instant) dialogue. The micro blog Twitter is one such way, where comments on events and actualities are given and shared with followers. Another dialogic resource is social community sites, such as Facebook. Teachers in Sweden have started to use this resource to a great extent in the past year. Facebook offers the opportunity to comment and to share, like twitter and other websites, but it also offers the 'members' to ask questions and to get response from other members. Thus the members themselves activate pedagogical discussions on mathematics teaching and learning. This differs from how more monologue Internet resources work. In the next section a brief overview of the situation in Sweden will be given – regarding the use of Facebook by teachers.

1 The examples given in this paper are taken from a Swedish context. However, the phenomenon of Social network sites is not limited to merely Sweden, therefore the examples can be generalized.

Teachers' professional development

In a review of research on teachers learning from teachers, White, Jaworski, Agudelo-Valderrama and Goya (2013) find that there is a complexity of settings in which teachers learn. The complexity is "influenced by both global and local forces, such as the recent pressure on teachers to meet different demands imposed on them [...] directly by politicians and national laws" (p. 421). There is interdependence between the institutional context and the teachers themselves as learners. Thus: even if practicing teachers need to change their teaching because of external reforms, it can be difficult to integrate reform practices due to institutional and social expectations (Nickerson, 2008).

White and colleagues (2013) show that the relationships between the support given (e.g., by expert/ experienced teachers, teacher educators, research/ researchers) and the supportee (e.g., the individual teacher, a group of teachers) can be of different kinds, such as teacher educators as guides, teachers and researchers working together, or teachers working together to design their own developmental activities. White and colleagues point out the similarities and differences between the knowledge that teachers and teacher educators/researchers respectively bring to the learning interface. They state: "neither group had all the knowledge that was needed for the development of teaching, but working together they could become a unified, powerful developmental force" (p. 422). Mutual respect and collaboration that allow the input of critical elements of knowledge, by teacher educators, colleagues etc., are found to be valuable to developmental practice and hence deepening their pedagogical content knowledge. In a review of teacher education Leder (2008) put forward the core factors of 'community building' and 'networking' as a means for in-service teachers' out-of-class meetings. She continues:

> Providing time out of class for meetings and involving academics to supplement the expertise within the group, for example, to add a stronger research dimension to the network's activities, have also been found to be facilitative, if not critical. (p. 361)

Nevertheless, White and colleagues (2013) stress that teachers' knowledge is pre-eminent in the in-school situations, and researchers and teacher educators have "much to learn about issues that influence what can happen in schools, and what is needed to put research-based knowledge into practice" (p. 422). As social network sites can be seen as such out-of-class meetings, a systematic study of social network sites will give the opportunity to look at the factors and issues of importance.

Social network sites

Bechmann and Lomborg (2012) describe three characteristics that define social network sites: 1) the communication is de-institutionalised, as each user has the ability to contribute, filter and share content, 2) the user is thus seen as both producer and participant, and 3) the shifting roles and communicative practice of the users can be described as interactive and networked.

Social network sites are widely used in Sweden; for instance, 50% of the inhabitants actively use Facebook every day (Findahl, 2013), although boyd[2] and Ellison in 2007 conclude that "...[social network sites] are primarily organised around people, not interests... structured as personal (or 'egocentric') networks with the individual in centre" (2007, p. 219). However, the rapid evolution of the Internet allows us now to see groups formed around a theme, and it is noteworthy that special groups for the issues of teaching and learning have been created on Facebook (see e.g., Bissessar, 2014; Ranieri, Manca, & Fini, 2012; Rutherford, 2010). Facebook offers the opportunity to comment and to share, as with Twitter and other websites, but it also offers the 'members' to ask questions and to get responses from others (henceforth: *posts and comments*). Thus the teachers themselves can activate pedagogical discussions of teaching and learning. This differs from how more monologue Internet resources work, such as blogs or web sites. Rutherford (2010) concludes that "Facebook provides teachers with an opportunity to engage in informal professional development that is participant driven, practical, collaborative" (p. 60).

Social network sites can be viewed as emerging communities of practice (Goodyear, Casey, & Kirk, 2014; Gunawardena et al., 2009). For example, some of the Facebook groups are specialised for mathematics teachers (e.g., "Mathematics course 2b for upper secondary school"; "Mathematics for lower primary school"). Other groups are gathered around more gen-

2 Note: danah boyd spells her name with lowercase letters.

eral themes in education (e.g., "The big five"; "Ipads in school"). Narrow thematic themes can have very few members, such as "Mathematics for course 2b in upper secondary school" with only about 60 members. Not surprisingly, more generic themes attract more teachers; hence the group "Mathematics for lower primary school" has 4 500 members. Generic themes that are interesting to all Swedish teachers can consist of groups of up to 20 000 members. Findings from various educational settings reveal how social network sites used as professional resources are not an isolated phenomenon and that the impact of social network sites on professional development varies (see e.g., Bissessar, 2014; Borbra & Llinares, 2012; Liljekvist, 2014; Manca & Ranieri, 2014; Pepin, Gueudet, & Trouche, 2013; Rutherford, 2010). However, Leder (2008) problematizes the tension between recognising results from particular studies and the wish to generalise the findings to broader settings. She calls for studies on whether, and when, interventions from professional development programs remain more permanently. She reflects on how the possibilities and the accessibilities of ICT are "opening new pathways for professional development with their own – often yet not fully realized – fresh strengths and challenges" (p. 368).

Some studies have been made of Facebook groups and teachers' professional development. One study investigated five Italian Facebook groups and focused on the motivation, activity level and outcome (Ranieri et al., 2012). This study gives valuable information about and insight into teachers' concerns and teachers' behaviour in the groups. Bissessar (2014) sees in her study that the teachers address issues on curriculum, and didactical and pedagogical concerns, but we need more studies to examine the extent to which critical discussions occur.

Aim of the paper

In this paper, we want to introduce a discussion in order to problematize some aspects when conducting a study in social network sites (in this paper: Facebook), and discuss how these kinds of studies can inform the TWG community on, for instance, how it influence teachers' practice. Webster-Wright (2009) points out in her review of research informing professional development practice that

> There is a need for more research beyond the 'development of professionals' that investigate the 'experience of PL' [professional learning] as constructed and embedded in authentic professional practice. (pp. 712–713)

She calls for research understanding more about the experience of professional learning – to support it more effectively; rather than just developing professional development programs. In teachers' social network sites, such as Facebook groups, we might find such an environment. In the following pages, we will outline some possible directions for our coming research on social network sites. We propose, with departure in our pilot study and literature review, three possible foci for further research into this new phenomenon: 1) mapping the arena, 2) inquiry into the collective knowledge created, and 3) consider the social network sites as extended working place learning. Our aim is to converge the discussion on the question: In what way can mathematics teachers' use of, for instance, Facebook inform the mathematics education research community?

SUGGESTION 1: MAPPING THE ARENA.

Some attempts have been made to map the arena of Facebook groups and professional development. One such study investigated five Italian Facebook groups and focussed on the motivation, activity level and outcome (Ranieri, Manca, & Fini, 2012). Such a map might be of interest concerning the Swedish Facebook groups as well giving valuable information and insights in teachers concerns and teachers behaviour within the groups. Two aspects are suggested to map: facts and professional development issues.

Facts

Concerning the facts: Statistics can be obtained on the fluctuation of the number of members in the groups. A relevant question to look at would be when people become a member, if that is related to specific timeslots in the year, or special events (e.g., yearly events, or more specific as launching new curricular goals). Statistics can also reveal when people are most active, what time of day for instance. This could shed a light on in what way Facebook is experienced as a formal or informal way of professionalization. One could argue for the idea that teachers, who are active on Facebook during working hours, look upon this phenomenon as a formal way of professionalization. Teachers who only are active during after-working-hours might look upon these Facebook groups as informal ways of professionalization.

A questionnaire posted on the site would give some first indications on the motives for joining the Facebook group, but also expectations of what teachers expect to gain from participation in the specific Facebook group. Members in this group could be contacted to conduct interviews in order to gain deeper insights in their motives and expectations of membership within the group. A strategic choice of members should be made: for instance new members, active members in responding to posts, or active members in posting a status, etc.

Questions to be asked will be of the kind: 'why did you chose to join the group', 'when do you decide to post a question within this group', 'what kind of questions do you post', 'what kind of questions do you respond to?', 'what kind of topics do you discuss' etc.

Professional development "issues"

A pilot study revealed that different types of questions appear in the groups at different time during the year. For instance, at the beginning of the school year a common post would be to ask for help with a good starting exercise for the beginning of the semester. Just before the summer holiday, a lot of teachers posted questions about textbooks – often explained by the motive that they were about to change textbooks and needed advice on qualities in different items. Prior to public holidays, questions were asked about suitable exercises for 'Easter', or 'Christmas', etc. Hence, the teachers' pedagogical considerations, as they differ over the year, can be studied more in detail. This informs teacher educators and professional development programs in terms of when to address specific topics or support teachers.

Furthermore, our pilot study revealed that different groups address different types of questions. For instance, one of the Facebook groups has a focus on discussing relevant and interesting research papers. All posts in that group concern either the choice/argumentation for a specific paper, or the content of the chosen paper. This indicates teachers' diverse conditions (e.g., depending on school level, topic, etc.) and what kind of support specific groups of teachers need.

As the description of TWG18 says, research has focussed on "topics like reflection, collaboration, or teachers' professional growth. In particular, models and programmes of professional development, as well as their respective contents, methods, and impacts were described and analysed" (Call TWG18, CERME9). With Facebook being another kind of arena: teachers' social network sites, to 'map' this new phenomenon inform the community of professional development of mathematics teachers on new reflections, collaboration and professional growth.

Mapping the arena is of importance as the discussion at CERME9 revealed that Swedish Facebook groups might differ from Facebook groups in other countries concerning the norms within a group. As we described a positive open non-anonymous atmosphere in the groups, other participants of TW18 at CERME9 described similar groups in other countries as hostile, with anonymous members, and a focus on complains.

Nevertheless, however interesting mapping the arena might be, more information is 'hidden' in the Facebook groups that could inform the community of professional development of mathematics teachers. Besides mapping the arena, two more suggestions are of interest. We don't suggest that further research consist of merely one of our suggestions, nor that is the only possible ways to conduct research. Mapping the arena probably is a prerequisite for the following two suggestions, starting with an inquiry of the collective knowledge in Facebook groups.

SUGGESTION 2: INQUIRY INTO COLLECTIVE KNOWLEDGE

Some studies have looked at single posts within specific Facebook groups. Rutherford (2010), for instance, has looked at one Canadian Facebook group, and categorized each posts in this group according to Shulmans' categorization of teachers knowledge. To continue on such categorization, we suggest going further than the individual posts, and hence look upon each Facebook group as a whole to make an inquiry in the collective knowledge. Facebook can be looked upon one of the emerging communities of practice (Goodyear, Casey, & Kirk, 2014; Gunawardena et al., 2009).

To do so, one could categorize all posts in a similar way as Rutherford did, but with the difference not to distinct each post, but to look upon the results as an indicator for the collective knowledge of the community of teachers in the specific Facebook group. Previous studies have looked at discussions where they have taken out single posts, meaning: if a question was posted and nobody responded, that question was not taken into consideration for data analysis (Rutherford, 2010). However, once teachers can formulate their questions, they have reflected upon their own teaching knowledge. Therefore, we argue, that both the questions posted and the reactions from the group show us the collective knowledge, expressed through the members' communication– including single posts. Again it is of importance to point out that the norms in the groups influence such collective knowledge and this might be different in different cultural settings as expressed by the TW18 at CERME9.

In the previous example, Shulman's categorisation was used to analyse the data. Different frameworks have described the knowledge needed for teaching mathematics (cf. Ball, Phelps, & Thames, 2008; Huckstep, Rowland, & Thwaites, 2003; Niss, 2004; Shulman, 1987). All of these have their own specifics (See Kaarstein, 2014, for an extended comparison of three of such frameworks) and hence, one of these could serve as a framework for analysis for posts within each Facebook group. Yet another option could be to analyse the mathematical content of the posts and focus on the mathematical topics addressed, including possible references to competencies (Niss, 2003) or proficiencies (National Research Counsil, 2001). The Swedish curriculum has changed recently and the pupils' possibilities to develop five competencies are the overarching principles in the current curriculum (Swedish National Agency for Education, 2011). Within Facebook groups for mathematics teachers at primary school, questions concerning the five competencies arise frequently. There is also one generic Facebook group 'The big five', aiming at teachers of all subjects.

This second suggestion, we believe, would inform the community of professional development of mathematics teachers via an explanation of the collective knowledge made in the groups, concerning the mathematical content as well as the knowledge needed for teaching mathematics.

SUGGESTION 3: EXTENDED WORKPLACE LEARNING

In the previous suggestions the attention has been on activity and on what kind of knowledge created in the Facebook groups of mathematics teachers. However, it can also be worthwhile to investigate how this knowledge is constituted. Social media and social network sites are, as we all know, used in professional development programs (for instance, 'Mathematical Boost', matematiklyftet.skolverket.se). In this paper, we want to discuss social network sides as an informal part of mathematics teachers' professional development; we suggest approaching social network sites as an arena for extended workplace learning. Professional development programs are culturally bounded and the Mathematical Boost is one such program that locally can influence in what way teachers look upon their extended workplace. Comments from TW18 at CERME9 implied that a detailed description of such programs is necessary in order to be able to clarify cause and effect.

Borko (2004) points out that teachers' discussions on work-related issues tend to be on a surface level, such as discussing ideas or materials; and that it takes support to foster critical discussions on teaching. She states that teachers need to "collectively explore ways of improving their teaching and support one another" (Borko, 2004, p. 7) in order to develop their teaching. Thus communication norms enabling a critical dialogue need to be established and maintained. In a study of Facebook groups it would be possible to study such communication practices, and examine to what extent these kinds of communication norms occur. Moreover, as we know the development of teacher communities is difficult and time-consuming (see e.g., Grossman, Wineburg, & Woolworth, 2001) are Facebook groups a way for teachers to foster such discussions – despite its instantaneous format and more or less loose gathered groups?

For instance, Bissessar (2014) sees in her study that the teachers address issues on curriculum, didactical and pedagogical concerns, but we need more studies to examine to what extent critical discussions occur. That is, does the informal arena of social network site nurture workplace learning? Can we see communication patterns changing due to changes in, for instance, curriculum, or due to impact of formal professional development programs? One way of looking at this informal arena would be via inquiry as a developmental tool in a community of practice, as described in Goodchild (2014).

Webster-Wright (2009) thinks it is a lack in research designs in professional development programs. She states that it is necessary for us to learn from teachers' authentic learning situations: "To gain further insights to enhance support for professionals as they learn, there is a need to understand more about how professionals continue learning through their working lives" (Webster-Wright, 2009, p. 404). We believe that studying; for instance, Facebook groups can help our community understand more, since it is a situated digital, hence extended workplace for the teachers.

ETHICAL CONSIDERATIONS

Although it is not the main focus of the discussion of TWG18, we need to address some aspects of ethical concern when conducting research on social network sites. Normally in a classroom the observer might influence the practice, and now a new question arise: in what way does the presence of researching members in groups influence the group?

This is not merely a methodological question; the blurred distinction between the private and the public in social network sites must also be considered (Bryman, 2008).

SUMMARY

In this paper, we have introduced a discussion continued at CERME9 in the Thematic Working Group 18 in order to problematize some aspects when conducting a study in social network sites. We proposed three possible foci for further research into this new phenomenon: 1) mapping the arena, 2) inquiry into the collective knowledge created, and 3) consider the social network sites as extended working place learning. Our aim was to converge the discussion on the question: In what way can mathematics teachers' use of, for instance, Facebook inform the mathematics education research community concerning mathematics teachers' professional development? Regarding issues of teaching and learning mathematics in social network sites, the uniqueness of the Swedish Facebook groups should be taken into account where an open, positive climate describes the conversations in these groups.

How future teachers improve epistemic quality of their own mathematical practices

Yuly Vanegas[1], Vicenç Font[2] and Joaquin Giménez[2]

1 Autonoma Barcelona University, Faculty of Education, Barcelona, Spain, yulymarsela.vanegas@uab.cat

2 Barcelona University, Faculty of Education, Barcelona, Spain, vfont@ub.edu, quimgimenez@ub.edu

In this paper, we present how future mathematic teachers improve their self-reflection in didactical analysis competency. We draw on data collected from two groups of prospective teachers, using qualitative methods. We use a prospective teacher as an example to discuss how the training on the use of didactical suitability criteria and reflective tools lead them to learn about the experience, and explain in a deep way how they will change their own practices in the future.

Keywords: Mathematical quality, future teachers, professional development, didactical analysis.

INTRODUCTION

In this paper, we analyze how a specific pre-service mathematics teachers' training program produces changes in terms of future secondary school teachers' competence of didactical analysis. In particular, aiming at the growing and building mathematical knowledge for teaching (Zaslavsky & Sullivan, 2011) by using theoretical tools for self-analysis. Our general intention in such a program is to lead future teachers to develop the professional ability of reflecting about changing their own planning by using didactical analysis theoretical tools. In this paper, we focus on explaining how future teachers value the need of analyzing mathematical quality in their final reflections when they tell us how and why they will improve their school practice for the next future. The research relates to the dilemmas of task redesign that provides a framework that can be used for analysis of quality and suitability of tasks (Giménez, Font, & Vanegas, 2013). Our aim in this presentation is *to describe how a specific set of professional tasks, promotes the emergence of using theoretical tools from future teacher's reflections, when valuing epistemic/mathematical suitability of an instructive process in a multidimensional way.*

In our study we call 'professional task' those task s that we propose to future teachers in order to encourage them doing didactic analysis and developing their didactical analysis competences. We want to focus on some immediate effects of the task redesign done by the future teacher. In previous researches (Vanegas et al., 2014), it was found it when analyzing prospective teachers' thoughts emerging from their feedback [work assignments] with the researchers; and also emerging from our analysis of some impacts of the program itself. Such above mentioned development, it is stated when future teachers incorporate and use tools for the description, explanation and process valuation of mathematical school teacher/learning practices. Thus, our main hypothesis is that future teachers can reflect and value their own practices in a deep way, and to have ideas to structure a possible redesign that improves the quality of their own mathematics and teaching for the future.

THEORETICAL FRAMEWORK

In our research, we assume a learning through teaching perspective between the design of classroom tasks, the pedagogies associated with the effective implementation of tasks and the learning of mathematics (Leikin, 2006) and task design problematics. The role of the Mathematic teacher in such a framework is to select, modify, design, redesign sequences, implement and evaluate mathematical practices. The analysis and description of the mathematical activity is conducted using the theoretical constructs proposed by the 'Ontosemiotic' approach (OSA). According to this perspective (Godino, Batanero, & Font, 2007), the mathematical activity plays a central role and it is modelled in terms of systems of operative and discursive practices. From these practices the different types of related mathematical objects emerge building cognitive or epistemic configurations among them. Problem situations promote and contextualize the activity; languages (symbols, notations, and graphics) represent the other entities and serve as tools for action; arguments justify the procedures and propositions that relate the concepts. Lastly, the objects that appear in mathematical practices and those which emerge from these practices might be considered from the five facets of dual dimensions (Godino, Batanero, & Font, 2007). Both the dualities and objects can be analyzed from a process-product perspective, a kind of analysis that leads us to the processes shown.

In fact, there are two possible perspectives to analyze the quality of a mathematical practice. On the one hand, international experiences focusing on rigor and mathematical richness (Hill et al., 2008). They introduced a set of categories to measure the mathematical quality of an instructive process (Hill, 2010): (1) well done format, (2) work done in a connected way to mathematics, (3) richness of the mathematics itself, (e) work done with the students (4) errors and imprecise language used, (5) students' participation. It's also explained that for mathematical richness, we can see some indicators as: mathematics explanations, multiple procedures or solving methods, mathematical generalization development, use of a mathematical language, and general mathematical aspects of richness as representations, among others. On the other hand, by considering OSA we interpret that it is necessary to see the theoretical tools not as a priori solution, but an emerging process from the practice itself. We consider that it relates to a way of constructing quality criteria by the future teachers during the professional training process. Hypothetical trajectories should reveal not only the acquisition of theoretical tools for analysis, but also to see how personal didactical principles are assumed by future teachers in an open and personal way. The notion of epistemic quality proposed by OSA is centered on representativeness of mathematics taught by the future teachers in a lifelong learning perspective according a holistic meaning of mathematical objects to be learnt, understood as a pair (mathematical practices, primary objects and processes activated in such practices). The determination of such a global meaning or holistic meaning requires an epistemological/historical study about the origin and evolution of the mathematical object. We must take also into account the diversity of "using contexts" in which it's possible to play each of the possible configurations of these primary objects. There is a consensus on considering what epistemic suitability mean: Representative and articulated sample of diverse types of problems (contextualized, according different levels of difficulties, etc.); use of different modes of expression (verbal, graphic, symbolic...), also with translations among representations. In such a way we could consider an adequate level of mathematical language; definitions and procedures should be correctly stated and adapted to the level of the students; presentation of basic statements of the "topic" in order to, establishing relations and meaningful connections among definitions, properties, problems and so on. The complexity of perspectives about mathematical objects from OSA perspective, introduces the idea that a mathematical object is not simple but a complex system. The idea of representativeness as quality criteria is related to coherence and connectness aspects.

In a previous research, it was observed that epistemic suitability criteria and epistemic configurations, could be useful tool to organize self- reflection, but those tools were not used by future teachers in a pre-implementation as planning phase (Giménez et al., 2012). Now, our research aim is to confirm if the future teachers could emerge the suitability criteria from their final analysis. We also want to see how they use it, by describing a future teacher case study.

METHODOLOGY

According to the proposed aim for this study: a) a set of professional tasks had been designed; b) these tasks are implemented in the training program; c) the written productions of future teachers are considered as essential data and d) a student production is analyzed as a case study.

We assume a learning by teaching approach based on an inquiry and reflective practicing in which it was observed the tensions presented for task designers and teacher adaptation whether they are designing tasks for themselves or for others. Framework in which we design and implement diverse teacher training cycles as teaching experiments for developing didactical analysis competences among others. In particular, we discuss some effects of a teacher training cycle named "Epistemic Analysis" (as a part of a more general cycle of didactic analysis). The development of this cycle includes four main professional tasks: (a) First naïf analysis of a teaching episode about proportional reasoning, and refined analysis using suitability criteria (b) Looking for errors, ambiguities, and construction of different meanings by analyzing three episodes about perpendicular bisector concept; (c) Analysis of connectness and representativeness; (d) The need of improving richness of processes, by analyzing episodes of introducing integral concept. After that, the future teachers designed and implemented a lesson into their period of internship. They did a first reflection and valuation of the suitability from their didactic implemented unit. Finally, we ask for an improvement and re-planning of their lessons designs (for future implementation), within the Master's Final Project (MFP).

As a general schematic framework, we see in Figure 1 the developmental process.

During the cycle we present theoretical tools (suitability criteria, according Godino, Batanero, & Font, 2007) to conduct evaluative analysis to answer "what could we improve from our self-analysis?" We understand that the study of descriptive and explanatory analysis for a didactical situation is necessary to justify the evaluations. As the aim is to give tools for reflection, we use methodology based on case study design based research (Gravemeijer, 1998): the use of a real environment, to generate new and efficacy learning environments, collaborative enquiry perspective among trainer-researcher and future teachers, searching simultaneously construction of theories and practice innovation (Cobb, di Sessa, Lehrer, & Schauble, 2003).

The study was conducted by two groups of 32 future Secondary School teachers of Mathematics from the Interuniversity Program in Catalonia. For the results, we analyze the final work of a single student in terms of his use of tools. The data were registers on virtual platform, audiovisual comments about classroom episodes, final Master's work valuing mathematical quality about their implemented own practice. Now, we explain each of the analysis through the four main activities introduced.

(a) Task 1. Noticing mathematical objects and processes in a math task

A first task had been introduced to show how constructs emerge from a school practice as cognitive and semiotic conflicts, epistemic obstacles, types of norms, interactive, patterns of models of management, etc. It was selected an initial task in which students confront a short case study about proportional reasoning, using transcripts of a classroom situation. Such an initial *tasks* introduce the students for reading and analyzing the classroom example, by using their previous knowledge and beliefs of didactic analysis. During the first task, future teachers did naive comments about a proportion class talking about the comparison of two quarters with different density of population. It's easy for them to identify mathemat-

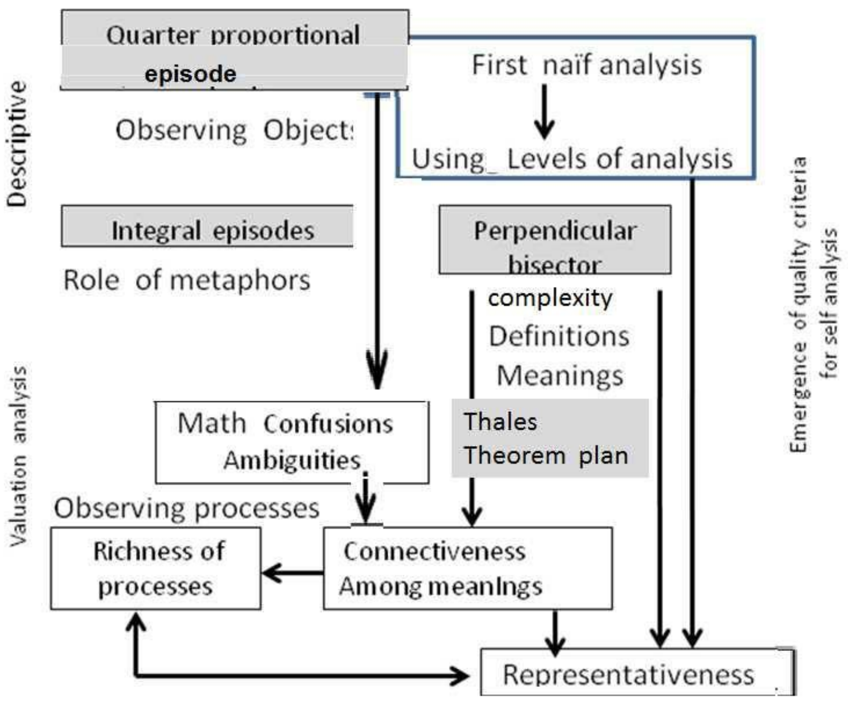

Figure 1: Scheme of different constructs involved in epistemic cycle

ical objects but it's difficult for them to recognize all the processes involved in the task.

Refining the analysis by using theoretical tools

It was analyzed a class about equations by applying structured suitability criteria. The students start by analyzing mathematical practices, by observing objects and processes. Then the trainer develops an example in which it was revised suitability construct. After that the future teachers reflect, improve and refined their analysis by using the notion of epistemic suitability. In such professional task, it's still difficult for the future teachers to identify some semiotic conflicts. Later, in the different subjects of the Master, the students realize other analysis of practices, objects activated in the above mentioned professional practices (problem, definition, proposition, representation and argument) and mathematical processes. Observing such initial analysis realized by the future teachers, we expect to improve some difficulties to distinguish between concepts and definitions. It's also found that during second analysis, the future teachers recognize their duplicities between definitions, propositions and procedures, and also their duplicities between propositions and thesis of arguments. It's still difficult for them to have a good description of practices because they overlap the configuration of objects and the description of processes. It's also difficult to see and to catalogue mathematical processes. The reflective process in this training period, try to add historical values of mathematical objects, relations among concepts, and to analyze how the use of resources can change the construction of different meanings. Therefore, it is expected to see mathematical structure behind the mathematical practice.

(b) Task 2. Analyzing the role of mathematical errors and ambiguities

Initially, the first proportion professional task was enough to see that if you did or introduced misconceptions or errors you will promote semiotic conflicts. It's common sense of quality the idea of coherence when using mathematical errors. But another task was introduced to review such idea about perpendicular bisector.

Analyzing the role of definitions and meanings

In such epistemic analysis, we notice that it's needed an adequate contextualization, in order to delete abuses, to focus on mathematical purposes, and to promote transference of knowledge. As a prototyping professional task to promote such analysis, it was proposed the observation of three short ways of introducing perpendicular bisector with 12–13 years old students, by observing three different teachers. The main idea to present a discussion about the different practices, objects and mathematics processes and to introduce a reflection associated to how each of these episodes contribute to introduce different kind of epistemic configurations and objects associated to three different definitions. First practice introduces perpendicular by the middle point of the segment. Second teacher use a definition as right-lane formed by the points being equal distance from the end points of the segment. Third teacher uses the idea of border of two regions determined by the closest neighbour principle) It was observed that both first and second teachers did classical proposals and management about the content and the classroom. The third teacher proposal is innovative not only because of the management but mathematically as a way of changing the regular use of mathematical content as a change of configuration of practices, objects and mathematical processes by using a non-routine task. Future teachers observed interpretation processes, communication of didactical and mathematical meanings, etc. Furthermore it appears a reflection about distinguishing complex processes from simple processes and also a general reflection about the idea of processes itself.

(c) Task 3. Analysis of connectness and representativeness of knowledge

To characterize epistemic quality, we analyze how representative and articulated set of activities/problems (contextualized, different levels of difficulty, different modes of representations and translations, etc.) had been proposed. It as a way to see the need of clarification of questioning and exemplifying, because in such situations we can see how different meanings appear, how we establish relations and connections among definitions, properties, and problems.

A prototypical example of this task analysis is a case based analysis upon a previous future teacher reflection that: first planned a sequence with 7th grade (13–14 years old students) for Thales theorem. She analyzed her own practice about Thales Theorem after the school practice, but she didn't notice a good mathematical connection among different activities. The trainer introduces epistemic configurations to see that some connections had been forgotten. The aim of this professional task is to recognize a deep level of analysis from such previous prospective teacher's practices (Choppin, 2011). Thus, the future teachers learn from this analysis, the need of connecting several epistemic configurations.

(e) Task 4. Improving richness of processes

It was decided to use the integral concept to start such a general analysis. The episodes presented come from a school experience in which a substitute teacher uses her common knowledge with a regular textbook to introduce integrals for 18 years old students. The trainer explains the idea of richness of processes, and talk with future teachers about the complexity of the integral concept by noticing seven meanings as geometric, result of a change process, inverse of a derivative, limit approach, generalized content, algebraic, and numerical method (Contreras, Ordóñez, & Wilhelmi, 2010). After that, it was questioned which processes they think it's possible to promote by using some problems. We considered if the situations activate some of the following processes: contextualization, algorithmisation, communication, argumentation and problem solving. In such analysis it's also discussed the relevance of some specific questions. After such task analysis, there was a consensus about the low level of accuracy in terms of promoting processes associated to different meanings.

RESULTS AND DISCUSSION

In order to reflect about how the future teachers introduce and interesting self-reflection, we exemplify some important unexpected acquisitions as a special case study to understand possible influences of the above professional tasks upon their epistemic valuation. The future teacher (N from now), was considered interesting for being analyzed because he is not mathematician, but economist, and he uses very carefully the theoretical framework above presented for his own reflection. Some teachers tell us that they didn't introduce mathematical errors. It is important to say that in previous years, they were not worried about it.

> I did an error introducing the notion of compatible undetermined system, by using an apparent good example of prices, but telling the students that there are infinite solutions. It was difficult to see, but I promoted an error, because the contextual situation is related to a finite set of answers. The children conclude that there are many solutions, but limited because of non existence of negative money. Nevertheless, I didn't say anything about the limited use of coins in Spanish currency. (N)

The same teacher explains explicitly how he will change a statement in a problem, because of the reflection.

The future teachers accept that they did ambiguities relating language problems that they identify as creating possible semiotic conflicts.

> I promote some statements, not enough clear as we see in the task … Finally, my tutor tell me about the need for clarifying why we used the expressions "It passes subtracting" "We delete denominators … and others". (N)

According formalism introduced, the future teacher assumes that he started with not necessary sentences. The teacher T relates such ambiguity to a theoretical article. For instance, he said about "*the need of searching analogies found because of an incorrect use of contextual framework*". He read a text from Reed to reflect about the use of two important variables influencing the decisions of the teacher.

> "The context understood as a set of traits perceive d in a certain problematic of real world involving objects, and facts"… But, the laws, principles, relations among quantities, and equations, constitute the structure of a problem". It is interesting that the future teacher explain some conclusions from this discussion: "the need to describe the similarities and differences among structures and surfaces of the source problems and aiming problems, because it influences the decisions about the equations presented to solve the aiming problems. It is also important to identify that familiarity can help the transference processes, but it also could be an obstacle to see the similarities and structural differences among problems". (N)

About richness of processes

The future teacher expressed the need to incorporate problem solving from the perspective of Polya, which had not been considered in his planning. He also explains the need to articulate the role of letters and unknowns.

> It would be necessary to change the status of quantities designed by letters We must identify the global traits of mathematical competency, not only because of my experience, but the studies conducted in which it's found the serious difficulties to produce right equations. If it's correct, is because of the use of Cartesian methods in a flexible way, producing a diversity of equalities for the same problem... It's also important to identify different patterns when we build equalities. (N)

We also found in his work, much unexpected reflections about the need of modelling processes in an inquiry perspective. The future teacher N tells about "*the emphasis on algorithms instead of modelling that gives opportunities to observe similar structures in the same model...*" Quoting Chevallard "*presented three important steps for modelling in algebraic situations: To introduce letters to define variables of the system, that gives opportunities for generalization and increase mathematical power. To establish relations among variables and to work mathematically to establish new relations...*". The future teacher N, not only recognize the students' difficulties but also indicate that "*some researches explain the possibility to validate the model and learning from such a perspective ... de signing courses using graphic calculators*".

About representativeness

The future teacher tells us that it's needed not only a look for meanings, but to see a historical, epistemological and curricular perspective. Then proposed a set of ideas about the Arabic way of solving problems to be introduced next time. In this case, he just offer a reflection about "*considering algebra as part of cultural legacy*".

About connectiveness

N explains the need for applications to other disciplines.

> As an economist, I can say the use of systems of equations to find equilibrium points, as intersection of different conditions, interpreted by curves of offer and demand... and planning problems of dead points... programming problems...We also use algebra as a process to solve engineering problems...chemistry problems, restoring digital images. About intramathematical connections, algebraic systems of equations are referent knowledge for optimazation problems... We assume that some of these knowledge must be introduced and adapt according the age of the students.

CONCLUSIONS

The professional tasks proposed, promote that the future teachers did positive reflections about their own practices. In each set of tasks and analysis we could identify the emergency of the different aspects characterising the epistemic suitability. Some of these are in agreement to which were presented by Wilson, Cooney and Stinson (2005).

The different type of analysis done during the implemented Program, not only gave opportunities for establishing categories and structure for the reflection, but also permitted to explicit how to improve the didactical sequence as we have seen in the case study. We consider that such attitude for changing from reflective analysis is important for professional development.

ACKNOWLEDGEMENT

Professional development of primary teachers during a lesson study in mathematics

Valérie Batteau

HEP Lausanne, Lausanne, Switzerland
University of Geneva, Geneva, Switzerland, valerie.batteau@hepl.ch

We study the evolution of primary teachers' practices in mathematics by analyzing the effects of a professional development training called lesson study (LS) in Lausanne, Switzerland. We answer the following question: what practices will change and what will resist change?

Keywords: Teachers' practices, lesson study, professional development.

LS is a field of research and professional development in Asia, in US and in Northern Europe (Lewis & Hurd, 2011; Yoshida & Jackson, 2011). LS is a collective and reflexive process that involves a group of teachers and coaches. LS has four steps to a cycle (Lewis & Hurd, 2011): the group studies a mathematic subject (step 1), prepares a lesson plan (step 2), one of the teachers conducts the lesson while others observe (step 3), and finally, the group analyses and may revise the lesson (step 4), with the option of teaching it again.

Teachers' practices are analysed using the theoretical framework: the double approach (Robert & Rogalski, 2002, 2005) based on a French didactical approach and an ergonomic approach (Leplat, 1997) based on activity theory. In the ergonomic approach, the main goal is to distinguish prescribed work (the prescribed task, or what the teacher must do, planned together during step 2) and real work (the conducted task, or what the teacher does in reality, enacted during step 3). To appropriate the prescribed task, the teacher should modify it. We study the teacher's activity as a process of modifications between tasks (Leplat, 1997; Mangiante, 2007). The prescribed task includes the mathematic task, the mathematical knowledge, the lesson plan and the planning material. Leplat (1997) adds two tasks: the represented task (how the teacher represents the prescribed task and what he thinks the group attends of him) and the redefined task (the teacher redefines his task according to the prescribed task and his own professional goals).

In this framework, teachers' practices are seen as a complex, coherent and stable system. Regularities are observed in teachers' practices during three important moments of teacher's activity (process of devolution, regulation and institutionalization (Brousseau, 1997)) and correspond to teachers' strategies and choices.

MEHODOLOGY AND DATA ANALYSIS

The prescribed task is analysed *a priori*, which means we study the mathematic knowledge at play in the task, the possible resolutions and the didactical variables.

From the conducted task, we analyse the proceedings and the students' offered activities. We set up indicators to describe the teachers' practices in order to categorise their practices in i-genre. We define the represented task and the redefined task from research data (particularly with collective sessions enacted during step 2 and step 4).

We transcribe all video data (lessons and collective sessions) and we analyse with indicators (in Nvivo) video data, written documents and students' productions during the LS cycle.

SAMPLE

The group consists of seven primary teachers ranging from experienced, voluntary and generalist teachers, and two coaches. The LS process occurs over two years with two collective sessions occurring per month.

FORMAT CHOSEN

We present a figure of the LS cycle with first analysis, indicators and results applied to teacher's practices by visual material. Next to visual material there are short sections: (1) Context of the research and theorical framework, (2) Research questions, (3) Methodology and (4) References.

A professional development program in formative assessment for mathematics teachers – Which changes did the teachers do and why?

Erika Boström and Torulf Palm

Umeå University, Umeå Mathematics Education Research Centre, Umeå, Sweden, erika.bostrom@umu.se, torulf.palm@umu.se

This study is part of a larger research project about a comprehensive professional development program (PDP) in formative assessment for mathematics teachers. The aim of the study is to investigate in which ways the teachers' classroom practice change, with respect to formative assessment, after participating in the PDP, and which some of the reasons may be for these changes. Fourteen randomly chosen grade-seven mathematics teachers participated in the PDP. The teachers were interviewed and their classroom practices observed, before and after the PDP. They also answered two questionnaires about the PDP. Preliminary results show that all teachers were motivated to change and did change their practice, but to varying degrees.

Keywords: Professional development, formative assessment, mathematics education.

BACKGROUND

Several studies have demonstrated that the use of formative assessment in classroom practice is one of the most educationally effective ways of increasing student achievement (e.g., Black & Wiliam, 1998; Hattie, 2009). But Wiliam (2010) also highlights that little is known about how to effectively help teachers implement a formative classroom practice, and that designing ways of supporting teachers to developing their formative assessment practice is an important issue. This study is part of a larger project about a comprehensive professional development program (PDP) in formative assessment for mathematics teachers. The overall aim in the project is to contribute to the understanding of factors that are significant in the support of teachers' implementation of a formative assessment practice. In this specific study the aim is to investigate in which ways the teachers' classroom practice change, with respect to formative assessment, after participating in the PDP, and which some of the reasons may be for these changes. In the project, we use a conceptualization, suggested by Wiliam and Thompson (2008), of formative assessment as practice based on an adherence to the "big idea" of using evidence about student learning to adjust instruction to better meet student learning needs, and a competent use of the following five key strategies: (1) clarifying, sharing and understanding learning intentions and criteria for success, (2) engineering effective classroom discussions, questions, and tasks that elicit evidence of learning, (3) providing feedback that moves learners forward, (4) activating students as instructional resources for one and another, (5) activating students as the owners of their own learning.

METHOD

Fourteen randomly chosen grade-seven mathematics teachers participated in the PDP. The PDP was process-oriented, focused on the "big idea" and the five key strategies of formative assessment and had duration of 24 full days distributed over 4.5 months. The teachers were interviewed and their classroom practices were observed, before and after the PDP. They also answered two questionnaires about the PDP. The analysis of the teachers' changes in classroom practice was carried out using the framework of formative assessment described above.

PRELIMINARY RESULTS AND CONCLUSIONS

After the PDP all teachers changed their classroom practice but to varying degrees. The most common and frequent change was that the teachers more often elicited evidence of student learning with the purpose of adjusting their instruction. Another common change was that they used more effective activities to engage and create thinking among all students during whole-class sessions. They did so by using an "all-response system" and a system for random distribution of questions when asking questions in class. These changes were mainly connected to Key strategy 2. Small changes connected to the other key strategies were also made. After the PDP the teachers were motivated to change their classroom practice since they believed in the idea of formative assessment, had tried activities and experienced positive effects on students and also felt that they had sufficient knowledge to develop their formative assessment practice. Some reasons to why the teachers did not change their classroom practice more was that the teachers experienced that they needed more time and that old habits are hard to change. This study may contribute with knowledge that can be used when designing professional development programs in formative assessment in the future.

Analysing student teachers' lesson plans: Mathematical and didactical organisations

Louise Meier Carlsen

The University of Copenhagen, Department of Science Education, Copenhagen, Denmark
The University of the Faroe Islands, Department of Education, Tórshavn, Faroe Islands, LouiseC@setur.fo

I investigate 17 mathematics student teachers' productions, in view of examining the synergy and interaction between their mathematical and didactical knowledge. The concrete data material consists in lesson plans elaborated for the final exam of a unit on "numbers, arithmetic and algebra". The anthropological theory of the didactic is used as a framework to analyse these components of practical and theoretical knowledge.

Keywords: Didactic divide, lesson study, mathematical and didactical organisations.

INTRODUCTION

Mathematics teacher education is often described as consisting of several components such as mathematical contents, didactics and pedagogy. Bergsten and Grevholm (2004, p. 125) introduced the term *didactic divide* to indicate a lack of connection between such components. In this paper, I wish to investigate the degrees of didactic divide (or coherence!) by analysing certain productions of Faroese mathematics student teachers for an exam in a module that seeks to integrate the teaching of mathematical contents and didactics (in the context of algebra and arithmetic). This is my first research project as part of my work towards the Ph.D.

THEORETICAL FRAMEWORK AND RESEARCH QUESTIONS

In the anthropological theory of the didactic, human practice and knowledge is modelled in terms of *praxeologies*, which consist of a *practice block* and a *knowledge block*. The practice block consists of *types of tasks* and corresponding *techniques*. The knowledge block contains *technology* (discourse on techniques) and *theory* (unifying discourse on technology). For more detail see Barbé and colleagues (2005). In our study we consider *mathematical* and *didactical* praxeologies (defined by tasks being of mathematical and didactical nature) and their mutual connections. We can then formulate the research question of the study as follows: *What links and gaps can we observe in the mathematical and didactical praxeologies of students as evidenced in their plans for a lesson on school algebra, produced in the setting of a teacher education course?* Naturally, a methodological problem is closely linked to this question: *How can we, concretely, extract the components of mathematical and didactical praxeologies from a lesson plan?*

CONTEXT AND STUDY

The mathematics teacher education programme at the University of the Faroe Islands can be described as mainly consecutive (cf. Winsløw et al., 2007) in the sense that general pedagogy and other generic courses make up the first two years of the programme, while the last two years comprise units with a main focus on contents and a secondary, integrated focus on didactics. One of these units in the third year is the source of our data for investigating the above research question. Halfway through the course, the format of *lesson plan* is introduced (in connection to the wider idea of *lesson study*) as a way to work with a school mathematical theme.

The task (a didactical one) is "to plan a lesson on a specific theme" (e.g., "how to add two fractions?"). The theme in turn can be described as a mathematical praxeology, in this case focused on techniques for adding fractions, descriptions and justifications of the techniques (technology), and mathematical links to similar practices (including theoretical notions such as commutativity, inverses etc.). The lesson plan will potentially articulate both elements of this mathematical praxeology and also present choices of didactic techniques, and as these are explicit (written) there will be elements of didactic technology and theory to analyse. The students elaborate (individually) one such lesson plan which forms the basis of the final oral exam in the course. Their presentation of the plan may take up to 20 minutes followed by questions from the lecturer. While the main data will be the lesson plans themselves, transcripts from the exam will also be used to complement the information regarding students' mathematical and didactic theory blocks.

My analysis focuses on the students' choice of didactic techniques, the justification of these techniques in relation to the mathematical praxeology, the preciseness of their didactic technology, their reference to explicit didactic theory and the connection between didactic and mathematical theory blocks (for instance, didactic theory on the teaching of fractions could be more or less connected to the theoretical components of the mathematical praxeologies proposed by the lesson).

Questioning as formative assessment and its quality measurement

Veronika Hubeňáková and Dušan Šveda

Pavol Jozef Šafárik University in Košice, Faculty of Science, Košice, Slovakia, veronika.hubenakova@student.upjs.sk, dusan.sveda@upjs.sk

This paper presents the tool for measuring the quality of questioning in mathematics classes. Its construction is based on video analysis and interviews with teachers. Actually, we identified five different categories within the constructs of questioning. These rubrics have potential to be used in research and in teacher education

Keywords: Questioning, formative assessment, quality measurement tool.

BACKGROUND

Education in Slovakia has recently overcome a lot of changes. They were forced by poor results of Slovak students in PISA measurement. Unfortunately, this reform movement seems to miss its goal. The last mathematics PISA measurement revealed significantly worse Slovak students´ results in mathematics when compared to previous measurements (NÚCEM, 2012). Influential reasons of this failure are unchanged teachers´ practice and beliefs while the content and the aims of mathematics education were modified.

THEORETICAL FRAMEWORK

We consider questioning to be the one of the most important teachers´ skills. As pinpointed by Aizikovitsh-Udi, Clarke and Star (2013), the questioning is not only an issue of good questions, further, there is a strong importance of the way the questions are asked, timing and number of times each question is asked. Webb (2004) claims that classroom discussions present an ideal opportunity to explore students´ understandings and to inform instructional decisions. In good questioning, a teacher asks questions – to gain information about students´ knowledge, misconceptions, etc. – provides feedback and/or asks the next question based on elicited evidence. Therefore, the questioning fulfils the definition of the formative assessment introduced by Black and Wiliam (1998).

METHOD

At the beginning, we have reviewed scientific literature on the topic of formative assessment and prepared theoretical rubrics to describe different quality levels of the questioning (and three other constructs, connected to formative assessment).

The next step was to videotape four high school teachers with positive beliefs about inquiry based teaching. We found out the importance of this in our previous research (Hubeňáková & Šveda, 2013). Each teacher could say which topics are good for her to be videotaped, thus there are four different topics recorded, one for each teacher. Now, we are at the beginning of their qualitative analyses. The teaching passages of each class are fully transcribed. We use the software NVivo10 for their precise analyses. The next step will be the discussion with the teachers to choose the rubrics that are useful for them.

RESULTS AND IMPLICATIONS

We have found five different categories within the construct of questioning up to now: if and when are procedural versus conceptual questions asked; who is asked procedural versus conceptual questions; who is questioned; who answers questions asked to whole classroom; teachers reply on wrong answer. Elaborated rubrics are available upon request via email.

The implications of this work are in the research and in the teacher professional development, as well. We will be able to quantify the differences in teachers´

questioning practice and this enable us to observe its influence on students´ results and beliefs about mathematics. Hopefully, such information provides us with a good way how to enhance teachers´ questioning.

Motivating student teachers to engage with their own mathematics teaching and learning

Suela Kacerja and Beate Lode

Bergen University College, Bergen, Norway, suela.kacerja@hib.no

The focus of our study is on student teachers' engagement in and with their own learning during a teacher training for primary school program. Different ways of working at the university college are combined with students' practicum at primary school. The aim is to motivate students to actively participate in, and be critical towards, their preparation in a meta-level in discussing their experiences.

Keywords: Teacher education, learning loop, primary school, practicum.

THE LEARNING LOOP AND CRITICAL MATHEMATICS EDUCATION

The study involves second year students during their mandatory mathematics course of 30 ECT in a teacher training for primary school program (1st to 7th grade). Different methods of working are integrated in the course where we attempt to engage students at different stages in their learning loop (Figure 1).

One part of the course is based on common lectures for all student teachers, where the lectures are held either by lecturers from the university college or primary school teachers. The largest part of the course is group-based lectures on mathematical concepts and didactical aspects of teaching/learning these concepts. An important part of the teacher education programme is students' practicum at different schools where they collaborate closely with practicing teachers and are followed by university college lecturers. During the first semester students have a group assignment in which they analyse data collected during their practicum based on didactical

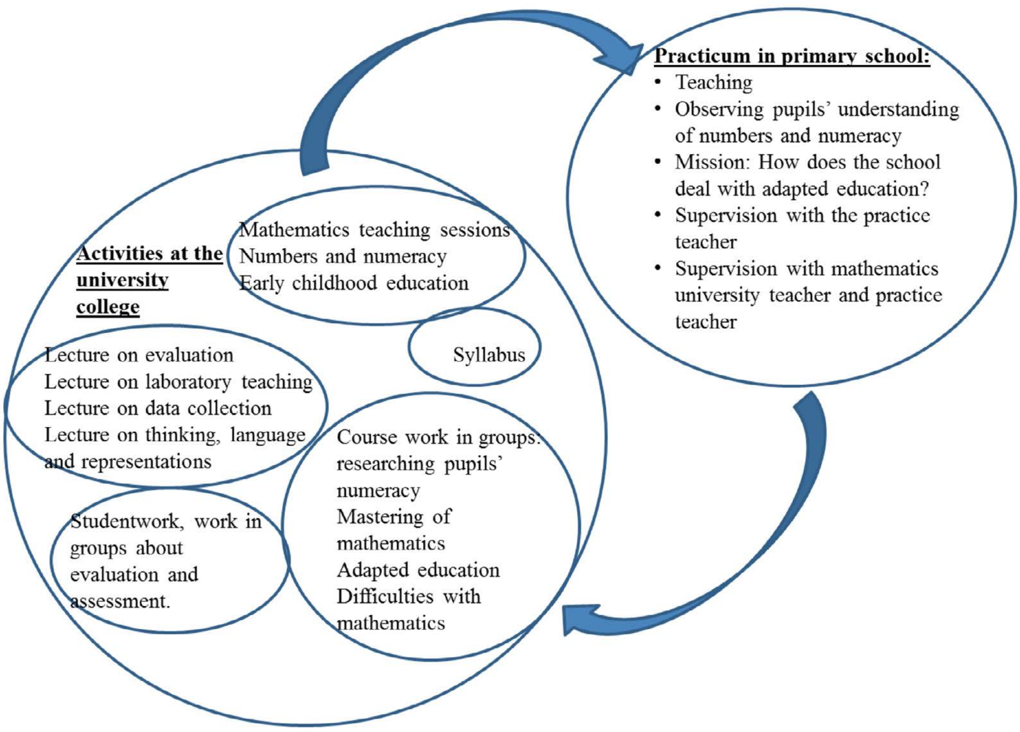

Figure 1: Student teachers' learning loop

concepts and theories included in the mathematics' course curriculum. The focus of the group work is pupils' learning of different mathematical concepts. During the semester(s) students also have different seminars on relevant topics in which they themselves prepare presentations of articles in groups for the rest of the class.

We have developed an initial learning loop inspired by an idea from Johnsen-Høines (2010). In our study we make clear the structure of the learning loop for the students and try to integrate the theoretical preparation of students with their practicum. The aim for this is to motivate students to be involved in their learning and their pupils' learning of mathematics by helping them in creating a meta-perspective, thus a whole picture, of their preparation at the university college. Our research perspective is one of critical mathematics education (Skovsmose & Greer, 2012) and it is concerned with students being critical to their own learning and teaching practice.

Skovsmose and Borba (2004) talk about current, imagined and arranged situations as "part of the research perspective in which classroom change plays a crucial role" (p. 214). We want to engage students in formulating imagined situations of teaching mathematics in the classroom, to teach those and then critically discuss the differences between the actual arranged situations and the imagined situations and reasons for such differences. This will hopefully help students to always find room and ways for improving their teaching in relation to pupils' numeracy, and to develop a critical attitude toward mathematics learning and teaching in general. We plan to use these critical discussions in teaching sessions at the university college where students summarize their practicum period.

Using multimedia in mathematics teaching – New challenges for teachers' competencies

Julia Ollesch, Markus Vogel and Tobias Dörfler

University of Education Heidelberg, Heidelberg, Germany, olleschj@ph-heidelberg.de

The application of multimedia-based representations provides new opportunities for teaching mathematics. As the students are offered new options and new challenges, teachers are also faced with modified requirements respective to their teaching competencies. This project focuses on the development of an instrument to assess and foster multimedia teaching competencies.

Keywords: Computer, multimedia, video-vignettes, teachers' competencies.

Using multimedia-based representations in mathematics teaching could support the students to gain a different access to the underlying structure of the mathematical problem which probably leads to a deeper understanding of the topic (Ainsworth, 1999).

However, too many representations can provoke a cognitive overload (Chandler & Sweller, 1991). Furthermore, teachers have to be careful not to generate misconceptions through the representations (e.g., Hadjidemetriou & Williams, 2002).

While several studies investigated the effect of multimedia-based representations on learning outcomes, little is known of how to measure the competencies teachers need in order to take advantage of the potential of multimedia-based representations.

To measure these competencies, video-vignettes, which show various situations during mathematics teaching using multimedia-based representations, have been developed. These representations have been integrated in a classroom situation with interactions between students, teachers and the computer. The vignettes are constructed with a closed-ended question type, where each statement has to be answered on a scale from one to six according to its appropriateness for the situation. This type of assessment is thought to be effective to measure teachers' competencies (Blomberg, Stürmer, & Seidel, 2011).

35 vignettes have been developed, with 6 to 14 statements each, validated by a multistage expert reviewing process. The first step consisted of qualitative interviews with nine experts to assure relevance and clarity of the situations. In the second step, the vignettes were implemented in an online-tool, which was reviewed by 104 experts to get insights into the appropriateness and difficulty of the assessment. This is the data-base for the choice of the vignettes. For the current study only 10 vignettes are planned to be used. They are chosen from the data-base by sequentially applying different criteria, comparable to the stepwise selection procedure of Witner and Tepner (2011). The content of the individual vignettes was analysed separately after the second step of the expert reviewing process and only vignettes comprising interactions between students and computer were chosen, so that the number of vignettes could be reduced to 26 (criterion 1). A second analytical criterion does not refer to a whole vignette, but to each statement. The more of a consensus between the experts concerning a statement, the better it would be ranked. To measure this consensus, we will have a closer look at the quantity of experts that chose each of the possibilities from one to six. We are going to determine the absolute value of the differences between these quantities varying from the modal value and furthermore from the median, calculate the sum of the differences of each statement and standardise this value, so that the statements can be ranked. Furthermore, the experts' ratings concerning relevance (criterion 2) and clarity (criterion 3) will be analysed (as well as any available comments of the experts). Relevance and clarity of the vignettes were also ranked by the experts on a scale from one to six.

According to these four different criteria, the vignettes will receive a score corresponding to the criteria, so that ten vignettes with four statements each will be chosen for the pilot study in spring 2015.

In a next step, an experts' norm will be generated. A selection of vignettes, based on psychometric properties, will be used in the final assessment that will be validated in summer 2015.

Implications from elementary mathematics teachers' lesson study experience

Deniz Ozen[1] and Nilufer Kose[2]

1 Adnan Menderes University, Faculty of Education, Aydın, Turkey, denizozen2009@gmail.com

2 Anadolu University, Faculty of Education, Eskişehir, Turkey

The purpose of this study is to reveal the experiences of lesson study being a model implemented by secondary school mathematics teachers participating in the Professional development project for the first time. Five secondary school mathematics teachers comprise the participants of the study. In the end of the study, acquirements and problems experienced by the teachers while implementing the model were determined. As a result, it can be said that lesson study is a model to be utilized by the teachers for professional development in the perspective of Turkey.

Key words: Teacher professional development, lesson study, experience.

INTRODUCTION

When we examine studies focused on professional development of teachers, the model of lesson study draws attention to the mathematics education research (Murata, 2011). Lesson study comprises of planning the lesson by the group as the teachers come together in a way that the student will learn the lesson efficiently, implementing and discussing (Lesson Study Research Group, 2002). This model is mentioned as the professional development process that Japanese teachers participate to evaluate the practices systematically to be more efficient in their professions. While this model improves teaching of teachers, it is also a professional development model contributing to benefiting from experience and knowledge of each other. In addition to this, it is emphasized that Murata (2011) lesson study model places the teachers in the center of efficiency of professional development. This study is quite significant in terms of revealing contributions of their professional development and experiences of mathematics teachers implementing the lesson study model seen in few studies since 2011 in Turkey.

METHODOLOGY

Participants of the study comprise of five mathematics teachers working at four different schools and having different years of service. Seminar was held with these teachers for a month before the sessions of lesson study started within the scope of the study. The model of lesson study was described at these seminars and also discussions on methods and techniques they could use during the process were held. Then the sessions of lesson study were carried out with teachers for 3 months at geometry classes. Data obtained from these seminars were analyzed by qualitative data analysis methods. In this poster, findings of the study will be presented as diagram under the titles of contributions of teachers to their professional development, problems they encountered and advantages of lesson study.

FINAL DISCUSSION

It was observed in this study that teachers benefited from the ways of thinking of each other in planning, implementing and discussing the implementation. Moreover, it was observed that teachers expressed that lesson study enabled them to see different methods and points of views. Teachers emphasized that since different opinions were presented during lesson study, a rich discussion environment was created and it enabled them to prepare an efficient lesson plan. In addition to this, they mentioned about the fact that it created team spirit and improved skill of making decision together. Also, since school conditions of teachers participating in the study were different and lesson study lasted longer, it was seen that they indicated that participation of teachers working at the same school would be more efficient for implementation of this model. As a result of this study, it can be expressed that the model of lesson study is a model to be employed for the professional development of secondary school mathematics teachers.

Lesson study as a professional development framework to support an exploratory approach

Marisa Quaresma, João Pedro da Ponte, Joana Mata-Pereira and Mónica Baptista

Universidade de Lisboa, Instituto de Educação, Lisbon, Portugal, mq@campus.pt

Our aim is to present the views of a group of basic education teachers involved in a lesson study as they discuss the features of tasks, students' difficulties, and how to conduct exploratory work about rational numbers in the mathematics classroom. Data collection was made through audio/video recording of the lesson study sessions, teachers' written reflections, individual and group interviews, and a researcher's journal. The results show that the teachers developed a vocabulary to speak about mathematics tasks, and developed an appreciation for students' reasoning processes such as generalizing and justifying as well as for classroom discussions as important moments for argumentation and negotiation of meanings.

Key words: Professional development, lesson study, exploratory approach.

LESSON STUDY AND EXPLORATORY APPROACH

Lesson study is a professional development process focused on professional practice with origin in Japan, which, in recent years, has been widely used in many countries. An important feature of lesson studies is their reflexive and collaborative nature (Fernandez, Cannon, & Chokshi, 2003; Perry & Lewis, 2009). Teachers identify an important issue and work together, analysing students' difficulties, discussing curriculum alternatives, and preparing what they expect to be an "exemplary" lesson. Afterwards, they verify to what extent this lesson achieves the desired objectives and what difficulties arise. Therefore, a lesson study is a process very close to a small investigation developed by the participating teachers on their own professional practice, informed by curriculum guidelines and by research results on the given issue. Our aim is to present the views of a group of grade 5–6 teachers as they discuss the features of tasks, students' expected difficulties and how to conduct exploratory work in the mathematics classroom. We focus especially on the professional learning of the teachers regarding the nature of the tasks, students' reasoning processes, and classroom communication.

A central aspect of lesson studies is that they focus on students' learning and not on teachers' work. Indeed, lesson studies aim to examine students' learning and to observe the way they learn. By participating in lesson studies, teachers may learn about mathematics, curriculum guidelines, students' processes and difficulties, and classroom dynamics. Lesson studies provide opportunities for teachers to reflect on the possibilities of an exploratory approach to mathematics teaching which is receiving an increasing support in curriculum orientations for mathematics education (e.g., NCTM, 2000). In this approach students are called to deal with tasks for which they do not have an immediate solution method (closed or open problems), constructing their own methods using their previous knowledge. Exploratory work creates opportunities for students to build or deepen their understanding of concepts, procedures, representations and mathematical ideas. Students are thus called to play an active role in interpreting the questions, representing of the information given and in designing and carrying out solving strategies which they must justify to their colleagues and to the teacher. However, conducting exploratory mathematics teaching is a serious challenge for teachers, demanding specific knowledge, competency and disposition.

RESEARCH METHODOLOGY

The methodology is qualitative, using participant observation. The participants are a group of grade 5–6 teachers of a school in Lisbon involved in a lesson study focusing on rational numbers. Data collection was made through audio/video recording of the sessions, teachers' written reflections, individual and group interviews, and a research journal made by a member of the research team.

RESULTS, IMPLICATIONS AND CONTENT OF THE POSTER

By participating in this lesson study, focusing on mathematical tasks and on students' reasoning, the teachers had many opportunities to get involved in doing mathematics through exploratory approach. They had many occasions to discuss the features of tasks that make them simple exercises or more engaging problems or explorations as well as features of reasoning processes such as justification and generalization (Lannin, Ellis, & Elliot, 2011) with rational numbers. Anticipating possible difficulties of students and looking at what they actually do in the classroom were key features of lesson study (Perry & Lewis, 2009) that were effective in leading the teachers to reflect and consider changes in their practice to conduct a more exploratory teaching in their classrooms. This led to significant learning regarding the nature of the tasks, students' reasoning processes, and classroom communication.

Using photos, schemes, and text, the poster presents the aims of the study, our framework on lesson study as a professional development setting, samples of the teachers' work on lesson study sessions, as well as implications of this kind of work for mathematics teacher professional development.

Pre-service mathematics teachers' view of mathematics in the light of mathematical tasks

Johanna Ruge and Reinhard Hochmuth

Leibniz University Hanover, Hanover, Germany, ruge@idmp.uni-hannover.de

Mathematical tasks play a crucial role in mathematics education in the school context, in higher education and therefore also in the professional development of pre-service mathematics teachers. Pre-service teachers' views of mathematics are reconstructed in relation to experiences with mathematical tasks in those contexts.

Keywords: Pre-service mathematics teachers, mathematical tasks, view of mathematics.

INTRODUCTION

The findings presented in this paper are part of an ongoing qualitative study addressing learning experiences of pre-service mathematics teachers at university. Ten semi-structured interviews with pre-service mathematics teachers are analyzed using a combination of grounded methods (Strauss & Corbin, 1990) and objective hermeneutics (Wernet, 2009). The topic of mathematical tasks emerged to be worthwhile taking a closer look at in relation to the institutional dimension. Interestingly the topic of mathematical tasks is addressed in the interviews in relation to insecurities concerning the view of mathematics.

In her analysis of word problem tasks, Jean Lave (1993) has pointed out that the institutional dimension is an important aspect leading to a deeper understanding of meanings ascribed to mathematical tasks. She described that mathematical tasks fulfil a variety of different roles in the school context, which can be contradictory (e.g., "realistic" word problems being motivating to all students vs. the complication of tasks due to backward translation into mathematical language). Taking a closer look at teacher education, at least three institutional dimensions have to be considered; the pre-service teachers' experiences (I) at school level, (II) in subject matter courses at university and (III) in pedagogical content knowledge courses at university. These three dimensions do not stand alone, but are all embedded in the societal discourse.

One aspect of pre-service mathematics teacher's professional development is reflection on mathematical tasks. Taking a closer look at the influence of mathematical tasks on views of mathematics in relation to the different institutional contexts, the following question arises:

What meanings do pre-service mathematics teachers ascribe to mathematical tasks that they are confronted with throughout their university education?

The findings are discussed through the cases of Anna and Georg; both addressed modelling tasks in the interview as being a new aspect of mathematics for them.

THE ROLE OF MATHEMATICAL TASKS IN TEACHER EDUCATION

Bearing in mind the central role of mathematical tasks in mathematics education it is reasonable that they are an important topic for pre-service teachers. Experiences with mathematical tasks in school have already shaped students' views of mathematics (Hannula et al., 2005) and their perception of the teacher's role before they start their studies to become teachers. According to their view of mathematics, different meanings are ascribed to mathematical tasks in university courses: Anna's experiences with mathematical tasks in school led her to the stable view that doing mathematics will lead to definite solutions. In university courses she relies on sample solutions for learning mathematics. She perceives mathematical tasks provided by her subject matter courses to be guidelines of what she is supposed to learn. She plans on providing step-by-step instructions to her future pupils. Georg sees mathematics as a logic game. To him, mathematical tasks in university courses provide opportunities to learn a way of thinking.

Throughout their studies, pre-service mathematics teachers' views of mathematics are challenged by the different nature of mathematical tasks compared to those in the school context. For Anna and Georg, modelling tasks seem contradictory to their view of mathematics. Anna recognizes that modelling tasks differ from her view of mathematics and has difficulties integrating this new type of task into her mathematical practices and perceives teaching modelling in school as a burden. Georg recognizes, due to modelling tasks, the application facet of mathematics but even so he cannot imagine presenting the abstractness and application of mathematics in a coherent manner in a school context. At the time of the interview he favours promoting the application facet in school.

Different aspects of mathematics that seem contradictory to pre-service teachers need to be explicitly addressed and reflected on in university courses in order to help future teachers broaden their view of mathematics and integrate those aspects into their practice.

Mathematics teachers' meaning making – Problematizing the process of learning in and from daily practice

Helén Sterner

Linnaeus University, Kalmar, Sweden, helen.sterner@lnu.se

Mathematics teachers' development and the understanding of what constitutes learning are an on going topic and highlighting the complexity in the processes of learning in and from practice. This study builds on the idea that mathematics teachers' professional development needs to be based on their classroom practice (Goodchild, 2008; Kazemi & Franke, 2004). Teacher participating in a working group, a learning community, and reflect on their own teaching and students learning. Working collaborative the mathematics teacher developed understanding of mathematical communication and mathematical reasoning in their teaching algebra.

Keywords: Developmental research project, mathematical communication and mathematical reasoning.

AIM AND RESEARCH QUESTIONS

Results from a pilot study showed teachers' difficulties with describing the concepts mathematical communication and mathematical reasoning as well as with using these concepts in their teaching. Based on the results from a pilot study and by means of using developmental research (Gravemeijer, 1994) the main study was designed as a collaborative work between mathematics teacher and a researcher. Also based on the results from the pilot study the reflection group decided to focus on; how could teachers develop classroom communication to stimulate students' mathematical reasoning? The main purpose of this study is to gain understanding of a process, of what and how teachers learn when participating in a reflection group.

THE THEORETICAL PERSPECTIVE

The theoretical perspective used in this study is *communities of practice* (Wenger, 1998), where learning is considered to be a function of participation and participants are constantly involved *negotiation of meaning*. From this theoretical perspective *reification* and *participation* are used in the process of *negotiation of meaning* (Wenger, 1998).

THE METHODOLOGY

This is a study of single case, consisting of five mathematics teachers from different elementary schools (grade 1–6). The five teachers and a researcher meet monthly in a workgroup, *the reflection group*. The project has used the model of *the developmental research cycle* (Goodchild, 2008, p. 208) as a methodology. This model is a cyclic process for both the professionals' mathematics teachers and the researcher. The model gives opportunities to analysing developmental activities with special emphases on the relation theories and practice (Goodchild, 2008). My interpretation and using *the developmental research cycle* (Goodchild, 2008, p. 208) is mutual between the researcher and the mathematics teachers, empirical data was generated from discussions and activities in the reflection group. The preliminary and on going results of the analyses fed back in the reflection group to provide development for practice (Goodchild, Fuglestad, & Jaworski, 2013). In the reflection group the teachers prepare mathematic tasks collaboratively, to be used in different classrooms. The participants use reflections in three different levels. These reflections are both individual and shared in the reflection group. The teachers make individual reflection before, during and after implemented lesson. When the teachers meet in the reflection group they discuss and reflect together both on own reflections, on the student work generated and on the videotapes from their teaching. The third level of reflection the researcher present as questions from previous meeting. These reflections are used as a tool to problematize the on going education in mathematics.

PRELIMINARY RESULTS

The study indicates how teachers in this learning community came to understand the concepts communication and reasoning in mathematics and shifted their ways of talking about students´ mathematical reasoning. I identify four shifts that teachers made in there learning about students' mathematical reasoning. *Understand, identify*, *interpreting and applies* the mathematical reasoning in their education.

First-year teacher students' mathematical beliefs

Benedikt Weygandt[1] and Reinhard Oldenburg[2]

1 Goethe University Frankfurt, Frankfurt am Main, Germany, weygandt@math.uni-frankfurt.de

2 University of Augsburg, Augsburg, Germany, reinhard.oldenburg@math.uni-augsburg.de

This poster focuses on the beliefs accompanying first-year teacher students with respect to aspects of mathematics as a product of human creativity that might be designed in various ways.

Keywords: Teacher education, mathematical beliefs, genetic teaching.

INTRODUCTION

Transition issues are a frequent problem in academic mathematics education, particularly appearing in teacher students' education. Currently, there are several projects intervening in this field in German-speaking countries (e.g., Beutelspacher, Danckwerts, Nickel, Spies, & Wickel, 2012). We created a lecture, "Mathematical Genesis", held parallel to the corresponding calculus course in which the transition gap seems to be at maximum. The lecture deals with the development of mathematics in and by the society of mathematicians. First-year students learn about the importance of creativity and experience the process of developing mathematics. This study assesses effects of the lecture on their beliefs (cf. Weygandt & Oldenburg, 2014).

THEORETICAL FRAMEWORK, METHOD AND RESULTS

This research is based on Törner's theory and conclusions about German math teachers' beliefs, in which he stated the "key role [of beliefs] in the teaching and learning process" (Törner, 1996). Moreover, Törner, Grigutsch and Raatz (1998) identified four aspects of mathematics: "formalism-", "scheme-", "process-" and "application-aspect". Only the "process aspect" corresponds to the genesis of mathematics. Our initial hypothesis stated that this should be analysed in more detail as more aspects of mathematics that might be especially important in the beginning of academic mathematics education appear to exist. We adopted Törner's survey on prospective teachers' mathematical beliefs and added 60 items focussing on lecture-related subjects. During the course of the study we surveyed 178 first-year (mixed math and math teacher) students concerning their acceptance of each statement. Exploratory factor analysis of the 37 test items (introduced by Törner et al., 1998) verified those four factors with good reliability. An analogously conducted factor analysis of the newly designed 60 items suggested the exploration of five further factors. The extracted factors are homogeneous concerning their content. Thus we propose to add the following aspects to those postulated by Törner (1996): (a) "output efficiency", (b) "structure of mathematics", (c) "creativity" and (d) "universality". The aspect (e) "latitude" can probably be included as well. In order to get an idea of these new factors, Table 1 illustrates three aspects through corresponding example items.

The current research concentrates on an inter-aspect correlation matrix and compares the pre- and post-

aspect	example item(s)
(b)	Learning maths, it's a waste of energy to take a non-productive approach.
(d)	Mathematical objects are comparable to natural principles, i.e., they may be discovered, but are unchangeable. / Any extra-terrestrial intelligence would reach same mathematical conclusions.
(e)	If one dislikes the consequences of a definition, one may modify the definition accordingly.

Table 1: Example items for some of the five assumed aspects

aspect shift \ group	**attending MG (n=15)**	**not att. MG (n=22)**
scheme-orientation decreases	d=-.70 (p=.02)	d=-.45 (p=.04)
structure of mathematics increases		d=.60 (p=.01)
universality decreases	d=-.61 (p=0.03)	
latitude might increase	*d=.49 (p=.07)*	
application might decrease	*d=-.43 (p=.08)*	
output efficiency might decrease		*d=-.35 (p=.09)*

Table 2: Effect sizes of differences in mean values

test results of teacher students having or having not attended the lecture on "Mathematical Genesis" with the corresponding effect sizes in Table 2.

Mathematics teacher and classroom practices

Introduction to the papers of TWG19: Mathematics teacher and classroom practices

INTRODUCTION

This Thematic Working Group (TWG) together with TWG18 and TWG20 addresses questions related to mathematics teachers, teaching, and their development. TWG19 focuses particularly on mathematics teaching, including important micro and macro factors that frame it. Classroom research has been the focus for many years in mathematics education, but new theoretical and methodological directions have been reported in this group aiming to study on the one hand the overall complexity of teaching and on the other the particular aspects that characterize it.

TWG19 initially received 64 proposals (56 papers and 8 posters), and being the largest group in CERME9, it was split in two new groups (TWG19 and TWG20). Finally, 31 papers and 6 posters remained in the group. The reviewing process led to revisions in most of the papers and eventually 27 papers and 6 posters were presented in the conference and are included in the proceedings. The papers and posters were classified in three thematic groups: instructional practices (14 papers and 4 posters); classroom interaction (8 papers and 1 poster); and tasks and teaching resources (5 papers and 1 poster). The papers and posters in the first thematic group mostly concern general teaching practices, whereas there are some which focus on teaching practices related to the teaching and assessment of specific mathematical issues. In the second thematic group, the topics addressed are patterns of interaction, teacher's questioning, and classroom discourse. In the third thematic group task and textbook analysis is the main focus. Below, we discuss the papers and posters with reference to these thematic areas.

INSTRUCTIONAL PRACTICES

Most papers and posters in this area report on small-scale, qualitative studies of the interactions in one or a few school classrooms aiming to support practices for effective teaching, but also to gain a better description of teaching practices by looking for patterns of argumentation in classroom interaction (Zalska & Tumova). However, there are also examples of more quantitative approaches (Felmer et al.; Gunnarsdottir & Pálsdottir) and of researchers who do not report on their own observations of classrooms, but on teachers' interpretations of classroom events (Reid et al.) or task design (Opheim). Between them, the papers deal with all levels of schooling, from primary (Allard; Caseiri et al.; Gade; Velez & Ponte; Taylan), over middle (da Ponte & Quaresma; Zalska & Tumova) to secondary (Dias & Santos; Mata-Pereira & da Ponte; Reid et al.) and vocational (Opheim). One paper addresses instructional designs of novice teacher educators and the practices that unfold in their course for in-service teacher education (Kalogeria & Psycharis), and another one does not deal directly with interpretations of classroom events, but is based on interviews with teachers on how imposed assessment practices may significantly transform teaching practices in ordinary schools (Pratt). Also one of the posters deals with external evaluation and the teachers' attitude towards it (Signorini). Two posters explore the effects of formative assessment on teaching practice (Anderson & Boström; Vingsle).

Theoretical and methodological issues

Pratt's paper highlights the significance of taking contexts beyond the individual classroom and school into consideration. His theoretical framework, based primarily on Bourdieu, allows him to do so. *Context*, in one or other understanding of the term, is dealt with also in other studies (Reid et al.; Opheim; Taylan), and in fact the notion of context is mentioned in 10 of the 14 papers. However, it is not always clear how the term is used and how its significance is taken into account in the theoretical framework and the methodology. This seems to be an issue that needs attention in research on mathematics classroom practices.

The theoretical or conceptual frameworks that are used vary. Gade draws on CHAT, Reid and colleagues on Maturana (among others), whereas Allard as well as Kalogeria and Psycharis refer to the French school. Others base their studies on more local theories of classroom communication, problem solving, or the teaching and learning of particular mathematical topics. Clearly, there are strong limitations to what theoretical frameworks can be presented in a conference paper. Nonetheless, the interest in *context* combined with the limited attention paid to theoretical frameworks in most of the papers may indicate that it is a challenge to develop and use approaches that allow for a combined analysis of micro-, meso-, and macro issues of significance for instruction.

The approach in most of the papers is a carefully conducted qualitative analysis of unfolding classroom events, sometimes combined with stimulated recall interviews and textual analyses of tasks and student work. Other studies are based exclusively on interviews. In both cases, the research participant(s) are often purposefully selected teachers, who are either co-researchers engaged in teacher-researcher collaboration (Gade; Dias & Santos), experienced teachers whose participation in the study is based on their reputation and/or their participation in long-term teacher development initiatives (Allard; Taylan), or teachers who are engaged in focused collaboration with their colleagues on issues of interest to the study in question (Velez & da Ponte). In these studies, the research participants qualify as critical cases (Flyvbjerg, 2006), this means, as particularly useful cases that allow for conclusions of the type: *if reform intentions do not materialise with these teachers, they never will.* Although some of the studies invite this type of conclusion (Allard), most of them do not. As mentioned above, most of the papers report fairly positive findings, and the general conclusions seem more related to ways in which interventions or the work of competent teachers may inform teacher education or induction programmes. This is so for instance with a series of studies from Portugal by Caseiro and colleagues; Mata-Pereira and colleagues; da Ponte & Quaresma; and Velez & da Ponte and with the Turkish study by Taylan.

Reid and colleagues do not make use of critical cases, but adopt a second order perspective on classroom practice: they analyse groups of teachers' collective interpretations of video recordings of "typical" and "exemplary" lessons from their own classrooms. The intention is to understand the criteria that guide the teachers' observations. It is interesting that research participants focussed on different aspects of typical and exemplary lessons, when they had access to the videos and when they did not. Reid and colleagues argue that this indicates the research design needs to allow for different ways of accessing teachers' views of what is valued in mathematics education.

Substantive issues

There seems to be a shared vision of quality teaching underlying most of these papers. Some papers make explicit reference to *the reform*, but, even in the majority of papers that do not there appears to be a set of shared understandings inspired by current reform efforts about good classroom practice. In particular, students are expected to become involved in independent and creative activities much beyond their repetition or imitation of ready-made concepts and procedures as presented by the teacher or the textbook. In turn, this requires teachers, for instance, to organise problem solving activities (Felmer et al.); to orchestrate whole-class discussion and promote other forms of classroom communication (Gade; Ponte & Quaresma; Mata-Pareira, Ponte & Quaresma); to facilitate the development of students' ability to assess their own mathematical progress (Dias & Santos); and to base instruction on interpretations of the students' mathematical thinking, including their unexpected questions, comments, and suggestions (Taylan).

The papers mentioned report on relatively successful examples of instruction, when seen from the perspective of the researchers. Some studies are part of or follow up on intervention programmes and in these studies research participants generally appear to cope well with the challenges of teaching according to the reform (e.g., Felmer et al.). The most significant of these challenges appears to be the contingencies that arise as students are to make their own mathematical contributions to classroom practice. The specific contents of students' inputs are not necessarily part of the teacher's agenda, as their contributions may take the form of a surprising question or an unforeseen conjecture (Ponte & Quaresma). In this sense, the reform inserts an element of planned unpredictability in instruction that teachers need to capitalise on in the moment (Skott, 2004). One major challenge for teachers is to cope with the inherent unpredictability.

Despite the positive descriptions of the interactions in most of the papers, some point to problems in relation to the reform. Gunnarsdóttir and Pálsdóttir report on a study from Iceland on dominant ways of organising instruction in grades 1 to 10. There are examples of group work and whole class discussions, but students appear to spend most of their time working individually on textbook tasks. Allard's paper points to problems that arise because of difficulties involved in linking instruction to students' thinking. Her study on a highly qualified elementary teacher in France shows a tension between devolution and institutionalisation, that is, between handing over initiative to the students to support their independent activity and ensuring that what is learned is decontextualized and in line with the discipline of mathematics. One particular problem when taking students' thinking into account is that of the time needed for task completion. Opheim, working with vocational schools in Norway, suggests that the diversity of the student population poses particular problems related to timing for teachers' selection and use of tasks.

A somewhat different approach is adopted by Pratt. Working in the UK, he reports on part of a study of how a dominant assessment culture influences the position of teachers and the relationships among them. In turn, this is likely to significantly influence instruction.

CLASSROOM INTERACTION

The papers in this area consider various aspects of the interactions taking place in mathematics learning and teaching settings and the ways these interactions shape participants' learning. All but one of the papers concern small-scale, qualitative studies often situated or initiated in the context of a larger project. Only the study by Seker and Ader adopts a quantitative approach, focusing on teachers' written answers to items allowing for tensions between students' perceptions and teachers' intentions to be explored. The remaining research reports deal with aspects of interactions taking place in various mathematics education contexts: teachers' discussions in mentoring sessions (Mosvold); teacher practices when exploiting contingent opportunities (Kleve & Solem) or when aligning values to smoothen learning (Seah & Andersson); whole-class discussions (Drageset; Larsson); and students' grasp of teaching changes initiated by an intervention (Evans & Swan) or by a national reform (Wester, Wernberg & Meaney). Most studies are based on observations, the exceptions being the ones by Larsson and by Wester, Wernberg & Meaney, which are predominantly based on interviews. The interest in the impact of the emergent interactions on students' mathematics learning and directly or indirectly on teachers' learning about teaching mathematics is central to all the studies presented here, whose focus extends from the upper primary to the secondary school level.

Theoretical and methodological issues

The design and the implementation of the research reported in the papers are framed by the conceptual focus chosen, the theoretical perspective adopted and the methodology employed. The studies deal predominately with classroom practices related to promoting interaction and thus facilitating particular aspects of mathematics learning, mainly through teachers' management of teaching incidents (e.g., Seah & Andersson), classroom communication (e.g., Larsson), tasks (e.g., Evans & Swan), tools (e.g., Seker & Ader) and resources (e.g., Wester, Wernberg & Meaney). The theoretical frameworks employed in the studies concentrate on mathematics classroom interactions related to advancing students' learning or to developing teachers' knowledge for teaching. The former might refer to management (e.g., Drageset; Evans & Swan) or socio-cultural (e.g., Larsson; Seah & Andersson) issues of the interactions involved, whereas the latter frameworks adopt either a practice oriented (Kleve & Solem) or a discursive perspective (Mosvold). Finally, the methodological choices are qualitative in character (with the exception those of Seker and Ader), include mostly selection and analysis of classroom events, sometimes combined with interviews (e.g., Larsson) and involve teachers who agree or are willing to experiment with new ideas (e.g., Wester, Wernberg, & Meaney). The results reported are generally positive, illustrate how and shed some light on why interactions can promote classroom participants' learning, but may also limit their learning opportunities.

Substantive issues

The research presented in the papers under consideration is based on a shared view of learning as a process of pursuing challenging tasks and activities via student-student and/or teacher-student interactions. Opportunities for such tasks and activities to be introduced are sought in instances of the moment-to-moment decision making or in carefully planned and implemented teaching interventions, aiming in all cases at particular, well defined learning outcomes. In the former category, we find contingent moments of teaching seen as unplanned opportunities of supporting students' mathematical learning (Kleve & Solem); unexplained students' answers exploited as occasions for effective intervention (Drageset); tensions between teachers' intentions and students' interpretation taken as instances for improving participatory learning (Wester, Wernberg & Meaney); teachers' value alignment strategies related to the quality of the students' learning experiences (Seah & Andersson). As for the tasks and activities that are planned, some are based on and explore the power of theoretical models of learning, cognitively (Seker & Ader; Evans & Swan; Klein) or a socio-culturally oriented (Larsson; Mosvold).

The classroom practices supported by the tasks and activities utilized in the studies described above are characterised by significant to moderate teacher-student and only occasionally noticeable student-student interaction. For example, unexplained answers appear to attract teachers' attention (Drageset) and the same is true for contingent teaching moments (Kleve & Solem), leading to a range of teacher-student interaction strategies, which are generally beneficial for students' learning. Similarly, well-designed and established social and socio-mathematical norms contribute to pupils interacting effectively with one another, giving rise to an inquiry classroom culture (Larsson). However, overall, students find it hard to cope with and build on interactions with their peers in the classroom (e.g., Evans & Swan).

Overall, the studies reported here reveal that mathematics classroom interactions constitute critical teaching incidents that function in complex ways and offer opportunities for students' and teachers' individual and collective learning. However, the studies also indicate that there may be difficulties involved that we are just about to begin identify and understand.

TASKS AND TEACHING RESOURCES

Teaching can be regarded as plausible conceptions of teachers' professional practice, and most of the papers in TWG19 deal with such conceptions. Among the different approaches to conceptualize the work of teaching, one considers teaching as a didactic encounter between teacher and students about a certain mathematical content. In such an encounter, the teacher presents the content by using mathematical tasks or resources. Two of the papers discussed here, mainly concentrate on the content of textbooks and textbook tasks (Burke; Wijayanti), whereas three papers focus more on teachers' use of tasks in their work of teaching mathematics (Ayalon & Hershkowitz; Kwon; Matic & Gracin). In addition to these papers, a poster focused on mathematics teacher guides (Ahl & Koljonen).

Theoretical and methodological issues

The textbook is a central resource for mathematics teachers and students alike. Appraising, adapting and administering mathematical textbook tasks constitute professional challenges for the mathematics teacher. Textbooks are not only a source of mathematical tasks, but they also include demonstrations of techniques. When analysing Indonesian mathematics textbooks, Wijayanti focuses on tasks and techniques presented in the textbooks and uses Chevallard's Anthropological Theory of the Didactic (ATD) in her analysis. Burke focuses on the strategies deployed in textbooks and the pedagogical tasks embedded in them. As a theoretical framework, he applies Dowling's Social Activity Method (SAM). From such a theoretical perspective, he aims at describing possibilities for engagement between author and audience in a pedagogical relation.

Most textbooks also have a teachers' guide, and Ahl and Koljonen analysed the teachers' guides to the two most commonly used mathematics textbooks in Sweden. They apply content analysis in their analysis of these teacher guides.

Whereas the above-mentioned studies focus on the texts themselves – the textbook, the tasks, or the teachers' guide – the other three papers have a particular focus on teachers' use of textbooks and mathematical tasks in the work of teaching. In their study, Ayalon and Hershkowitz survey 17 Israeli secondary school teachers. They attend to the teachers' rationale for selecting particular mathematical tasks from the textbook in order to facilitate argumentative activity in the classroom – considering argumentation as a social process. Whereas these researchers investigate teachers' different explanations for the choice of tasks, Matic and Gracin analysed two Croatian primary teachers' use of textbook tasks. When applying the socio-didactical tetrahedron in their analysis, the connection between student, mathematics and textbook appeared important. In her attempt to conceptualize the teachers' work in supporting students' development of mathematical explanation, Kwon focused on the encounter between an expert teacher and five different cohorts of students around some mathematical tasks. Kwon's analysis revolved around core tasks of teaching, and this corresponds somehow to Burke's focus on pedagogical tasks.

Altogether, the papers and poster presented in this group vary considerably in their use of theoretical framework, instruments, and methods of data collection and analysis. This variation can be seen as a challenge for the further development of the field.

Substantive issues

From these studies, some emerging issues can be observed. First, there is the connection between teaching and students. Investigations of this connection differ among the studies, but the teachers' work cannot be dissociated from the students' learning activities. Second, the connection between mathematical tasks and the decomposition of teachers' practice into core tasks of teaching emerged as a central issue (e.g., Kwon). Such tasks of teaching are arguably important to study when attempting to conceptualize teachers' professional practice. Finally, an issue emerges in the various theoretical conceptions of teaching. The papers in this group adopt different theoretical frameworks, and different interpretations of core concepts like tasks and teaching are applied. Some papers appear to describe tasks merely as mathematical problems from textbooks (e.g., Ayalon & Hershkowitz), whereas others also discussed pedagogical tasks (Burke), or tasks of teaching (Kwon). Future studies in this TWG need to be more specific about their use of such core concepts and develop shared language necessary for establishing solid conceptions of the professional work of mathematics teachers.

GENERAL ISSUES – MOVING FORWARD

Research on mathematics teaching has been developed in mathematics education during the last few decades. Different research questions as well as theoretical and methodological tools have been formulated throughout the years. The papers and the discussions in this TWG show that we have taken some steps forward. For example, we have developed questions and frameworks that allow us to: look closer into critical moments of classroom interaction; consider contextual, epistemological and social issues that frame mathematics teaching; build general models that describe mathematics teaching; understand better in what ways the resources and tools that teachers use in the classroom transform mathematics teaching and learning. We have also started to consider mathematics teaching in its complexity and move away from dichotomies of what is "effective" or not and adopt deeper explanations of teacher's decisions and actions. We work with teachers in more collaborative contexts and care more about what our research says for them.

However, we still need to look more critically at our research concerning mathematics teaching. For example, many papers study the teaching of an expert teacher. Do we work under the assumption that there is an ideal teacher and/or an ideal teaching? We possibly need other interesting cases of mathematics teachers in different school contexts that will allow us to understand better the dynamic character of teaching. We also see that many studies use multiple research methods. Is there the underlying assumption that different methods provide differential access to the same phenomenon, for example, teachers' meaning making? It may be that different methods shed light to teachers' views and meaning making in decidedly different contexts that frame teacher actions very differently. In the discussions in the group, it appeared that because mathematics teacher education and teacher resources were discussed in other groups, we missed the dialectical relationship between mathematics teaching, resources and teacher education. Do we really have theoretical and methodological tools that allow us to study this dialectical relationship?

We close this introduction by addressing a number of challenging questions that were discussed in the group: How can we link students' activity to teacher's activity? How can we include the significance of context in our research on mathematics teaching? Can we listen to teachers' voices? How complementary are the different theoretical frameworks we use for studying mathematics teachers and teaching? Is there a coherent meaning underlying the different constructs we use?

Analysis of teachers' practices: The case of fraction teaching at the end of primary school in France

Cécile Allard

University of Paris VII, LDAR, Laboratoire André Revuz, Paris, France, cecile.allardb@free.fr

My study deals with Institutionalization Process in French primary school. Institutionalization Process (IP) is defined in the Theory of Didactical Situations (TSD) as a process enabling to decontextualize and depersonalize knowledge. I focused both on what decontextualizing and depersonalizing imply in teachers' actions and on knowledge exposure, proposed by teachers. I particularly focused on fraction teaching at the end of primary school. My methodology allowed me to collect everything that is said diffused about fractions.

Keywords: Institutionalization, practices, fractions, decontextualization, depersonalization.

INTRODUCTION

In TSD (Brousseau, 1998) also explains that the aim of TSD was the production of mathematical situations because there was a lack of such situations in teaching, so questions about institutionalization (knowledge exposure) arose much later. More recent works question this process and show in what manner it is important for teachers to take over didactical memory of the class (Brousseau & Centeno, 1991). Butlen (2004), Butlen, Peltier-Barbier and Pezard (2004) show that a tension exists between devolution and institutionalization for the benefit of devolution. Coulange (2012) obtains similar results to those of Butlen and colleagues (2004) and of Margolinas and colleagues (2002). Coulange talks about deletion of the formulation and knowledge exposure for the benefit of practices that puts ahead a "permanent shoring". Observations and results of these authors lead us to question how expert school teachers (Tochon, 1993) deal with knowledge exposure. What are their constraints (Robert, 2001), which regularity and variability (Robert & Rogalski, 2002) will it be possible to determine when they institutionalize (for their meaning as for our)?

QUESTIONS AND OBJECT OF STUDY

In TSD, institutionalizing is defined as the action of depersonalizing and decontextualizing knowledge that arise following a situation of action. Pupils face a situation they need to solve by mobilizing knowledge and skills. The results of this situation lead them to build new knowledge. Brousseau (1998) thus shows one of the first institutionalization paradoxes: how to convince pupils that they have just learned something new despite the fact they were not able to solve the given problem. The teacher's main role here is to demonstrate and focus on this new knowledge. For this he has, on the one hand, to promote discussions between pupils in order for them to realize the great variety of their strategies involved to solve problems. On the other hand, they need teacher's support to agree due to their lack of a common language. In addition, the teacher has to show and name the new knowledge. These moments when the teacher names and shows the knowledge engaged will be called knowledge exposure.

Several recent French works (e.g., Butlen, Pezard, & Masselot, 2011; Coulange, 2012; Margolinas & Lappara, 2008) have shown difficulties met by junior faculty to deal with these knowledge exposures. Butlen and colleagues (ibid) show that teachers know how to devolve situations but meet strong difficulties to institutionalize knowledge. They then talk about tension between devolution and institutionalization. These difficulties to say and show involved knowledge at school, partly explain educational inequalities in France (some parents can help their children, some others not) (Rochex & Crinon, 2011).

A first study (Allard, 2009) has shown that written knowledge exposures, were few in number at the end of primary school (around twenty short texts for 36 class weeks for an average of 5 hours mathematics lesson per week). This small number of written traces let us assume the hypothesis that knowledge exposures are made orally most of the time. For my PhD I have tried to check this hypothesis.

These knowledge exposures can take place at the end of a lesson, at the beginning of another (reminder-phase), during the lesson, or during the correction of exercises. These knowledge exposures are quite fuzzy and I had to design a specific methodology to study them. We will describe it in a next part.

Although recent works are generally focused on junior faculty, we have decided to deal with skilled teachers. These teachers passed a specific exam (CAFIPEMF) to validate their expertise. These expert teachers are called PEMF (for "Professeur des Ecoles Maitre Formateur"). The exam consists in three parts. The first part consists in presenting two lessons in two different disciplines in front of a five-people jury (inspectors, PEMFs, academic advisors, university professors). The second part takes place in the classroom of a pre-service teacher whose practice has to be analyzed by the candidate to CAFIPEMF. The final event consists in making a short presentation about his/her professional dissertation. These PEMFS are teachers that receive and train teacher trainees. In this paper, I will approach the following research question: How do these skilled teachers deal with knowledge exposure?

METHODOLOGY

My methodology is comparative and qualitative. Comparisons are possible between several PEMFS but also, over several years for the same PEMF. Depending on comparisons, we had to use different methodologies. I followed five PEMFS over a year, including two for three years. In order to make comparisons easier, I set down some particular variables such as the use of a common manual and keeping to one mathematical problem: fractions. To make comparisons easier I filmed the teachers during all their lessons on fractions. In this paper, I will focus on the comparison of teaching practices of the same teacher for two years. I will therefore be able to talk about regularities and variabilities of these practices.

For this teacher, teaching fractions represents seven sessions of 50 minutes each for the entire year. I have transcribed all the lessons I filmed. These videos enabled me to retrieve a large variety of data. I mainly focus on the words expressed by the teacher depending on pupils' activities. I will particularly focus on the fidelity of the field of mathematics during three moments in the classroom: explanations given to pupils, before and after a research phase, and during knowledge exposure. These oral knowledge exposures are part of teacher-pupil dialogues. Through the analysis of these fragments of sentences, I will be able to put them together to recompose a text of knowledge as was shown to pupils. These knowledge exposures are studied according to their decontextualization level (Pezard & Butlen, 2003). I also kept the exercise books in which exercises were given and done and also the other exercise books that contained mathematical texts to be learned at home by heart. This data collection enables me to determine what kind of tasks pupils have done and what they have to learn at home. In France, it is forbidden to give written homework. Despite this prohibition that has been in effect since 1956, parents in certain social environments claim homework for their children. The only type of authorized homework, however, is reading and learning mathematical rules by heart.

These different data enable us to fill in the various practices components of PEMFs and to determine variabilities and regularities (Robert & Rogalski, 2002). I thus adopt the methodology described by Robert and Rogalski (ibid). These authors break down practice into 5 components (personal, social, institutional, cognitive and mediative) then recompose them. The personal component is only accessible by interviewing the teacher. It gives information on the relationship that the teacher has with mathematical knowledge, and choices made to help him/her carry out in comfortable manner his/her classroom teaching. The social component gives information on the teacher's working place, his/her colleagues and the social environment of his/her pupils (both in disadvantaged and advantaged areas). The official curriculum, the mandatory hourly amount of math lessons, the use (or lack of use) of certain handbooks and the relationship with inspection and inspectors, all give information on the institutional component. The cognitive component corresponds to teacher choices about content, tasks, organization and forecasts on how to manage. The mediative component is particularly relevant since it deals with improvisations, speeches, pupils' participation, devolution of instruction and knowledge exposures.

Thus, in order to describe practices and inform mediative and cognitive components, I focused on the choice of handbooks, the mathematical problems, on exercises books and on the teacher's speech. I then had the necessary's data to know how things are said and what is transmitted to pupils.

CASE STUDY

I chose to study the particular case of teaching fractions because it is a new notion that is introduced at the end of primary school. In French primary school, fractions are only studied under the subconstruct, called part-whole (Kieren, 1983). Introducing fractions is backed up by materials such as paper strips and circular areas.

I will name "Solene" the teacher I followed from September 2011 to June 2014. I previously followed this teacher from 2008 to 2011 but with a different focus. During these five years, I have collected enough data to describe her teaching practice carefully. 2011 was the first year when she had to deal with a double level class (CM1 and CM2: from 9 to 10 year old pupils). That year she proposed only three sessions on fractions. These sessions consisted in coding shapes. Shapes were subdivided into several equal parts. Fractions can be described by a numerator (colored area, part of a whole) over a denominator (all the parts, the whole). Solene proposed little written knowledge exposure. In 2012, she did not teach fractions to her group of CM2, but her colleague carried out this teaching.

We are now going to describe the five components found in Solene's particular case.

Personal and social components

Solene have a good personal relationship with mathematics. She declares that she loves mathematics and considers that she has a solid knowledge in this field. She has a Master degree in the field of Developmental Psychology. She is confident enough in her choices and her professional skills to use the resource designed by the ERMEL team (a group of PEMFs, didacticians and mathematics teachers). She has been using this resource since 2008 even though this handbook is considered to be difficult.

Solene has been a teacher for 15 years, 10 of which she served as a replacement teacher. In 2008, she took the responsibility of a class in a rural school and she still teaches there today. She passed the specific exam to become a PEMF (CAFIPEMF), in 2013. She collaborates with a colleague (also a PEMF). The school team is stable. Pupils who attend the school have a good general scholastic level (above average for national evaluations), and none of the parents are unemployed.

I can conclude that Solene has a good relationship with mathematics and works with a good team in a pleasant, working environment.

Institutional component

To describe this component, it is necessary to study the official curriculum proposed by education department in 2008. In this curriculum, teaching of fractions is spread over the last two years of primary school. The proposed progression is dedicated to decimal building "from fractions to decimal fractions". It relies, on Perrin-Glorian and Douady's (1986) work without explicitly naming them. The progression is built over several steps: learn, name and write fractions of the unit, know how to break up fractions into the sum of a whole number and a fraction of unit.

After this introductory work is carried out, teaching of fractions will begin. Decimal writing or "with dot" are introduced as a different way of writing, after the one of decimal fractions, to name decimals.

Arditi (2011, p. 95), in his PhD on the use of a written resource by didacticians, explains that, "the study of fractions is only a prerequisite to install decimals". Note that the French program adds an indication on using fractions in a particular context which is the coding of size measures. The official instructions have not changed over the three years of my study even though, in France, they are often updated. The last versions occurred in 1995, 2002, 2008 and will change again in 2015.

Solene uses the ERMEL handbook, which is recommended during teacher training. This resource is appreciated by the inspectors. In France, inspectors come to observe teachers in their classrooms. They check that the curriculum is followed conforming to official instructions and, finally, they evaluate teachers. This evaluation is important for career development.

Cognitive component

Solène spent seven sessions devoted to the teaching of fractions (including evaluation) and then continued with decimal fractions. Solene introduced fractions using paper strips. Using these strips, pupils draw and measure segments whose lengths are expressed under the form of fractions smaller than a unit or as the sum of a whole and a unit fraction. To understand what is proposed to pupils, it is important to describe the activity presented by the teacher. I noted that the cognitive path was identical in 2011 and 2013, because same activities and same instructions were given to pupils. The global project remained stable.

The first situation proposed to pupils by ERMEL aims to:

— Set in mind the first meaning of simple fractions: 1/2, 1/4, 3/4, 1/8, 3/8.

— Know and use the relationships between fractions, express them in multiplicative and additive writings.

Ermel offers two activities. In the first activity, the pupils are asked to fold a paper strip in order to cut out three quarters of the strip. Then an additional instruction is given: from a strip measuring three-quarters of a unit strip, pupils have to restore the unit strip. Below is a brief description of this activity.

The unit strip is named A. Pupils have two strips of the same width (B and C strips).

— B strip longer than the A strip

— C strip is three quarters the length of A strip.

The "A-strip" is shown on the board. The "C-strip" has two folds to visualize each quarter. Pupils are now given the task on the strip B to duplicate four times a quarter, two times a half or even duplicate the "C-strip", and then add one quarter. "C-strip": can be read in two ways¼ + ¼ + ¼ or ½ + ¼.

Solene has proposed this same activity for three years, and her instructions were always the same. Despite the similar teaching pattern, variations have also been noted. The first session is organized in the same way, and pupils carry out mental arithmetic on doubles and halves. Solene then goes on to the second step of the session by presenting the paper strips. Even though questions and global project stay identical, significant differences arise according to the duration of the sessions.

The first session lasted 48 minutes in 2011 and 90 minutes in 2013. In each year, the session is divided into three main parts (Table 1).

The duration of these three parts is well balanced, but, in 2013, the entire duration of the session was doubled. For all the other sessions I observed, the time for each session was also doubled. A notable difference can be explained by taking into account what the pupils have to say. In 2013, Solene clearly understood this situation and was ready to listen to her pupils.

Mediative component

To describe this component, I will rely on the transcription of what the teacher says about mathematics. I will then propose possible explanations of why the duration is doubled for the same session.

In 2011, Solene proposed ten calculations on halves and doubles. Solene spent a very short time on observing pupils procedures. She only listened to pupils who found the correct answer, and she concluded by giving the following rule: "cutting a number or figure is two times less, cutting a number or a figure by four is four times less".

The second part of the session is dedicated to the manipulation and folding of strips and to understand

	2011	2013
Part 1: thoughtful calculation : calculate doubles and halves	21 minutes	30 minutes
Part 2: fold a strip and cut three quarters. (see instructions for session A in Table 2)	10 minutes	30 minutes
Part 3: make a one unit strip from the three quarters of this unit strip. (see instructions for session A in Table 2)	17 minutes	30 minutes

Table 1

what a fraction of the unit (context part/whole) can represent.

In 2011, it was the first time the teacher introduced this concept, using the support of paper strips. The teacher exposed knowledge at two moments. The first moment occured just after bringing the procedures together. For example, she said that "four times one quarter is equal to a unity" without writing the number one.

> 46 Teacher: So initially, you have a half plus a half equals two halves (this written on the board as ½+ ½= 2/2), you have cut each half in half and four quarters (¼+¼+¼+¼) is equal to a unit. Is that okay?

At the time the aim of the lesson was given, Solene showed what she wanted to teach but keeping within pupils' vocabulary. She oriented her explanations towards resolution strategies. Knowledge exposures were targeted to the exposure of resolution strategies.

> 82 Teacher: I have a question ... the two strategies that have been used to do the work, is to add a quarter. Second strategy ... to use a half, to reproduce a half to obtain my strip. That's it! Perfect.

In 2013, the global scenario (Butlen, 2007) was the same with a view to the written preparations of the teacher. It is at the micro level that differences arise. There was no conclusion at the end of mental arithmetic. The teacher asked pupils to expose their strategies "a quarter is half of a half", and explained that it was more difficult to find the half of 24 that of 38. In 2013, the teacher let pupils elaborate more about their procedures. I can note that half is defined as the action of "cutting by two" and "it's two times less", whereas a quarter is defined as "the half of a half". Same expressions are used with reference to the school equipment: "cut in two". Two pupils did not manage to carry out these calculations correctly.

I can only hypothesize that pupils' knowledge is acquired by action. When pupils expose their strategies, they used their current vocabulary language instead of mathematical terms. They refer to actions as "cutting by two". The teacher also uses pupils' vocabulary, which may not help the pupils learn and understand mathematical terms.

The teacher questions numerous pupils and spends a long time explaining their strategies again without proposing other reformulations. The teacher uses pupils' vocabulary and does not propose other more "mathematical" vocabulary.

Most of the pupils manage to carry out the task, and it seems satisfying enough to go ahead with the rest of the session. The following session consists in folding sheets of paper to represent what one half is.

I therefore think that this phase of mental arithmetic was a means for the teacher to recall the knowledge of her pupils on what a quarter and a half are. The teacher reminds pupils of knowledge in a numerical context. I note that taking ½ of a number (operator point of view) is not the same point of view as the fraction which is as considered a part of the whole. Whether or not pupils are able to take this into consideration without the help of the teacher is hard to tell.

During this second step, Solene finally said and wrote that four quarters are "four times a quarter, but also three times a quarter plus one quarter". A pupil proposed "three quarters plus two quarters minus one quarter". This indicates that pupils are capable of producing equalities on fractions by the use of strips. They therefore produced more varied different equalities than in 2011, but all references to the unit disappeared.

At the end of the session, the teacher asked what they have learned today. She did not do this in 2011. Two pupils were capable of answering. They said that they had "learned quarters and halves" or "strips". The teacher concluded her lesson and reminded her pupils of the successive interventions. She proposed what seemed to be a synthesis of what was said: "These are fractions; we learned to fold strips to get quarters, three quarters in a strip plus several fractions enable to reconstruct a whole strip, OK?" The synthesis underscores actions on school equipment and vocabulary used.

These knowledge exposures are not prepared in advance. The knowledge exposure moment, is planned, but the content isn't. The knowledge exposure is produced in action after a discussion with the class. They re-use certain pupils' terms, excluding others. Fraction is defined by reference to an action using school equipment. Pupils are responsible for understanding that the whole strip is a reference to the unit.

632	Teacher:	the halves ... we learned the strips? We have not learned strips. We learned to do what with these strips? Three halves ... no, we did not learn to do three halves, we did quarters. How do you call this? (Shows a fraction) What is called?
635	Pupil:	fractions
636	Teacher:	These are fractions, we learned to fold the strips to get quarters, three quarters in a band plus several fractions allow us to rebuild a whole strip. Ok?

During the following lesson, Solene distributed a text to be learned by heart at home. This text was the same in 2011 and in 2013. Whereas she spent 20 minutes to exploit this text in 2011, it took her more than an hour in 2013. Pupils were asked in 2013 to comment on every line of the text that was distributed. Once again, I noted this difference in duration and the attention given towards what the pupils had to say.

CONCLUSION

For two years, I followed 5 teachers, but in this paper, I have only developed one case. The knowledge exposure does not develop mathematical exposure but develops methodological knowledge much more. These institutionalizations (knowledge exposure) remain strongly contextualized. The context does not remain entirely the same from one year to another and depends on interactions with pupils.

The study of the five components leads us to point out regularities and variabilities. For this teacher concerned, the teaching project is consistent concerning official programs and didacticians' recommendations (context of lengths). Apparently, the teaching project remains the same, although differences appear. I question these differences. The variabilities I noticed appear at the level of the mediative and cognitive components and more precisely in the content of knowledge exposure moments. What the teacher says orally seems randomly improvised and depends on discussions with the pupils. The oral content of the lesson leans on the pupils' vocabulary and moves away from mathematical vocabulary.

The game of questions/answers, difficulties met to name mathematical objects, to express the target taught, lead me to introduce the notion of negotiated institutionalization.

Expecting the pupils to be able to say what they have learned at the end of a session seems to be quite ambitious. Taking into account what the pupils declare they understood, by using imprecise vocabulary enables them to formulate and share their newly acquired knowledge between their peers. It can be questioned, however, if it is reasonable to propose incorrect and unclear mathematical definitions. This leads me to ask myself new questions oriented towards the practices of training teachers and more precisely on their professional gestures. What mathematical and didactical knowledge should a teacher acquire in order to achieve the transition from contextualized institutionalization to de-contextualized institutionalization?

Teachers' attention to task's potential for encouraging classroom argumentative activity

Michal Ayalon and Rina Hershkowitz

The Weizmann Institute of Science, Israel, michal.ayalon@weizmann.ac.il

This study investigated secondary school mathematics teachers' attention to task's potential for argumentative activity in the classroom. Analysis of the teachers' choices of tasks and their explanations revealed categories that fall into two dimensions: (1) Attention to the mathematics in which the argumentative activity is embedded, focusing on three aspects: the mathematics inherent in the task; the mathematics related to the teaching sequence that the task is a part of; and meta-level principles of mathematics. (2) Attention to socio-cultural aspects related to the argumentative activity. Four attention-profiles of teachers were identified: Teachers who attended to both dimensions; teachers who were attentive only to the mathematics aspects inherent in the task; teachers who were attentive only to the socio-cultural dimension; and teachers who were attentive to neither of these dimensions.

Keywords: Argumentative activity, teachers, attention, task.

THEORETICAL BACKGROUND AND GOALS

The approach taken in this study is socio-cultural; therefore, we considered approaches to argumentation as a social process in which two or more individuals engage in a dialogue, and where arguments are constructed and critiqued (e.g., Ayalon & Even, 2015; Conner, Singletary, Smith, Wagner, & Francisco, 2014; Krummheuer, 1995). In recent years, there has been a growing appreciation of the importance of incorporating argumentation into mathematics classrooms: first and foremost because mathematics is intrinsically connected to argumentation. The principal facets of argumentative activity – justifying claims, generating conjectures and their justifications, as well as evaluating arguments – are all essential components of doing and communicating mathematics. In addition, accumulating research suggests that participation in argumentative activities – which encourage students to explore, confront, and evaluate alternative positions, voice support or objections, and justify different ideas and hypotheses – promotes meaningful understanding and deep thinking (Schwarz, Hershkowitz, & Phrusak, 2010). Moreover, involvement in argumentation in the classroom may provide students with a feeling of sharing responsibility with the teacher for the learning that occurs in the lesson (Forman, Larreamendy-Joerns, Stein, & Brown, 1998).

Research suggests that the teacher plays a crucial role in establishing norms and standards for mathematical argumentation in the classroom (e.g., Forman et al., 1998; Yackel, 2002). These roles include prompting students to establish claims and justifications, encouraging students to critically consider different arguments, explicating the argumentative basis of students' claims, and supplying argumentative support that was either omitted or left implicit, presenting to students what constitutes acceptable mathematical arguments, and modelling specific ways of constructing and confronting arguments. These various roles express the rich and complicated dimensions of establishing learning environment in which mathematics and argumentation are integrated (Yackel, 2002).

Research also suggests that argumentative activities are not often implemented in class, and that teachers need adequate training and scaffolding if they are to improve classroom argumentation (Conner et al., 2014; Hiebert et al., 2003). A possible first step towards offering such assistance may be to investigate teachers' approaches to and sensitivity towards argumentation as a practice in the mathematics classroom. Our study goes to this direction: It investigates teachers' attention to the argumentative potential of mathematical tasks.

The concept of attention is currently used in studies concerning mathematics teaching (e.g., Paparistodemou, Potari, & Pitta-Pantazi, 2014; Sherin & van Es, 2005). Common to these studies is the assumption that teachers' ability to notice is a key feature of teaching expertise, and that such an ability can be improved. This study shares the above assumption, and we focus on teachers' attention to task's potential of utilizing argumentative activity, i.e., what teachers take into consideration when they choose tasks from their textbook with the aim of promoting argumentative activity in their mathematics classroom. The specific research question was: What do teachers attend to when they choose tasks that, in their view, encourage argumentative activity in their mathematics classroom? Unlike other studies, our focus on teacher attention was not part of teachers' training; rather we intended to learn on teacher's attention towards argumentation in teaching, within a situation close to their day-to-day individual work of planning their teaching.

METHODOLOGY

Participants

A group of 17 secondary school mathematics teachers in Israel, at the beginning of a year-long in-service-course, participated in the study. Their teaching experience varied from 1 to 30 years; each holding a B.Ed. in teaching mathematics or B.Sc. in mathematics. The teachers were not explicitly exposed to the issue of argumentative activity before the research was conducted. All the teachers used the same 7th grade mathematics textbook in their classrooms.

The research tool

We developed a questionnaire that focused on the teachers' practice of selecting mathematical tasks. The teachers were individually asked: (1) to choose three tasks from a unit of the 7th grade textbook (Ozrusso-Hagiag, Bouhadana, Friedlander, Robinson, & Taizi, 2012) that they view as encouraging argumentative activity, and (2) to explain and justify their choices. All the teachers taught this unit in their classes while the data were being collected.

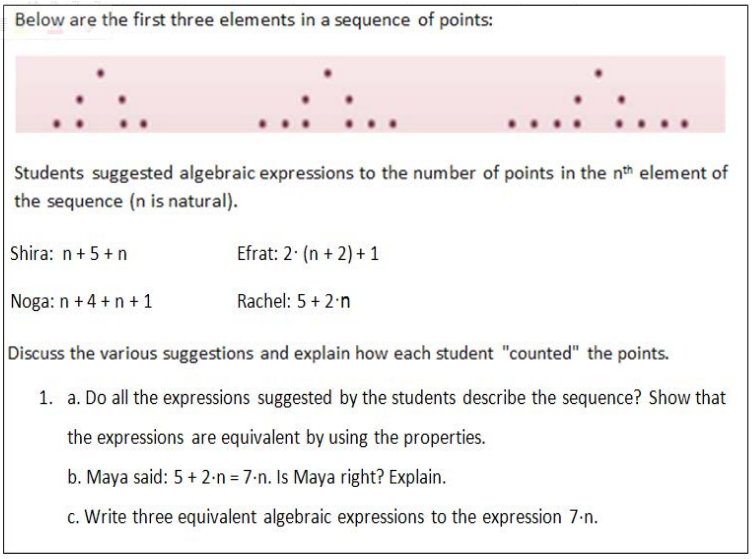
The textbook and the unit

This is the fourth unit of the 7th grade textbook, a part of the *Integrated Mathematics* junior-high school curriculum. This curriculum is specifically designed as a series of trajectories of tasks, one of the main characteristics of which is to engage students in conjecturing and justifying. The preceding three units include some work on algebraic generalization of patterns and some drilling on the properties of real numbers. The unit comprises five lessons; each includes tasks for direct teaching used as part of the whole class discussion and exercise tasks (total of 72 tasks). The main mathematical emphases are: using algebra as a tool for generalization; acquaintance with equivalent algebraic expressions; and purposeful use of simplification and substitution.

Data analysis

The 17 teachers produced 52 responses (16 teachers chose three tasks as they were asked and one teacher chose four tasks); each response consisted of the choice of a task that will encourage argumentative activity in the classroom and an explanation for their choice. Overall, 21 different tasks from the unit were chosen by the 17 teachers. As a first step, we identified the tasks' distribution within the unit, including the lesson the task was taken from (1–5), its function in the lesson (direct teaching, exercise), and the number of teachers' responses per task. We then took two directions when we analyzed the data: Top-down direction and bottom-up direction. The reason why we used top-down analysis was to learn how researchers, as presenters of the scientific educational authority, conceptualize the chosen tasks as encouraging argumentation. Our intention was to use this conceptualization as a backdrop against which to highlight and characterize the teachers' attentiveness, which emerged from the bottom-up analysis.

Top-down analysis of the 21 chosen tasks' affordances for argumentation, by adapting a widely used analytical framework suggested by Stylianides (2009), and was adapted by Bieda, Ji, Drwencke, and Picard (2014). This framework is commonly used to examine the opportunities provided in mathematics textbooks to engage in what Stylianides called reasoning-and-proving (RP), which means "the overarching activity that encompasses... identifying patterns, making conjectures, providing non-proof arguments, and providing proofs" (Stylianides, 2009, p. 259). Following this framework, we coded each chosen task according to the (1) Purpose of the RP Problem, e.g., making claims, making justifications; (2) Intended Outcome of the RP Problem, i.e., the type of justification expected: proof-type argument (demonstration or generic example), or non-proof-type argument (empirical or rational). For example, the task presented in Figure 1 was taken from the direct teaching part of lesson 1. Question a



Below are the first three elements in a sequence of points:

Students suggested algebraic expressions to the number of points in the n^{th} element of the sequence (n is natural).

Shira: n + 5 + n   Efrat: 2· (n + 2) + 1

Noga: n + 4 + n + 1   Rachel: 5 + 2·n

Discuss the various suggestions and explain how each student "counted" the points.

1. a. Do all the expressions suggested by the students describe the sequence? Show that the expressions are equivalent by using the properties.

   b. Maya said: 5 + 2·n = 7·n. Is Maya right? Explain.

   c. Write three equivalent algebraic expressions to the expression 7·n.

Figure 1: A task chosen from the direct teaching section of lesson 1

in the task engages students in generalizing visual patterns algebraically and introduces them to equivalent of algebraic expressions. Several teachers chose question b, which addresses a common mistake. Using Stylianides' framework, and assisted by the textbook's teacher guide (Integrated Mathematics, 2012), we coded the Purpose of the RP Problem as making a claim (Maya is not right) and a justification (e.g., multiplication precedes addition). The Intended Outcome of the RP Problem was coded as a proof-type argument of demonstration (e.g., relying on the properties of real numbers). We analysed in the same way all the 72 tasks within the five lessons unit.

Bottom-up analysis of the 52 teachers' responses, through which the categories of attention to the task's potential for argumentative activity were generated and consolidated, and then used to identify teachers' attention profiles, as will be elaborated below.

In both phases of analysis, the data were coded independently by each researcher, followed by a comparison of the codes. All disagreements were resolved by discussion and a consensus was reached.

FINDINGS

The distribution of the 21 chosen tasks across lessons

The distribution of the 21 chosen tasks was found to be rather homogeneous across the five lessons, and also across their function in the lesson (direct teaching or exercise). Out of 52 teachers' responses, the number of responses per each of the 21 chosen tasks was between 1 and 7.

Top-down analysis of the tasks' affordances for argumentation

Using this framework, we analyzed the 21 tasks chosen by the teachers, which revealed that the purpose of 19 of them was to make claims and justifications and the purpose of the other two tasks was to make claims; this is where 32 tasks of the 72 within the whole unit asked for justification, while the other 40 asked for claims only. In 16 out of the 19 tasks the intended outcome was a proof-type argument of demonstration, which is "at the top of the hierarchy" (Stylianides, 2009, p. 280), In the other three tasks, the intended outcome was an empirical argument, where from the 32 tasks within the whole unit, aimed at justification, 24 were of proof-type and 8 of empirical argument. Thus, we can conclude that the teachers chose tasks that by and large match Styliandies' RP spirit.

Bottom-up analysis: Dimensions of teachers' attention to the task's potential for argumentative activity

Bottom-up analysis of the 52 teachers' responses led to identifying categories that fall into two dimensions of attention:

— (D1) Attention to the mathematics in which the argumentative activity is embedded (23 out of 52 responses).

— (D2) Attention to socio-cultural aspects related to the argumentative activity, such as student-teacher interactions and the nature of the class discussion (20 out of 52 responses).

Note that each response may refer to one of the dimensions, both dimensions, or neither dimension.

Upon further analysis, we found that teachers focused on three aspects of dimension D1: (D1a) the mathematics inherent in the chosen task itself (23 out of 23 responses; this means that each response that was attentive to D1 was attentive to D1a); (D1b) the mathematics related to the teaching sequence that the task is a part of (9 out of 23 responses); and (D1c) global/meta-level principles of mathematics that transcend the particular task (8 out of 23 responses).

When looking at each teacher's responses separately we found that each teacher was consistent regarding the nature of his/her attentiveness across his/her 3–4 responses – i.e., the responses associated with the 3–4 tasks that each teacher chose fell in the same categorization in terms of D1 a-c and D2.

Overall, four different profiles of teachers' attention were found, as shown in Figure 2. It is worth to note that there was no correlation between a certain profile and a certain chosen task: different tasks were chosen by teachers of the same profile, and the same task was chosen by teachers from different profiles.

Next, we describe the various profiles in more detail and with examples.

Profile 1: Teachers whose all responses referred to the two dimensions of attention: the mathematics (D1) regarding its three categories (D1a–c) and the socio-cultural aspects (D2) (three teachers).

Example: A profile 1 teacher chose the task presented in Figure 3, which was taken from the exercise section of lesson 2. In the previous lessons students became acquainted with methods for justifying the equivalence of algebraic expressions.

She explained her choice (our coding appears in brackets after each utterance):

> Here different algebraic expressions may be suggested, some correct and perhaps some incorrect. It is possible to write all of them on the board and ask the students to say what they think about each expression (D2). The answers should be based on mathematical justifications: Use of the properties of real numbers to prove that the expressions are equivalent and use of substitution for a counter example or use of the properties to show that the expressions are not equivalent (D1a+D1c). If there is a disagreement about a certain expression, they (the students) will have to convince each other until they reach an agreement (D2). It is possible

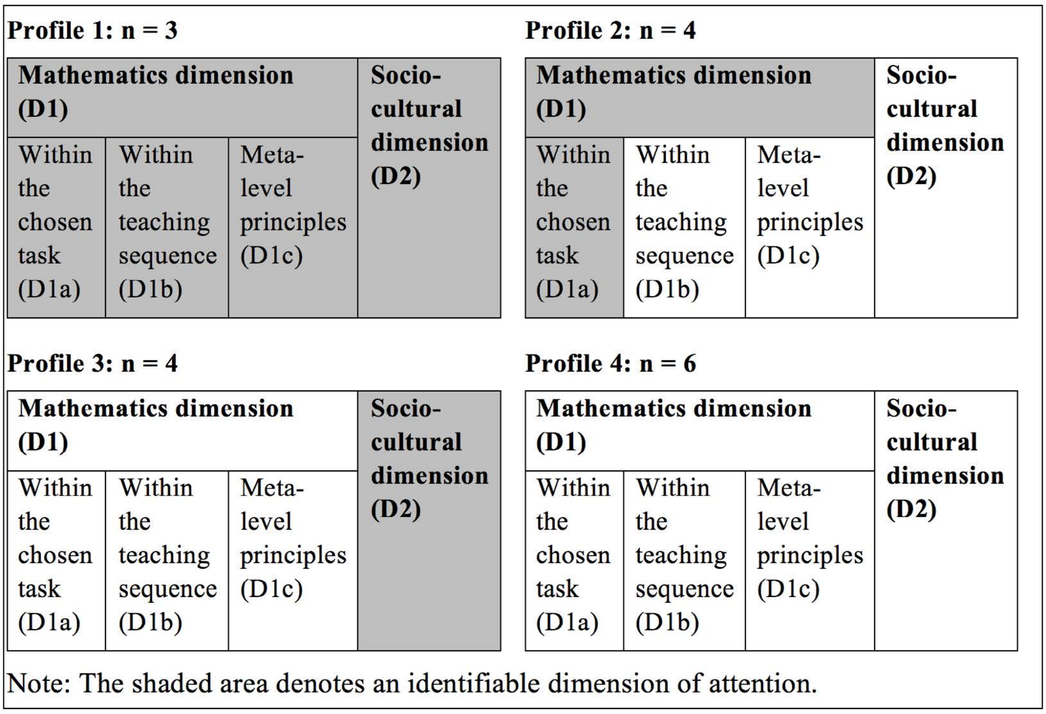


Figure 2: Profiles of teachers' attention

Write five algebraic expressions that are equivalent to the expression $1 + 6(x + 3)$

Figure 3: A task chosen from the exercise section of lesson 2

> that first students will suggest numerical examples as a proof for equivalence, but they will have to convince me and their peers that it is correct (D1a, D2). If no objection is raised in class, I might suggest a counter example in order to show them that an example is not necessarily sufficient to prove equivalence (D1c, D2). I want them to move to a general algebraic justification (D1c), which is one of the goals of this study-unit (D1b). If a student will justify equivalence by substituting a number, it is an opportunity to talk about the idea that one example is not enough for proving equivalence. Here is an opportunity to talk about how, in general, it is acceptable to justify in mathematics (D1c).

In her response, the teacher considers the mathematical justifications related to the task itself, the role of the task in the unit's learning trajectory, and the general principles of proof in mathematics, and interweaves them all in the socio-cultural process of shaping collective argumentation in class.

Profile 2: Teachers whose all responses referred to the mathematics within the task (D1a) and not to the other elements in D1. In addition, they did not refer to socio-cultural features (four teachers).

Example: A profile 2 teacher chose question b in the task presented in Figure 1, taken from the direct teaching section of lesson 1. This question was aiming at addressing a common mistake. In explaining her choice, the teacher considered only the mathematical claims and justifications related to the task:

> The task involves argumentative activity in which the argument is that Maya is not right because multiplication precedes addition, or you substitute a number on both sides of Maya's equation and receive different values, meaning there is no equality here (D1a).

Profile 3: Teachers whose all responses referred to the socio-cultural dimension (D2) and not to the D1 aspects (four teachers).

Example: A profile 3 teacher also chose question b in the task presented in Figure 1:

> In this activity students are requested to explain whether Maya is correct or not. Each student holds a different point of view. I will ask for more and more arguments. Students will describe their opinion and justify it and will have to convince their friends and me, or change their opinion and together reach the right answer (D2).

In her response, the teacher considers the socio-cultural aspects of organizing collective argumentation including raising arguments, convincing peers, and reaching a consensus. However, the response lacks any mathematics.

Profile 4: Teachers whose all responses were not considered to relate to any of the categories of attention (six teachers).

Example: A profile 4 teacher chose the same task and wrote:

> Is Maya right? Explain. Engaging in this activity requires students to raise arguments.

DISCUSSION AND CONCLUDING REMARKS

We consider as a major achievement of this research the possibility of getting close to a group of mathematics teachers and revealing some of their views concerning the argumentative potential of mathematical tasks in a textbook's unit for the teaching-learning processes in their classrooms. Our methodology was naturally integrated into the teachers' work, allowing us to reveal teachers' actual choices of "argumentative tasks" and their genuine attentiveness to different dimensions of what they consider the task's argumentative potential.

In examining the teachers' choices of tasks through the lens of established research "tools" (Bieda et al., 2014; Stylianides, 2009), we found that most of the chosen tasks are of the proof-type argument (RP) of demonstration, which is "at the top of the hierarchy" (Stylianides, 2009, p. 280), whereas more than a half of the unit-tasks did not ask for argument of any kind. This suggests that teachers were attentive to tasks that afford argumentation. Moreover, viewed collectively, the teachers attended to important rich dimensions of argumentative activity in their explanations. These dimensions – the mathematics in which the argumentative activity is embedded and the socio-cultural aspects related to the argumentative activity – reflect the complex process of establishing argumentation in the mathematics classroom and the simultaneous tasks teachers need to manage in order to facilitate it (e.g., Yackel, 2002). However, the attentiveness of individual teachers in the group was quite diverse; whereas some teachers were attentive to both the mathematics and social dimensions, for other teachers, such attentiveness was partial or nearly absent; they attended only to the mathematics embedded in the task, or only to the social situation, or did not exhibit attentiveness in either of the dimensions.

Our finding of consistency of the dimensions of attention found within each teacher's explanations for their choices and the fact that a same task was chosen by teachers of various profiles, suggest that the effect of the teacher's approach to argumentation was greater than the effect of a particular task. It is worth to note that no correlation was found between a teacher's profile and teaching experience, neither between a teacher's profile and education.

Restricted to the rather small sample, the findings of this study raise several intriguing questions and issues for further research. One is related to possible connections between what teachers attend to when choosing tasks and their actual teaching in the classrooms: Does a teacher who attends to the social aspects of argumentation but does not attend to the mathematics aspects in which the argumentative activity is embedded find it difficult to interweave the pedagogical practices successfully with the mathematical ideas (e.g., in presenting to students what constitutes acceptable mathematical arguments, in supplying argumentative support that was omitted or left implicit)? Does a teacher who focuses on the mathematics aspects but does not attend to the social aspects of argumentation make less room or find it difficult to support collective argumentation in the classroom?

Another question is related to the finding that the teachers who attended to the mathematics aspects within the task only, did not attend to the social aspects at all, whereas teachers, who attended to the mathematics aspects within the task, within the teaching sequence, and to global principles, attended to social aspects as well. Can this point at certain connections between attention to the mathematics in a broader sense and attention to social aspects? And if yes, what are the implications concerning the education and support planned for teaching focusing on argumentation? Further study will address such questions.

Paparistodemou and colleagues (2014) showed that teachers can learn to enrich their attention by reflecting on their teaching. We plan to devise ways to support teachers' development of attention, taking into consideration two main issues identified in this study: One is the diversity of the teacher population concerning attentiveness to argumentation in the learning-teaching process. The other is that this diversity ranged between attentiveness to mathematical aspects and socio-cultural aspects, and no attentiveness at all (at least not explicit). The fact that some of the participating teachers considered both dimensions as an integral part of enhancing argumentation processes in the classroom is encouraging; apparently teachers are at least partially open to adopting these "habits of teaching".

Still, another issue that emerges from our findings is related to design. We saw that the same task was chosen by teachers of different profiles; i.e., teachers saw differently "through" the task. This raises the question of how we can make a task more transparent in its argumentative potential so as to be "seen" by varied population of teachers.

Being told or finding out or not: A sociological analysis of pedagogic tasks

Jeremy Burke

King's College London, Department of Education and Policy Studies, London, UK, jeremy.burke@kcl.ac.uk

Pedagogic tasks can be considered as a resource for engaging an audience and manipulating their apprenticeship. Different strategies can be deployed according to the pedagogic aim and what constitutes competence in the practice being pedagogised. The position taken here is that message acquirers will assume a degree of authority in the practice and the degree to which that is achieved is dependent on the possibilities made available in the task(s) set. A sociological analysis recognises that the engagement between author and audience in a pedagogic relation will lead to a distribution of message across positioned acquirer voices; the argument presented here seeks to map those possibilities in an explicit way. Texts on trigonometry are taken to exemplify this.

Keywords: Social Activity Method (SAM), pedagogic strategy, pedagogic tasks, textbooks, trigonometry.

There has been concern expressed about the use of textbooks in school mathematics teaching from a number of perspectives including a preponderance of procedures and calculation rather than conceptual development (Dole & Shield, 2008) allied with an authority position assumed in the author voice (Herbel-Eisenmann & Wagner, 2007). Whilst procedures are frequently used in mathematics practices there are other features which are available to make up a broader competence. My argument is based on the premise that in a pedagogic relation acquirers of the practice may have a range of subjectivities made available: a high level would be indicative of attaining some recognition as an adept in the practice and a low level suggests a degree of dependency (e.g., Dowling, 2009, p. 244). My concern here is the pedagogic strategies deployed in mathematics teaching may lead to the availability or restriction of access to some independent competence in the practice. My analysis is sociological insofar that I am concerned with social strategic action within pedagogic relations.

I wish to draw on Dowling's (2013) Social Activity Method (SAM) in which he outlines the practice being pedagogised as the yet to be acquired esoteric domain. The esoteric domain is recognisable through strongly institutionalised (I+) signification. In school mathematics texts I+ expression will include a specialised use of words, algebraic notation, technical diagrams or graphs. The expression will link to I+ mathematics content. The esoteric domain practice is realised through an assemblage of strategies that includes procedures and instrumentation, but also interpretive action including "discursive definitions, principles, theorems [...and] visual exemplars" (Dowling, 2013, p. 332). For further recent work in SAM see Dudley-Smith (2015), Olley (2015) and Burke, Jablonka and Olley (2014).

DISCURSIVE SATURATION

In Dowling's (1998) study of the very widely used School Mathematics Project (SMP) scheme in the UK, which was provided in sets of books, colour coded according to a 'level' of ability attributed to the readers. Here he found that there were different textual strategies played out in the Yellow (highest) and Green (lowest) series. Of particular note was a difference in the degree to which the texts provided access to the esoteric domain. A key distinction was between strategies which make the principles of the practice explicit within language (high discursive saturation) and those which are tacit in this respect (low discursive saturation) (Dowling, 2013, p. 322).

Textbooks, as extensively used resources, provide a good indicator of the specificity of classroom practice, and gives an indicator of the intensity of discursive saturation provided in a pedagogic message. For this reason, I have looked at a current, widely used, textbook series focused on the General Certificate of Secondary Education (GCSE) examination set for school students aged 16 years across England. The GCSE examinations are set and administered by examination boards one of which is Edexcel. The books I am referring to are from the Heineman/Edexcel texts, 1996 and the Pearson/Edexcel texts, 2010. The earlier series were divided into three tiers Higher, Intermediate and Foundation and the later series into Higher and Foundation, which, like the SMP books, construct a body of potential readers as having different 'ability'. I have taken, here, an example from the introduction to trigonometry from the Higher tier Books where there appears to have been a shift between the Heinemann/Edexcel texts (Pledger & Kent, 1996) and the Pearson/Edexcel texts (Pledger & Cummings, 2010) in terms of the discursive saturation of the texts.

Trigonometry

In the first chapter on trigonometry the 1996 book provides a detailed exposition based on a unit circle, generating three functions sin x, cos x and tan x. The limits of the range of the functions are introduced and then their application to right angled triangles. The hypotenuse of the triangle in the unit circle becomes analogous to the scale factor of enlargement which in turn explains the ratio sin x = opposite/ hypotenuse and so on. The text here is DS+, making relatively explicit the form and structure of trigonometric functions. I notice that the strategy in this book is also integrative of the esoteric assemblage (in providing the non-discursive visual resource to work in relation to the well specified theorems and procedures). There is, then, more *interpretative* work to be done by the ideal reader compared to the *proceduralisation* exemplified in the next paragraph

In the more recent Pearson/Edexcel textbook each chapter is written to a template where the topic is introduced largely referring to esoteric domain content. The presentations are focused on stepwise procedures for answering word problems, with call-out text boxes pointing where to do calculations, where to 'remember' certain steps or conditions and so on. The book provides an introduction to trigonometry thus:

> Key Points
>
> — The hypotenuse (hyp) of a right-angled triangle is the longest side of the triangle and is opposite the right angle. The other two sides are named adjacent and opposite. The side opposite an angle is called the opposite side (opp)
>
> The next side to this is called the adjacent side (adj)
>
> — Here is a right-angled triangle with its hypotenuse of length 1.
>
> The length of the opposite side (opp) in this triangle is known accurately and is called the *sine* of 70° and is written sin 70°.
>
> Its value can be found on any scientific calculator. Not all calculators are the same but the key sequence to find sin 70° applies to many calculators.
>
> (Pledger & Cummings, 2010, p. 383)

This text is considerably more limited than in the earlier book. There is no detail about what trigonometry is or where it comes from, as in the earlier text. It provides abbreviations and reference to calculator generated values, perhaps a literal 'black box'. A little later the book offers SOHCAHTOA to help memorise the three specified trigonometric ratios. The exercise that follows this introduction directs the use of a calculator to find the value of the trigonometric function given an angle, for example,

> Use a calculator to find the value of
>
> a) sin 20°
>
> b) b. sin 72.6°
>
> c) c. cos 60° [...]
>
> (ibid, p. 385)

This text provides more *procedural* work utilising both discursive (e.g., the procedural definitions of trigonometric ratios) and non-discursive (e.g., a calculator) resources, than the 1996 text.

In both of these books there is a pattern of introducing new content with an explanatory text of some form. Stacey and Vincent (2009) looked at modes of reasoning deployed in these introductions but they differentiated between, "a set of instructions that explain, for example, how to set up a stem-and-leaf plot ... [and] a deeper sense of explanation and connection involving derivation, justification and/or proof of a new mathematical result." This is consonant with my findings, but I shall argue that I have provided a finer analytical purchase on the strategies deployed.

OSTENSIVE AND RESERVED PEDAGOGIC MODES

One way of approaching a lesson plan is to consider what task will be set with which the audience can engage, and what prior introduction is needed in order to facilitate the engagement with the task. This presents a task as a two stage process of presentation and activity. In these texts, and those referred to by Stacey and Vincent, the content is *introduced* before the task activity. The task activity is anaphoric in relation to the pedagogic presentation: that is the presentation may make sense only through the task that follows it. The pedagogic mode, in these texts, is to point to the *how* or *why* attributes of the topic, which is redolent of Wittgenstein's description of *ostensive* explanation, pointing at the content and providing the expression, Wittgenstein (2009, 17§28). Wittgenstein also considers some limitations of "ostensive explanation" and here an alternative is conceived as a cataphoric pedagogic mode, where the task activity refers to the detail yet to be explicitly given. I turn now to an example of this, drawn from a different text altogether.

Shadows

Ollerton (2002, p. i) argues for an apparent freedom that is afforded teachers by not using a textbook in order to wrest "control away from authors of schemes and texts". Instead he offers a range of "starting points and extension ideas". Typical of these is a task, 'Shadows', included in the Association of Teachers of Mathematics (ATM) *Points of Departure, vol. 4*, as follows:

> 63. SHADOWS
> A child is standing near a lamppost. What happens to the child's shadow
>
> — if the child walks directly towards the lamppost
>
> — if the child walks in the other direction [...]
>
> ATM (1989)

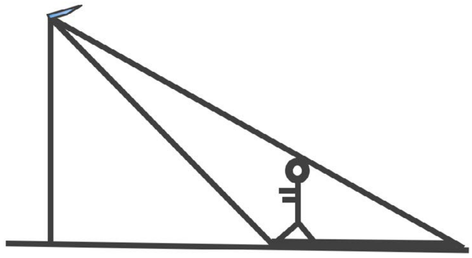

Figure 1

Here the introduction is minimal. A diagram is given showing how the shadow is formed, but other than that there is no prior guidance. In terms of a pedagogic task there has been little action on the part of the author. There is no explanation given as to what to do next. There is no procedure to follow. There is no answer at the back of the book. What then might be expected of a student engaging with such a task? It could be addressed through taking various examples, perhaps using a dynamic geometry package. Or it may lead to a recognition of 3 different triangles which are all similar and consequently have the same ratio of sides. In this case, the focus would be on a tangent ratio, and recognising that as the distance from the lamppost changes, so does the angle of elevation. However, that the similarity of the triangles maintains the ratios of the sides is fundamental in theorising trigonometry, in which case the task becomes DS+, that is the principles are made explicit.

This appears to be the obverse of the example from the GCSE textbooks. Instead of an ostensive explanation there is none given in advance of the *situation* presented. There may have been prior lessons on finding areas, or on strategies, such as Polya's heuristics, for dealing with "investigations", but these are not available from the text in this case.

The point to note is that there is still a pedagogic relation. The authorial voice sets a task, and there is little option but for the audience to engage in some way with it, and I rather suspect that Mike Ollerton's pupils, also, cannot opt out. This is because, as Bernstein (2000, p. 32) proposes, there are (at least) two discourses: the one relates to the disciplinary discourse (instructional) and the other a non-disciplinary discourse (regulatory). The latter will typically position the instructional author as the authority in respect of the disciplinary discourse also (Burke, 2011). The pedagogic relation is maintained even without an ostensive explanation. I consider this to be the case of a *reserved* pedagogy. The principles of evaluation of the practice are still retained by the author who will determine whether the performance of the audience is adequate. The ATM book does not provide any 'answers' and the opportunity is provided for definitive statements of coherence and arguments for solutions to questions developed in response to the situation. This would constitute a move towards a highly discursively saturated text (DS+), albeit one that is produced in the first instance through the engagement with the task.

However, whilst this has the appearance of the open text (Eco, 1984) it is not ultimately a *writerly* text (Barthes, 1974). The closure will come in the evaluative judgment of author, although this has been held in reserve for the duration. I will return to the discussion of the open task.

Tarsia

The three examples given outline tasks which are differentiated in terms of the discursive saturation of the texts produced, either as prior presentations or as performances based on engagement with the task. A fourth example will suffice to complete a schema. There is a widely used task activity referred to as Tarsia puzzles where students tessellate parts of a larger design according to the connection between two statements given on the sides of two pieces. An example of a puzzle requires pairing trigonometric identities, and here the blogger reports that pupils were keen to (Roy, 2013). Another example is given on the National Centre for Excellence in the Teaching of Mathematics (NCETM) website of a triangular puzzle constructed from 16 equilateral triangular pieces. A teacher says:

> I produced a triangular Tarsia puzzle for my class on the topic of number sequences. The questions consisted of number sequences with two missing terms [...] I gave out the puzzle to the students with no input at all and was specific in not providing any initial assistance. Although some students were disconcerted at first, they soon settled to the task and quickly solved the puzzle. (NCETM, 2010)

The task has no prior introduction from the teacher, so similar to Shadows, there is a reserved pedagogy. However the reservation appears to have lasted a relatively short period of time as the student "quickly solved the puzzle". The solution does not, as it stands, lead to making the principles of the 'solution' clear. In fact the teacher notes that students use a strategy of answering easier questions first suggesting a probabilistic response to the final questions. The task activity consists of a set of components to be assembled, but this is a DS- text.

PEDAGOGIC TASKS

I am now able to show these four tasks as pedagogic strategic engagements in a SAM type schema. The horizontal axis distinguishes DS+ and DS- discourse. The vertical axis distinguishes the pedagogic mode as Reserved or Ostensive.

The cells now give a typification of a strategic process of task engagement. With reference to the 1996 trigonometry text, there was a clear exposition of the principles followed by word problems including some of an analytical nature. The text was DS+ and the pedagogic mode was ostensive. This can be characterised by the anaphoric relation *exposition and problem*. The more recent GCSE textbooks had a rapid demonstration of how to find the value of a trigonometric function using a calculator and the application of SOHCAHTOA, followed by exercises using a calculator. This I am showing as *demonstration and drill*. The 'Shadows' task, on the other hand had a cataphoric task-pair relation. The task had no prior introduction other than the situation. However the production, following engagement can be considered in the form of a composition, which in mathematical terms would include an argument for both the strategy adopted and the coherence of any statement – 'discursive definitions and principles' (Dowling, 2013, p. 332) The task offers access to the esoteric domain

	Discourse	
Pedagogic mode	DS+	DS-
Reserved	situation/composition	components/assembly
Ostensive	exposition/problem	demonstration/drill

Figure 2: Pedagogic tasks

albeit through the action of engagement with it. I have termed this pair as *situation and composition*. The final cell is exemplified in the Tarsia task, with no introduction and little development of esoteric domain principles, comprising the presentation of *components* to be *assembled*.

The scheme does not fix action around pedagogic tasks. Empirically there will be activity by both the practice adept and the audience being potentially apprenticed to the practice. There can be moves between the task instantiation and the task activity. The way that the task is read will also depend on a number of factors.

READER THEORY AND CUEING

Weinberg and Weisner (2011) are concerned with how students use a textbook and develop an analysis which contrasts the intended, implied and empirical reader of the text. They note that whilst the text constructs an ideal reader the empirical reader may not conform with expectations. The pedagogic tasks outlined above may be responded to in a way which seeks to change the strategy initially promoted. The teacher in the Tarsia report observes that the "students were disconcerted". Weinberg and Weisner note that undergraduate mathematics students might look for a rule or procedure to guide them through their task activity. If the opening presentation had been in exposition mode, the students might respond as though it was a demonstration. Similarly the presentation might be in one format, but a response from the reader might lead to a change. In the Shadows example, the situation was given and a response could be to raise a question, "What should I do now?". Such a response is also strategic. Maintaining a reserved pedagogic mode the response to the cue to close down the task would be to ask a question in response. This could be as bald as, "What do you think you should do?" More productive questioning might be along the lines of Brown and Walter's (2004) 'What if?' and 'What if not'? If the response was to provide a procedure, 'compute the ratio of the height and base of the triangles' the move would be towards demonstration and drill.

Weinberg and Weisner also draw on the idea of Eco's open text where the invitation is for the reader to compose in response. This is the appearance of tasks such as Shadows, but the task is given in the context of a mathematics classroom. The text is already subject to its setting, and the reader expectation of (minimally) a mathematics classroom will also be a feature of a reader response. I wish to argue that the text is not open and that the relation between the author and reader is pedagogic – whether it is the author of the textbook or the empirical adept.

The form of responses to cues might be considered as further questioning to maintain a reserved DS+ strategy or simply a correction to maintain an ostensive DS- strategy. In the other two cases, then an explanation maintains an ostensive DS+ strategy and a hint a reserved DS- strategy. This is shown in Figure 3.

Herbel-Eisenman and Wagner (2007, p. 8) are also concerned about the positioning of students within mathematics textbooks and they provide a framework to examine "the way a textbook might influence a mathematics learner's experience of mathematics." The analysis is based on "the social positioning experienced by students" (ibid, p. 10).

They are careful to note that an analysis of a text does not give an unequivocal reading of the positioning effect on the reader. This is consonant with Dowling and Burke (2012) who pointed out that the various gendered representations in mathematics textbooks appeared not to have had an effect on girls out-performing boys in GCSE, at least up until 2010 when the format of the exam was changed. It seems likely that the pedagogic tasks deployed will have more of an effect on outcome, which is perhaps why the later Pearson/Edexcel texts provide, almost uniformly, tasks formed from demonstration and drill strategies which have been associated with a gradual rise in the number of GCSE passes at grade C and above over recent years. The 'effect' on learning mathematics might be different from an effect in terms of a wider social difference in other settings.

	Discourse	
Pedagogic mode	DS+	DS-
Reserved	situation/composition/question	components/assembly/hint
Ostensive	exposition/problem/explanation	demonstration/drill/correction

Figure 3: Pedagogic tasks and adept cuing

Stacey and Vincent (2009) in their study on reasoning in school mathematics textbooks concluded:

> ...the critical point for developing students' mathematical reasoning is whether they understand that some modes of reasoning are indeed part of the acceptable range of reasoning in mathematics, whilst others serve a local pedagogical purpose, such as helping them remember a rule, building connections between topics, making mathematics plausible. Textbooks could more often make these distinctions explicit, and in so doing, give students a stronger sense of mathematical justification. (Stacey & Vincent, 2009, p. 287)

Indeed textbooks could be more explicit about the strategies they are deploying but it is also perhaps as critical that mathematics teachers have some clarity about the resources they are using. The current Pearson/Edexcel textbook adopts, almost entirely, a pedagogic strategy of demonstration and drill, similar to the observations of Dole and Shield rather than distinctive, contingent strategies observed by Stacey and Vincent. The schemas I have given provide a coherent description of the process of interaction and pedagogic strategy in pedagogic tasks, demonstrated here through mathematics texts. They might also prove to be productive in classroom contexts to analyse the process of task presentation and student engagement in terms of whether they are being told, or they are finding out, or if there is a ubiquity of procedure.

Elementary teacher practice in project work involving statistics

Ana Caseiro[1], João Pedro da Ponte[2] and Cecília Monteiro[3]

1 Instituto de Educação da Universidade de Lisboa and Escola Superior de Educação de Lisboa, Lisbon, Portugal, anac@eselx.ipl.pt
2 Instituto de Educação da Universidade de Lisboa, Lisbon, Portugal
3 Escola Superior de Educação de Lisboa, Lisbon, Portugal

This study aimed to analyze the practices of an elementary teacher in conducting project work involving statistics. The study follows a qualitative case study design with data gathered by means of video and audio recording of the teacher's class. The results showed that the teacher followed an exploratory approach with constant reflection during the teaching process. The results also showed a diversity of types of communication and teacher's interventions during the development of the students' projects and a high concern for students' involvement.

Keywords: Teacher practice, statistics, project work, communication.

INTRODUCTION

In Portugal, the 2007 Mathematics Curriculum of Basic Education emphasizes statistics, recognizing that this is a key area in modern society in which students must have a good preparation. To achieve this, students must carry out statistical investigations in school (Groth, 2006). Wild and Pfannkuch (1999) suggest that this is an important way of the learning of statistics.

Teachers' practices are one of the key factors that influence students' learning (Ponte & Serrazina, 2004). So, in order to support the quality of teaching and learning, it is important to develop research on this field (Franke, Kazemi, & Battey, 2007). As project work is about formulating questions and finding information to answer these questions in an engaged and participative way, our research question is to know how do teachers explore students' ideas and promote discussions during this process.

TEACHERS' PRACTICE IN STATISTICS

The concept of teachers' practice is a complex one. O'Donnell and Taylor (2007) emphasize the tasks that teachers use in their classes. Among the various kinds of tasks, project work can be used to foster students' learning as it favours their affective and cognitive involvement. Alarcão (1996) defines six phases in carrying out project work: (i) Choosing significant problems based on the desire to solve them or at least to study ways of solution; (ii) Establishing a plan and outlining ways of doing things, providing resources, planning possible interventions, dividing tasks and managing time; (iii) Contacting with reality, doing data collection through field work; (iv) Organizing and processing data, by comparing, analysing and reflecting on the data; (v) Preparing presentations to others to make known to others the results and the processes experienced; and (vi) Presenting the most significant aspects in a motivating way followed by evaluation of all the work carried out.

The stages of a statistical investigation are similar to those of project work. Problem solving using data is carried out through the investigative cycle (Burgess, 2007). Graham (1987) and Franklin and colleagues

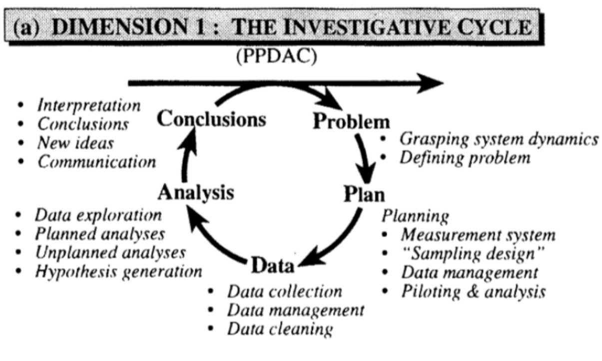

Figure 1: The statistical investigation cycle (Wild & Pfannkuch, 1999)

(2007) refer that a statistical investigation typically involves four steps: asking a question; collecting data; analysing data; and interpreting the results in an organized manner. Wild and Pfannkuch (1999) consider five basic phases of a statistical investigation: choosing the problem, defining a plan, gathering data, analyzing it, and drawing conclusions (Figure 1) and consider three additional key dimensions in statistical work: types of thinking, questioning cycle and provisions.

As Makar and Fielding-Wells (2011) refer, the formulation of the problem is important and should be related to the students' interests. The research question is the starting point of the work and is often overlooked by teachers who end up focusing on the other phases of the cycle. The problem to be investigated should take into account aspects such as the age level and the mathematical development of the students (Ponte, 2001). The second phase of the investigative cycle (plan) is also an important step. According to Shaughnessy (2007), little time is devoted to this phase. Most students are only taught "pre-statistical" topics, being presented with a ready-made problem formulation, plan, and production of data. The next two stages (data collection and analysis) allow students to become familiar with statistical concepts and representations. Finally, in the last phase of the cycle (conclusions) students should be able to verify if their initial questions were answered or whether is necessary to formulate and conduct a new investigation.

Another key aspect of teacher's practice refers to the nature of the classroom communication (Franke, Kazemi, & Battey, 2007). Brendefur and Frykholm (2000) propose a model with four types of communication: (i) uni-directional communication, where the teacher dominates classroom discourse while students listen, so they can reproduce, i.e., in this type of communication the main role belongs to the teacher; (ii) contributive communication, where there is a large number of interactions between actors (teacher and students and among students), although mostly short and where the teacher continues to have a major and dominant role; (iii) reflective communication, where the work carried out is subject to constant reflection, with the students engaging actively in discourse and having freedom to express themselves; and (iv) instructive communication where the teacher systematically draws on students' contributions to improve teaching and learning

Wood (1999) notes the importance of teachers leading students to justify their choices, encouraging everyone to participate in classroom discussions. Based on previous research, Ponte, Mata-Pereira and Quaresma (2013) developed a framework for analyzing the teacher's actions in conducting mathematical discussions, distinguishing four main types of actions: (i) inviting, in which the teacher promotes the initial involvement of students in the discussion; (ii) supporting/guiding, in which the teacher leads the continued participation of students through questions or other interventions; (iii) informing/suggesting, in which the teacher introduces information, providing arguments or validating student responses; and (iv) challenging, in which the teacher seeks that students make generalizations and justifications and question the responses of their colleagues.

METHODOLOGY

The methodology is qualitative and interpretative, following a case study design (Bogdan & Biklen, 1994). We study the case of a grade 4 teacher, Maria (fictitious name) who is 28 years old and has been teaching for 8 years in a private school in Lisbon. After getting her degree as a primary school teacher, Maria strived to deepen her mathematics preparation, making a master's degree in mathematics education and is now enrolled in a doctoral program in mathematics education. In addition, she regularly attends mathematics teachers' professional meetings. In this paper, we analyze her case, as the construction of the other cases is still in progress.

Data collection was carried out from April to June of 2013. Usually, she proposes statistics tasks with situations in which a graph is given and the students had to answer questions about it. The teacher showed some discomfort with this practice, stating that "I would like to do a work like that with other curriculum topics [such as environmental issues] including project work by the students".

The data presented in this paper was gathered through video and audio recording in seven classes taught by Maria. It is presented in the various stages of the investigative cycle of Wild and Pfannkuch (1999) and analyzed according to the types of communication proposed by Brendefur and Frykholm (2000) (uni-directional, contributive, reflective, and instructive communication) and teachers' actions suggested by Ponte, Mata-Pereira and Quaresma (2013) (inviting, supporting/guiding, informing/suggesting and challenging).

The decision to conduct project work with the students was taken on a collaborative group work that was composed by the first author of this paper (hereafter referred to as researcher), Maria and two other grade 3 and 4 teachers. In this session the researcher proposed to discuss the investigative cycle (Wild & Pfannkuch, 1999) and an article about different types of tasks, which included an explanation of project work. After this discussion the teachers decided to use this material to plan their lessons in the frame of project work. For teachers, a key idea was to engage students in their own learning, motivating them through interesting themes, and having them working in small groups. As the teachers had already worked tables and graphs with the students, it was decided that this work would verify the students' knowledge on these representations. Thus, the work was planned, discussed and adjusted together in the teacher collaborative group. The research presented here refers to data collected in Maria's classes in which the researcher assumed the role of participant observer, collaborating with the teacher and interacting with students.

The introduction of the task sought to involve the students in all decisions, especially in deciding how to format their project as a statistical investigation. The only condition imposed was to use quantitative data that could generate statistical representations. The first lesson was intended for proposing the project work, with the teacher seeking to motivate and engaging students. In the second lesson, in a plenary session, all suggestions for topics and study questions were discussed. The following three lessons were reserved for the collection, compilation and processing of data. The sixth lesson aimed to analyse the data and to prepare the presentation and the seventh lesson was designed to the presentation of results to the whole class.

MARIA'S PRACTICE

Introduction of the task and choice of the projects

Maria begun by informing the students that they would develop a project work involving data handling and explaining the different phases that they should follow. The teacher referred that all the work would be discussed with them. A student asks:

Ana: But we are supposed to do a project work? It takes so long.
Teacher: I do usually tell you what to study? No. Now what we want to do is to make a project work. It takes time, very well, so we have to organize ourselves. Do you know the planning sheet that we usually do? We will also do it to organize our work.
José: You can choose to be a 2 in 1.
Teacher: The theme is of your choice and our concern is that you have to present information in graphical representations.

Thus, the teacher introduced the work seeking to engage students in making decisions about the whole process. This introduction led the students to begin thinking about what they would like to study. The teacher guided the students' work from a perspective of reflection by all (*reflexive communication*), promoting their early involvement in the discourse (*inviting* actions), giving them freedom to express themselves. The challenging nature of this proposal made students to promptly begin participating in the discussion.

The students indicated some topics of interest. The class discussed whether their study made sense to carry out and was of general interest. Many students made suggestions:

Beatriz: We had the idea of making Chinese characters. Are more than ours.
Teacher: Well, are symbols, so it is so hard.
Mafalda: In which countries are different from the letters A, B, C, D, E.
António: It was also turning to ask what they think: think how many letters have alphabet X.
Teacher: But that's just an opinion, an answer.
Mafalda: They could say how many think they have every number of letters and then give the correct answer.
(...)
Teacher: The group of Rome: "What monuments? What are the Roman gods? What is the number of visitors who visited one (or

more) monument each year?" What they want to know with this project work?
Leonor: We want to know the number of visitors to monuments per year.
Ana: Why not make the Greek gods who are over?
José: Why do not the mean or the mode of the number of visitors?

This dialog shows that students were quite participative, making suggestions for the work of their colleagues. The teacher kept a low level of intervention thus enabling the discourse to be carried out mainly through student-student interactions (*reflexive communication*). All the students proposed themes and questioned their colleagues who received their opinions and questions in a constructive way. The teacher involved all the students in the discussion (through *inviting* actions) and promoted their participation, leading the discourse through *supporting/guiding* actions. In the end nine themes were raised by the students to study: "Monuments and Roman gods"; "Stars and planets"; "Curiosities about the world"; "Sharks"; "Rally Dakar"; "Butterflies"; "The strangest animals in the world"; "Trivia about writers"; and "Professions".

The plan

The teacher began by referring the importance to design a plan to serve as guide to carry out the subsequent work. With this goal Maria distributed a sheet of paper with a model in order to guide the students to organize the work reinforcing the idea that they should record the questions they wanted to study and begin to think about the representations they intended to build with the data collected to answer each of their questions. The teacher emphasized that they should think about what kind of graph they considered appropriate to use.

A student asked the teacher if they could put some information about the topics under study without doing graphical representations. At this stage, Maria showed a more directive attitude, not allowing a discussion of some aspects of the work she had already decided (as the work plan) or had to decide at the time of the class (such as the introduction of a part writing more information on the subjects). In spite of allowing students to be inquirers, she took a leading role intervening at all times of discussion in the large group (*informing/suggesting* action). In turn, when supporting the small groups in the development of their work plan, the teacher showed a less interventionist attitude and a more questioning role. She led some groups to think about the issues that their work would address and on the adequate representations concerning the data they would collect. Thus the kind of communication privileged by the teacher was *contributive,* and also, at times, *reflective*.

Data collection

To collect the data they need for the project, some groups decided to search for information in magazines, books and internet, while others decided to construct a questionnaire. The teacher supported the groups in this crucial phase of the investigation cycle, especially two groups that had never done this kind of work. One of these groups decided to study the occupations of parents of students in the class, based on a small questionnaire. The teacher provided some guidance questioning the students about the various aspects they could ask and suggested some elements which students could not be aware:

Teacher: And no matter whether you are male or female?
Afonso: But to know that we have to put that "is the father of Monica" or "is the mother of Duarte".
Teacher: But that is what is important or you just want to know the occupations of the parents of the class in general?
António: Oh, we could get to put a cross in the genre, and then write the name of the child.
Teacher: Oh, good. And they should not put the objective of the questionnaire?
(...)
Afonso: We want to know the unemployed.
Teacher: But knowing what about the unemployed?
Afonso: The number.
Teacher: And do you not ask parents what college degrees they have? And you are not interested to see if the parents are working in your area?

This excerpt shows the help that Maria gave to her students who had never built a questionnaire. When she felt that the students could reflect on their issues and could improve by themselves the wording of the questions of their questionnaires, she performed *supporting/guiding* actions. When she realized that the work was not moving forward she suggested what students should put in the questionnaire, with *informing/suggesting* actions. In this phase the teacher was both a guide and a reflective participant privileging *reflective communication.*

Data analysis

The students had to process and analyze the data (organizing it in tables in Excel and then making a graphical representation). The teacher circulated by the several groups in order to support their work and to assist in solving their questions. When checking that the question was not just specific of a group or referred to aspects already worked out and discussed in class, Maria conducted a whole class discussion:

Teacher: Now stop a little because now I want to discuss something with you. All of you can help that group studying butterflies... The group of butterflies discovered several species of butterflies and so now they want to make a bar chart and want to put here [in the x axis] the name of the butterfly and then here [y axis] heights. And my question is: this is a bar chart?

Gonçalo: It's not because it has no frequencies.

Teacher: And what is the frequency?

Gonçalo: It was for example if they where [x axis] had 2m to 5m. Imagine that these two [butterflies] one has 3m and another has 4m, then both were in that range and so it was a bar chart with frequency.

Teacher: I do not know if it is okay but what he is saying is that maybe it would be a good idea to arrange size ranges. (...) You must have what the Gonçalo said: frequencies, how often it happens, the number of times, the number of butterflies with 20cm (...).

In this example the teacher strived to involve the entire class in discussing an aspect of interest to several groups, the construction of a bar chart. She took the opportunity to explain students about the concept of bar graph, stressing the distinction between variable and frequency. The teacher assumed the central role of the classroom discourse by systematizing some knowledge of statistical representations, and the role of students was to listen to her explanations. At this stage of the investigative cycle the teacher tended to have a *uni-directional and contributive communication*, and her main actions where *informing/suggesting* and *supporting/guiding* students.

Conclusions and presentations of projects' results

Due to the end of the school year students ended up not having much time to draw conclusions from the data analysis that have made, and for preparing presentations. Maria suggested that all groups prepared a presentation with the data that they had already collected and analyzed so far. Thus some studies only presented a brief analysis of the data, and the teacher questioned some aspects to lead the students in reaching some conclusions. For example, the group that conducted a study on the Rally Dakar elaborated the graph (Figure 2) that displays information about the bikes used by the winners between 1979 and 2011. The students were asked by the teacher:

Teacher: So if we want to win you have to be with a ktm?

Miguel: The ktm is usually that almost all winners use. It is almost always the ktm wins.

Despite the short time available for this phase was still possible for the teacher to discuss some important aspects with their students, with a great student's involvement in the discussion, having the possibility to express themselves and to question the colleagues. At this stage of the investigative cycle, the role of the teacher became more questioning and challenging providing the formulation of conjectures by students.

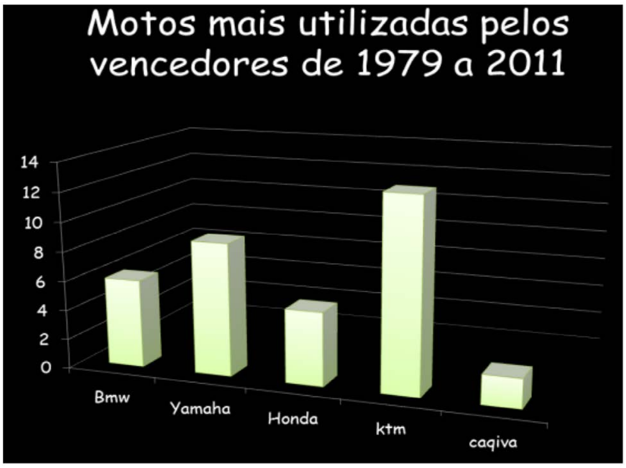

Figure 2: Graph constructed by the group, whose project was on the Rally Dakar

FINAL REMARKS

In the introduction of the task and in the phases of *problem*, *data* and *conclusions* of the investigation cycle (Wild & Pfannkuch, 1999) the teacher encouraged the students to get involved in the classroom discourse with complete freedom of expression. The communication developed along these phases may be seen as *reflective communication*. In the reflection phase of the *conclusions* the communication promoted by the teacher tended towards *instructive communication*. In the phase *plan*, Maria tended to promote *contributive communication*, notably in the whole class discussions in which she allowed small interactions between the students but made many validations and kept a major role in the decisions. This aspect may be due to the fact that she did not feel safe in carrying out project work involving statistics, as it was the first time she was doing it in her class. In turn, during small group discussions, the teacher enabled the students to discuss the issues and representations they wanted to do, which demonstrates *reflexive communication*. In the *analysis* phase, Maria tended to dominate the discourse explaining and transmitting knowledge, assuming a dominant role in the classroom discourse. Sometimes she put some closed questions and gave direct responses, which seems in line with *uni-directional communication* and *contributive communication*. This may be due to the fact that she felt the need to address some statistical aspects with the class that had already been worked before, as she just realized that such aspects had not been understood by students.

In terms of the actions of the teacher, they varied depending on the progress of the class and the development of the projects. In the introduction of the task these actions were mainly *inviting* students to participate, which also happened in the choice of the *problem*. At this stage, Maria also took *supporting/guiding* actions in the discussions. During the phases *plan*, *data* and *analysis*, the teacher tended to *informing/suggesting* actions, which during *data* and *analysis* are complemented by *supporting/guiding* actions. Finally, the phase of the *conclusions* the teacher tended to *challenging* actions, seeking to lead her students to go further

Finally, the choice of project work methodology shows that the teacher follows an exploratory teaching approach. In this approach the teacher does not have full control, to the extent that, for example, she cannot predict what topics and issues the students will select to study and how they will want collect the data. In summary, and responding to the research question, how do teachers explore students' ideas and promote discussions during the project work process, we see that the teacher enabled students to express themselves, using mostly *supporting/guiding* actions and following a *reflexive* communication.

An assessment practice that teacher José uses to promote self-assessment of mathematics learning

Paulo Dias[1] *and Leonor Santos*[2]

1 Secondary School of Moita, Moita, Portugal, paulo.dias.7@gmail.com

2 University of Lisbon, Institute of Education, Lisbon, Portugal, mlsantos@ie.ul.pt

In this paper, we present some results concerning an assessment practice, composed of oral interaction between a teacher and students that a mathematics teacher, José, in a context of a collaborative work, uses to develop the capacity of self-assessment of his secondary school students. The assessment practice developed by José includes two ways to promote self-assessment: self-assessment of the answer and self-assessment of performance. While the former is ensured by cognitive and motivational strategies, the latter is mostly based on meta-cognitive strategies.

Keywords: Assessment practices, self-assessment, mathematics learning, collaborative work.

INTRODUCTION

The tasks that simultaneously serve to teach, learn and assess students' performance have an effect on their school results, mainly because they are not associated with the practice of common assessment and aims to promote self-assessment skills for mathematics learning (Hodgen, 2007). Moreover, when teachers analyze students' answers and give them an appropriate feedback, they deepen the knowledge that students need to organize information and reply (Price, Handley, Millar, & O'Donovan, 2010). This practice helps the student to get a better knowledge structure, allowing an adequate self-questioning, contributing therefore to develop the capacity of the students to self-assess. It promotes mathematical efficiency and self-assessment of the mathematical knowledge, skills and capacities (Quinton & Smallbone, 2010).

But in Portugal, as in several other countries, this kind of practice is really still far from reality in mathematics classes (Santiago, Donaldson, Looney, & Nusche, 2012). We studied, in a collaborative work context, assessment practices done by secondary school's mathematics teachers, whose aim was to promote self-assessment of mathematics learning. In this text, we present only part of the study (Dias, 2013), focusing upon a secondary school mathematics teacher, José, and one assessment practice, the oral interaction between teacher and students (IT-S). In particular, we aim to answer to the following research question: What is the nature and the characteristics of IT-S assessment practice of a secondary school's mathematics teacher, developed in a work context of collaborative nature, which seek to promote self-assessment of learning?

THEORETICAL OVERVIEW

The study of teaching practice of mathematics teachers is relevant to understand their performance in the classroom (Ponte & Chapman, 2006). The understanding of the meaning given to the mathematics teachers' decisions contributes to deepen the knowledge of how the mathematics teachers work in the classroom. Regarding assessment practices in specific, it is not sufficient to assess whether students have mastered facts and algorithms or developed attitudes, skills and knowledge advocated in mathematics curriculum. It is necessary that assessment practices reflect teaching and learning processes. For this purpose, rich tasks are required (Smith & Smith, 2014) and the assessment questions have to be constructed so that, when analyzing the answers of the students, it is possible to get an idea of how students organize information (Price et al., 2010). To accept that the students have an essential part in the construction of their knowledge implies that the teacher must pay particular attention to feedback processes and self-assessment of learning (Santos, 2002).

The focus on self-assessment of learning is justified by the importance of student success in mathematics assignments and consequently in mathematics learning. Self-assessment develops the ability to assess a task and to implement the necessary corrections or adjustments. It is a group of actions that the student develops when regulates his or her own work (Zimmerman & Schunk, 2011). Self-assessment is the process in which students develop the strategies needed to achieve the desired objectives, creating conditions for a successful learning. But self-assessment of mathematics learning do not develops spontaneously (De Corte, Mason, Depaepe, & Verschaffel, 2011). It is the teacher who has the responsibility to promote it through several actions. This study emphasizes the oral interaction, conversation between students and teacher while performing a mathematical task (Henning, McKeny, Foley, & Balong, 2012). Because it is an intentional action from the teacher and occurs in the daily work of the classroom, may be considered an assessment practice for learning (Wiliam, 2007).

Interaction and communication in a mathematics classroom is definitely essential to improve student learning (Santos & Semana, 2012). Nevertheless, some aspects have to be respected. On one hand, teacher has to use relevant information about students reasoning and ways of learning in order to deal properly with the process of teaching and learning (Pinto & Santos, 2006). On other hand, some conditions have to be respected concerning the act of questioning, such as not correcting errors but giving clues, not confirming but asking in a way that leads the students to develop a convincing argument about their reasoning.

IT-S is characterized by questions, stimuli and directions given by the teacher during the implementation of a mathematical task. The impact of this practice may be conditioned by the opportunity of the intervention and the increased student confidence in building their mathematical knowledge (Schwarz, Dreyfus, & Hershkowitz, 2009). In this practice, the teacher should avoid correcting errors and adopt an attitude that contributes to students formulate questions independently. Students can be referred to their own productions or to the proposed tasks, or can be suggested to share and discuss, in pairs or in groups, their interpretations of the answers (Henning et al., 2012).

METHODOLOGY

Following a qualitative and interpretative methodology approach, through a case study design (Stake, 2009), the assessment practice of a secondary school's mathematics teacher, José, has been observed along two school years. José was chosen because of his recognized experience (31 years of teaching, both in schools of basic and secondary education), and his willingness to develop assessment practices that promote self-assessment.

The collaborative context (Jaworski, 2007), constituted by José, another secondary school's mathematics teacher and the researcher (first author), was created by invitation from the researcher, and has as main objective to develop and implement assessment practices to promote self-assessment. Episodes of classroom reported in almost all the texts read by the group were considered essential to trigger discussions and to define the assessment practices to study. After each lesson, there were moments of reflection between the three members of the group. The selection/creation of mathematics tasks was a great challenge for teachers when seeking to integrate assessment, teaching and learning (James, 2006; Pinto & Santos, 2006) and to promote self-assessment of mathematics learning (Black & Wiliam, 2006). Noteworthy the assessment practices planned by the group features challenging tasks (Smith & Smith, 2014), including the themes Trigonometry, Geometry and Functions.

Data collection was done in a 11th grade class (students aged 16–17) and included observation of 10 mathematics classrooms (A), that includes 5 tasks, respectively with trigonometry, geometry and mathematical functions, and collaborative work sessions (ST) from February 2009 to April 2010, with audio recording, a structured interview to José at the beginning of the study (E), and documental analysis, that collected documents used by the teacher and the mathematical work done by the students.

Data analysis was performed by content analysis considering three domains, planning, implementation and reflection (Clark & Peterson, 1986). Planning, before class was focused on the role of the teacher in interpreting, managing, planning and putting into practice his curricular choices. The implementation, during class, focused in the actions of the students during the development of the task and the role of the teacher in the oral interaction between teacher and student. Finally, the third moment, reflection, after class, helps teachers to make progress in their professional development and to build their own way of knowing. In this moment, the teacher makes explicit the strengths and weaknesses of his assessment practice.

In each of the distinct phases sought by José's actions showed his intention to promote the success in the task, either by teacher's questioning of the analysis, and the analysis of the self-regulation of mathematics learning by the student. Later, elements were organized as seen in Table 1.

Self-assessment of the answer	Commitment with mathematical tasks
	Stimulus to individual strategies
	Articulate student ideas
Self-assessment of performance	Self-regulate mathematics efficiency
	Self-assessment

Table 1

ORAL INTERACTION TEACHER AND STUDENTS (IT-S)

Planning

The assessment practice was defined and planned within the collaborative work. Initially, students' difficulties were identified. According to José, the most relevant ones were written and oral mathematics' communication as well as the understanding of mathematical content, although students master some techniques in solving exercises. In this context, the IT-S planning gave attention to the selection of the task and to the support given to students during the task, avoiding correcting the errors and to give too many guidelines for shaping. According to José, questions and stimuli are guidelines that can help students *to increase student confidence in improving their mathematical knowledge*:

> I understand the students' difficulties, but how can I help them? I might answer through interaction. Asking, stimulating, and giving clues to each one. [ST, 12nd]

Looking for the best approach in the classroom was essentially one of the texts discussed in the collaborative group (Santos, 2002). To avoid correcting errors was considered an important contribution *to help students to think for themselves* while solving tasks. Some of the questions suggested in the text were harnessed by José as an example of how it should be the role of the teacher in the classroom:

> "What have you done?", "Why did you take that option?", "Why did you think like that?" "Where did that idea come from?", "In which other situations does this process may be applied?", "If you want to convince someone that this is true, what would you say?" and I would wait for their reaction. [ST, 12nd]

In achieving the tasks, José prefers that students work in pairs, considering that this method may help students to learn:

> If students work in pairs, they can help each other, explore, understand and look for the solutions. [E, 1st]
>
> José recognizes the importance of questioning to help students to accomplish the task. This action neither includes the correction of errors, nor provides many guidelines. He seeks students to explore their work in pairs or in groups, encouraging discussion among students.

Implementation

While the pairs of students develop the task, José observes and interacts with them.

In a task of Trigonometry (Figure 1), José pointed out for the importance of the task assignment and called attention for it, trying *to commit the students to the task*:

José:	Read again. You should go on after understanding the picture \ figure and what it is said about it.
David:	But we just have to look at it and we understand.
José:	The information is important. It is essential to the solution. [A, 1st]

In this task, students had difficulty in selecting the information and José *stimulus to individual strategies*,

The figure illustrates a simple process to determine the radius of Earth. This method consists in measuring the angle α, horizon depression angle, from a high altitude point from which one can see the ocean.
The figure is not to scale. Consider that:

— B represents the observation point;
— C means the centre of the Earth;
— α is the amplitude, in degrees, of the depression angle, ($0^{\circ} < \alpha < 90^{\circ}$);
— h is the altitude of the place, in kilometres;
— the triangle [ABC] is rectangle in A;
— R , is the radius of Earth, in kilometres;
— $BC = R + h$

1. Show that:
$R = \frac{h \cos \alpha}{1 - \cos \alpha}$

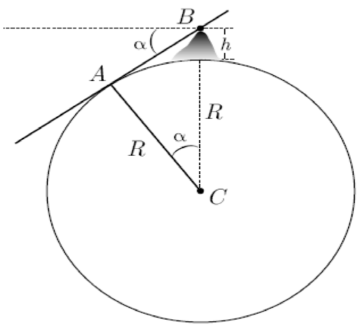

Figure 1

supporting this selection and helping them to find a solution strategy, encouraging them to continue (speaking 9), guiding them to the analysis of the figure and from the strategies designed for each pair of students (speaking 5):

1 David: Teacher, we already know, it is the trigonometrically reason: sine, cosine and tangent
2 José: Are you going to use the three?
3 Alexandre: No, no. we will see. the triangle needs the opposite cathetus AB
4 David: No way! AB is useless, what matters is h!
5 José: Where is h?
6 Alexandre: On the hypotenuse. but we also have R in it
7 David: We will do it with the cosine
8 Alexandre: We have the adjoining cathetus and the hypotenuse that goes for the cosine and then we find the value of h, can that be?
9 José: it can be, there are many ways, that´s yours choice. Go on! [A, 1st]

In the same task, other item (Determine the value of h, when $R = 1000$ meters and $\alpha = 60^{\circ}$ and when $\alpha = 45^{\circ}$. Present the results rounded to units. Compare the two previous results), he managed the same with two other students (Magda and Ruth). These students worked $\cos 60^{\circ} = \frac{1000}{1000 + h}$ and $\cos 45^{\circ} = \frac{1000}{1000 + h}$ equalities. From these equalities, they said, just watching the figure, that as h increases, the value of the angle has to increase too. José feels a little hesitant, because he was not expecting this task solution. He *articulated students' ideas*, not validating the work and asking students to articulate these ideas so that they may be able to present arguments of the result:

Rute: Is this true?
Magda: Adjoining cathetus upon the hypotenuse
José: Yes, it is right, but you did not use the equality $R = \frac{h \cos \alpha}{1 - \cos \alpha}$
Magda: But it is the adjoining cathetus upon the hypotenuse or not?
Rute: It is the cosine!!!
José: Yes, but how do you justify the comparison?
Magda: When h increases, the fraction value decreases and the obtained angle increases.
José: But you have to convince me that it is right! [A, 1st]

José wanted the students to identify the errors and report it orally. He believed that this explanation would help them to *self-regulate mathematics efficacy* and the ability of self-questioning about some important issues, such as how to work with the calculator:

> For instance, a student answered $R = \frac{2{,}35 \cos 1{,}5564^{\circ}}{1 - \cos 1{,}5564^{\circ}}$, so $R \approx 0{,}034$, and other student answered $R \approx 1{,}35$. I can identify that the first changed in the calculator "*Rad*" for "*Deg*". I would accept it as correct and alerted the student for the lapse. But I could not consider correct the second one. After some experiences, I could identify that the second student wrote on the calculator, 2,35 × cos 1,5564 ÷ 1 − cos 1,5564. In both cases, they are serious mistakes. [ST, 13nd]

In this assessment practice, José encourages the identification of mistakes. For example, he gave clues to the students so that they may *self-assess their performance*:

David: Are these the calculations?
José: How did you do the equations?
Alexandre: I think it was very fast, but it´s right.
José: Remember the change of signs...
David: Let´s see but this way leads us to what we wanted [A, 2nd]

In another task (Functions) after identifying a student's difficulty, José questioned him and, in some cases, the error was identified by the student *through self-assessment*:

David: It is 40 days.
José: Are you sure?
David: From 4 to 40 it is 30 plus 10.
José: But it is 4th January.
David: January
José: And the month of January has 30 days?
David: Okay, so t=41days [A, 3nd]

When students recognize difficulties to understand the mathematical situation, José do not hesitate to give them a clue to proceed, to pursue the approximation of their work to what the teacher expected them to do (*self-assessment*):

Alexandre: I am going to need help. I cannot understand.
José: Write first the formula of the area of the figure that you want to estimate, to calculate.
Alexandre: The area of the triangle?
José: Yes and now you can go on. [A, 5nd]

Reflection

José highlighted the improvements made by the students and the promotion of self-assessment as two aspects to value in his assessment practice. IT-S has raised José knowledge about the students, about the difficulties of writing and oral communication, poor connection between trigonometry and geometry content, the increase mode of understanding of mathematical content, and how to keep them motivated students.

In the first task, he realized through the help he gave the development of the student *capacity to select information*. This support, according to José, was essential to meet the first items of the task and *to motivate the students* to achieve it:

> I had to help them at the beginning, but I think that with that help they improved and accomplished the first questions. It also motivated them, it guided them to go through. [ST, 13nd].

José remembered the episode where he was confronted by the unexpected strategy followed by Magda and Rute, which he decided to not validate. He justified his decision by the need to verify the extent to which students arrived to the presented solution and *to understand the knowledge* that students have applied:

> They were confident that they were right, but when would they give up? (...) I left it unknown so they could think over it and that really amazed me, they knew what they were doing and rightly. [ST, 13nd]

In his opinion, students used strategies that work out things they learned previously. Strategies are not always predictable, but *to use these strategies with confidence* reveals effectiveness:

> Magda and Rute answered item solving it in a way I wasn´t expecting, but even so it was correct. It is like this, students use methods that I was not expecting, and we must validate them. These students knew what they were doing and were very confident about it. [ST, 13nd]

Difficulties concerning the understanding of information given in a short text are obstacles to self-assessment, which, according to José, make it harder to understand the question:

> When students read the assignment of a task and are not able to select the information, sometimes they get lost through the text. They do not even read the given information, which makes it much more difficult the approach of self-regulation strategy. They cannot use the knowledge they have, because they do not understand the worksheet. My questions sometimes do not make any sense to the students. [ST, 15nd]

One essential characteristic of this assessment practice is the existence of an understanding between teacher and students, so that they can understand the issues that the teacher poses. It is important that students understand what is asked in the tasks (on paper) or orally (inquiry in the classroom).

This reflection was important to José as it allowed him to identify different behaviors in the students: students participated more, discussed the tasks among themselves and produced work. In addition, José avoided answering directly to the questions of the students, chose to encourage them to overcome the difficulties without help, which resulted in students taking the necessary attitudes to comment on each other's ideas. This outcome has led José to reflect on his practice, making him particularly aware of the positive consequences of a reduction in the number of teacher inputs in the interaction with students.

FINAL CONSIDERATIONS

After observing and analyzing José's practices, we can infer two ways to promote self-assessment of learning mathematics: answer and performance. Self-assessment of the answer includes the action of the teacher, providing monitoring of the final work of the students, while the performance is concerned to the action to monitor processes and knowledge needed to find a solution. *Self-assessment of the answer* is provided by cognitive strategies and motivation for students who face questioning and oral feedback (Santos, 2002). Since planning, José prepares possible practices such as not correcting errors to help students to be autonomous in their cognitive strategies. He also pays attention to the need of students' confidence in doing mathematics, continuing in encouraging them during the development of the tasks. Once achieved, it leads students to increase the engagement with mathematical tasks, to develop strategies and to promote the integration of students' own ideas about learning mathematics.

Self-assessment of performance is assured by meta-cognitive strategies. It occurs to assess the efficiency of the mathematics performance of students and to encourage self-assessment of mathematical strategies to solve the tasks. José demands that their students deem complete answers, and present arguments to support their reasoning. He promotes self-assessment by not confirming the answers and guiding students to read the question again. To promote self-assessment, José also seeks to assess the depth of knowledge of mathematics and to identify errors when needed, leading students to think about the results (Quinton & Smallbone, 2010).

Although this assessment practice was new to José, he developed it over a whole school year, supported by a collaborative context, which led him to develop his self-confidence and ability in using it, recognizing positive aspects in the capacity of self-assessment of their students and, consequently, in the learning of mathematics. José assumed that his role is to support students' knowledge and learning processes, helping them to learn. Questioning, in IT-S, assumed the characteristics of oral feedback (Hodgen, 2007): to be focus on the task and not on the student; to be challenging, and to require achievable action. The IT-S practice shows progress in how students participate and engage in mathematical tasks, albeit the full understanding of the factors that increase the motivation and commitment of students with the mathematics tasks can and should be further explored.

Teachers' response to unexplained answers

Ove Gunnar Drageset

UiT – The Arctic University of Norway, Tromsø, Norway, ove.drageset@uit.no

This paper studies students' unexplained answers and how teachers respond. The data is from observations of teaching in five different classrooms at Norwegian upper primary schools. Using frameworks and concepts usable to describe classroom discourse on a turn-by-turn basis, it is found that teachers more often attend to details of how and why when responding to unexplained answers than in general. This creates opportunities to learn for the students and opportunities for teachers to gather information usable for formative assessment. It is also observed that these teachers rarely attend to details of how and why when students answers incorrectly and by this limiting opportunities to learn.

Keywords: Communication, discourse, IRE, teachers' response.

INTRODUCTION

Several scholars have studied how teachers orchestrate classroom discourse in general. While the IRE pattern (Initiation – Response – Evaluation) (Cazden, 2001; Sinclair & Coulthard, 1975) only offers two concepts describing how teachers' intervenes, others have developed concepts such as extending, supporting and eliciting (Fraivillig, Murphy, & Fuson, 1999), advocating, reformulating and challenging (Alrø & Skovsmose, 2002), and simplification, requesting details and notice (Drageset, 2014c). Such concepts enable us with tools for describing communication in more detail, and also inspect how teachers responds to different types of student interventions.

In a recent study Drageset (2014a) has described five different types of student interventions (explanation, initiative, teacher-led responses, unexplained answers and partial answers) and described how teachers responds to these (Drageset, 2015). Unexplained answers might be one of the most interesting types of student interventions because it describes student comments where the reason for the answer is not given. The aim of this article is to go one step deeper into the data and re-visit the unexplained answers and study how teachers respond to these.

This aim resulted in the following research questions: How do teachers respond to students' unexplained answers? And what might this mean for students' opportunities to learn mathematics?

LITERATURE REVIEW

Conversation analyses developed from the hypothesis that ordinary talk is a structurally organized and ordered phenomenon (Hutchby & Wooffitt, 1998) where turns are the most fundamental feature (Sacks, Schegloff, & Jefferson, 1974). The default option is that people take turns of speaking one at a time (Sidnell, 2010). But even if the turns are sequentially organized, it is not possible to characterise a conversation as a series of individual actions, instead each turn is thoroughly dependent on previous turns and individual contributions cannot be understood in isolation from each other (Linell, 1998). This means that in a study of teacher and student turns (interventions, comments, responses, answers) it gives no meaning to study or describe turns isolated from the sequence. A description of the role of each turn is in fact a description of how it relates to prior turns and how it affects subsequent turns.

One example of such a description is the redirecting, progressing and focusing framework (Drageset, 2014c) where each single teacher turn were studied related to how teachers used student comments (turns) to work with mathematics. This developed into thirteen categories in three groups describing different ways in which teachers orchestrated the mathematical discourse in the classroom. The framework describes three types of redirecting actions (put aside, advising new strategy, and correcting questions) four types of progressing actions (demonstration, simplification, closed progress details, and open progress details) and six types of focusing actions (enlighten details, justification, apply to similar problems, request assessment, recap, and notice).

Using the same data, Drageset (2014a) developed five main types of student interventions; explanation, initiative, teacher-led responses, unexplained answers and partial answers. The most frequent type of student turns were teacher-led responses, and this is an illustration of how dependent a turn might be of prior turns as teacher-led responses are more or less given by the teacher through the prior turn (typically a question). Both (Sidnell, 2010) and (Linell, 1998) describes that usually only one or a few responses are preferred or more relevant than others and when the preferred or relevant response is given no explanation is needed. Teacher-led responses are a strong example of this. Unexplained answers are different from this as the reason of the answer is not given during the turn or becoming obvious from prior turns. The answer might be obviously correct or incorrect to the teacher and skilled students, but no information about student thinking or how the student arrived at the answer is given. The answer seems to come out of a black box. One such example could be when a teacher asks how much 1/4 added to 1/3 is, and a student only answers 7/12. It is obvious that students that do not immediately see that this answer is correct would benefit from an explanation about how the student was thinking to arrive at 7/12, and according to Franke, Kazemi, and Battey (2007), making details explicit is one of the most powerful moves a teacher can make. This means that unexplained answers create an opportunity for the teacher to focus on how to calculate or why an answer is correct or incorrect, either by telling it, asking the student to tell or challenge other students to explain.

Another example of a framework describing teacher and student comments on a turn-by-turn basis is the eight communicative features suggested by Alrø and Skovsmose (2002); getting in contact, locating, identifying, advocating, thinking aloud, reformulating, challenging, and evaluating. This framework does not differ between student and teacher turns. Advocating relates to justification and student explanations, challenging relates to redirecting actions, thinking aloud relates to enlighten details and student explanations, and evaluation relates to notice, recap and put aside. By relating it does not mean that they are identical, but that these concepts seem to describe related phenomenon.

While Alrø and Skovsmose (2002) and Drageset (2014b, 2014c) both describe frameworks intended to cover all different types of teacher and student turns in the observed classrooms, others describe teacher actions related to specific purposes. One such example is the Advancing Children's Thinking framework (ACT) (Fraivillig et al., 1999). The ACT frameworks were developed by intensive studies of one skilled teacher, describing three different teacher actions; elicit children's solution methods, supporting children's conceptual understanding, and extending children's mathematical thinking. While the eliciting and supporting components focus on the assessment and facilitation of mathematics with which the students are familiar, the extending component is focusing on further development of the students' thinking.

Another phenomenon is the tendency teachers have to reduce the complexity of tasks and rules. One way of reducing the complexity is by adding information, hinting or even changing the task in order to help the student find a (the) correct answer. Brousseau and Balacheff (1997) describes this as the Topaze effect, and the category of simplification (Drageset, 2014c) essentially describes the same. Anther way to reduce the complexity is described by Lithner (2008) as guided algorithmic reasoning where the teacher takes care of the process while the students answer basic questions. Closed progress details (Drageset, 2014c) is quite similar to guided algorithmic reasoning, describing how the teacher splits up a task into smaller steps, decides the method to be used and asks students basic question (typically calculations) with just one correct answer. Such reduction of complexity is seen as a hinder for students learn and understand mathematics (Lithner, 2008), probably because it reduces their opportunities to work and struggle with important mathematical ideas. And according to Kilpatrick, Swafford, and Findell (2001), opportunities to learn is considered the single most important predictor of student achievement. It might be obvious that when students are exposed to a topic they have a better chance to learn it than students that are not. But opportunities to learn is also about how students are exposed to topics, and teaching plays a major role in creating learning opportunities through emphasis on different goals, expectation for learning, time allocated, kinds of tasks, kinds of questions, kinds of responses accepted, and the nature of the discussions (Hiebert & Grouws, 2007).

The above frameworks relate to how learning can be fostered or hindered, and Wiliam (2007) offers five key strategies related to assessment for learning. One is to clarify and share learning intentions and criteria for success, a second is to engineer effective classroom discussions that elicit evidence or learning, a third is to provide feedback that moves the learners forward, a fourth is to activate students as instructive resources for one another, and a fifth is to activate students as owners of their own learning. The frameworks offered by Alrø and Skovsmose (2002), Drageset (2014b, 2014c) and Fraivillig and colleagues (1999) provides us with tools to describe mathematical discourse in the classroom in detail on a turn-by-turn basis. But there is still an open question if and how this can help us understand more about how teachers can engineer discussions in such a way that it elicits evidence for learning, how the feedback can more learners forward, and how to activate students as owners of their own learning. It is also an open question how such framework can help us describe how the opportunities to learn vary in quality between different situations and classrooms. The devil might lie in the details, and in a recent study Drageset (2014b) studied how students explained and teachers responded. This resulted in a description of three different types of student explanations; explaining how, explaining why and explaining concept. But even if the three types of student explanations were quite distinct, no major differences were found in how teachers responded to these. Looking for further detail, this article will look deeper into how teachers respond to students' unexplained answers and what this might mean for their opportunities to learn mathematics.

METHOD

This study is based on the same data that were used to develop the redirecting, progressing and focusing framework (Drageset, 2014c) and the five types of student comments (Drageset, 2014a). Based on a survey of 356 teachers, five teachers from upper primary (year five to seven, students aged 11 to 14) were selected for further study. These five teachers had a variation related to the survey constructs of mathematical knowledge for teaching and beliefs about teaching and learning. They all had several years experience as mathematics teachers and were educated as general teachers, which is the typical education for Norwegian teachers. All mathematics teaching for one week was filmed in each classroom (typically four lessons of 45 minutes). The camera followed the teacher, and a microphone attached to the teacher recorded all conversations in which the teacher was involved.

During the development of the frameworks describing teacher and student comments every turn were studied, describing its role in the conversation, grouping similar turns and developing categories gradually using a grounded theory approach. In the study reported in this article, the students' unexplained answers were re-visited, inspecting how the teachers responded to different types of unexplained answers in different ways. Unexplained answers are the ones where no information is given about how the student reasoned. This means that important details are hidden for the teacher and fellow students. An overview over different types of teacher responses to unexplained answers give a deeper insight into how these teachers use, or not use, the opportunities to make the hidden details explicit.

FINDINGS

By simply counting different types of teacher responses to unexplained answers and overall responses in the five classrooms, some interesting differences occur. As Table 1 illustrates, the five teachers tend to use progressing actions less frequently when responding to unexplained answer, and instead uses redirecting and focusing actions more often. A first impression is that the teachers uses the opportunity to focus on the answer more often when it is unexplained, but also more often tries to change the students approach by redirecting.

	Redirecting actions	Progressing actions	Focusing actions
Responding to unexplained answers	22%	36%	42%
Overall response to student comments	11%	55%	34%

Table 1: Responses to unexplained answers versus overall responses

	Redirecting actions	Progressing actions	Focusing actions
Responses to unexplained and *correct* answer	2%	17%	36%
Responses to unexplained and *incorrect* answer	20%	11%	3%
Responses to students *unable* to answer	0%	8%	3%

Table 2: Responses to unexplained answers separated for correct, incorrect and unable to answer

In order to understand what this means it is necessary to go one step deeper. The unexplained answers could be divided into three distinct groups or sub-categorise. One group is the correct answers that come without any explanations what was done, how the student was thinking or why this is thought to be correct. Another group is the incorrect answers, which vary from those close to correct to those where the student simply chooses a strategy than cannot work, and also these have in common that no information about the solution process or thinking is given. The third group of answers is those were the student is unable to answer or come up with a suggestion and where there is no information about why the student struggles. As Table 2 illustrates, these sub-categories gives us new information.

One striking difference is how redirecting and focusing actions follows different types of unexplained answers, which illustrates how a turn is thoroughly dependent of previous turns (Linell, 1998). It might not be surprising that redirecting actions mainly follows incorrect answers or strategies, as there is less need to redirect correct answers. Then it might be more interesting that focusing actions almost exclusively follows correct answers and rarely follows incorrect answers.

In general, teachers use redirecting actions to guide students towards other strategies, progressing actions to help students progress towards an answer, and focusing actions to make students work with, or to point out, mathematical ideas. So far we have observed that redirecting, progressing and focusing actions are used more or less often based on how the prior turn looks like. But which types of redirecting, progressing and focusing actions were used, and which types of such actions are used more or less frequently?

Just over half of the unexplained answers were correct. The main response to these was the focusing actions, and especially requesting students to enlighten details or requesting justification. When a teacher requests students to enlighten details the teacher typically asks how or what ('how did you find that answer?', 'what did you think when you solved this task?'). This is about making details explicit, which according to Franke and colleagues (2007) is one of the most powerful moves a teacher can make. In addition to this, such information is the basis on which a teacher can make formative assessment. A justification is typically requested by asking 'why is this correct'. This is different from requesting students to enlighten details as a relevant answer to why something is correct involves mathematical argumentation and not just a description of what is done to reach the answer. Also justifications are important for other students to understand or discuss. Together, both requesting students to enlighten details and to justify their answers are about making details explicit, which again might create opportunities to learn how to solve, think and reason. Requesting justifications are also vital for the teacher to get insight into a student's thinking and sense making which again is necessary for the teacher to be able to carry out formative assessment. It is particularly interesting to see that these five teachers' responds with requests for justification three times as often following a correct unexplained than they do following student comments in general.

About one third of the unexplained answers were incorrect, and as Table 2 illustrates the teacher responses changes strongly. The most typical response was to redirect students towards another strategy, and the main way this was done was by asking correcting questions. Typically, these were questions that involve a correction such as 'yes, but what if…'. It is hardly a surprise that teachers tries to guide students when they answers incorrectly. However, it is interesting to see that they are rarely exploring student thinking or reasoning when answers are incorrect. By only exploring thinking and reasoning when answers are correct some opportunities to learn are lost, for example since it is difficult to involve students in real discussions if only the correct are presented. Also, the teachers loose access to vital information about what students think and why they are not reaching a correct answer. This seems to tell us that these five teachers do not think such information is of any use to themselves or to other students.

The least frequent of the unexplained student answers were when the students were unable to give an answer. The teachers typically responded using the progressing actions of simplification and closed progress details and the focusing action of notice. Simplification is about making the task easier so that the student might be able to progress. This typically involves extra information and hints that reduces the complexity, and sometimes the teacher changes the entire task to create what Brousseau and Balacheff (1997) labels a Topaze effect. Closed progress details are rather equal to guided algorithmic reasoning (Lithner, 2008) and describe a situation where the teacher takes the responsibility of the process while the student contributes with answering basic tasks. Simplification and closed progress details describes two different ways to reduce complexity. It is not surprising that teachers try to help students that are unable to answer by reducing the complexity, and this might even be a good idea. The danger is when teachers consistently reduce complexity of tasks because then the students loose opportunities to learn the important mathematical ideas at their grade or level. The focusing action of notice is different, as it describes actions where teachers point out important information during task solving. This seems to be done in order to help students remember what we already know and can use, or help them to get back on track. It is also typical that notice is used to point out important arguments or things to remember.

In addition to the above, Table 2 also illustrates that a relatively large part of teacher responses to correct and incorrect answers are progressing actions. But looking into the different types of progressing actions does not give much information, it only reveals that it is used less responding to unexplained answers than in general.

CONCLUSION

The aim of this study was to look closer into students' unexplained answers and how teachers respond to them. Unexplained answers are defined to be those where information about the solution strategy or student thinking is not observable, neither during the student turn nor during prior turns. Using the redirecting, progressing and focusing framework (Drageset, 2014c) it was possible to see that teachers tended to more often use redirecting and focusing actions and less often use progressing actions than in general. By dividing the unexplained answers into three distinct sub-categories (correct, incorrect and unable) it became possible to observe that most redirecting actions came as a response to the unexplained answers that were incorrect and most focusing actions came as a response to the correct ones. By looking into the different types of redirecting, progressing and focusing actions it was found that as a response to correct answers teachers typically requested students to explain how and what (enlighten details) and why (justification). Also, it was found that responding to incorrect answers teachers typically guided the students by asking correcting questions, and when responding to students unable to answer the teachers typically reduced the complexity of the task (simplification and closed progress details) or pointed out important elements or earlier findings (notice).

Kilpatrick and colleagues (2001) states that opportunities to learn are the single most important predictor for student achievement. If so, one should look at which opportunities are given during discussion and not. By requesting details (enlighten details and justification) the teachers make these explicit for other students to reflect upon, discuss or ask, and for the teacher to understand the students thinking, reasoning and understanding. Making details explicit is important for student learning in general (Franke et al., 2007), and this is about creating opportunities to learn the important mathematics by attending to thinking, strategies and reasoning. But it is worth to emphasise that these teachers often requested such details when responding to an unexplained answer that was correct, and rarely did it when the answer was incorrect. This means that opportunities were lost, both for students to explore the reasons for the error, and for the teacher to gather information about students incorrect or incomplete thinking as a basic for formative assessment. Also since students need to struggle with mathematical ideas to learn (Hiebert & Grouws, 2007), something important might be lost if the students are only struggling with understanding what somebody else already understands and rarely have to struggle with something incorrect or incomplete and how to develop from there.

Developing student questioning when problem solving: The role of sample student responses

Sheila Evans and Malcolm Swan

University of Nottingham, School of Education, Nottingham, UK, Sheila.Evans@Nottingham.ac.uk, Malcolm.Swan@Nottingham.ac.uk

This paper describes intervention resources designed to provide opportunities for student self-regulation, with a particular focus on setting subgoals when problem solving. Each task includes a range of pre-written inter-related "sample student responses" that expose students to multiple perspectives on an unstructured non-routine problem. After students attempt the problem they are given the responses to collaboratively complete, critique and compare. We explore students' capacity to adopt another person's (the sample student's) goals in order to complete a solution, and their capacity, through the use of comparison, to identify worthy criteria when critiquing the completed solutions. We then reflect on how we can make subsequent improvements to the resources.

Keywords: Problem solving, comparing solutions, peer assessment.

INTRODUCTION

Many studies cite planning and monitoring as key discriminators for problem solving success (e.g., Schoenfeld, 1992; Carlson & Bloom, 2005). During the initial planning phase, the subgoals students set determine the mathematical and self-regulating strategies used. Novice problem solvers often set vague, unstructured goals or their goals are flawed (Juwah et al., 2004). They often use naïve, inefficient strategies (e.g., trial and error), rather than considering the more powerful methods at their disposal. They pursue unfruitful or inefficient lines of enquiry relentlessly, without stopping to consider alternative strategies (Schoenfeld, 1992). Furthermore, they remain uncertain of the criteria to judge the quality of their work (Bell et al., 1997), other than checking the correctness of the answer. In contrast, expert problem solvers spend time setting hierarchical goals (Schunk & Zimmerman, 2012), carefully monitor their progress against these goals, and persist in the face of obstacles (Schunk & Zimmerman, 2012). They routinely use these goals to step back and ask themselves or their partner questions such as 'Where is this strategy going?', 'Should it be so complicated?', or 'Does this solution make sense?' (e.g., Schoenfeld, 1992). Answers to which may prompt a change of direction in order to improve, for example, their solution's appropriateness, elegance, efficiency or generalizability. Furthermore, using subgoals makes progress visible, and their realization may sustain motivation to persist (Schunk, 2006).

Empirical studies suggest that students might develop these self-regulating skills by critically reflecting on the work of others (e.g., Pintrich & Susho, 2002). In so doing, students' criteria for success are made visible for scrutiny (Black & Willam, 1998), differences surface, and opportunities arise for students to reflect on, and adapt their success criteria to accommodate new values. Through a series of case studies Juwah and colleagues (2004) found that providing students with opportunities for peer (and self) assessment encouraged the identification of goals implicit in solutions and judgments about how these goals related to their own solutions to a problem.

We have carefully designed resources intended to help students develop their self-regulating skills. In these resources, students are asked to interpret, complete, compare and critique pre-prepared, handwritten "sample student responses" to non-routine, unstructured problems. The responses are designed to simulate different ways students may solve a problem (Evans & Swan, 2014) and provide opportunities for students to use and reflect on the goals set by others. We begin by explaining the theory and method behind the design of these resources, then discuss how our intentions were interpreted in the classroom and detail the subsequent improvements.

THEORETICAL BACKGROUND

This study is rooted in a design research paradigm. Design research involves both the development of intervention resources and studying what happens when they are enacted in the classroom. Accordingly, the design process of iteratively designing, testing and revising a resource and the research process of conjecturing, collecting, analysing data and contributing to theory, occur simultaneously and in parallel. Thus the development of an intervention forms a symbiotic relationship with the development of the research. Within this flexible environment, both the intervention and the initial research questions or conjectures may be refined. This flexibility is particularly beneficial when the research base is thin and provides only limited guidance for the design of an intervention (McKenney & Reeves, 2012).

The design of the resources emerges from the findings from a large design research project (Swan & Burkhardt, 2014) but with some distinguishing features. Namely, the pre-written sample student responses are all incomplete. Thus the context has been mathematized; the students' task is to complete the mathematics and communicate results. This design structure provides students with an opportunity to ask themselves questions about each sample student's goals. Questions such as: 'What is this student doing?' and 'Why are they doing that? and 'What should they do next?' This awareness of goals set can positively influence their own performance when solving problems, promoting self-regulatory skills and productive goal-directed action, engendering persistence in the face of obstacles (Schunk & Zimmerman, 2012). After completing solutions, students attempt to *explicitly* compare and connect them. To prevent students from simply comparing handwriting or checking for mistakes, responses were short, accessible and error-free (Evans & Swan, 2014).

Comparing artifacts is routine practice in other disciplines. For example, English Language students may be asked to compare newspaper articles describing the same event. The literature suggest this practice, particularly if supported by a meaningful framework, focuses students attention on similarities and differences, and so facilitates the noticing of more features than if artifacts were viewed separately (e.g., Gamer, 1974; Chazan & Ball, 1999). Accordingly, in this study, students are asked to compare alternative approaches to non-routine unstructured mathematics problems. Thus encouraging students to ask themselves questions such as: 'What are the differences between these two responses?'; 'How do these differences benefit or constrain the solution?'; 'Why do *x* rather than *y*?' By encouraging students to not only to make sense of a solution but to make judgments about its quality, may shift their perspective from viewing solutions as a process, to viewing them as objects to be evaluated. This shift can promote deeper understanding of the mathematics (Sfard, 1991).

We know from the literature that transferring learning from one problem situation to another can be challenging as students often form highly concrete, context-specific, understandings of the solution (e.g., Gentener, 2003). This may be partially addressed by exposing students to multiple solutions, particularly if these solutions are compared rather than considered individually (e.g., Catrambone & Holyoak, 1989). By comparing students' focus on structural, often abstract, commonalities rather than idiosyncratic, situation-specific, surface features (Gentener, 2003). A study within mathematics education supports these findings. The study (Rittle-Johnson & Star, 2007) likewise focused on transferring methods studied in one context to another. Students learnt to solve equations by either comparing alternative methods or by reflecting on each method separately. The students in the 'compare' group made greater gains in procedural knowledge and flexibility to solve routine problems in multiple ways and comparable gains in conceptual knowledge. Although the studies on comparing solutions did not involve unstructured, non-routine problems, (we could locate no studies of this kind) we conjecture that comparing solutions to these types of problems could help to improve students' 'flexibility' when solving other problems. Thus increasing their capacity to monitor their progress against interim goals as their solution is slowly created.

METHOD

The resources for each lesson include a task and a detailed teacher guide. Based on materials from a larger US project (Swan & Burkhardt, 2014), the interventions represent the initial phase in a design research cycle of the UK study. Feedback from this phase will inform the refinement of resources, methods used for data collection and analysis for the UK study. The intervention lesson described here was the first in a series of four taught to 30 students in a top (advanced) set Year 9 class in a UK secondary school. The students had little experience of working with unstructured problem solving tasks or sample student responses, however, the teacher had taught many such tasks

Structure of the intervention lesson:

— Students worked on the task in a prior lesson. This provided the teacher with insight into the ways students were understanding and representing the problem.

— After the teacher briefly reintroduced the problem to the whole class, students worked first individually then in pairs, completing sample student responses.

— Because students were not used to comparing responses, the teacher briefly explained, using a non-mathematical example, the benefits of making comparisons.

— Students then glued the now completed responses to a poster and interpreted, completed and compared the solutions.

— In a whole-class discussion students reviewed what they had learned.

Figure 1 shows the problem used. Figure 2 shows the pre-written student responses. We carefully designed the responses to encourage students to make connections between approaches in order to create or strengthen networks of related ideas (Silver et al., 2005) and enable students to achieve 'a coherent, comprehensive, flexible and more abstract knowledge structure' (Seufert et al., 2007).

We summarised students' individual attempts to solve the problem. However, the prime source of data is the 15 student posters, each produced by 2 students. Throughout this paper, the word 'set' defines a group of assessment comments on 1 poster about 1 response. The word 'response' refers to the incomplete 'sample student' work, and 'solution' refers to a (real) student's attempt to complete a response. We used a grounded theory approach to assess the 45 sets of assessment comments made by the 15 pairs of students about the 3 responses. To interpret the comments we used 3 themes corresponding to the 3 tasks students under-

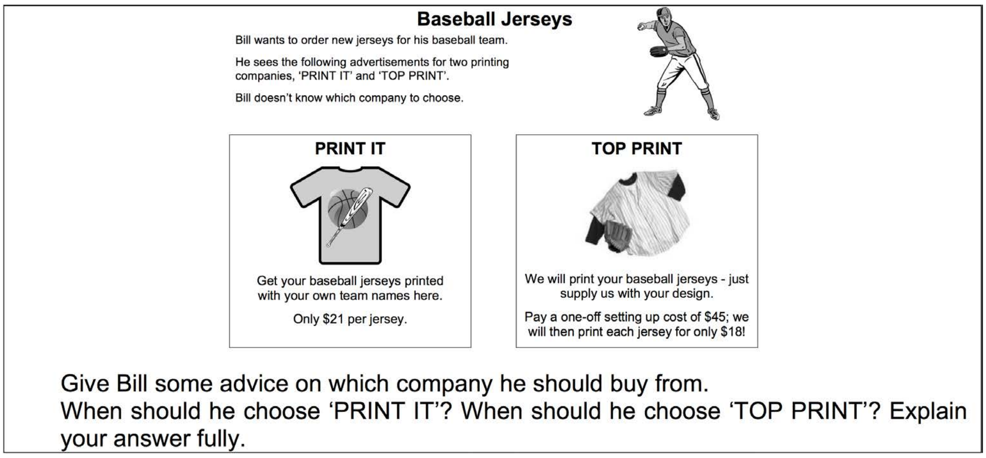

Figure 1: The problem

Dylan

Print it cost $21n
Top Print cost $45+18n
$21n = 45 + 18n$
$3n = 45$
$n = 15$
n = 16 Print it $336 Top Print $333

Cath

took: how students completed; assessed and connected the sample student responses.

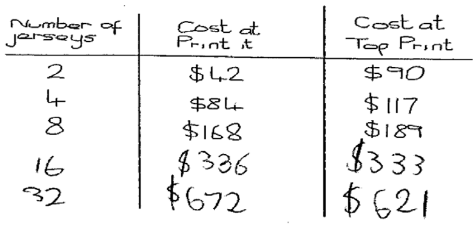
SECTION 4: RESULTS AND DISCUSSION

When initially attempting to solve the problem one student used a graphical method and another an algebraic method. The rest of the class used a form of 'trial and improvement'. This concurs with our earlier research (Evans & Swan, 2014) that suggests students often prefer this method rather than, for instance an algebraic strategy. Trial and improvement can forge a way into the problem but the information available within answers are often limited. For instance, trends may not be revealed. Furthermore, most students failed to effectively communicate their answer to 'Bill', thus overlooking the purpose of the problem. These results agree with the literature that suggests students often disconnect mathematical representation from the context of the problem and make little attempt to reconnect them (e.g., Friel, Curcio, & Bright, 2001). As trial and improvement was the commonly used strategy, students were to be exposed to two *new* approaches and a familiar one in the intervention lesson.

How students completed the responses

Table 1 summarises how pairs of students completed each response and attempted to advise 'Bill' (e.g., 'Top Print is cheaper after 15 jerseys').

Despite (or possibly because of) most students figuring out the correct answer on their own, some failed to complete the sample student responses. For instance, one pair of students added two more rows to Cath's table (Figure 3).



Number of Jerseys	Cost at Print it	Cost at Top Print
2	\$42	\$90
4	\$84	\$117
8	\$168	\$189
16	\$336	\$333
32	\$672	\$621

Figure 3: Response of two students

These students understood the context, but responded in a superficial way, by finding something procedural to do. They followed the pattern in the first column, and used the procedures for calculating costs correctly, but did not engage in solving the problem using Cath's method. Thus students did not attempt to understand and adopt Cath's goals. This may be due to the teacher not fully explaining the purpose of the activity at this stage: once complete the solutions were to be critiqued and connected.

Consonant with students' original attempts to solve the problem there was a notable lack of attempts to interpret their solution in terms of the context (21 out of a possible 45. Of these, only 3 pairs explicitly advise 'Bill', the remaining 18 simply explained what the solution showed). However, again not fully understanding the purpose of the activity may discourage students from providing all 3 answers (12 out of the 15 pairs of students did attempt to recontextualise at least one of their solutions). Students may assume they would simply be repeating themselves.

How students assessed the responses

32 of the 45 'sets' of assessment comments suggested students were making direct comparisons between the responses. For example, comments such as 'it is clear to see the pattern [Ezra's response] compared to Dylan's'. There were numerous other assessment comments that

		Did/did not attempt to advise Bill
Dylan (Algebraic)	4 pairs of students substituted $n = 15$ into the expressions $21n$ and $45 + 18n$. Most of the remaining pairs substituted a combination of $n = 14$, $n = 15$ and $n = 16$ into the expressions. Most did not explain their work.	6 / 9
Cath (Numerical)	7 pairs of students figured out the prices of the jerseys when $n = 14$, $n = 15$ and $n = 16$. Others figured out between one and four prices. 9 pairs of students figured out the cross-over point, $n = 15$. Usually the existing table was extended to accommodate these figures.	7 / 8
Ezra (Graphical)	All pairs of students successfully plotted a 2nd line on the graph. There was very little written work.	8 / 7

Table 1: Summary of how students completed the sample student work

implied students were making comparison. For example one pair made the two comments 'only talked about one particular value [Dylan's response] and 'showed the full range of results in a graph [Ezra's response]. Our evidence suggests that most students were not simply considering the attributes of individual approaches to the problem, but were using comparison to draw out the relative advantages and disadvantages of each. Most students (33 of the 45 sets) were able to make at least two comparative comments on each response and only 8 'sets' made totally positive or totally negative comments; indicating students were using a range of questions when assessing the work and did not feel compelled to declare one solution as the 'correct one'. This behaviour contradicts the commonly held assumption that mathematical solutions always consist of one right response amongst a hazardous field of wrong ones. It appears that as students compared solutions, similarities, differences, advantages and disadvantages were revealed, discouraging the emergence of a 'best' solution. We used 5 categories to investigate the nature of the assessment comments:

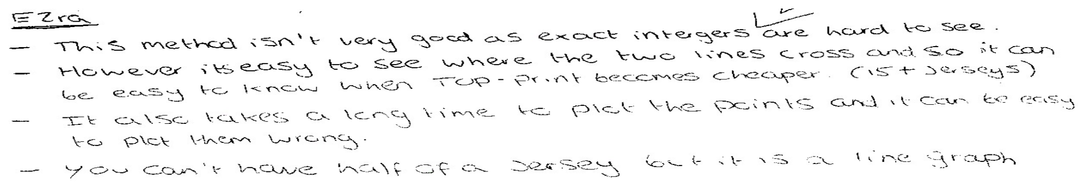
- *Assessments about clarity*. These comments referred to the personal challenges of understanding the response. For example, 'Easiest to understand'
- *Assessments about accessibility*. These comments referred to the personal challenges of using the method. For example, 'Cath's method may take a while to do'.
- *Assessment about fitness for purpose*. These comments referred to students' assessment of the legitimacy of the response given the context of the problem. (E.g., 'hard to find an exact price, big scale, so pretty much guess work'.)
- *Assessment about the incompleteness of the method*. These comments arose despite students being asked to complete each solution. For example, 'doesn't answer the question'.
- *Undefined assessment comments*. These were comments we were unable to categorise. For example, 'easiest'.

We then categorised all assessment comments into those expressing advantages and those expressing disadvantages. The results of the coding are given in Table 2.

A large proportion of assessment comments drew on a student's personal perspective (9 + 17 = 26) rather than on whether or not the solution was fit for purpose. For example, 'Quite complicated if you don't get it'. This was unsurprising. What students' notice in a solution and the questions they ask themselves about it are often influenced by past experience of mathematics classes. In a traditional concept-focused classroom a problem is often used by the teacher to introduce a new technique, then students practise and illustrate the technique using similar problems; what Burkhardt and colleagues (1988) calls 'exposition, examples, exercises.' It follows that students may assume, when critiquing solutions, their task is simply to decide if they understand it and if they could use the method to solve other problems. Accordingly, students may ask questions such as 'Do I understand this method?' or 'Do I have the maths needed to undertake this method?', or 'Would it take me a long time to solve a problem using this method?' These are legitimate questions, however they do not critique the mathematics used, nor the validity of the solution within the context. To do this, students need to ask further questions. Questions such as 'Is this method efficient, elegant, generalisable?' and 'Is this method suitable for the given context?' and 'Is the answer appropriately communicated?' We were encouraged to note 57 comments did answer questions such as these. For example, Figure 5.

Assessment about:	**Algebra (Dylan)**	**Table (Cath)**	**Graph (Ezra)**	**Total**
clarity	3 (1,2)	5 (4,1)	1 (1,0)	**9 (6,3)**
accessibility	7 (7, 0)	5 (0,5)	5 (1,4)	**17 (8,9)**
fitness for purpose	11 (1,10)	16 (9,7)	30 (17,13)	**57 (27,30)**
incompleteness of method	3 (0,3)	0	0	**3 (0,3)**
Undefined	4 (3,1)	7 (5,2)	1 (0,1)	**12 (5,3)**
Total	**28 (12,16)**	**35 (18,15)**	**37 (19,18)**	**98 (49,49)**

Table 2: The numbers in brackets refer to the (advantages, disadvantages)



Ezra
- This method isn't very good as exact integers are hard to see.
- However its easy to see where the two lines cross and so it can be easy to know when Top-Print becomes cheaper. (15+ Jerseys)
- It also takes a long time to plot the points and it can be easy to plot them wrong.
- You can't have half of a Jersey but it is a line graph

Figure 5

Now we will analyse the nature of these assessments. Rather than critiquing the graphical solution from a personal perspective (6), students clearly preferred to focus on the suitability of the graph within the context (30). The positive comments include: 7 on how the graph allowed them to easily see a trend, 4 on the wide range of costs, and 3 non-specific comments about the appearance of the graph (e.g., 'easy visually to see'). There were 11 negative comments about the graph's lack of accuracy due to the scale (e.g., 'hard to find an exact price, big scale so pretty much guess work'). The tabular method drew 16 comments about the appropriateness of the solution, including positive comments about the accuracy of the costs (2), ease of comparing companies (3), and presentation of specific costs (2). Negative comments referred to the lack of a range of costs (2) and poor visual representation (2). Negative comments about the algebraic method referred to lack of values (4) and lack of detail about which company was cheaper (3). Thus we can detect themes across all three solutions: the accuracy of the work, the range of values used, and the ease of comparing costs. It is conceivable that these themes were instigated through the act of explicitly comparing solutions. For instance, an advantageous property noticed in one solution, may then be assessed in another.

How students connected the responses

Most comments about how solutions were linked were generic. For instance, 'The two solutions both used the same formula.' This concurs with research suggesting the need for instructional prompts that draw students' attention to how methods are linked (e.g., Chazan & Ball, 1999). However, time was another important factor contributing to the quality and number of comments on how responses could be connected. Students simply did not have enough time to complete the task.

CONCLUSION

To effectively complete the responses students needed to adopt and use each sample student's goals. To effectively critique each solution they needed to recognise the goal of the task (the comparison of the companies) and the role they were to adopt (advisers to 'Bill'). Students struggled with these activities. For instance, when completing responses students were able to follow algorithms, but sometimes failed to engage with their purpose, rendering insubstantial solutions. Furthermore many students failed to effectively communicate their results to the intended audience, 'Bill'. These findings highlight the difficulties students have recontextualising the mathematics both as they complete a solution and as they communicate the results. Possibly indicating some students were not asking questions such as 'Why am I figuring out this value?' or 'How does this result help Bill?' To ask these questions students need to engage in the 'student's' hierarchical goals.

The findings do support the perspective that comparing properties of solutions to problems does indeed draw out the affordances and limitations of each but without compelling students to decide which one is correct. Students often critiqued solutions from a personal viewpoint, focusing on whether they understood the method and whether they would be able to use it again. However, many students did also critique the suitability of each sample student response within the context of the problem. This was particularly the case with the graphical response.

Although we cannot make any generalisations beyond this classroom setting the findings from this study together with feedback from trials of other lessons will help shape a further iteration of all the resources. It is clear students need more support when undertaking these activities. For example, to help students complete the responses we will suggest teachers provide opportunities for students to reflect on the goals 'students' have set. Furthermore, if teachers ensure students understand the purpose of this activity, then they may be motivated to not only complete the mathematics, but also interpret it in the context of the problem. In so doing, differences may emerge in information gained from each completed solution.

This in turn may help students undertake the next activity, critiquing the solutions.

We endeavour, through the resources and teacher instruction to further raise awareness of what gets noticed when critiquing, and whether what is noticed and critiqued is of relevance to the context. This may help students move from simply noticing features of the solutions from a personal perspective to noticing them from the perspective of the context of the task. In this case, the 'sample student's' and 'Bill's' perspective. For example, it may require just a small shift in perspective to move from asking questions such as 'How long would this method take me to do?' to 'Is this an efficient and elegant method?' We also plan to design follow-up task in which 'Bills' goals are slightly altered. Students will need to think carefully about the criteria for success when planning a strategy and monitoring its progress as it unfolds on the paper or in discussion. We will continue to frame these student tasks within the activity of comparing solutions. We regard this as a successful design strategy.

Problem solving teaching practices: Observer and teacher's view

Patricio Felmer, Josefa Perdomo-Díaz, Valentina Giaconi and Carmen G. Espinoza

University of Chile, Center for Mathematical Modeling and Center for Advanced Research in Education, Santiago, Chile, pfelmer@dim.uchile.cl

In this article, we report on an exploratory study on teaching practices related to problem solving of a group of 29 novel secondary mathematics teachers. For this purpose, two independent instruments were designed, the first one is based on lesson observations, and the second one is a questionnaire answered by teachers about their teaching practices while working on non-routine problem solving with their students. For each instrument, we perform a statistical analysis to define relevant dimensions regarding problem solving teaching practices and we compare these new dimensions. We find that results from the two instruments are coherent in the case of quantity of problem solving in lessons and quality of teaching practices. These results are encouraging for further studies in this direction.

Keywords: Problem solving, observed teaching practices, self-reported teaching practices.

THE IMPORTANCE AND CHALLENGE OF ANALYZING TEACHING PRACTICES

No doubt that the analysis of teaching practices is crucial for many aspects of education, for teacher, school or program evaluation, for more general purposes of defining and understanding good practices or for theoretical studies aiming to understand the teaching-learning process.

Methods used to collect teaching practices data have an ample variety, for example teachers/students reports, lesson observations and questionnaires, just like the type of analysis done with these data that could be qualitative, quantitative or a vast variety of mixed approaches. Having all of them advantages and disadvantages, depending on the type of collected data and the analysis method used, the research could show in-depth, small-scale results as in the case of qualitative analysis of videotaped lessons, or a more general view of teaching practices as in the case of quantitative analysis of teachers' surveys.

In particular, the analysis of teaching practices through questionnaires is of great value since it allows studies with a high number of teachers. PRIMAS project is an example of this analysis, in which teachers' self-reported practices in inquiry based learning in different countries are described (Engeln, Euler, & Maaß, 2013). On the other hand, teaching practices observations by a research team, without the teacher intervention (external analysis), has been widely used in mathematics education too. These analyses have been conducted with different purposes: to study a specific feature of teaching and compare different types of teaching practices in relation with this feature, for example the mathematical quality of instruction (Hill et al., 2008) or the presence of mathematical elements as definitions, properties or processes (Badillo, Figueras, Font, & Martínez, 2013), to identify teachers' participation patterns in the class (Skott, 2013) or to analyze attributes of teachers that could affect their teaching practices, for example their beliefs about mathematics and teaching (Stipek, Givvin, Salmon, & MacGyvers, 2001).

Nevertheless, how self-reported practices and externally observed practices are related is not an obvious issue. Important differences may come from distinct conceptions of "practices", that is, the researcher has something in mind which differs from what teacher have in mind or they may come from biased answers based in social desirability.

To sum up, there are many important reasons to analyse teaching practices and, at the same time, collecting data to do that is a critical point (Maaß & Artigue, 2013).

Our interest in methods for collecting teaching practices data is in the context of a R&D project related with mathematics teacher's professional development on problem solving practices. In this project, teachers design and implement problem solving lessons with their students, which are later discussed jointly between teachers and researchers. In the context of two previous projects we have designed two instruments to collect data from practices from a group of secondary mathematics teachers: a Lesson Observation Rubric (LOR) and a Questionnaire about Problem Solving (QPS). We are interested in the information that can be obtained from each instrument separately and we want to explore on the information that can be drawn using both instruments at the same time.

The research question of this study is: Which are the dimensions that characterize teaching practices in relation with problem solving when using each of the two instruments and how do they correlate? To answer this question is relevant from a data collection methodological point of view and also for deepening in the understanding of the teaching practices related with problem solving.

TEACHING PRACTICES RELATED WITH PROBLEM SOLVING

The framework for designing research instruments and analysing data to answer our research question includes a conception of problem and of teaching practices that promote students' work in a mathematical environment.

We agree with Schoenfeld (1985) considering that

> Being a problem is not a property inherent in a mathematical task. Rather it is a particular relationship between the individual and the task that makes the task a problem for that person [...] if one has already accessed to a solution schema for a mathematical task, that task is an exercise and not a problem. (p. 74)

Other characteristic that some authors give to a problem is that it needs more time to be solved (e.g., Kloosterman & Stage, 1992).

Our experience with in-service teachers shows that some teachers think that a problem is just a math exercise contextualized in the "reality", and that many teachers use the term "non-routine problem" to refer to what Schoenfeld call "problem". In order to face this common misconception among Chilean teachers, the QPS teachers answered starts with the following definition:

> We are going to consider that a non-routine problem is one where the person that solves it doesn't know a strategy or algorithm to solve it. Some of the characteristics that non-routine problem usually have are: They need more reflection and time than regular problems or exercises; they cannot be solved with a simple rule or just remembering and applying a known fact; usually they can be solved using different strategies; they can have one or more solutions; they are challenging for the person that is solving them and they don't have to be confused with problems with real context, to have or not real context doesn't determine a non-routine problem.

In relation with teaching practices the key pedagogical aspect of problem solving tradition is that students have to think mathematically. To accomplish this it is necessary to have student centred teaching practices and a climate that support for the autonomy. Swan (2006) uses the term "student-centred' to describe practices where

> [T]he teacher takes students' needs into account when deciding what to teach, treats students as individuals rather than a homogeneous body, is selective and flexible about what is covered and allows students to make decisions, compare different approaches and create their own methods. Mathematics is seen as a subject open for discussion. It is not necessary to cover everything on the syllabus and time may be taken to explore and discuss. (p. 63)

METHOD

Participating teachers

This study considers teaching practices from 29 novel secondary mathematics teachers (between 1 and 4 years of teaching) randomly selected from graduates of three of the Chilean reference universities for teacher formation (10 teachers from two of the universities and 9 from the other one).

Each teacher selected a class, in which he/she was teaching, to be observed during three consecutive lessons. The level of each class went from 7th to 12th and the topic treated during the observed lessons was varied, like numbers, algebra or geometry. Some months later (from 6 to 12 months) teachers answered a questionnaire about their teaching in relation with problem solving practices taking into consideration the same class that was observed.

Classroom observation

For each teacher, three consecutive lessons of the selected class were observed and coded (2 live lessons and 1 video recorded lesson), completing 270 minutes of observation. It was chosen to observe only three lessons since, according to methodological research findings; no significant information is obtained by observing more than 3 lessons (Hill et al., 2008). A lesson observation rubric (LOR) was designed to code lessons by sections of 7.5 minutes. The LOR is divided in three main parts described next, with 14 practice indicators in total.

Work dynamics: in this part, the rubric identifies if time is dedicated to mathematics or not and the general way teacher and students interact. It is a first approximation to know if the lesson focus is on the teacher or the students. There are 5 indicators: down time (DT), direct instruction (DI), individual work (IW), group work (GW) and class work (CW). Each 7.5 minutes the indicator which is most observed is marked.

Class management: in this part, more specific characteristics of teaching practices are collected using 7 indicators: teacher does not participate (TNP), teacher makes questions (TMQ), teacher returns responsibility (TRR), teacher does not answer (TNA), teacher gives solutions (TGS), non-routine intervention of a student (NRIS) and teacher promotes discussion (TPD). When one of these indicators was observed during a segment it was marked.

Type of task: in this part, the type of mathematical task was collected using 2 indicators: routine task (RT) and non-routine task (NRT), depending if student were performing routine or non-routine tasks. Just one of them was marked in each time segment except in the case both were present during a very similar amount of time.

For our analysis we use all variables described above as percentages. In the case of DT, DI, IW, GW, CW, RT and NRT they are the percentage of segments were the indicator was marked, for example if for a teacher 9 segments out of 36 were marked non routine task, his score in NRT was 25%. In the case all the other variables, they are percentages of the total number of variables marked in the three lessons, for example if TRR was marked 3 times in the 36 segments and all other variables were marked 15 times, TRR was 20%

Questionnaire (QPS)

The questionnaire answered by teachers (QPS) is designed to measure the quantity and quality of problem solving (PS) activities used by them. The QPS starts with the definition of non-routine problem indicated in the framework (section 2) and it requires teachers to answer considering that definition. The questionnaire was answered through an online form sent by e-mail.

Quantity of PS was measured asking about the frequency of use of PS in their lessons with one item with options from 1 (never) to 5 (almost every lesson). Quality of PS was measured with 19 items (see Appendix A) based in scales of autonomy supportive climate (Leroy, Bressoux, Sarrazin, & Trouilloud, 2007) and scales to measure the level of student-centred approach and teacher-centred approach (Swan, 2006). Also some items were created to complete our view of a good problem solving activity as indicated in the framework. The teachers were asked to answer each question with the following prompt "When I use non-routine problems". Each item in this part has 6 options in a Likert scale ranging from 1 (never) to 6 (always).

Statistical methods

To summarize the variables from each instrument we made a Principal Components Analysis. The purpose of this analysis is to create interpretable and reliable scales that allow us to simplify and organize the data, understanding the limitations of using this method with low number of individuals. We made the analysis over the correlations matrix and, in order to have more interpretable results, we applied a Varimax rotation. The number of factors was chosen with the analysis of the scree plot. We define new scales averaging the items that had the biggest loadings in each factor. If a factor had items with negative and positive loadings we multiplied the items with negative loadings by -1 after calculating averages and reliabilities.

In the case of QPS, the principal components analysis was made with a bigger sample (N=240) of secondary and primary mathematics teachers applying for participating in a Problem Solving Workshop. Nevertheless, when we look for correlations between variables of both research instruments we used the common sample of 29 novel secondary mathematics teachers described at the beginning of the section.

ANALYSIS

Dimensions characterizing teaching practices by external observation

The statistical method applied to data from the LOR retained 4 factors explaining 71.2% of the total variance. The first factor explains 27.9 % of variance and the items with highest loadings were GW, TNP, TMQ(-) and DI(-) (the items with (-) had negative high loadings). With these items we create the new scale or dimension *Classroom Management* with a Cronbach's alpha of 0.681. We interpreted this factor as a dimension that describes the class management because a high positive score in this factor means that the teacher used most group work (GW) without intervention (TNP) and a negative score means that the teacher used mostly direct instruction (DI) and make questions (TMQ).

The second factor explains 16.2% of the variance and the items with highest loadings were TGS(-), NRT, TRR and CW. With these items we create the new scale or dimension *Quality Practices* with a Cronbach's alpha of 0.62. This factor put together variables that we presented in our framework as related with a good problem solving activity. First the frequency of non-routine tasks (NRT) and return the responsibility (TRR) are key variables. To have the frequency of working with whole class (CW) also makes sense, because CW was distinguished from direct instructions (DI), and only was coded if the protagonist were the students and they were working in a mathematical task. Teacher return responsibility was coded when at the moment of been asked teacher answered with a question or guide that allows the student to build, develop or discover a mathematical idea. The frequency of teacher gives solutions (TGS) has a negative loading; this makes sense to us because a teacher that gives the answers kills any attempt to think. So, having a high score in this dimension means that a teacher has a high frequency (compared with the other teachers) of non-routine tasks, returns the responsibility to students, uses whole class discussions and usually does not give the answers or solutions to their students.

The interpretation of the other two factors was not clear enough so we decided not to use them in the subsequent analysis. Studies with larger samples would be necessary to clarify these factors.

Dimensions characterizing problem solving teaching practices by teachers' self-report

The statistical method applied to data from the QPS retained 4 factors explaining 67.9% of the total variance (see Table 1) The first factor is formed with items that indicate students' behaviour denoting student centred practices, for example student's discussions (8,16) and work independently (3). The second factor was formed by items that indicate teacher's behaviour describing student centred practices, for example the teacher promotes that students takes their time (12) and guides with questions (11). The third factor is interpreted as a teacher centred dimension because most of the items situated the teacher as the protagonist. The last factor is about class organization because a high value in the factor means that teachers group their students (1) and a low factor means that teachers set their students working individually (6). Since this dimension has a very low reliability we do not use it for the correlation analysis.

In the next two sections we will combine the information obtained with the analysis of data from both research instruments: LOR and QPS.

Factor	% of Variance	Items with highest loadings	New Dimension	Reliability Cronbach's alpha
1	31.8	8, 13, 16, 14, 19, 3, 4, 9, 7	*Student centred (students)*	0.919
2	16.2	12, 18, 5 11	*Student centred (teacher)*	0.841
3	12.9	17, 10, 2, 15	*Teacher centred*	0.768
4	7	6 (-), 1	*Class Organization*	0.291

Table 1: Description of factors and the new dimensions from the QPS

Relation between observed and self-reported quantity of problem solving

Regarding the quantity of problem solving, the QPS has one item asking explicitly for the frequency of non-routine problems, and the LOR has an indicator of non-routine task. The correlation between the average of observed non-routine task and self-reported quantity of non-routine PS is r=0.447, p=0.015, N=29. This shows that information reported by teachers is not so different from information registered in lessons observations, in relation with the quantity of non-routine tasks or problems used with students of the observed sample. Nevertheless there are some particular cases as teachers reporting they use PS most of the time and where non-routine task was not coded during the observed 3 lessons. Cases like this require a deeper analysis we expect to make in a future study.

Relation between observed and self-reported quality of problem solving

In the analysis of the relation between the observed and self-reported quality of problem solving teaching practices we have to recall that all 19 items of QPS were answered under the prompt "When I use non-routine problems". This lead us to consider with a different weight the answers to items, depending on the reported frequency of use of PS in classes: we multiply the answer of each item by 1, 2, 3, 4 or 5 according to frequency of use of PS reported by the teacher.

In the following table, we present correlations between the new reliable dimensions obtained through principal components analysis starting with data from LOR and from QPS.

Regarding the dimensions from the QPS, we highlight the significant high value between the Student centred (student) and Student centred (teacher), dimensions 1 and 2, which may be interpreted as coherence in the answers of the teachers, those teachers that have a student centred practices have students performing student centred activities. In the same direction the significant positive correlations between 3 with 1 and 3 with 2 suggests a sort of incoherence in teacher's answers. However, having weighted the items answered by teachers with a weight based on a question in the same QPS (quantity of RP) may have increased artificially the correlations between the variables within QPS.

The most important result in Table 2 is the significant correlation between the dimension 5 with the dimensions 1 and 2. In this case, we are correlating dimensions obtained through our statistical analysis for the two instruments, LOR and QPS. These three dimensions express quality in teaching practices related to problem solving measured with two different instruments. These findings are in the same direction as the positive correlation between the frequency of observed non-routine task and self-reported quantity of non-routine PS mentioned above, telling that the two instruments are coherent. Certainly the results of this analysis are not conclusive, but it encourages going deeper in the analysis and tuning of these two instruments with larger samples.

DISCUSSION

We would like to summarize some results found with each LOR and QPS instrument, highlighting those characteristics of teaching practices related with problem solving where both instruments coincide. This is to be done having in mind that this is an exploratory study and that the instruments were not designed for information triangulation purposes. Teaching practices are multidimensional in nature, nevertheless a principal components analysis of both instruments lead us to summarize the information obtained through a big quantity of indicators, (14) and items (19), in two main types of dimensions: those related with classroom management or classroom organization and those linked with teaching practices promoting students development of problem solving skills and autonomy, in the terms described in our

		1	2	3	4	5
QPS	1. Student centred (student)	_				
QPS	2. Student centred (teacher)	0.858**	_			
QPS	3. Teacher centred	0.549**	0.583**	_		
LOR	4. Classroom Management	0.143	-0.018	0.275	_	
LOR	5. Quality Practices	0.369*	0.543**	0.178	-0.075	_

Table 2: Correlations between the new QPS and LOR dimensions **p < 0.01 *p < 0.05

framework. From our point of view, this is an interesting result although, since both instruments are new, further research is needed to prove the stability of these dimensions.

Correlations indicated some coherence between the information obtained with both instruments. For example, teachers that reported to use more non-routine problem solving activities were the same for whom non-routine task was coded in the external observation of the lessons.

Correlations between dimensions in the case of observed teaching practices point to that there is no relationship between classroom management and quality practices.

Correlations between the three dimensions expressing quality in teaching practices related to problem solving measured with two different instruments were high and significant, showing that the two instruments are coherent in this crucial dimension of our analysis. This is the most important finding in our study that encourages to conduct further studies in this direction.

To sum up, both instruments became useful to identify dimensions related with teaching practices on problem solving and there was coherence between the information obtained using each of them, what it is interesting from a methodological point of view, especially having in mind that classroom observation is very expensive in relation to questionnaire answering.

Moreover, it will be interesting to investigate if obtained dimensions for problem solving teaching practices are stable or not, taking a bigger sample, and go deeply in some cases with a qualitative study that let us to understand better some of the results of this analysis.

APPENDIX A: QPS

We present an English translation of the items. The original version was applied in Spanish. The items with an (i) are considered to measure practices that we hypothesized are not related to good problem solving activities.

1) I organize my students working in groups

2) If my students take too much time in find the solution of a problem, I solve it in the board. (i)

3) My students solve problems independently

4) My students express their different strategies to solve their problems even though they are wrong

5) I walk around the tables watching my students work

6) I organize my students working individually (i)

7) Usually I get amazed with my students ideas

8) My students are able to discuss with each other different ways to solve non-routine problems

9) I use plenary discussions with all the class

10) My students depend too much on my help to move forward with the problems (i)

11) If a student is too frustrated with a problem, I try to guide him/her only with questions

12) I promote students to take time to solve non-routine problems

13) My students generate different solution strategies

14) My students make interesting questions

15) If a student is too frustrated with a problem, I show him/her how to solve it (i)

16) My students discuss their own mistakes

17) My students progress too slow in the problems resolution (i)

18) I ask questions all the time

19) My students explore new problems arising as a result of the problems we are working on

Teacher-researcher collaboration as Formative Intervention and Expansive learning activity

Sharada Gade

Umeå University, Umeå, Sweden; Sharada.Gade@umu.se

Extended teacher-researcher collaboration is reported in this paper, by drawing upon cultural historical activity theory (CHAT) perspectives. Teaching is herein conceived as dialectical practice in which teachers are both shaped by and shape instructional practices. Three instructional interventions conducted at a Grade four mathematics classroom in Sweden constitute and exemplify the construct of Formative Intervention. Teacher-researcher collaboration which paralleled such conduct next exemplifies the construct of Expansive learning activity. Such transformation and change sheds light on how mid-level taken for granted phenomena in schools can be worked with and around, besides contributing to the motivational sphere of students and teachers.

Keywords: CHAT perspectives, collective unit of analysis, transformative agency, Formative intervention, Expansive learning activity.

TEACHER-RESEARCHER COLLABORATION

In this paper, I draw upon cultural historical activity theory (CHAT) perspectives and exemplify the constructs of *Formative intervention* (Engeström, 2011) and *Expansive learning activity* (Engeström, 2001). In doing so I draw on my extended collaboration as university researcher with a school teacher Lotta, as Charlotta is known, at her Grade four mathematics classroom. Such collaboration relates to project funding obtained by Lotta from the Swedish school authorities (Skolverket Dnr 2009:406) towards promoting students' communication in mathematics and includes three specific interventions. First, action research in relation to students' use of the mathematical = sign (Gade, 2012), second a problem posing practice in relation to students' use of textbook vocabulary (Gade & Blomqvist, 2015) and third, Lotta's plenary conduct of exploratory talk in relation to everyday measures (Gade, 2014). The very nature of teacher-researcher collaboration changed during such conduct from my being participant observer in Lotta's classroom, to her becoming theoriser and co-author of scientific reporting of our collaborative research. I argue that while the conduct of classroom interventions exemplifies Formative intervention, my extended collaboration with Lotta exemplifies Expansive learning activity.

Prior arguments in three research domains steer arguments in this paper. In the first, mathematics education research which seeks linkage between theory and practice in a comprehensive manner (Arbaugh, Herbel-Eisenmann, Ramirez, Knuth, Kranendonk, & Quander, 2010). Highlighting for reflective rationality instead of instrumental rationality, it is also sought that researchers become stakeholders in teachers' instructional practices just as teachers become stakeholders in classroom research (Krainer, 2011). Second, arguments in action research recognise the theory-practice relation to be a practical issue, wherein personal knowledge teachers have and their instructional realities are often found denied and/or generalised in idealised theory formulated by researchers from outside (Elliott, 1991). Finally, it is recognised that most research at K-12 levels of schooling is not conducted by K-12 teachers, leaving out and silencing the voice of teachers and their world of teaching (Cochran-Smith & Donnell, 2006). In three interventions alluded to in this paper, Lotta and me respond to many an issue here outlined. Lotta's own role is conducting these included working to stride the theory-practice divide, become stakeholder in research and contribute to K-12 research as a Grade four mathematics teacher. In doing so Lotta took on two significant roles. First and as teacher she elevated the problem of students' faulty use of the = sign in everyday instruction to one worthy of resolution via action research. She also steered instruction to have students make explicit use of textbook vocabulary and conducted a plenary of talk for students to explore understanding of everyday measures. In each of these Lotta was willing partner in deploying CHAT constructs which I brought to bear as researcher. Second and in this process Lotta went on to became co-author and theoriser of research, lending voice to its conduct and reporting. In such manner of reflective rationality, Lotta and myself became stakeholders in each others' professional practices (Krainer, 2011). More recently I unpacked our extended collaboration with different theoretical lenses (Gade, 2015). Lotta, her class teacher and me also report our problem posing practice in a teacher's journal (Persson, Blomqvist, & Gade, submitted). It is against this backdrop that I ask, What manner of change can teacher-researcher collaboration, identified by constructs of Formative intervention and Expansive learning activity, bring about?

CHAT BASED UNDERPINNINGS

Cultural historical activity theory (CHAT) grounds discussion in this paper with two arguments. First that the capacity to teach and benefit from teaching is a fundamental attribute of human beings. Second that educational processes are conceived as being active at three level – the student, the teacher and the environment between them. In fact CHAT perspectives view teaching as a practice wherein a teacher and his or her environment are in a dialectic whole, in which teachers not only shape but are shaped by instructional practices (van Huizen, van Oers, & Wubbels, 2005). With dialectical exploration of public and personal meanings, CHAT disavows a transmission model of teaching and conceives teacher subject knowledge to develop within instructional practices (Ellis, 2007). Such a conception is at odds with objectified, individualistic and dualistic conceptions of teaching, and proposes an alternative wherein teachers could take actions based on negotiated outcomes of collaboration and participation in a community of learners (Shulman & Shulman, 2004). This latter contests the idea that teachers are heroic individuals given societal status in lieu of their ability to work autonomously facing all odds in everyday practice (Edwards, 2010).

Bronfenbrenner's (1977) *Transforming experiments*, wherein environments can be restructured to bring unrealised potentials of participants to life is useful in realising viable practitioner collaborations. Engeström, Sannino and Virkkunen (2014) term Transforming experiments as *Formative interventions*, elucidating three assumptions that underpin their conduct. First the principle of double stimulation, which highlights how human beings use not one but two stimuli to overcome the problem situation they find themselves in. With the first stimuli being the problem situation itself, the second stimuli is used to make a meaningless situation meaningful resulting in individuals regulating their own behaviour, for example, the ticking of a clock in a waiting area is used to kill time, besides leading to volition. Second the principle of ascending from the abstract to the concrete, whereby any phenomenon is studied holistically from as many perspectives as possible (Luria, 1979). In the CHAT tradition the term abstract means underdeveloped, lacking in connections and thin in content as against concrete phenomena which are mature, well connected and rich in content (Blunden, 2010). Third Engeström and colleagues' (2014) principle of transformative agency,

> Transformative agency differs from conventional notions of agency in that it stems from encounters with and examinations of disturbances, conflicts, and contradictions in the collective activity. Transformative agency develops the participants' joint activity by explicating and envisioning new possibilities. Transformative agency goes beyond the individual as it seeks possibilities for collective change efforts. (p 124)

The three assumptions outlined above which underpin Formative interventions, allow for non-linear, agentic conduct of classroom interventions. Engeström (2011) further outlines four distinguishing features of these. First the starting point of Formative interventions are not pre determined but found embedded in the life activity being studied. Second, in resolving any problematic the individuals involved gain agency in its conduct. Third, that any pedagogical idea utilised in a Formative intervention has potential of being utilised later on as well. Finally and in such conduct the role of the researcher is to conceptualise and support the growth of interventions, as these evolve over time. I highlight these very aspects in Lotta's conduct of the three instructional interventions, which taken together constituted a Formative intervention.

The nature of teacher-researcher collaboration as realised by me and Lotta not only paralleled our interventions but expanded qualitatively over time, from my initially being participant observer in her classroom to her becoming co-author and theoriser of research reported. It is such manner of transformation that Engeström (2001) terms *Expansive learning activity*. Arguing against reactive forms of learning based on dualistic conceptions of the mind, Engeström (1987) argues for learning as an expanding and historically evolving activity. In line with Engeström, Lotta and me overcame many a contradiction we faced in her classroom practice, resulting in our collaboration becoming a case of Expansive learning activity. By this is meant that it was possible to view the learning that transpired during our collaboration in three distinct ways (Engeström, 1999). First and instead of benign mastery of what was already learnt hitherto by us as practitioners, our learning involved partial destruction of the old in our intentionally intervening and conducting an action cycle to restore say her students' faulty use of the = sign. The realisation of such conscious reflection was also possible in the problem posing practice, as well as Lotta's plenary conduct of exploratory talk with respect to everyday measures. Second and instead of conceiving transformation and change in individualistic terms, in our interventions we conceived students' development in collective terms involving all students in Lotta's classroom. Finally and instead of vertical movement along hierarchical levels, it was possible to conceive students' learning and development as a horizontal movement across subject specific borders. In addition, Lotta and me participated in each otherσs professional practice as stakeholders. Our object was not to become the other but realise new activities at the margins of our existing practices. Our realisation of co-authorship and theorising with Lotta is illustrative of such horizontal, as against hierarchical aspects. Detailed in Gade (2015) and geared towards Lotta's project goals, our collaboration evolved into newer forms of activity which grounded in her classroom realities were also not envisaged beforehand. As articulated by Engeström (2001),

> The object of expansive learning activity is the entire activity system in which the learners are engaged. Expansive learning activity produces culturally new patterns of activity. Expansive learning at work produces new forms of work activity. (p. 139)

I now turn to outline the instructional interventions which together constituted our Formative intervention, outlining the development of teacher-researcher collaboration as Expansive learning activity in the section that follows.

FORMATIVE INTERVENTION

Before detailing Lotta's instructional interventions at her Grade four classroom, I mention our collaboration to benefit from my conduct of a pilot study with her prior batch of Grade six students (Gade, 2010). It was during summer vacation in between that Lotta took the initiative of applying for funding of a project she conceptualised in terms of communication and mathematics. Yet since such a topic is broad in spirit and scope, it was only in some topics of the curriculum that we designed and conducted instructional interventions. In line with Engeström (2011) the very starting point of the overarching Formative intervention I discuss in this paper, was not determined ahead of time but found embedded in Lotta's everyday instruction. This happened when Lotta came upon her students' faulty use of the mathematical = sign. In Lotta reporting this to me, we designed and conducted an action research cycle based on CHAT perspectives of self-directed activity (Bodrova & Leong, 2007) and explicit mediation (Wertsch, 2007). While we detail the background, rationale and conduct of action research in our reports (Gade, 2012; Blomqvist & Gade, 2013) it is reasonable to assume the incidence of faulty use to transpire in other mathematics classrooms as well. Yet Lotta's actions of highlighting the problem to me, in our collaboration, held with it an expectation that we address the problem by means of research. It was then that I drew upon CHAT constructs to conceive a relevant and implementable semiotic practice. Continued participation by Lotta's students' in four stages of this practice led not only to restoring students' appropriate use, but also to Lotta achieving satisfaction of such use as teacher. We realised two significant aspects in these actions. In the first we implemented a practice that was active at three levels – Lotta's students, Lotta as teacher and the environment between them. In the second, we enabled Lotta to utilise her teaching in a dialectic manner, wherein she not only shaped her students' learning and development but was herself shaped by the instructional intervention she led (van Huizen et al., 2005). In line with Engeström (2011) Lotta's agency was realised in her conduct of the action cycle, with that of her students as they worked in dyads and offered mathematical statements of equality. In this intervention we handed out numbers and signs on slips

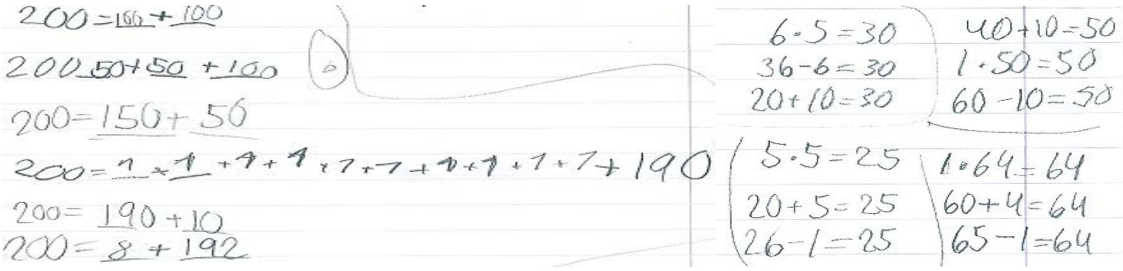

Table 1: Example of students' statements of equality in *lappar* based activity

of paper (*lappar* in Swedish) asking students to pick these at random and offer mathematically accurate statements. Two excerpts from such work detailed in Gade (2012) are given in Table 1.

We used *lappars* to hand out textbook vocabulary in the problem posing intervention as well (Gade & Blomqvist, 2015). As example while conducting this intervention Lotta herself partnered with a student Noel whose problem was as follows,

> 1000 people voted for president Noel but 600 voted for President Blomqvist. How many more voted for President Noel than President Blomqvist.

In the same session Ulla and Sara, two students who sat in desks behind Noel, posed the following problem almost in retort.

> There is a presidential election in the United States for the President. Noel was dismissed. President Ulla received 320 votes, President Sara 165 votes. How many people voted?

We next utilised *lappars* in Lotta's plenary, handing out improbable questions on everyday measures to provoke talk, for example: Can Eva and Anton measure the length of Sweden on foot?; Can Lars and Iris measure their age in decimetres? (Gade, 2014). An excerpt from Lotta's plenary conduct of the first question is given below:

Lotta:	Once more
Eva:	Can Eva and Anton measure Sweden's length with/on foot
Many:	Nooo ... @@
Lotta:	No, no, not now, Eva and Anton will attempt this question ... only them first
[??]:	It works (*Det går* in Swedish)
...	...
Liam:	You have to go straight ahead
Ulla:	What if you go into a building
[??]:	Then you go over the house
Lea:	Noel! Do you have anything good to say
Noel:	And you can go through the house ... and you can go inside the house and jump off the balcony ...
Leon:	And what if it is a high building
Nils:	If you have a map, you can take that, you can look how much a foot is and use the scale of the map ...

In realising students' agency in the three interventions we conducted, my own role as researcher saw me drawing upon relevant CHAT constructs, sharing these with Lotta and supporting her instructional practice. Where for the = sign intervention we drew on action research literature (Ladkin, 2004), in the problem posing intervention we drew upon van Oers' (2009) guidelines for Developmental education and for plenary conduct of Exploratory talk we drew on pioneering work of Barnes (2008). It was also the case that in each of the three interventions we conceived Lotta's teaching as a dialectical practice, in which Lotta shaped students' learning and development as well as reflect (Krainer, 2011) and be shaped by pedagogical actions she herself took (van Huizen et al., 2005). In was in this manner that Lotta was able to factor her practical knowledge (Elliott, 1991) besides develop rich nuanced understanding of pedagogical actions within her teaching (Ellis, 2007). Lotta went on to acknowledge our extended collaboration to be equivalent to her doing a professional development course in her classroom, which was rich preparation for her to foster a community of classroom learners in the future as well (Shulman & Shulman, 2004).

I finally discuss the four CHAT assumptions which Engeström and colleagues (2014) outline as underpinning any Formative intervention. First is the notion of double stimulation, in terms of which human beings resolve problem situations they find themselves in through a second stimulus, so as to gain volition. I argue that in each of the three interventions Lotta conducted, her students gained both agency and volition. I also argue such agency to be aided by their participation in instructional practices we had set up, in which the second stimulus was provided by the many *lappar* we utilised in a pedagogical sense and the CHAT constructs we utilised in a theoretical sense. The use of these together served the purpose of double stimulation. The understanding that Lotta and myself reached, was a result of observing and reflecting on each stage of the cyclical manner in which we deployed either intervention. Such an approach enabled us to view each of the three interventions from as many angles as possible and understand how various aspects were interrelated (Luria, 1979) besides how each intervention appeared as a pedagogical whole in concrete practice (Blunden, 2010). Finally and importantly it was in our conduct of interventions as classroom practice, that Lotta's students were able to jointly participate as well as contribute to collective transformational agency (Engeström et al. 2014). As example Lotta went far beyond treating the faulty use of the = sign by one of her students as a stand alone case and welcomed successive whole class interventions. Having shed light on the manner in which Lotta's instructional interventions exemplified the construct of Formative intervention (Engeström, 2011), I now turn to examine the manner in which teacher-researcher collaboration evolved correspondingly over time.

EXPANSIVE LEARNING ACTIVITY

As mentioned earlier on, my pilot study with Lotta's Grade six students prepared ground for teacher-researcher collaboration (Gade, 2010). It was during this study that either of us had opportunity to gauge each other as working professionals and take the many small steps which went on to eventually realise what Engeström (2001) terms as Expansive learning activity. In line with CHAT perspectives such a process was dialectical in spirit in that we both related and understood each other's actions. I was able to observe Lotta's teaching as participant observer and Lotta too was able to gauge how I interacted with her students, sharing a trick on one occasion and stoking their interest in mathematics on another. This led to her suggesting that I work with a few students who either needed special attention she did not have time for, or to those who were able to comply with her instructions before all others. From gauging each other and in terms of these actions, Lotta accepted me as a professional whom she could trust her students with. I argue that it was this trust that she took for granted when applying for project funding, whose aims were realised over time in the interventions which constituted our Formative intervention. In these it was possible to do away with older relations that students had with mathematical signs, textbook vocabulary or even talk and build relationships which we considered productive and mathematically rich. Our reporting of these aspects allowed for co-authorship and theorising by Lotta as K-12 teacher (Cochran-Smith & Donnell, 2006). Not only did we come up with and carry out new forms of shared activity (Gade, 2015) we also changed the very object of our collaboration from our jointly facing contradictions to conceiving alternatives and conducting interventions. As argued by Edwards (2010) and in the cumulative history of collaborative efforts, we brought our expertise as teacher and researcher to bear in our joint actions. In place of individual autonomy we lay emphasis on thoughtful practice and inclusive reflexivity. Our professional expertise was thus a negotiated one, which was not only born of practitioner struggle but also altered many times over. In line with Engeström and colleagues (2014) our agency was a transformative and collective one which realised systemic change. Such manner of change is captured once again by Engeström (2010, p 88) in 'Expansive learning is a process of material transformation of vital relations.'

CONCLUSION

I conclude by highlighting an outcome of significance about my collaboration with Lotta, which is that in our combined efforts we did not fail. Our actions, judgements, trust as well as relationships nurtured with one another, students and mathematics all contributed to the manner of outcomes I report in this paper. In line with a CHAT driven agenda, we worked towards as well as achieved transformation and change. Three observations follow. First and as recognised by Elliott (1991) there is reason to view the theory-practice relation as a practical issue for teachers. We saw the kind of efforts that Lotta and me took upon ourselves to bring CHAT based theoretical constructs to bear within everyday classroom instruction. Second and in line with Engeström (2001) such efforts necessitated expansive forms of learning, which were neither reactive nor predetermined but realised in our reflective actions which were grounded in Lotta's classroom. Such actions have potential besides of seeding as yet unforeseeable expansive learning in our trajectory ahead. Finally, such meta-level analysis sheds light on two historical trajectories, that of successive interventions conducted and teacher-researcher collaboration realised in parallel. Such insight in turn reveals how mid-level taken for granted phenomena in school, lying between rules and budgets on one hand and curricula and textbooks on the other can be worked with and around. Such actions and knowledge have potential besides to contribute to the motivational sphere of students and teachers within teaching-learning in everyday mathematics classrooms (Engeström, 2008).

Instructional practices in mathematics classrooms

Guðný Helga Gunnarsdóttir and Guðbjörg Pálsdóttir

University of Iceland, School of Education, Reykjavík, Iceland, gudnyh@hi.is

In the last decade, research on instructional practices has been carried out in mathematics classrooms in Iceland, mostly in the lower secondary school. In this study, the structure of 51 mathematics lessons in all compulsory school grades were analysed. The data came from a study called Teaching and Learning in Icelandic Schools, where 518 lessons from all school subjects were observed. To shed light on the structure of the mathematics lessons, diagrams were made which included the categories: non-mathematical work, teachers' public interaction with the whole class, individual seat work, assessment, group work, and playing of games. The analysis revealed that in most of the mathematics lessons the students were working individually in textbooks. There was little public interaction between the teacher and the class but the teacher went around the class and interacted with the students. There were a few examples of varied instructional practices that emphasized group work and discussions.

Keywords: Instructional practices, mathematics lessons, lesson diagrams, compulsory school.

INTRODUCTION

Findings in research on instructional practices in Icelandic mathematics classrooms have indicated that there is little variation in teaching approaches. In research by Savola (2010), where he compared lessons in Icelandic and Finnish schools, it was noticeable that in Icelandic classrooms the teacher often had no public interaction with the whole class and students were often working on their own pace in textbooks, while the teacher walked between the desks and interacted with students.

Karlsson (2009) also observed lessons in Iceland and Finland. According to Karlsson's results, Icelandic teachers were more likely to stay on the sideline and were not as central in the classroom as the Finnish teachers who also used more versatile teaching methods than the Icelandic ones. A recent study on the teaching of mathematics at lower secondary level in eight schools all around Iceland showed that in 56% of lessons students were working individually on workbooks. In 35% cases, there were some interactions between teachers and students around the topic followed by individual work on problems. In 6% of lessons, students were working in groups on tasks and in 3% they were playing some kind of games. During individual work, students often helped each other and the teacher encouraged them to do so both in public and also when walking between the desks (Þórðardóttir & Hermannsson, 2012). The study by Karlsson (2009) was the only one that contained some data from mathematics teaching at lower levels.

In Iceland, limited research has been done on mathematics teaching and learning and it has mostly been done by researchers who are stakeholders in many respects (teacher educators, authors of curriculum etc.). We therefore find it important to use available data, gathered by others, to add to our knowledge. In this paper, we use data from a recent study called *Teaching and Learning in Icelandic Schools* (Óskarsdóttir et al., 2014). In the study, 51 lessons in mathematics at all grade levels from 1–10 were observed. We gained access to the observation protocols and wanted to explore what they could tell us about what goes on in mathematics classrooms in Iceland, or more precisely: How are mathematics lessons structured? Of the observations, 32 were from grade levels 1–7, which have not been studied much previously. We therefore also wanted to find out if instructional practices at different grade levels were similar or if we could spot any differences.

We think that comparing teaching within a culture allows educators to examine their own teaching practices from different perspectives by widening known possibilities, in a similar way as comparing teaching between cultures does (Hiebert et al., 2003). It can reveal alternatives and stimulate choices being made within a country. It is also important to know what actual teaching looks like on average so that national discussions can focus on what most students experience. Using data from a general study on instructional practices also allows us to examine whether the practices in mathematics are any different from practices in general.

THEORETICAL BACKGROUND

Research on general instructional practices in Iceland

Various studies on general instructional practices in Icelandic compulsory schools have been carried out in recent years. According to Sigurgeirsson, Björnsdóttir, Óskarsdóttir and Jónsdóttir (2014), these studies all indicate that direct and teacher-centred methods are most widely used and to a much less extent methods where students take a more active role. Curriculum materials guide the teaching in academic subjects to a very large extent and the most common structure of lessons is a short introduction by the teacher followed by individual seatwork. There are though indications that instructional practices in lower grades are more varied than on lower secondary level.

According to a 2013 TALIS (Teaching and Learning International Survey) study (Ólafsson, 2014), Icelandic teachers on average seldom review content recently taught, they also more rarely review homework or try to relate new knowledge to daily life, than teachers in the other TALIS countries. There is a considerable difference here. For instance, 38% of Icelandic teachers state that they often or almost in every lesson review content recently taught, where the TALIS average is 78%.

The study *Teaching and Learning in Icelandic schools* (age levels 6–15) was conducted in 2009–2010 (Óskarsdóttir et al., 2014). The study was done in cooperation with many stakeholders from universities, school authorities, schools, teachers and parent organisations, and partners from an architectural firm and an information technology firm. The study focused on many aspects of teaching and learning, like the learning environment, student learning, teaching strategies and internal structures. A special focus was put on the development towards individualised and cooperative learning advocated by school authorities both on the local and national level. The framework for the research project was a model of school practices developed as an evaluation tool by educational practitioners in Reykjavík School District. Data were gathered by using multiple methods like observations, interviews, focus groups, questionnaires and action research in 20 schools out of 175 schools in the country. Three of the schools were chosen because they had been designed with the aim of changing the instructional practices from traditional to more open and individualized learning. Other schools were randomly chosen. In total, 518 lessons in all school subjects were observed, and 240 interviews were conducted with students, teachers, principals and other staff in schools (Óskarsdóttir et al., 2014).

The results showed that teaching strategies that can be labelled as “direct” are most commonly used and strategies like discussions, group work and project work which are recommended in national curriculum guidelines are rarely used (Sigurgeirsson, Björnsdóttir, Óskarsdóttir, & Jónsdóttir, 2014). It is also noticeable that there is a considerable difference between teaching strategies depending on school level. The teaching of the youngest students seemed to be more varied than the teaching of upper grades. Schools in the study were grouped into three categories, based on whether teachers mostly worked alone with their class, or classes if they were subject teachers (6 schools), were team teaching and responsible for a whole year group together or mixed age groups (9 schools), or a mixture of both (5 schools). The teaching strategies used in schools where team teaching was the norm, were more versatile. The results also indicated that the development towards more individualised learning in light of the frameworks used is not very advanced.

International research on instructional practices in mathematics

In recent years, several studies have been conducted in different parts of the world with the aim of identifying common features of mathematics teaching in countries scoring relatively high in studies like TIMSS or PISA or by teachers who are considered outstanding math teachers in their respective countries (Clarke, Mesiti, Jablonka, & Yoshinori, 2006; Hiebert et al., 2003). Even though it is impossible to generalize or identify a common lesson script on the basis of these studies, some important characteristics of effective mathematics teaching have been located.

The TIMSS 1999 video study brought to light that no single method of teaching 8th grade mathematics, was observed, in all the relatively high achieving countries taking part in the study (Hiebert et al., 2003). However, all eight-grade classrooms in all seven countries shared some general features. Mathematics was often taught through solving problems and 90% of lessons made use of a textbook or worksheet of some kind. Lessons were organized to include some public whole class work and some private individual or small group work. It was most common for students to work individually rather than in pairs or groups. The lessons included some review of previous content as well as some attention to new content and the teachers usually talked much more than the students. It was also observed that a variety of methods were employed rather than a single shared approach of teaching mathematics. Each country combined and emphasized instructional features in various ways, sometimes different from all other countries and sometimes partially the same.

Boaler's (2006) long-term study of mathematics teaching in three different schools in the US, showed that students from a school called Railside both enjoyed mathematics more and reached higher levels of mathematics than the students in the other two schools. According to Boaler, their success was a result of the unusual approach to mathematics at the school. The classes were heterogeneous, the students worked in groups on group-worthy problems that could be solved and represented in different ways. Moreover, the students spent a lot of time discussing mathematical ideas, learnt to help each other and were made responsible for teaching their peers. The lessons were 90 minutes long and the teachers worked closely together while preparing their teaching and shared the same ideas about teaching and learning.

Hiebert and Grouws (2007) identify, by reviewing research on the impact of classroom teaching on student learning, two main features of classroom mathematics teaching that facilitate students' conceptual development. These features are, firstly, an explicit attention to mathematical concepts and connections between ideas, facts and procedures, and secondly, that the students were given opportunities to engage in and struggle with important mathematics. According to Hiebert and Grouws (2007), these features seem to be general and operate across various contexts and teaching systems.

In their review of research on classroom practice in mathematics, Franke, Kazemi and Battey (2007) focus both on the teachers' role in mathematical work and students' experiences in the social context of the classroom. They point out that the nature of mathematical discourse in classrooms is central if teachers are to gain opportunities to learn from their practice. Students' individual work cannot alone provide such opportunities. In creating opportunities for discourse, teachers also need to attend to the social and socio-mathematical norms in the classrooms and develop relationships with their students where they take into account the students' cultural backgrounds. The IRE discourse pattern (teacher *initiated* question, student *response,* and teacher *evaluation)* is still prevalent in many mathematics classrooms, and this needs to change. The IRE discourse pattern falls within the exercise paradigm (Skovsmose, 2001) where the teacher presents some mathematical ideas and the students work with selected tasks from textbooks. The teacher presentation can vary in length. It can take up to a whole lesson and the students could also be working with exercises for the duration of the lesson. Justifications of the relevance of the exercises are not a part of the lesson and there is usually only one answer to the task.

Even though it is clear that classroom practice is complex and many cultural differences can be found when studying mathematics teaching across cultures (Givvin, Jacobs, Hollingsworth, & Hiebert, 2009; Franke, Kazemi, & Battey, 2007; Hiebert et al., 2003), there seems to be consensus regarding the idea that both teachers and students need to play an active role in the mathematics classroom. It is important that students both actively engage in mathematical discussions, making sense of mathematical concepts, and that teachers are able to learn from their students and develop their practice. Students also need to be engaged in solving challenging problems and given opportunities to share and present their ideas (Givvin, Jacobs, Hollingsworth, & Hiebert, 2009).

DATA AND DATA ANALYSIS

Our data consist of observation protocols from mathematics lessons made by researchers in the research project *Teaching and Learning in Icelandic Schools* described above (Óskarsdóttir et al., 2014). The researchers came from various disciplines within the University of Iceland and the University of Akureyri, mostly from general pedagogy. None of the researchers had specialized knowledge about mathematics teaching and learning. The observers made detailed notes in an observation protocol during the lessons. The focus of the observations was more on the progress of the lesson and the students' activity during the lesson than on the content and how that was dealt with. In some of the observation protocols, it was clear what the focus of the lesson was but in others there was no mention of the content of the lesson. This has its limitation but nevertheless we feel the observation protocols give us an idea of what is happening in the classroom and how the teaching is organized. We, the authors of this paper, have been actively engaged in teaching math teachers and making curriculum materials for a long time and are therefore well known to most math teachers in Iceland. We felt that by using this data we could gain some information about mathematics teaching in Iceland without collecting the data ourselves and thereby probably influencing the results.

As mentioned previously, Savola (2010) studied mathematics lessons in Iceland and Finland. He videotaped 20 lessons (two from each teacher) in each country. He made lesson diagrams for each lesson based on the coding of his data. His main coding categories were review, introducing new content, practice/applying, and other. The category 'other' included classroom management, mathematics management, homework, interruption, social talk and independent learning (IL). Three different types of IL were noted, between-desk instruction, where the teacher walks around the classroom and helps, and teacher or student presenting at the front, addressing only few students while the others are working individually.

Johansson (2006) studied videotaped lessons from three Swedish teachers, considered competent mathematics teachers in their community, at lower secondary level (4–5 consecutive lessons from each teacher). She tried to identify a common lesson script and in coding her data she used four main coverage codes: classroom interaction, content activity, organization of students and textbook influence. She also directed her attention to the teachers' activity and how often specific events like problem solving, assignment of homework, assessment, goal statements, summary of lessons etc. occurred within a lesson.

In our analysis, we started by reading carefully all the observation protocols. We then formed some categories on basis of the data with categories used by Savola (2010) and Johansson (2006) in mind. Our data is much more limited because it is only based on written notes by the observers and not video recordings and therefore does not allow a fine-grained analysis. Classrooms practices are complex and by analysing lesson structure we try to capture some important elements of both the form and the function of the lesson. However, it has its limitations and researchers should be careful not to draw too many conclusions on the basis of this kind of data, but it can shed some light on important aspects of classroom practices (Savola, 2010; Clarke et al., 2006).

Our main categories were: non-mathematical work (a), teacher's public interaction with the whole class including presentation of new material and checking and assignment of homework (b), individual seatwork (c), assessment (d), group work (e), playing of games (f). We made a diagram of each lesson using these codes and also described in few words what was happening in each part of the lesson, for instance, whether the students used textbooks or not. This made it possible to spot differences and similarities across the sample.

FINDINGS

We summarize our findings according to grade levels.

Grade levels 1–4

For grade levels 1–4, we have 19 observations. Most of the lessons (13) were 40 minutes but six had duration of 60–80 minutes. In almost all the lessons it took at least five minutes before the actual lesson could begin and in ten of them the mathematical work was finished five minutes before the actual lesson ended. In ten of the lessons there was some public interaction between the teacher and the students lasting 5–15 minutes. In most cases the teachers explained algorithms and procedures or discussed and showed students how to work with pages from the textbook using an overhead projector. When explaining algorithms and procedures, the teachers were not using textbooks but supplemented the textbooks with material from other resources. The biggest parts of the lessons students were working individually in textbooks or on worksheets provided by the teacher. Activities like working with attribute blocks, playing dice games, working with Tangram and unit cubes were inspired by textbooks. During individual seatwork, the teacher circulated and assisted students and in nine lessons an unqualified assistant or another teacher/specialist was present either working with specific students or assisting in general. When working individually in textbooks students sometimes worked with the same chapter or worksheets but in at least six lessons they worked at their own speed but with the same textbook or workbook. In three lessons the students worked in groups. Two of these lessons were organized as workstations where the groups worked on different activities. In one class, all the workstations focused on practicing multiplication but in the other, a first grade class, the activities were unrelated but varied. In the third lesson with group work, all students were working with attribute blocks, first making a picture together in a group and then they got some time for free play with the blocks.

Grade level 5–7

From grades 5–7 we have 13 observations. Most of the lessons were 40 minutes but three were 80 minutes long. In ten of the lessons it took about five minutes before the mathematical work started. Here, in six lessons, there was some public interaction between students and teachers and it centred on guiding the students through the textbook and reviewing homework. In one lesson the teacher was discussing properties of geometric forms with the students and then they were to make their own forms but it was not clear whether this was inspired by the textbook or not. In seven lessons the students were working individually on their textbooks almost the entire time of the lesson while the teacher was circulating and assisting them. In one lesson the students were working on a test for 30 minutes and then they handed in the test and were given an opportunity to work on it again the next day with the aim of looking things up at home and then improving their solutions. In one 80 minutes lesson, the students, after completing a self-assessment, worked in groups planning a table tennis tournament and after that they played the tournament and then came back to class and discussed and shared their solutions of the task.

Grades 8–10

From grades 8–10 (lower secondary level), we have 19 observations and eight of the lessons were 60–80 minutes long. Here it took less time for teachers and students to get to work with the mathematics. In most lessons they had started within 2–3 minutes. Eight of the lessons started with some public interaction between teacher and students, either by reviewing homework or presenting new material or problems. Even though in most lessons these interactions only took around ten minutes, there were examples of them taking from 20 and up to 60 minutes, and usually the teachers tried to engage the students by asking questions and encouraging discussions. In three classes the students were divided into two groups where a part of them worked individually while others were taught by the teacher or took a test. In five lessons the students worked individually on textbooks during the whole lesson, and in six more lessons, the students worked individually after a short introduction by the teacher. In many of the lessons, the students seemed to be working on the same topic even though there were examples of individual students working on material from higher grade levels, even upper secondary level, or students working with different material from the rest of the class because of learning difficulties. In three of the classes the students worked independently according to a plan made for the chapter or a month with a daily quota. In one lesson, students worked on an assessment. In one school two lessons were observed where students worked in mixed age groups on problem solving. Here the lesson started with some introduction of important concepts in relation to the problem at hand and then the students were divided into groups.

DISCUSSION

The findings from this study support previous findings on instructional practices in Iceland and add some new knowledge about mathematics teaching in compulsory schools as a whole. In many lessons there was a strong focus on individual seatwork where students worked mostly on textbooks. The teachers seemed to rely on textbooks and their contents for the whole class, aimed at helping or guiding students through the problems or exercises in the textbooks. Students were active in their work and the teachers moved around the classroom and helped them. There were examples of teachers creating opportunities for whole class discussions about topics or ways of working sometimes in the beginning and sometimes in the middle of lessons in connection with the individual seatwork. However, there were also many lessons with no public interactions and therefore the teachers were not creating enough opportunities for students to elaborate on and discuss with others mathematical concepts and connections. More whole group discussions should also help the teachers to develop and learn from their practice (Franke, Kazemi, & Battey, 2007). The socio-mathematical norms in the classrooms seemed to be that you learn through working on problems/exercises in textbooks, and the communication between teachers and students was centred on supporting the students in completing the work. This is what is often termed as traditional mathematics teaching or the exercise paradigm (Skovsmose, 2001). We do not know much about the nature of the tasks that the students were working on but from the observations it seemed like the teacher put an emphasis on guiding the students through their work with the problems. In several cases, the teachers in the lowest grades worked through the pages in the textbook by using overheads. With the older students, the teacher often discussed specific problems in textbooks. In six lessons, students worked in groups and there the teaching was more in line with what many researchers (Franke, Kazemi, & Battey, 2007; Hiebert & Grouws, 2007; Boaler, 2006) claim to be important features of effective mathematics teaching.

Our findings reveal that instructional practices in mathematics are similar to the general results on teaching practices in the study *Teaching and Learning in Icelandic Schools* (Sigurgeirsson, Björnsdóttir, Óskarsdóttir, & Jónsdóttir, 2014).

The lesson diagrams gave a good overview of the lessons and their structure and drew attention to similarities and differences both within grade levels and between grade levels. In the lower grades, the teachers used more time on non-mathematical work, which is not surprising. It could also be seen that teachers use considerable more time working with the whole class as the children get older.

The data consisted of observations from only one lesson in each class. Previous research has shown that lesson patterns can vary considerably from lesson to lesson with the same teacher (Clarke, Mesiti, Jablonka, & Yoshinori, 2006; Hiebert et al., 2003). In the data there was little information about the mathematical content of the lessons and what the teachers chose to emphasize in their interactions with the students. As mentioned earlier, most of the observers came from general pedagogy and they did not note what the focus of the lesson was. They sometimes referred to pages or specific problems and from that we could see whether the class was working on the same problems at the same time or not, but it provided limited information about the goals with the lessons.

From this study it is evident that Icelandic teachers use a considerable time walking between the desks interacting with students. Research has shown that there can be great variations in regard to what the teacher is actually doing when he is circulating in the class and that affects the quality of the teaching (O´Keefe, Xu, & Clarke, 2006). Therefore, it would be interesting and valuable to find out what characterizes the teachers interactions with students in Icelandic mathematics classrooms.

Investigating two trainee teacher educators' transformations of the same resources in technology enhanced mathematics

Elissavet Kalogeria[1] and Giorgos Psycharis[2]

1 University of Athens, Educational Technology Lab, Athens, Greece, ekaloger@ppp.uoa.gr

2 University of Athens, Department of Mathematics, Athens, Greece

We address the documentational work of two trainee teacher educators in the context of their practicum in an in-service program concerning the use of digital tools in mathematics. Since they drew upon the same existing resources, we investigated the operational invariants – i.e., implicit aspects of their knowledge and epistemology underlying their designs – that influenced and differentiated their documentational work. The identified operational invariants were (a) their focal points during the observation of other teacher educators' classrooms, (b) the constrains and opportunities provided by the educational context, (c) their epistemologies regarding the role of technology in the teaching of mathematics as well as their conceptions of trainee teachers either 'as students' or 'of students'.

Keywords: Documentational approach, teacher educators, digital tools.

INTRODUCTION

In this paper, we study the didactical design and corresponding material developed by trainee teacher educators in teaching mathematics with the use of digital tools. The trainees drew upon existing resources as they started to teach in teacher education classrooms during their practicum and created their own documents. Our focus is on the factors that influence the development of the trainees' documents based on the same existing resources and the classroom implementation of their design.

The study took place in the context of an in-service program adopting reform-oriented perspectives to train teacher educators into the use of digital tools in the classroom of mathematics. The aim of the program was to provide the participants with methods, knowledge and experience in in-service teacher education and to educate them in the pedagogical uses of digital technologies for the teaching and learning of mathematics. One of the reform aspects of the approach for teacher education (see Kynigos & Kalogeria, 2012) concerned teacher educators' and teachers' active engagement in creating their own didactical design and material as coherent part of their professional development. Taking into account that teacher educators have very few resources to draw on directly (Zaslavsky, 2008), it was critical for the trainees to get used to developing their own material. In this course, the trainees were engaged in designing and generating resources in the form of microworlds and scenarios (i.e., structured activity plans addressing critical aspects of a pedagogically sound use of technology for the teaching and learning of mathematics). A structure [1] for addressing these aspects was developed by Educational Technology Lab (http://etl.ppp.uoa.gr), which participated in the design of the course and the corresponding material. The training program took place in specialised University Centres (UC) for 350 hours. The participants were experienced qualified mathematics teachers but the majority of them had no previous experience in the pedagogical use of digital tools. The plan was to employ the newly trained teacher educators in wide-scale 96h courses to groups of teachers in specific Centres for Teacher Education Support (CTES). The trainees in UC were given material by the trainers after each lesson and an official document containing theory and a set of twelve generic scenarios as a basis for organizing their subsequent teaching in CTES. During the course, the trainee educators gained significant experience with the pedagogical use of five categories of digital media: Computer Algebra Systems, Dynamic Geometry

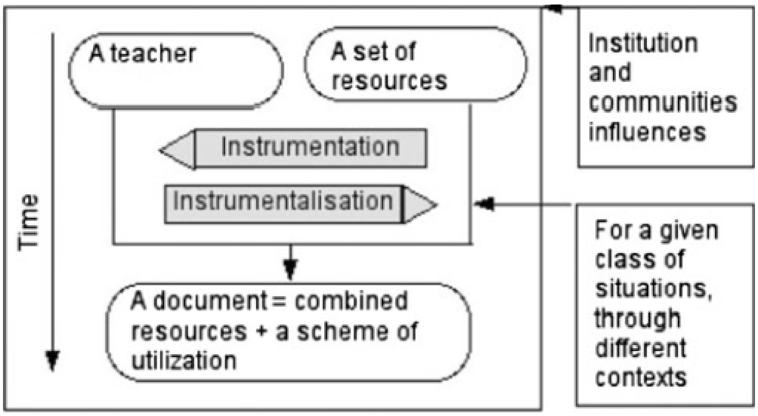

Figure 1: Documentational genesis

Systems, Programmable software, Simulations and Data Handling tools. By the end of the course the trainees had to have developed one scenario for each of these categories as well as scenarios for the practicum. Practicum was part of UC official structure provided shortly before the end of the course, so as to engage trainees in field activities and give them the experience of implementing their design in real classroom conditions and reflecting on it. Practicum took place in 30 hours and it was divided in two parts: teaching in school and observation – teaching in CTES. Here in focus is the second part consisted of (a) observation of other teacher educators' teaching in CTES, (b) design of a 3-hour lesson for teachers in CTES under the supervision of a mentor, (c) implementation in the classroom, (d) presentation of design and implementation in whole class special reflective sessions, (e) activity report by the trainees.

THEORETICAL FRAMEWORK

Over the last years a number of researchers have indicated that the study of resources in practice and context constitutes an important theme in mathematics teacher education and deserves a focus of attention (Adler, 2000). We adopt the documentational approach of didactics according to which the teacher's work is developed with and on resources in a dialectic process where design and enactment are intertwined (Gueudet & Trouche, 2009). An implication of this approach is that curriculum material is not conceived as a static body of resources that guides instruction but rather as a set of objects amenable to changes depending on the teacher's didactical design. Gueudet and Trouche (2009) use the term resources to describe a variety of artifacts such as a textbook, a piece of software, a student's sheet, discussions with colleagues etc. Through a class of professional situations and teachers' experience, the existing resources are transformed into documents according to the formula: *Document = Resources + Schemes of Utilization.*

A scheme of utilisation of a set of resources incorporates "*practice* (how to use selected resources for teaching a given subject) and *knowledge* (on mathematics, on mathematics teaching, on students, on technology)" (Gueudet & Trouche, 2011, p. 401). Practice entails observable parts of teachers' stable behaviour for a given class of situations (called usages). On the other hand, knowledge embodied in resources is implicit and can be inferred from the usages. This knowledge is intertwined with teachers' beliefs and it is difficult to distinguish one independently of the other (Thompson, 1992). The constituent elements of this kind of knowledge are the *operational invariants* built through different contexts of using the resources.

Creation of documents is considered as unfolding through a dual process of *instrumentation* (the resources act on the teachers and influence their activity) and *instrumentalization* (teachers act upon these resources as they appropriate and reshape them) (Gueudet & Trouche, 2009). This process is named documentational genesis (ibid, see Figure 1) and gives birth to a new entity: a document, which can be further transformed to a new document over time.

The importance of interrelating knowledge and epistemology, the difficulty to distinguish them, as well as their influence on the everyday teaching practice has been stressed by many researchers (Nespor, 1987; Thompson, 1992; Ernest, 1994). However, the relation between teachers' epistemologies and practices is complicated and not linear as it is strongly affected by constraints and opportunities afforded by social context (Ernest, 1994). For example, a teacher's conceptions regarding the teaching of mathematics may be rooted in the epistemological paradigm of absolutism while her/his own practices might be closer to the paradigm of fallibilism and vice versa. Thus, interconnections between teacher's practices and epistemologies formulate the following different roles in her/his own teaching (ibid): instructor (i.e., targeting skills' mastery and correct performance), explainer (i.e., targeting conceptual understanding with unified knowledge) and facilitator (i.e., targeting problem posing and solving). At the same time each role signifies a different stance towards the curriculum and the corresponding teaching material and leads to three patterns of curriculum use (ibid): the strict following of a text; the modification of the textbook approach, enriched with additional problems and activities; and the construction of the mathematics curriculum by the teachers themselves. As we will analyze later in the paper, the trainee teacher educators of our study – despite the fact that they were given the same initial resources – adopted different roles and corresponding didactical designs when they started teacher education themselves in the context of their practicum. We consider that these differences were determined by a combination of operational invariants that was unique for each one of them. Thus, in order to explain the differences between trainees' design and implementation, it was our choice to investigate the underlying operational invariants both in the design of documents and their usages in real educational contexts. Existing research on teachers' documentational work highlights the need to identify categories of operational invariants permitting refinement of the analysis of schemes of utilisation (Gueudet & Trouche, 2009).

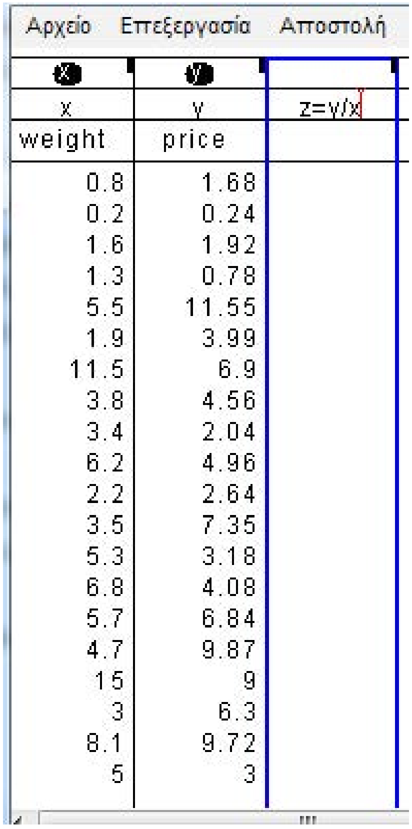
In this study, our aim is to investigate how the formula *Document = Resources + Schemes of Utilization* works when different teacher educators build the development of their documents upon the same existing resources. Thus, we investigate the underlying factors (i.e., operational invariants) that influence trainee teacher educators' design. We looked for these operational invariants within the space where the processes of instrumentation and instrumentalisation take place.

METHOD

The UC class of trainee teacher educators that we analyse here consisted of 16 qualified mathematics teachers (five of them had a doctoral degree, one was a PhD student and the rest held a Master degree). The data we analysed consisted of: (1) verbatim transcription of the discussions that took place during the 30 hours of the practicum in the UC classrooms, (2) the material constituting the trainees' designs for their lessons in CTES (scenarios, worksheets, ppts, etc.) and (3) their activity reports. The activity reports were templates in which trainees had to insert text describing aspects of their designs and their experience from its implementation. From the analysis of the 16 trainees' documentational work, in this paper, we present two cases with the aim to highlight differences in trainees' design of documents and implementation in teacher education classrooms. Particularly, we chose Ian and Jim as exemplary cases because their teaching in CTES was based on the same official scenario. This allowed us to view comparatively the documents they created and thus to address the underlying operational invariants. Our role as academic trainers and mentors in the practicum allowed us to capture the evolution of their documentational work in all phases of the practicum. In resonance with Gueudet and Trouche's (2011) principles regarding methodological aspects of research on documentational genesis we chose to (a) analyze Ian's and Jim's work in time periods in and out-of-class (reflexive investigation principle), (b) address their decisions taken in order to formulate their design through its use (design-in-use principle), and (c) consider their work embedded in and influenced by different collectives (e.g., teachers in CTES) (collective principle). We used data from different time periods: excerpts from their observations in CTES that took place before their design during the reflective sessions, the official material and its transformations by Ian and Jim including the arguments with which they documented their options and presented in the reflective sessions and finally Ian's and Jim's activity reports. In the analysis we adopted a data grounded approach (Strauss & Corbin, 1998). Initially, each one of us (the two authors) worked separately for coding trainees' work and identifying operational invariants. After reaching a common consensus, we jointly completed the analysis.

ANALYSIS

Ian's and Jim's lessons in CTES concerned the teaching of linear functions ($y = ax$) with Function Probe (FP) [2]. Their teaching was based on one of the twelve official scenarios provided for the course. The problem



x	y	z=y/x
weight	price	
0.8	1.68	
0.2	0.24	
1.6	1.92	
1.3	0.78	
5.5	11.55	
1.9	3.99	
11.5	6.9	
3.8	4.56	
3.4	2.04	
6.2	4.96	
2.2	2.64	
3.5	7.35	
5.3	3.18	
6.8	4.08	
5.7	6.84	
4.7	9.87	
15	9	
3	6.3	
8.1	9.72	
5	3	

Figure 2

included in this scenario was: "A salesclerk sales three products A, B, C of different prices. After every sale he records the quantity x (in kg) and the amount of money y received. When he had completed twenty sales he passed the values in two columns in the Table window of FP so as to check: (a) how many sales were made by each product and (b) if there had been mistaken sales. In how many ways can he conduct the check?". The indicative design of the official scenario suggested the following teaching sequence in three phases.

<u>Phase 1</u> *(Exploring regularities – relations between different groups of proportional amounts):* It is provided a ready-made table containing 20 pairs (weight, price) of 20 sales in two corresponding columns. Teacher can chose or discuss with the students the possibility to fill in one more column defined by the ratio $z = y/x$ (Figure 2). In this case, students are expected to notice that this ratio takes three particular values (0.6, 1.2, 2.1) except one. These values can be an indication for the existence of linear relations $y = ax$. Then the students send the points (x, y) to the Graph window (Figure 3) and they are expected to notice that the three values of the ratios correspond to three different groups of collinear points. Also they are suggested to construct the graph of $y = x$ and stretch it dynamically with the mouse so as to coincide to each of the existent groups of points (Figure 4). The corresponding formula for each transformation of the graph appears in the upper right corner of the Graph window. The students are expected to explore the problem either algebraically (i.e., by linking the corresponding ratios to linear functions) or geometrically (i.e., by dynamically manipulating the graph of $y = x$) and to connect the three ratios that encountered in the table to the three values of the coefficient a of $y = ax$ respectively.

<u>Phase 2</u> *(Testing the formulas of proportional amounts through different representations):* The students can be engaged in generating the exact prices of each product in three different ways: (a) In the Table window: they can construct one new column corresponding to the weight of each product (use of command 'Fill in' with values from 0 to 10 and step 0.1). Then, they are asked to construct three new columns so as to calculate the exact prices of each these products using the formulas $y = 0.6t$, $u = 1.2t$, $z = 2.1t$. This way the salesclerk will be able to know the exact price for each product until the weight of 10 Kg without calculating it. (b) In the

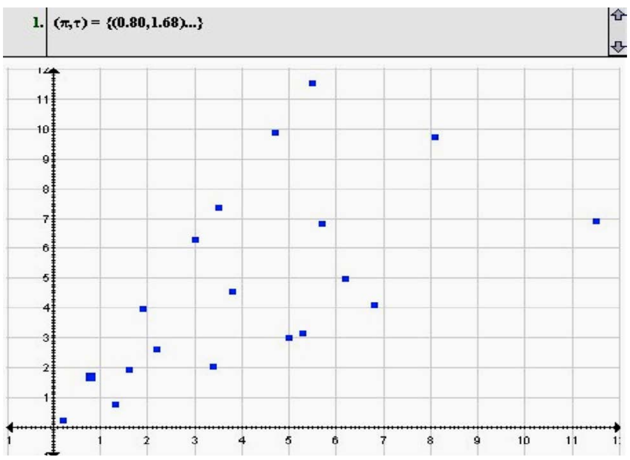


Figure 3: Sending points to the Graph

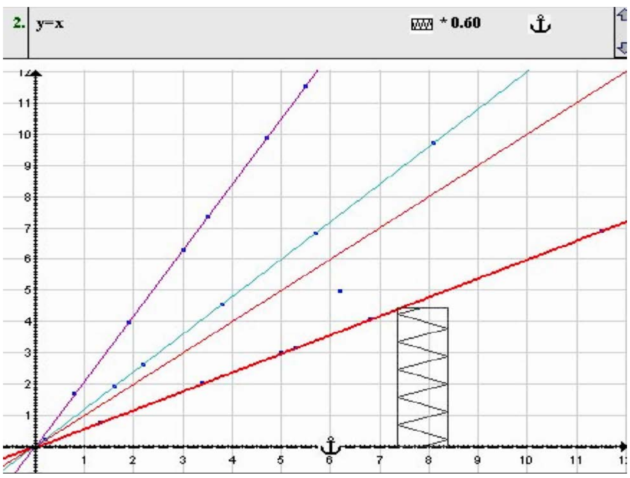

Figure 4: Stretching $y = x$

Calculator window: they can create three buttons (see [2]) for calculating all prices of the products through a functional relation. (c) From the Graph to the Table window: they can take points from the graph and send them to two columns in the Table standing for x and y respectively.

<u>Phase 3</u> *(y=ax+b as a transformation of y=ax):* $y = ax + b$ can be investigated through vertically stretching $y = ax$ at the Graph window and constructing new columns in the Table window defined by functional relations (e.g., $w = 0.6t + 0.5$).

Ian's documentational work

During his observation in CTES Ian, in both his activity report and the reflective sessions, concluded that in order to design his own lesson in CTES had to take into account the following aspects: (a) the different levels of teachers' familiarization with digital technologies, (b) difficulties with particular tools/functionalities of FP (e.g., creation of buttons in the Calculator), (c) difficulties in conceiving the links between the different representations of FP. Thus, he started his lesson in CTES by demonstrating particular functionalities of FP in a whole class session through the use of an interactive whiteboard. Then, he gave to the teachers a worksheet with the ready-made table of the official scenario. The worksheet covered the three phases of the official scenario and it was structured in the form of small steps-instructions insuring the correct use of FP tools for the requested activities. For instance, instructions concerning the first phase were the following: "Table window: Fill in the 3rd column with the ratio *y/x* and press enter", "Write down the resulting values and explain what they show", "Table window: Send points to the Graph", "Graph window: Graph → Graph choices → Check 'Show transformations' → Click on the icon '*y*=...' to create the graph of $y = x$". In the second phase, Ian provided a detailed account of the three ways by which teachers could have the prices of each product through the use of the Table, the Graph and the Calculator window respectively.

In his activity report Ian describes his choices in the design as shown in the following excerpt: "The development of my design follows the existing official material of CTES with a differentiation as regards the worksheet which is more instructional due to a better time control ... Though the worksheet should provide learners with freedom to pose and answer their own questions, I chose to make it more instructive – probably more than needed – so as to support teachers' familiarization with the available tools while solving the problem ... Another reason for choosing a more instructive perspective stemmed from the fact that the trainer of this particular CTES classroom had a similar approach in his own teaching. Thus, I targeted a more smooth transition from teachers' trainer to myself ...". During the reflective sessions in UC, Ian again justified his choices in the design of the worksheet after being asked by another trainee if he had been satisfied by his teaching in CTES and if he would change something in it: "I would prefer a less instructive design. But I was anxious about time. Through my choice, the worksheet was completed by all teachers in time. They liked the environment and seemed to have learned better the FP functionalities".

Teachers' and students' engagement in exploratory activities with digital tools was a central idea underlying the design of the UC course. Ian seemed to have shared this view, but he finally designed a rather instructive lesson in CTES. Thus, Ian seems to consider teachers mainly 'as students' and his design targets the development of two kinds of knowledge: (a) about technical aspects of software and (b) about the ways by which the available tools can be interrelated to subject knowledge. For instance, he provides detailed instructions on how to approach the targeted functional relation through the different FP windows (Table, Graph, Calculator).

The operational invariants underlying his design were related to the following factors: (a) his emphasis on constrains and opportunities afforded by the context (e.g., time restrictions, technological environment) which led him to follow instructive design and practices respectively, regardless of his (possibly different) epistemological conceptions for the teaching and learning of mathematics; (b) his observation in CTES concerning teachers' difficulties with FP and the previous teaching model adopted by the trainer in CTES; (c) his conception of trainees mainly 'as students' who need detailed instruction in order to overcome their difficulties. All these elements influenced the instrumentation/instrumentalisation interplay in his design leading to the integration of small-step instructions in the worksheets.

Jim's documentational work

Jim observed another trainer's lessons in CTES that preceded his own lesson and included teachers' initial familiarization with FP tools apart from the stretch tool. Thus, he started his lesson by demonstrating in the interactive whiteboard technical issues related to the use of FP with an emphasis on the use of the stretch tool. His worksheet included the following open tasks for the teachers (without any kind of instructions, even for aspects of the software): 1) The teachers were asked to work in groups of two and provide both an algebraic and a geometrical solution for the given problem. Construction of tables of values for the three products (in the Table window) or creation of buttons (in the Calculator window) is suggested. 2) Group discussions for the potential findings of a group of students and ways to approach them. 3) Whole-class discussion of the above findings. 4) Whole-class discussion for the added value of FP. 5) Design of indicative questions for the students by each group of teachers. 6) Presentation of groups' design in the classroom.

Describing his lesson in one of the reflective sessions in UC, Jim mentions: "I gave to the teachers a table with two columns corresponding to the weights and the prices for 20 sales of the three products. There was also a third empty column. I did not tell them to calculate a ratio or to send the two columns to the Graph. I was curious to see how many groups would be able to find them ... I asked them to solve the problem algebraically and geometrically. I recommended the creation of columns in the Table window for the values of the different products as well as the creation of three buttons in the Calculator ... I organized the class in groups of two following the model of their trainer ... All groups found at least one solution. I passed through the groups and encouraged them to find another one ... They discussed in their groups, they explored, I showed them how to stretch the graph of $y = x$. I was stressed by the possibility of not being able to use the FP tools. Thus, I had prepared another worksheet including more detailed instructions for the tool use. Finally, I didn't give it to them. If someone had faced problems with FP I would have given it to him. I believe that the level of instruction should be gradually decreased. When we first introduce new software we need to prepare a more instructive worksheet. But in the next lessons the worksheets should be as open as possible. The aim is to support teachers' thinking. You cannot tell them continuously 'press this' or 'press that'....".

Jim's design is closer to the ideas favored by the UC course. He took the risk to organize his lesson around an open worksheet and to confront potential teachers' difficulties with FP tools on the spot. In his design he initially considered teachers 'as students' and through a social process which evolved in six phases he came to view them as 'teachers of students'. Particularly, in phase one, he engaged teachers in exploring the problem (geometrically and/or algebraically), while in all subsequent phases, the teachers were asked to adopt the role of 'teachers of students' through a series of activities. At the instrumentation level, he took into account the model of teaching adopted by the official trainer in CTES as well as the fact that the main functionalities of FP had already been taught in previous lessons. Besides, his conception of the nature of worksheets regarding the degree of instruction led him – at the level of instrumentalisation – to incorporate open tasks. Facing the challenge to balance the correct use of technological tools and their integration in creating meaningful mathematical representations, Jim gives priority to the second. Jim is not interested in technological skills per se but how these would be incorporated in teachers' didactical design. Jim's choices reveal that he targets trainees' more complicated forms of knowledge as his design intertwines linear functions and its pedagogy with technology (approaching $y = ax$ algebraically or geometrically through ratios and dynamic manipulation of $y = x$). In terms of Ernest (1994), he adopts the role of facilitator who targets problem posing and solving and favors the development of meaningful material by the teachers themselves.

The operational invariants underlying the instrumentation/instrumentalisation processes were related to the following factors: (a) his epistemological conceptions of the ways mathematical knowledge should be approached though the use of technological tools; (b) his observation concerning the teaching agenda of the official trainer in CTES; (c) his conception of trainees initially 'as students' who work in groups to explore different solutions of the given problem with the use of tools and subsequently as 'teachers of students' who are facilitated by his mediation to exploit the tools and transform them into didactical instruments for mathematics teaching at the professional level.

CONCLUSION

Our analysis revealed the development of two kinds of documents: an instructive one and an open one. Taking into account the formula *Document = Resources+Schemes of Utilization*, we conclude that differences in the nature of the two documents can be explained through corresponding differences in the trainees' schemes of utilisation, i.e., identification of different operational invariants for each one of them. Both trainees intended to continue the CTES trainer's teaching model and to address the potential teachers' difficulties with FP. Ian's instructive approach seemed to have also been influenced by his concerns of differences in teachers' familiarisation with FP tools as well as by the time restrictions. While Ian aims to control all the above factors through an instructive document, Jim's design emphasises teamwork and appropriate teaching interventions by himself.

Thus, in the context of teacher education in technology enhanced mathematics, operational invariants that influence trainee teacher educators' documentational work in the context of their practicum seem to be closely connected: (a) to their experiences from the observation in CTES classrooms (focusing either in the trainee teachers' difficulties or the model adopted by the official trainers of the respective classrooms); (b) to the importance they attribute to the constrains and opportunities provided by the wider educational context; and (c) to their epistemologies regarding the role of technology in the teaching of mathematics and the ways they conceive trainee teachers, for example, emphasis on technology per se favouring the conception of teachers mainly 'as students' or on the integration of technology as a coherent part of teachers' designs favouring the transition of trainees from 'teachers as students' to 'teachers of students'. The first two operational invariants are directly linked to the teaching practice taking place in a real educational context and it is useful to be taken into account in every teacher education course. The third operational invariant reveals parts of the trainee teacher educators' beliefs that seem to influence the ways they design and use resources for teachers' meaningful integration of technology. Thus, the third seems to be a catalyst in favouring less instructive approaches by the trainee teacher educators and at the same time it indicates a domain for interventions in the design and further enrichment of the course. A potential suggestion for reinforcing the reform aspect of the course (or similar courses at the level of educating teacher educators) could be an earlier introduction of practicum. According to our findings, practicum provides a context dense of opportunities for challenging and questioning trainees' beliefs as they externalise them through the cycle 'design-implementation-reflection'. Thus, an early introduction of practicum in conjunction with appropriate mentoring could help trainees to negotiate and redefine their beliefs towards a pedagogically sound use of technology in their teaching.

Context of implementation (grade, duration, location, prerequisite knowledge, social orchestration of the classroom, goals), 5. Phases of implementation (sequence of activities, roles of the

participants, anticipated teaching/learning processes), 6. Possible extension, 7. References.2

2. FP is a multi-representational software with three windows: Table, Graph and Calculator. Function graphs can be produced in a number of different ways, for example, inserting a formula for the function, "receiving" ordered pairs (x, y) from a table ("x" and "y" columns can be generated). Particular icons allow horizontal and vertical transformations of functions (translations, reflections and stretches) through direct actions on the graph. Stretching is carried out with the stretch tool that allows mouse-driven horizontal and vertical stretching. In the Calculator, the user can incorporate functional relations into buttons which reserve these relationships for future use.

A contingent opportunity taken investigating in-between fractions

Bodil Kleve and Ida Heiberg Solem

Oslo and Akershus University College of Applied Sciences, Oslo, Norway

In this paper, we discuss a contingent opportunity from a 7th grade mathematics lesson about decimal numbers, percentages and fractions in Norway. The question if adding numerators and denominators of two fractions was a way to find an in between fraction, occurred. The teacher's response to this question, which we saw as contingent opportunity, is our focus here. Although the teacher did not have the substantive mathematics knowledge needed to give an answer to the problem, many mathematics activities took place in the lesson.

Keywords: Contingent opportunity, teachers' mathematical knowledge, mathematising activities, argumentation and proofs.

INTRODUCTION AND RESEARCH QUESTIONS

When teaching mathematics, teachers are faced with many opportunities – both expected and unexpected. Awareness of opportunities and teachers' decision-making when they occur, is crucial with regard to students' learning outcome (Bishop, 1976) and thus important issues in mathematics teacher education. In the mathematics research literature, several possible responses to contingent moments are discussed (Kleve, 2010; Rowland, Huckstep, & Thwaites, 2005; Rowland, Turner, Thwaites, & Huckstep, 2009; Rowland & Zazkis, 2013). In responding to contingent opportunities, teachers may run a risk.

In a mathematics lesson about fractions, decimal numbers and percentages in a 7th grade in Norway, which we observed, the problem finding an in between fraction arouse, and data from this classroom event create the background for this paper.

Our research question is:

— How can a teacher's decision making to an unplanned opportunity open up for mathematics discussions, even if the teacher does not know the answer?

In order to answer this question, we focus in particular on the mathematizing activities that took place and how the teacher took advantage of the contingent opportunity when it arose. We also investigate how the teacher's knowledge appeared to influence the course of the lesson and thereby supported the students' learning opportunities.

A CONTINGENT MOMENT FROM THE RESEARCH LITERATURE

Earlier research have suggested ways in which teachers may respond when a student suggests how to find a fraction between two given fractions (Bishop, 1976; Rowland & Zazkis, 2013; Star & Stylianides, 2013; Stylianides & Stylianides, 2010). However, authentic data, which display teachers' responses to students' contributions to the task or from classroom discussions, have not been presented. In these studies, how students *may* respond to the task to find a fraction between fractions and how teachers *may* respond to a student's response, have created the background for discussions among prospective teachers.

Referring to the fractions example[1], Bishop (1976) asked the question: "How would you deal with that response?" (p. 41) and he emphasized teachers' decision making, to be at the heart of the teaching process.

1 Teacher: Give me a fraction which lies between ½ and ¾
Pupil: ⅔
Teacher: How do you know that ⅔ lies between ½ and ¾?
Pupil: Because 2 is between the 1 and the 3 and 3 is between the 2 and the 4

Rowland and Zazkis (2013) presented possible (tacit) conjectures made by the pupil who responded to Bishop's fraction example[2]. However, they "did not know how the lesson proceeded mathematically nor whether the teacher took the advantage of the opportunity" (p. 150).

Stylianides and Stylianides (2010) referred a similar scenario in order to exemplify Mathematics Knowledge for Teaching. In this scenario, a student, Mark, suggested adding the numerators and denominators of two fractions to find one in between, and he illustrated that on a number line. They focused on implementation of special tasks in teacher education and discussed how the task (a student's response to finding an in between fraction) could support the development of mathematical knowledge for teaching.

Star and Stylianides (2013) used the fractions task for prospective teachers in mathematics teacher education in order to discuss teachers' mathematical knowledge asking the question: "What can be considered as procedural/conceptual knowledge?" (p. 172).

TEACHERS' MATHEMATICAL KNOWLEDGE

In order to investigate teachers' mathematical knowledge, several frameworks have been developed (Ball, Thames, & Phelps, 2008; Fennema & Franke, 1992; Rowland et al., 2005). Both Ball et al. and Rowland et al. based their work on Shulman's categories of knowledge (Shulman, 1986, 1987). Stylianides and Stylianides (2010) related their work to Ball and Bass (2000; 2003). Using the abbreviation, MKfT, they emphasised mathematical knowledge *for* teaching:

> This specialised kind of mathematical knowledge is important for solving the barrage of mathematical problems of teaching that teachers face as they teach mathematics: offering mathematically accurate mathematical explanations that are understandable to students of different ages, evaluating the correctness of students' methods, identifying mathematical correspondences between different student solutions of a problem etc. (Stylianides & Stylianides, 2010, p. 161)

They suggested that the teacher's mathematical knowledge would influence the course of the lesson and students' learning opportunities. Linked to argumentation and proof they discuss both teacher's mathematical knowledge, which sometimes may deviate from conventional mathematical knowledge (misconception), and knowledge, which is consistent with conventional mathematical knowledge. Harel and Sowder (2007) carried out a study, finding that students' use of numerical examples, as a way of proving, was prominent. In everyday discourse "no rule without exceptions" and "the exception proves the rule" are accepted ways of "proving" something. Studies on teachers' mathematical knowledge and their conceptions about proofs in mathematics, show similar conceptions as revealed by Harel and Sowder (Martin & Harel, 1989; Stylianides & Stylianides, 2010).

Contingency is one of four dimensions in the Knowledge Quartet, KQ, which is a framework for Mathematical Knowledge *in* Teaching (Rowland, 2008; Rowland et al., 2005; Rowland et al., 2009). The KQ provides us with tools for analysing how teachers draw on different kinds of mathematical knowledge in order to support learners in the classroom situations. Contingency is informed by the three other dimensions in the KQ (Foundation, Transformation and Connection) and is about situations in mathematics classrooms, which are not planned for. Identifying "contingent moments" or contingent opportunities in order to analyse aspects of a teacher's mathematical knowledge has proven to be helpful (Kleve, 2010; Solem & Hovik, 2012). The teacher's choice whether to deviate from what s/he had planned and the teacher's readiness to respond to pupils' ideas, are important classroom events within this dimension. The Contingency dimension has also been expanded in a later research (Rowland, 2008; www.knowledgequartet.org; Rowland et al., 2009; Weston, Kleve, & Rowland, 2012). One such expansion is "Teacher's Insight" which is demonstrated when a teacher is realizing that children are constructing the mathematical ideas and something that sounds 'half baked' which means that they are in what Vygotsky (1978) termed Zone of Proximal Development (ZPD) where teacher can help with a scaffolding question or two (www.knowledgequartet.org). In their article, Rowland and Zazkis (2013) discussed several contingent opportu-

2 (C1): Whenever the numerators of three fractions are consecutive integers, and the denominators likewise, the second fraction will be between the two
(C2): Whenever the numerators of three fractions are in arithmetic progression, and the denominators likewise, the second fraction will be between the two

nities, which may occur in a mathematics classroom and whether they are taken or missed. One contingent opportunity that they discussed was similar to the one that actually happened in the lesson we analyse here.

METHODOLOGY

Our data are taken from an ongoing action research project which is about classroom conversations in mathematics focusing on what questions teachers ask (Solem & Ulleberg, 2013). Seven experienced teachers participated in the project. In this project, how questions could be used reflectively in planning a lesson, implementing the lesson and in order to analyse the lesson, were investigated (Ulleberg & Solem, in press). All teachers were observed in teaching a mathematics lesson in own class. We have chosen an episode from a lesson with a teacher, here called Kim. The reason for choosing this episode was not that it was representative for the research project, but that we found it especially interesting with regard to the contingent possibility, which occurred, and the teacher's response to students' input. Our data are field notes (including pictures), transcribed audio recordings from the lesson, and the teacher's prepared notes for the lesson. The lesson is from grade 7 (12–13 years old), and a whole class discussion had taken place. How the teacher drew on his mathematical and pedagogical knowledge in orchestrating the whole class discussion in this lesson is discussed in Kleve and Solem (2014). The teacher's plan for the lesson was to place fraction, percentages and decimal numbers on a number line.

ANALYSIS

As a challenge, the teacher wanted the students to find a fraction that was bigger than 3/5 but smaller than 4/5. According to the teacher's notes for the lesson, finding the fraction in between was supposed to be done by finding equivalent fractions with denominator 10. A student, Lea, suggested 7/10, because "I only doubled both and found what was in between". Then the following contributions from other students in class occurred:

Stud 1: Now it is the same again. 4 plus 3 makes 7.
Stud 2: It was the same last time we did it.
Stud 3: It happened then too, but you said it was a coincident.
Kim: But, may be, there is a pattern here?
Students: yes, yes..
Kim: Wait a minute....
Stud 4: But last time it wasn't ten, but now it is ten, isn't it?
Stud 5: We can add them both, getting ten

Kim then went back to how to get from 3/5 to 6/10 ensuring that all students were following the discussion. He asked Ada to explain to the others. Another student supported Ada saying:

Stud: You just multiply by 2 both in the upper and in the lower.
Kim: We double. Ok. Then back to the exciting thing, we talked about. Some of you are starting to see a pattern, which I am not sure I can see. Hanna?
Hanna: Yesterday we had the same, or we multiplied both with two. And then we saw that- that those numbers, I mean, the numerators, if we added them, it became the same as, yes, as the answer. And it happened now again.

Kim did not miss this contingent opportunity (Rowland & Zazkis, 2013), but responded by letting the students come up with suggestions, and after stud 3, he asked if there might be a pattern. Thus, he deviated from his agenda, which was to find a fraction between two fractions through expanding the two. He eagerly joined the students in searching for a pattern.

In their article, Stylianides and Stylianides (2010) discussed two possibilities from a similar scenario. One was that the teacher might consider the students' method to be correct because it works in different examples. The other possibility was that unless the method was shown to work for all possible cases, it could not be accepted as correct. Let us see what happened in our lesson:

Kim: Ok. But if it has happened twice, are we then sure it will happen next time?
Tiril: No, but there is a rule which is that if it happens once it is a coincident, twice, it is especially, three times, it is Ok.
Kim: Three times, then it must be like that? Does such rule exist?
Students: it is, ... no, no
Students: Can just be luck
Kim: OK, let us try

This suggests that Kim had knowledge about the distinction between empirical argumentation and proofs in mathematics. Although he expressed doubt about Tiril's rule (a method is correct if it works in three different examples), he invited his students to try a third time (the first was from yesterday, the second was 3/5 and 4/5), suggesting 1/4 and 2/4 and asked for a fraction in between. He challenged Januscha to explain:

Januscha: One plus two, I added the numerators, which made three, and the denominators, made eight. And to be sure, I doubled it too..
Kim: And then you got 3
Januscha: of 8
Kim: Did you all find the same? (Students confirmed)
Kim: OK, So we can see a pattern here now. But are we sure, does this apply to absolutely all fractions?
Students: That we don't know.
Ronja: I think, I don't know if it applies to fractions with different denominators
Kim: Ok?
Student: I think it applies to all fractions, because if 1/4 – if you multiply by two you get 2/8 and then you get 4/8 and that is in between (explaining that 3/8 is between 1/4 and 2/4).

Kim now suggested that they were seeing a pattern, but he emphasized uncertainty that it applied to all fractions. Thus, he exposed his students to hypothesize and to come up with conjectures. Ronja's question, if it applied to fractions with different denominators, was one conjecture, which opened up the possibility to find a counter example.

Kim did not follow up the students' hypotheses at this point, but he insisted further investigations with fractions with same denominators, and drew attention to the distance between the numerators. Proposing 3/5 and 5/5, he asked: "what if the distance between the numerators are bigger than one"? The students did not find this challenging at all:

Student: But if it is bigger distance between them, there is no challenge. What is it that is between 3/5 and 5/5? It's got to be 4/5!
Kim: Good. I agree that the challenge may disappear a little, but we have to check this out now. We are curious to know, aren't we?

Here, we suggest that the task had changed. Kim's point was no longer to find a fraction between two given fractions but to investigate if the "rule" -adding numerators and denominators to find an in between fraction- worked in different situations, also when the solution was obvious. Kim's proposal to have more than one between the numerators resulted in an "obvious example" (3/5 and 5/5) suggested by a student, who expressed that it was not challenging at all. Instead of being engaged in Kim's obvious example, the students contributed with further conjectures (which are partly contracting):

— I think it always goes when there is one even and one odd numerator

— When there are two even numbers or two odd numbers there is always a number between

— When there is one number of each, then it goes

— When there are two even or two odd, it will not work, but if there are one even and one odd, it works.

This demonstrates that the way Kim was teaching opened up for students' engagement and participation in mathematizing activities. Making conjectures and hypotheses are important ingredients in the learning of mathematics. The conjectures the students made, were general (about odd, even, and different numbers) and not linked to concrete numbers. Kim's response to these hypotheses were:

Kim: Ok- good. We are getting short of time, but this we *have to* check out. How can we check it all out?
Students: Do it many times
Kim: Shall we use "Tiril's method" and try: if it works the third time, it is ok, or what, how shall we do this?
Students: Why don't we try?
Kim: Ok, Then, firstly, I would like to try once having more than one in between. Let us do that first. Afterwards we can do it like you suggest with different denomi-

nators. So if we have…. We can take 3 of 8 and 5 of 8, then we have, the distance here is 2.

The students now agreed to go for Kim's suggestion first, for which he gave the following reason:

> Just so you do not believe…. that we can do it this way with the rest – that we just can add them together.

Now an eager discussion now took place. They had expanded the fractions to 6/16 and 10/16. We can hear students saying, "yes it goes", "it is four in between". Kim asked if they could choose between 7, 8 and 9, when a student said:

Student:	The middle is 8/16 and if we take 3+5 you get 8.
Kim:	Yes, good, it works.
Student:	It would have been the same if we just took different fractions. 3 of 8, and 4 of 8, or 4 of whatever. Just making different fractions.

This discussion ended up with the following statement from Kim:

> You know, now we are within an area in which I haven't checked either. Neither do I know for sure where this entire end up. I am not in the position to see all the patterns here either. Therefore, I find it very exciting. [] At least. Here we have lots of material we can work on in the future. But, you know what? We haven't done what we were supposed to do in this lesson (to place the fractions, percentages and decimal numbers on a number line)

This statement shows that Kim neither knew if it was possible to find an in-between fraction generally by adding the numerators and denominators, and consequently nor to prove it. Although he expressed that he did not know where it all would end up, he expressed excitement and was challenged to work further with the issue.

DISCUSSION

In this lesson a contingent opportunity occurred. Several students suggested that it was possible to find a fraction between two fractions by adding the numerators and denominators (Fareys mediant). The analysis above shows that the teacher deviated from the agenda and followed up the suggestions from the students. In grasping this contingent opportunity Kim took a risk. Although he neither knew if the conjectures were correct, nor had the advanced mathematical knowledge needed for proving the conjectures made, he deviated from the agenda and incorporated the students' suggestions in the further course of the lesson. Hence we see, that the mathematical knowledge he had, and also the mathematical knowledge missed, influenced the course of the lesson and thus the students' learning possibilities. Together with the students, he investigated their suggestions and claims. In asking "But are we sure, does it apply to absolutely all fractions?" Kim demonstrated mathematical knowledge about mathematical proving and signaled that it is not sufficient with numerical examples to generalize in mathematics. On the contrary, trying out different examples could have opened up for a counter example, which we suggest that he was looking for. This indicates that his substantive content knowledge incorporated what is a mathematical proof.

Since Kim did not have the mathematical knowledge needed to answer if adding the numerators and the denominators would make an in between fraction, he was not in a position to say "yes, it is correct", nor "it is not correct". The only tool Kim had was to try, and this he did in collaboration with the students. He encouraged his students to come up with several conjectures. The mathematical activities which took place incorporated hypothesizing if the rule, adding the numerators and the denominators to find an in between fraction, would work in different situations: fractions with different denominators, fractions where both numerators are odd, both numerators are even, one numerator is even and one is odd, different distances between the numerators.

The conjectures made:

- Adding numerators and denominators made an in between fraction (common denominators).
- Does it apply to all fractions?
- Does it apply to fractions with different denominators?

— No, but there is a rule which is that if it happens once it is a coincident, twice, it is especially, three times, it is Ok.

Formulating hypothesis, making conjectures and searching for patterns are important activities in learning mathematical thinking. The way Kim took advantage of students' input and questions, offered possibilities for the students to participate in these activities. Kim was sensitive to the students' mathematical knowledge (knowledge of content and students) and posed questions accordingly (knowledge of content and teaching). Posing appropriate questions as Kim did, is extremely demanding (Kleve and Solem, in press) and this episode displayed how he drew on his mathematical knowledge for teaching.

Although Kim did not have the necessary command of substantive knowledge to prove the rule (Fareys mediant), he did not close the door for mathematising activities, and a fruitful mathematical discussion to take place.

IMPLICATIONS FOR TEACHER EDUCATION AND RESEARCH

Research referred in the beginning of this paper, have suggested ways in which teachers *may* respond to a similar contingent opportunity, which actually happened in the lesson we observed and have analyzed here. Authentic records of teaching, whether they are videos or transcripts of data, are extremely powerful sites for learning: "Teachers and researchers are finding that analyses grounded in actual practice allow a kind of awareness and learning that has not previously been possible" (Boaler & Humphreys, 2005, p. 4).

Our teacher did not know the answer. However, these data demonstrate for student teachers that taking the risk and grasping the contingent opportunity may lead to fruitful mathematising activities. In mathematics teacher education, proving $\frac{a}{b} < \frac{a+c}{b+d} < \frac{c}{d}$ algebraically is possible. Another possibility is to show with functions and graphs (Stylianides & Stylianides, 2010). However, these proofs are not accessible for children in 7th grade. Therefore discussions how to illustrate Fareys mediant for these children may be relevant. For example, if the juice analogy referred in Rowland and Zazkis (2013), is an accepted argument for "the adding numerators and adding denominators procedure" can lead to good discussions among student teachers.

In further analysis of data from this teacher's teaching, we are interested in finding out what socio-mathematical norms were established in his class and what role the norms played for the mathematical activities that took place, such as use of language and classroom discussions, and hence students' learning possibilities.

Supporting students' development of mathematical explanation: A case of explaining a definition of fraction

Minsung Kwon

University of Michigan, Ann Arbor, USA, mskwon@umich.edu

This paper aims to conceptualize the work of supporting students' development of mathematical explanation. To provide an empirical basis, I analyse instructional interactions managed by the same teacher for teaching the brown rectangle problem for different cohorts of students across five years. The four core tasks of teaching are (1) attending to the organic structure of the mathematical task; (2) mapping the scope of answers onto the targeted mathematical ideas; (3) hearing the mathematical needs embedded in students' explanations; and (4) distributing and building a mathematical talk collectively.

Keywords: Decomposition, the work of teaching, mathematical explanation, fraction.

INTRODUCTION

Teaching is often described as a complex activity because it involves managing multiple relationships simultaneously with students and with content over time (Cohen, Raudenbush, & Ball, 2003; Lampert, 2001). To make this complex work doable and learnable for teachers, especially for beginning teachers, several scholars (Boerst et al., 2011; Grossman et al., 2009; Sleep, 2012; Thames, 2009) have addressed the need to decompose the work of teaching into its constituent components. As a result, a core practice of teaching has begun to be decomposed into nested practices with varying grain sizes. Despite these initiatives, the call for "a specific technical language for describing the implicit grammar and for naming the parts" (Grossman et al., 2009, p. 2069) has not met an agreed-upon robust framework yet. For example, in decomposing the work of steering instruction toward the mathematical point, Sleep (2009) identifies seven core tasks of teaching and further decomposes each core task into strategies and problematic issues. The core tasks she identifies are not mutually exclusive but rather might be enacted simultaneously. Furthermore, in decomposing each core task into strategies, she does not associate it with particular teaching moves. On the other hand, in decomposing the work of leading a mathematical discussion, Boerst and colleagues (2011) start with the larger grain size of domains (e.g., leading a discussion) and then specify it into a smaller grain size of techniques (e.g., revoicing), while articulating intermediate practices (e.g., clarifying student thinking) that connect between domains and techniques. A brief review of literature on decomposition, despite focusing on a different domain of teaching practices, gives a particular prominence to the structure of decomposition, the level of decomposition, and the link to teaching moves or discourse moves.

Given the lack of agreed-on grammar for decomposing the work of teaching, this study aims to decompose one of the key teaching practices that are crucial for accomplishing the ambitious goal of developing mathematical power and mathematical proficiency for all students: the work of supporting students' development of mathematical explanation. The practice of giving, hearing, and evaluating explanation has been considered an important goal for learning because it resolves cognitive dissonance and facilitates cognitive development in the process of knowledge construction. More specifically, giving explanations can serve as opportunities for students to reflect on their own thinking and to reconstruct their existing knowledge, while hearing others' explanations provides opportunities for students to appropriate language that a teacher or more advanced students use, to recognize any cognitive dissonance that contradicts their own understanding, and to use others' explanation as a resource to extend their own knowledge.

Despite its crucial role for learning, there is a general consensus that most students do not have sufficient opportunities to develop their own explanations in U.S. mathematics classrooms (e.g., Stigler & Hiebert, 1999). One reason might be that many teachers believe that giving an explanation to students is more efficient and less complicated than eliciting an explanation from students. Even if this belief is being challenged as greater emphasis is being placed on eliciting an explanation from students, it is pedagogically demanding work for teachers. This is well captured by Cohen's (2011) metaphor in describing challenges in extending students' knowledge as he writes:

> Teachers and learners face the same gulfs of ignorance, but from different sides. Learners must somehow build bridges across the gulf, but these bridges are often fragile because the learners work from relative ignorance. The teacher's assignment is to help learners build those bridges, but they work from greater knowledge. ... Rather than helping learners construct and reconstruct bridges of their own, teachers present the finished results of their learning. That reduces the likelihood that teachers can cultivate a practice of teaching, for it can limit learners' understanding. (Cohen, 2011, p. 106)

This metaphor also applies to challenges in supporting students' development of mathematical explanation. On the one side, students do not have sufficient language to explain their mathematical ideas (Forman & Larreamendy-Joerns, 1998) and their explanations are distant from disciplinary explanation (Leinhardt, 2001). On the other side, teachers often present the compressed, polished, and finished form of mathematical explanations to students rather than helping students construct their own explanation. Considering this demanding but crucial work, this study examines what is entailed in supporting students' development of mathematical explanation, and particularly, the ways of using instructional resources to that end.

METHOD

The methods for studying teaching have adopted terms, concepts, and techniques from other disciplines (e.g., grounded-theory; ethnography), but have not further articulated how the selected method addresses issues that particularly matter for teaching. To make an explicit connection between the phenomenon being studied and the method being chosen, I briefly articulate the study design, which is situated in the instructional triangle (Cohen et al., 2003).

Teaching is often examined as a single case in which a teacher teaches a particular topic for a single group of students, but multiple cases of teaching are also examined. In such an examination, a variety of methods are employed. One way of examining multiple cases is to maximize the variation of components within the instructional triangle—a teacher, students, and contents. For example, to identify elements of expertise of teaching, Leinhardt (1985) contrasts performance of expert teachers with that of novice teachers. In another example, in order to identify the common model of instructional explanation and to specify the features of instructional explanation in each subject, Leinhardt (2001) analyses instructional explanations in history and in mathematics.

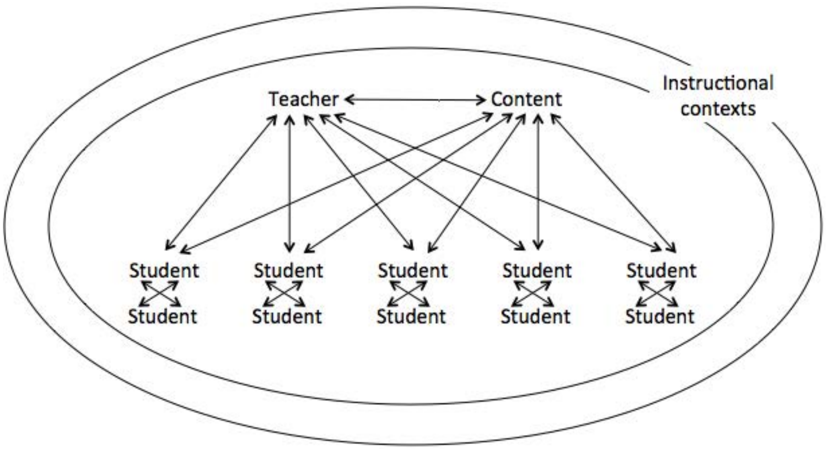

Figure 1: The study design

This paper approaches the problem in another way, minimizing much of the variation among components of the instructional triangle in a more controlled context in which only students vary (see Figure 1). As one of the greatest predicaments of teaching is its dependence on students (Cohen, 2011), analysing instructional interactions managed by the same teacher teaching the same mathematical task to different cohorts of students without substantial differences in students' mathematical abilities is crucial to identify the core tasks of teaching across the particulars of students and unfolding instructions. This method untangles the ways in which the same teacher adjusts the work of supporting students' development of mathematical explanation wherein each cohort of students brings different mathematical ideas, stances, issues, language, ambiguity, and difficulties in explaining the same mathematical task.

To provide an empirical basis, I analyse a longitudinal data set from the Elementary Mathematics Laboratory (EML), a two-week summer mathematics program for entering fifth graders taught by Professor Deborah Ball at the University of Michigan's School of Education, across five years (EML2007, EML2008, EML2009, EML2010, and EML2013). There are no prerequisites to participate in the EML, but it mainly focuses on students who are struggling with learning mathematics rather than students who are outperformed in mathematics. Considering the process of recruitment, there were no substantial differences in students' abilities in mathematics across five years. Each year, approximately 25–30 students, who are ethnically, racially, linguistically, and socioeconomically diverse, participate in a whole-group mathematics class every morning during the two-week program.

As part of a large-scale study which analyses instructional interactions managed by the same teacher for teaching four different mathematical tasks across multiple years, this paper mainly focuses on the brown rectangle problem (see Figure 2). The brown rectangle problem has been used with slight variations in the layout of the rectangle (i.e., where the shaded part is located; the rotation of the drawing), the colour of shaded parts, the inclusion of written problem statement on the poster, the presentation of two sub-problems (posting together vs. posting separately), and the wording of the problem statement (the big rectangle vs. the rectangle; shaded in vs. shaded

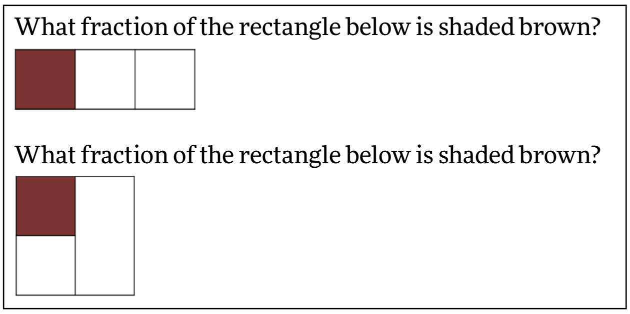

Figure 2: The brown rectangle problem

in brown), but the mathematical demand remains the same across years.

The analysis of each individual year provides detailed images of explanations that individual students produce, the process of constructing a mathematical explanation collectively by each cohort, and instructional supports that the teacher provides to develop a mathematical explanation for the brown rectangle problem. The cross-year analysis illustrates that instruction for teaching the same mathematical task unfolds somewhat differently, even by the same teacher. The similarities across multiple cases become strong candidates to be scaled up into the coherent structure of supporting students' development of mathematical explanation, whereas the differences across multiple cases offer analytical opportunities to examine whether or not the particular instructional feature plays a role in supporting students' development of mathematical explanation. In doing so, I do not treat such differences as discrepant or disconfirming evidence, but use the differences as the data to reveal the underlying structure of the work of teaching to support students' development of mathematical explanation. In addition, the differences observed across years do not necessarily represent the characteristics of the expert teacher's teaching practice. Looking at the multiple uses of the brown rectangle problem by the same teacher to different groups of students allows to elicit the demands entailed in the work of supporting students' development of mathematical explanation and framing the underlying structure that serves to meet such demands.

PROBLEMS OF STUDENTS' INITIAL EXPLANATIONS FOR THE BROWN RECTANGLE PROBLEM

In order to understand what is entailed in supporting students' development of mathematical explanation, it is critical to first diagnose problems that students have in explaining the brown rectangle problem. Some of these problems are more generic and apply to all mathematical tasks, but others are more unique to a particular mathematical task. If each mathematical task would require a specialized form of reasoning to develop a mathematical explanation, the problems that students struggle with would be different and the supports that a teacher needs to provide would be different accordingly. Identifying such problems, both generic and unique to the type of mathematical task, contributes to revealing how a mathematical task plays a role in the work of teaching and the use of instructional resources. The following list below is a more general characterization and a more comprehensive collection of problems that individual students have in offering an initial explanation for the brown rectangle problem across five years.

- Having difficulties providing, hearing, and constructing an explanation
- Not establishing the mathematical grammar to describe the objects to be explained
- Using inaccurate language in which its intended meaning is different from the accepted mathematical definition
- Using pre-defined mathematical terms
- Skipping the logical structure of naming a fraction or paying attention to the partial components of naming a fraction
- Losing the purpose and focus of what is being explained
- Not building correspondences between an answer, an explanation, and representations
- Heavily using demonstrative pronouns
- Grounding explanation on non-mathematical reasons or procedural knowledge
- Missing the key definitional ideas of naming a fraction

Despite sharing these similar problems in explaining the brown rectangle problem, the collective process of constructing mathematical explanation does not always remain the same across five years.

THE CONSTRUCTION OF COLLECTIVE RESOURCES: DIFFERENCES ACROSS COHORTS AND IMPLICAITONS FOR TEACHING

The process of recruiting and selecting EML students is quite similar from one year to another, so it is presumed that there are no substantial differences in students' mathematical abilities across five years. Despite the homogeneous features of the EML cohorts across five years, the cohort's mathematical ideas, stances, dispositions, and issues do not always remain the same. The observed differences are (1) the answers that the students collectively discuss in a public space; (2) the proportion of the students who produce correct answer to the students who produce incorrect answers; (3) the intensity of counterarguments made against a competing proposal and the process of being convinced by a competing proposal; (4) when the key idea of "equal" emerges; and (5) mathematical issues that matter the most for each cohort.

First, the answers that each cohort discussed collectively in a public space are not the same. For the first part of the brown rectangle problem, only one correct answer (1/3) was proposed in the EML 2007, the EML 2008, and the EML 2010, but three answers (1/3, 2/3, and 2/6) were proposed in the EML 2009 and two answers (1/3, 1/2) were proposed in the EML 2013. For the second part of the brown rectangle problem, four answers (1/4, 1/3, 1 and 1/3, and 1/2) were proposed in the EML 2007, two answers (1/4 and 1/3) were proposed in the EML 2008, one answer (1/4) was proposed in the EML 2009, five answers (1/4, 1/3, 1/6, 2/8, and 4/16) were proposed in the EML 2010, and three answers (not a fraction, 1/4, and 1 and 1/2) were proposed in the EML 2013. Even though the teacher made similar attempts to elicit multiple answers, different groups of students brought a different set of answers in a public space. Beyond attending to the number of answers elicited in a public space, an important task of teaching includes (1) not dismissing any proposals made in a public space but unpacking the reasoning behind the proposals; (2) introducing the key incorrect answers if they are not brought by students; (3) mapping the proposed answers to the targeted mathematical ideas; (4) deciding what needs an immediate agreement or disagreement and what needs to be preserved; and (5) customizing questions, probes, and prompts based on the dynamics of proposed answers.

Second, the proportion of the students who produced correct answer to the students who produced incorrect answer is not the same across cohorts. For the first part of the brown rectangle problem, nearly all of the students came up with the correct answer. On the other hand, for the second part of the brown rectangle problem, the incorrect answers were more prevalent than the correct answer in the EML 2007, the EML 2008, the EML 2010, and the EML 2013, but most of the students recorded the correct answer in the EML 2009. If the proportion of correct answer to incorrect answers might be related to the mathematical stance that students bring to the instruction, an important task of teaching includes (1) surveying the composition of students' mathematical ideas; (2) ensuring that a mathematical stance is not influenced by the idea held either by the majority of students or by advanced students; and (3) customizing questions, probes, and prompts based on the proportion of the students who produce correct answer to the students who produce incorrect answers.

Third, the intensity of counterarguments made against a competing proposal and the process of being convinced by a competing proposal was not the same. Except in the EML 2009, students proposed the key incorrect answer of 1/3 for the second part of the brown rectangle problem, but the degree of defending the incorrect answer and what made them being convinced by the correct answer was not the same. Some cohorts were more easily convinced by the idea that adding a line makes equal parts, but others were more resistant and hesitant to accept the idea because it contradicts their non-mathematical perception that adding a line changes the problem. The process of reconciling the competing proposals was not the same across five cohorts, but all of the cohorts ultimately arrived on the agreement that making equal parts is an important idea for naming a fraction and drawing a line provides an easy access to seeing the equal parts. As the intensity of counterargument and the resistance of accepting the competing proposal increased, the cohort constructed richer collective resources to convince others who had a competing proposal. It is not an easy task for a teacher to support students to have a strong stance on their mathematical ideas and to have them sustain their perseverance, but detecting such a moment, confronting competing ideas, and providing sufficient opportunities to defend one's proposal is an important task for supporting students' development of a mathematical explanation.

Fourth, the key idea of "equal" emerged at different stages of developing a mathematical explanation. It was early proffered by a student who proposed the answer of 1/4 in the EML 2007 as well as by a student who proposed the answer of "not a fraction" in the EML 2013, but emerged in the process of comparing between the equally partitioned rectangle and the unequally partitioned rectangle in the EML 2008, 2009, and 2010. Eliciting the targeted mathematical idea and developing the accurate mathematical language is key for developing a mathematical explanation, but an important task is not just accepting the targeted mathematical idea offered by a single individual student, but providing supports for students to use those collective resources.

Lastly, the mathematical issues that matter the most for each cohort are not always the same. For the second part of the brown rectangle problems, the EML 2007 cohort spent a significant amount of time to make sense of 1/2, the EML 2008 cohort discussed whether or not the line changes the problem, the EML 2010 cohort engaged in removing the existing line or adding an additional line to make unequal parts, and the EML 2013 cohort spent time making sense of 1 and 1/2. An important task of teaching is to adjust the instructional time according to the mathematical issues that each cohort struggles with the most.

In basic ways, the students and their mathematical proficiency were similar across years, but each cohort brought different mathematical ideas, stances, dispositions, and issues to explain the brown rectangle problem. Thus each cohort developed different collective resources that became available for use either by the teacher or by students. In comparing the mathematical ideas, stances, dispositions, and issue brought by different groups of students, I offer the following observations. First, the mathematical scope and terrain of collective resources that each cohort establishes varies to a certain degree, but all of the five cohorts develop the key ideas for naming a fraction. Second, there are variations in what collective resources are available for use to develop a mathematical explanation across cohorts, but the practice of constructing collective resources is quite the same. Third, some collective resources are for immediate or necessary use, but others remain in reservoir or are optional for use either by a teacher of by students. Fourth, the same mathematical issue is treated differently based on the established knowledge that each cohort constructs. Lastly, eliciting multiple answers has been considered an important pedagogical practice for fostering students' mathematical abilities and enriching mathematical discussion, but how the proposed answers could be used as resources for maximizing the development of mathematical explanation needs to be further examined.

THE CORE TASKS OF TEACHING

The four core tasks in supporting students' development of mathematical explanation for the brown rectangle problem are: (1) attending to the organic structure of the mathematical task; (2) mapping the scope of answers onto the targeted mathematical idea; (3) hearing the mathematical needs embedded in students' explanation; and (4) distributing and building a mathematical talk collectively.

The first core task is attending to the organic structure of the mathematical task. This core task includes (1) focusing on mathematical or non-mathematical attributes which impact the construction of an explanation (e.g., "big rectangle"; the affordance of sticky line; drawing the rectangle on the grids); (2) not attending to mathematical or non-mathematical attributes which substantially distract from the construction of an explanation; (3) recognizing how the design of the mathematical task creates or eliminates confusions and how the design of the mathematical task makes the key ideas implicit or explicit.

The second core task is mapping the scope of answers onto the targeted mathematical ideas. This includes (1) being aware of the scope of answers that students propose; (2) deciding which of the proposed answers needs an immediate acceptance or denial and which needs to be preserved; (3) not delving into the ideas that students do not have a shared access to; (4) not diverging into the ideas that seriously deviate from the targeted mathematical ideas; and (5) spending sufficient instructional time on scaling up the proposed answers to the targeted mathematical ideas.

The third core task is hearing the mathematical needs embedded in students' explanation. This core task includes (1) recognizing inaccurate or inconsistent language use that impedes building a mathematically acceptable form of common knowledge; (2) deciphering the vague, unclear, or implicit idea conveyed by students' explanations; (3) providing supports to build mathematical connections or correspondences instead of repeatedly asking general questions; and (4) recognizing the skip of or the deviation from the logical structure of building an explanation.

The last core task is distributing and building a mathematical task collectively. This core task includes (1) not exclusively relying on one students' contribution; (2) being attentive to the trajectory of constructing a mathematical explanation; (3) appropriately or sufficiently using a private space and a public space; and (4) making each other's contribution accessible in a public space.

DISCUSSION

Given that one of the greatest predicaments of teaching is its dependence of students, it is important to figure out how instruction might unfold with different groups of students. On the one hand, one might speculate that instruction would unfold in the same way by the same teacher teaching the same mathematical task because a teacher might make the same decisions based on his or her knowledge, skills, disposition, and instructional goals. On the other hand, one might suggest that instruction would unfold in a dramatically different way even by the same teacher teaching the same mathematical task because teaching entails being responsive to students. The question of how instruction unfolds with different groups of students might be answered based on one's personal sensibilities or perceptions built through years of their own teaching experiences, but it is not yet rigorously examined in the field how instruction managed by a teacher teaching the same mathematical task is likely to unfold differently with different groups of students; how collective resources are likely to be constructed differently with different groups of students; and what is the underlying structure of using collective resources with different groups of students. By analysing instructional interactions managed by the same teacher teaching the same mathematical task for different cohorts of students, this study contributes to identifying core tasks of teaching across the particulars of students and unfolding instructional dynamics.

The four core tasks of teaching are not just a mere collection of temporal stages, general pedagogical strategies, instructional routines, or discourse moves, but devised to structurally and attentively capture the essential elements of instructional interactions. Approaching through pedagogical strategies or discourse moves might be one way of examining what is entailed in supporting students' development of mathematical explanation, but it entails the risk of losing some key elements of instructional interactions. Instead, this study conceptualizes core tasks of teaching by taking into serious account the three-pronged arrows that a teacher has relationships with in the instructional triangle (students, content, and students-content) and by anchoring the core tasks of teaching into these relationships. These four core tasks are neither sequential nor mutually exclusive. Even though there exist differences in what bring to foreground and what leaves as background, all four core tasks of teaching attend to the coordination between students and mathematics.

ACKNOWLEDGEMENT

The data used in this paper were documented by the EML project at the University of Michigan. The author would like to thanks to the EML project giving me a permission to use the data. The opinions in this paper are those of the author, but not necessarily reflected by the teacher, Ms. Ball. This paper is a part of the author's doctoral dissertation.

Exploring a framework for classroom culture: A case study of the interaction patterns in mathematical whole-class discussions

Maria Larsson

Mälardalen University, Västerås, Sweden, maria.larsson@mdh.se

Research is needed on frameworks that support teachers in the important and challenging work of orchestrating productive problem-solving whole-class discussions. The aim of this paper is to explore a framework for classroom culture with the overarching goal of supporting teachers in conducting class discussions focused on argumentation as well as connection making. Analyses of video-recorded whole-class discussions result in the articulation of some difficulties in clearly distinguishing between certain interaction patterns within different classroom cultures. The overall findings, however, suggest that the framework can be useful for characterizing interaction in terms of an inquiry/argument classroom culture.

Keywords: Interaction pattern, whole-class discussion, classroom culture, inquiry/argument, instructional practice.

INTRODUCTION

There is great consensus within the mathematics-education field that mathematical instruction needs to provide opportunities for students to participate in instructional practices that develop their mathematical competencies (NCTM, 2000; NRC, 2001). To understand mathematics, reflection and communication are key (Hiebert, Carpenter, & Fennema, 1997). Participating in whole-class discussions of multiple solutions to a challenging problem have great potential to allow students to reflect and communicate. However, interactions in various reform-oriented classrooms differ significantly, and it is important to relate these differences to students' thinking and learning. Supporting teachers in engaging students in interaction that promotes their mathematical thinking is central, and frameworks for teachers' actions can help. More research is needed on such supportive frameworks.

I have previously (Larsson, 2015; Larsson & Ryve, 2011, 2012) investigated ways that teachers can plan and conduct productive whole-class discussions of students' different solutions to challenging mathematical problems and have discussed ways that Stein, Engle, Smith, and Hughes's (2008) model can support teachers in this important and demanding work. In short, the model consists of five practices that build on each other: anticipating, monitoring, selecting, sequencing, and connecting student solutions. However, this model does not explicitly focus on how a teacher could productively interact with students in whole-class discussions.

Among frameworks that focus on interaction (e.g., Boaler & Brodie, 2004; Brodie, 2010), I find Wood, Williams, and McNeal's (2006) proposal especially interesting because they have found that an inquiry/argument classroom culture is closely associated with higher cognitive levels of student thinking. Moreover, Franke, Kazemi, and Battey (2007) see the promise of connecting Wood and colleagues' (2006) interaction patterns to Stein and colleagues' (2008) model, which is central to my research. Wood and colleagues (2006) distinguish between two types of reform-oriented classroom cultures: strategy-reporting and inquiry/argument. In the latter culture, there is a "major shift in participation from an emphasis on the child reporting her/his different strategies to the children as listeners taking over the role of the teacher in questioning, clarifying, and validating mathematical ideas" (p. 235). The role of the listening students is hence crucial for distinguishing between the two types of reform classroom cultures. Wood and colleagues (2006) state that their most important finding is the differences between the two reform classroom cultures.

The overarching goal of my research is to help develop frameworks that support teachers in conducting productive whole-class discussions that focus on argumentation as well as connection making (see Larsson, 2015). In relation to this broad aim, this particular paper explores Wood and colleagues' (2006) framework for interaction patterns. More specifically, it aims to articulate the difficulties, if any, in distinguishing between interaction patterns—in particular, reform interaction patterns. I delineate the conceptual framework and the methodology that I use before presenting my results, illustrated by a fine-grained analysis of one particular whole- class discussion.

CONCEPTUAL FRAMEWORK

I use Wood and colleagues' (2006) conceptual framework for investigating specific interaction patterns in the whole-class discussion that I analyze. The purpose of their framework is to better understand which opportunities for learning arise in various classroom cultures. Wood and colleagues (2006) divide the interaction patterns into three categories: (i) patterns common to all instruction, (ii) patterns of conventional instruction, and (iii) patterns of reform instruction. The only pattern common to all instruction is *Collect answers*, in which the teacher collects answers to a problem with the purpose of making them public. I have summarized the interaction patterns that characterize conventional instruction and reform instruction in Tables 1 and 2.

METHODOLOGY

The data source for this paper is a collaboration with a very proficient teacher regarding mathematical problem solving discussions with over 15 years of teaching experience. I observed this teacher during eight days in one academic year without making interventions, with a particular focus on the teacher's orchestration of whole-class discussions of students' different solutions to challenging mathematical problems. The teacher strives to engage students in inquiry and argumentation in a collaborative spirit, making it interesting to analyze her whole-class discussions with Wood and colleagues' (2006) framework. Data consist of transcribed video-recorded lessons focusing on the teacher during whole-class discussions, audio-recorded pre- and postlesson teacher interviews for every lesson, and collected student solutions. To interpret the videotaped, transcribed whole-class discussions, I performed a fine-grained analysis of four whole-class discussions using Wood and colleagues' (2006) conceptual framework. All lines were coded in segments, each of which was categorized into one interaction pattern according to Wood and colleagues' (2006) descriptions (see my summary in "Conceptual Framework," above). One additional person coded one of the whole-class discussions. The categorizations were then compared, and we discussed them to resolve differences.

ANALYSIS AND RESULTS

As an illustration of how this particular teacher interacts with her students in a whole-class setting, I use excerpts from a discussion in sixth-grade about students' solutions to the problem "Houses of Cards" (Larsson, 2007). Students allowed for far-reaching generalizations, considering that they were only in sixth grade. This discussion has been chosen because it reflects the typical way this teacher interacts with her students in a whole-class setting.

Interaction pattern	Description	Purpose	Initiator
IRE (Initiate-Respond-Evaluate)	Teacher asks a test question, students' responses are confined to yes/no or right/wrong, and the teacher evaluates.	To check what students know.	Teacher
Give expected information	Similar to IRE, but students' answers can be more open.	To check what students know.	Teacher
Funnel	Teacher leads student(s) to the answer by a number of test questions.	To correct an incorrect student answer without telling the answer.	Teacher
Teacher explain	Teacher gives (often lengthy) explanations of key mathematical ideas/concepts.	To tell students what they are expected to learn and know.	Teacher
Hint to solution	Teacher gives a hint that takes away the challenge of the problem.	To ensure that students reach a correct answer quickly without struggle.	Teacher

Table 1: Conventional-instruction interaction patterns (summary of Wood et al., 2006)

Interaction pattern	Description	Purpose	Initiator
Explore methods	Students explain their solution strategy.	To give multiple solution strategies.	Teacher or student(s)
Inquiry	Teacher or student(s) ask questions because they do not understand.	To understand.	Teacher or student(s)
Argument	A student listener challenges an idea because (s)he disagrees, after which students participate, taking turns.	To reach to a resolution.	Student listener
Teacher elaborate	Teacher elaborates on a student's explanation because information is lacking.	To provide more information to the students.	Teacher
Proof by cubes	Teacher uses material either to find the correct answer or to gain understanding.	To get to the correct answer or provide insight.	Teacher
Proof of answer by student explanation	Teacher lets student(s) explain their correct solution.	To ensure that the class hears a correct solution.	Teacher
Focus	Teacher first provides a summary before asking a question that focuses students on what they need to resolve.	To orient students toward key aspects.	Teacher
Build consensus	Teacher tries to have the class agree on a key mathematical idea.	To establish common ground in the class.	Teacher
Check for consensus	Teacher checks with students to see whether they have questions or comments on a student idea.	To open up for questions and comments before moving on.	Teacher
Develop conceptual understanding	Teacher asks a question that addresses a specific idea or concept.	To facilitate students' conceptual understanding.	Teacher
Pupil self-nominate	A student voluntarily offers an idea or insight that goes beyond the topic and explains/justifies the idea.	To have students exercise their autonomy as participants.	Student

Houses of Cards (Larsson, 2007)

Albin and Melvin are building houses of cards as the picture shows.

1) How many cards does a house of cards contain that has

   a) 3 floors?

   b) 4 floors?

   c) 5 floors?

   d) 12 floors?

   e) n floors?

Figure 1

2) A house of cards consists of 408 cards. How many floors does it have?

3) Make up a problem of your own and solve it.

Four different student solutions were discussed by the whole class for the general case of the problem. Table 3 displays the solutions in the order they were brought up for whole-class discussion.

Before the whole-class discussion, the students have worked on the problem individually and in pairs. First, Paula and Johanna's unusual strategy is explored. The two students help each other, trying to explain their strategy, whereupon the teacher asks whether anybody understands (checks for consensus) and then asks for the n^{th} figure if it is odd. Johanna explains again and inquires: "But I don't really know how to find a formula for it." The teacher asks: "Can someone else find out how they could write it? The n^{th} figure is $n \cdot 3\cdot$ something [shows in the table]. If we have 13, it's 7. If we have 11, it's 6. If we have 9, it's 5. If we have 7, it's 4." In several turns, the students and teacher collaborate, which is central to inquiry instruction (Wood et al., 2006), to find that "something" must be $(n + 1) / 2$, and Paula concludes, "That works. Then it's $n \cdot 3$ times $n + 1$ divided by 2." Then Axel gets to explain his strategy (see excerpt below). The interaction patterns

  1.Paula and Johanna after discussion: $(n \cdot 3) \cdot (n + 1) / 2$	 2. Axel after discussion: $n \cdot (n + 1) \cdot 3 / 2$
 3. Lena and Frida $((n \cdot n) + n) / 2 \cdot 3$	 4. Andreas $(n \cdot (n + 1) / 2) \cdot 3$

Table 3: Student solutions in class discussion of "Houses of Cards," in sequential order

from Wood and colleagues' (2006) framework that my analysis yielded are included as headings.

Explore methods

1 Axel: I thought a little like Paula, like she did on this one with—what was it?

2 Students: Flowers.

3 Axel: With flowers, exactly.

4 Students: Aha.

5 Axel: Then I thought that you have to add another card house—but sort of upside down, on top of. And then I was doing that for a very long time. Finally, I arrived at that it first gets $n \cdot 3$ here [points at the tilted pile with four triangles]. Yeah, I have to write that, I think [refers to his expression]. 'Cause this is Figure 4. $n \cdot 3$ [points at the tilted pile] and $n \cdot 3$ plus 3 [points at the bottom row]. And then you see here 1, 2, 3, 4, so it's 4—no it's 1, 2, 3, 4, 5—it's five of these stripes here. And then you've got to take times $n + 1$.

Check for consensus

6 Teacher: Does anybody understand what he's saying?

7 Students: No. Yes. Hmmm...

8 Axel: Should I explain again?

Build consensus

9 Teacher: We don't understand anything.

10 Frida: Or do you mean like this? Wait, wait. Eeh, I think I might know what you mean. First $n \cdot 3$. 'Cause that's Figure 4, right?

11 Axel: Yes, it's Figure 4.

12 Frida: Yes, Figure 4. Yes, then you see there on the edge that it's four triangles going alongside there, and that's the same thing as n.

13 Lena: He counts the cards separately, I think.

14 Axel: No, but check this out—

15 Frida: First he calculates times, and then he calculates it times 3.

16 Lena: Ahaa.

17 Frida: Do you understand? So it's $n \cdot 3 + n \cdot 3 + n \cdot 3 + n \cdot 3$. And then you divide [.] Yeah, but then it gets [.]

18 Johanna: No, it's simply to do $n \cdot (n + 1)$. No, I'm just kidding [she laughs]. Yes, but check this out [points at the board]—n, there on the edge, and then $n + 1$. And that times, so that's like a quadrangle, but it's nudged. And that divided by 2. So $n \cdot (n + 1) / 2$.

19 Axel: That you've got to multiply by 3 for each of these [.] It's 3 in each: $n \cdot (n + 1) \cdot 3 / 2$.

20 Johanna: Yeah. So $n \cdot (n + 1) \cdot 3 / 2$. [Teacher writes it on the board.]

21 Axel: It works.

Lena and Frida's solution and Andreas's solution are then explained and discussed.

Check for consensus

22 Andreas: Do you understand? [Refers to his explanation of his own solution.]

23 Students: Yes, I get it. Yeah.
24 Teacher: Do you understand? Yes?

Argument

25 Paula: They're a little different [refers to solutions 2 and 4], or I don't know, because there it's times 3, also divided by 2, but there it isn't times 3 divided by 2. But maybe it doesn't matter.
26 Lena: They take times 3 in the end.
27 Paula: Exactly. They take times 3 without having divided it.
28 Lena: It's the same thing.
29 Paula: But there it's times 3 divided by 2, and there it isn't.
30 Lena: Yes, here it's—
31 Paula: But maybe it doesn't matter.
32 Teacher: Exactly. If you think of [writes and talks] $3 \cdot (8 / 2)$, what's that, Paula? 12 [writes and talks]. What's $(3 \cdot 8) / 2$?
33 Paula: It's also 12.
34 Teacher: Yes, that's also 12. So it's the same thing.

Focus

35 Teacher: So now my question is—now we've got 1, 2, 3 different [points at the formulas], and Andreas's here—that's another one—that's four different. My question is: Are all different formulas? Are all different?
36 Lena: Actually, they're all the same thing. Everything makes the same thing, the same answer. That means that they're all equal; you just write it in different ways.
37 Teacher: Exactly, they're all correct; it's the same answer, and it's the same card house. You just write it in different ways. This means that you can use algebra, the mathematical language, to express the same thing in different ways.

After an initial exploration of Axel's method [1–5], when he tries to explain his strategy and also makes a connection to Paula's solution to a previous problem, the teacher checks for class consensus by asking, "Does anybody understand what he's saying?" [6], with the purpose of opening the floor for questions and comments. Since the students' answers vary [7], Axel asks whether he should explain again [8], whereupon the teacher states, "We don't understand anything" [9]. Now comes the really interesting part [10–21]: instead of leaving Axel alone to try to explain once again, classmates help him out in a collaborative manner that is characteristic of an inquiry/argument culture, according to Wood and colleagues (2006). Together the students try to make sense of the ideas and build a shared understanding; they build consensus.

Note that the teacher does not need to say anything during these turns while the students build consensus. The pupils build upon one another's statements. This must be seen as a result of the social and sociomathematical norms (Yackel & Cobb, 1996) that this teacher had established in her classroom during a long period of time. Since I have observed and interviewed the teacher in connection with many lessons, I know that she strives to foster collaborative discussion in which students help each other and "are listening and participating students at the same time" (Interview). This approach hence relates to the role of students as active listeners who try to understand, question, validate, and build on one another's contributions. In my view, this example amply illustrates the connection between classroom norms and the interaction patterns that develop (Wood et al., 2006). On her own initiative, Frida helps Axel out, saying, "Wait, wait. Eeh, I think I might know what you mean" [10]. She ensures that they are talking about the same figure number and continues to explain [12]. Lena also contributes by describing how she thinks Axel has reasoned [13], which helps her understand [16] after she gets additional input from Frida [15]. Frida actually addresses Lena directly with her question, "Do you understand?" [17]. When Frida continues to explain, she hesitates [17], whereupon Johanna steps into the discussion [18], making clear that "No, it's simply to do $n \cdot (n + 1)$." To Johanna's formula, $n \cdot (n + 1) / 2$, Axel adds [19] "That you've got to multiply by 3 for each of these [.] It's 3 in each: $n \cdot (n + 1) \cdot 3 / 2$." Johanna clearly shows her agreement [20]. Axel seems content in his concluding comment: "It works" [21]. A correct formula for Axel's strategy has now been produced through the class's collaboration. The students act as "listeners taking over the role of the teacher in questioning, clarifying, and validating mathematical ideas" (Wood et al., 2006, p. 235), a salient feature of an inquiry/argument classroom culture.

After Lena and Frida's and Andreas's solutions have been discussed in a whole-class setting, four algebraic formulas are displayed on the board for the number of cards. Andreas checks the class for consensus by asking, “Do you understand?” [22], and the teacher repeats his check [24], whereupon Paula argues that Axel’s and Andreas’s solutions are different. Paula and Lena take turns [25–31] in an Argument interaction pattern, trying to resolve whether the two formulas are equivalent (the teacher steps in to help [32–34]). The teacher summarizes and focuses the discussion on a key aspect by asking whether all four formulas are different [35], and Lena says that “Actually, they’re all the same thing.” [36]. The teacher concludes the discussion by restating this key mathematical idea [37].

DISCUSSION

I find Wood and colleagues' (2006) framework straightforward for distinguishing between conventional and reform interaction patterns. The categories cover the interactions well. However, I see some difficulties in making a clear distinction between certain reform interaction patterns. Wood and colleagues (2006) state regarding the pattern *Check for consensus*, “The teacher participates by checking with the students and listening to find out if they have any questions or comments about an idea, strategy, or concept that a student explained.” So far so good. They continue: “The student explaining may be asked further questions or to re-explain by the listening students. In some cases, listeners give another different strategy for solving the problem or offer further explanation. The outcome is public agreement on the validity of an idea or concept given by the student explaining” (p. 255).

I am concerned about the second part whose interpretation constituted the major difference in the interrater coding. In my interpretation, a *Check for consensus* consists solely of checking with the students to see whether they have questions or comments on a student’s idea. This aligns with Wood and colleagues' (2006) statement that “Checking for consensus initiated by the teacher appeared to be a final attempt to open the discussion so any child could make comments or ask questions before moving on in the discussion” (p. 235). The teacher’s check can then be followed by, for example, a student asking a question in order to understand (*Inquiry*) or challenging an idea (*Argument*) or by the teacher trying to establish common ground on key ideas (*Build consensus*) in the class (cf. the short *Check for consensus* [6–8] and [22–24], followed by *Build consensus* and *Argument*). However, the interrater coding made clear that another interpretation could be that the entire interaction is a *Check for consensus* since “the outcome is public agreement” (i.e., [6–21] constitutes one extended *Check for consensus*).

Making clear that a *Check for consensus* is solely a check and is followed by other interaction patterns would render the framework more straightforward. Further, my analysis suggests that in addition to the teacher (as stated by Wood et al., 2006), a student might also initiate such a check (cf. Andreas’s *Check for consensus* [22]). Just as it is difficult to determine when the pattern *Check for consensus* ends, it is not completely clear when the *Inquiry* pattern ends. My interpretation is that the *Inquiry* pattern consists solely of the act of asking and does not include the clarifications that follow. Again, outlining clear criteria not only for when an interaction pattern starts but also for when it ends would make Wood and colleagues' framework less ambiguous.

Solutions are purposefully selected by the teacher when using Stein and colleagues' (2008) five-practices model. Therefore, the pattern *Exploring methods* is hard to distinguish from *Proof of answer by student explanation* in terms of correct solutions; only their purposes differ (see Table 2). The purpose of deliberately selecting a correct solution for display can be both to provide multiple solution strategies and to ensure that the class hears a correct solution (cf. solutions 3 and 4 in Table 3).

The difficulties with Wood and colleagues' (2006) framework relate mainly to distinguishing between certain interaction patterns that are specific to different classroom cultures. Hence, the difficulties in interpretation affect only the relative distribution of the interaction patterns within a specific classroom culture, not whether the culture should be regarded as inquiry/argument or strategy-reporting.

Since Wood and colleagues (2006) have shown that an inquiry/argument classroom culture is closely related to higher cognitive levels of student thinking, I contend that it is desirable for teachers to strive to establish inquiry/argument interaction patterns. I see tremendous potential in using Stein and colleagues' (2008) model as a tool to guide teachers’ actions and support teachers’ development over time in their orchestration of whole-class discussions. My ongoing efforts intend to take into account argumentation as well as connection making in the Stein and colleagues

(2008) model. The exploration of Wood and colleagues' framework in this paper contributes to those efforts.

Teacher and textbook: Reflection on the SDT-model

Ljerka Jukić Matić[1] and Dubravka Glasnović Gracin[2]

1 University of Osijek, Osijek, Croatia, ljukic@mathos.hr

2 University of Zagreb, Zagreb, Croatia

This study investigates in-depth how two teachers use the textbook in mathematics classrooms. Their use of the textbook was analysed in the light of a socio-didactical tetrahedron (SDT) which proved to be a powerful model to describe many aspects of textbook use that we encountered. Our results showed that the teacher acted as the mediator between the textbook and the students, but the lower part of the SDT helped us to identify the influence of social factors on textbook use which is an aspect that cannot be disregarded.

Keywords: Mediation, socio-didactical tetrahedron textbook, teacher, teaching.

INTRODUCTION

The issue of *how textbooks shape the teaching and learning of mathematics* has been the subject of many studies (Fan, Zhu, & Miao, 2013).Textbooks can be considered as artefacts which are dynamically used in classrooms, influencing the instruction (Johansson, 2006). Their content follows and largely reflects the requirements and intentions of the intended curriculum. Various studies have shown that teachers rely heavily on textbooks for lesson preparation, teaching new subject matter, practicing and giving homework assignments (e.g., Pepin & Haggarty, 2001; Johansson, 2006; Glasnović-Gracin, 2011).This paper investigates in-depth two mathematics teachers' practice in relation to the use of the textbook in the mathematics classroom.

THEORETICAL FRAMEWORK

Textbook-teacher-student

The teacher's role as a *mediator* between the textbook and the students has been considered by various authors (e.g., Luke, de Castell, & Luke, 1989; Love & Pimm, 1996). Pepin and Haggarty (2001) give the research systematization on the use of textbooks through six main domains, one of which relates to the teacher as the mediator of the text. They assert that it is the teacher who decides which textbook to use, when and how it is used, which parts to use and in what order, and when and to what extent the students will work with the text. Traditionally, mediating between the students and textbook has always been the teacher's function (Luke et al., 1989).

According to Remillard (2000), textbooks can alter the teaching strategies of teachers, but conversely it is the teachers who choose what to use and what not to use from the textbook. Sosniak and Stodolsky (1993) found that teachers have autonomy and that they like to mediate between the textbook content and their students. Also, teachers do not feel that the textbooks control their teaching. In addition, the authors believe that in order to understand the use of textbooks in classrooms, the thoughts, actions and working conditions of the particular teacher need to be taken into consideration. This brings us to the socio-didactical tetrahedron.

The socio-didactical tetrahedron

The use of textbooks in the classroom can be considered through the model of the didactical tetrahedron where the vertices are student-teacher-textbook-mathematics (Rezat, 2006). However, this model does not encompass societal and institutional aspects, which are also important factors in mathematics education. Therefore, Rezat and Sträßer (2012) proposed a more comprehensive model of didactical tetrahedron, called the socio-didactical tetrahedron (SDT). We imagine the basic didactical tetrahedron (Figure 1.) where the vertices are artefact-student-teacher-mathematics, as being put in such a position where the vertices student, teacher and mathematics lay on the bottom of the tetrahedron. These three vertices are extended by the social and cultural parameters, forming a comprehensive socio-didactical tetrahedron. The new bottom vertices in the SDT are: conventions and norms about being a student and about learning; conventions and norms about being a teacher and about teaching; and the public image of mathematics. These three vertices are connected to each other through the bottom edges. Since these social and cultural parameters lay in a complex relationship, other points on the bottom edges are highlighted, such as institution, noosphere, and peers and family (Rezat & Sträßer, 2012).These social and institutional parameters are often considered to be "hidden" or "less visible" because the persons involved are often not conscious of them. Therefore, we can see the SDT as an iceberg in the water: we often only consider the "visible" didactical tetrahedron involving just the teacher, student, mathematics and artefacts, and we forget (or we are not conscious of) the social and other parameters involved.

With all its highlighted points, the SDT model is a powerful enough tool to provide a structure for textbook use and to show the cultural interplay between educational and social context. For example, Rezat (2013) conducted a qualitative study on students' use of mathematics textbooks in Germany. The findings show that social impacts are important factors which influence students' use of textbooks. Some aspects of textbook use cannot be explained without taking into account the whole SDT.

Previous research and research focus

The study presented in this paper is a follow-up research on the large-scale study reported in Glasnović Gracin (2011). Using a questionnaire with multiple choice items, the previous study investigated the role of mathematics textbooks in lower secondary education in Croatia (grades 5 to 8). The survey involved nearly one thousand mathematics teachers, which is about half of the total number of mathematics teachers in grades 5 to 8 in Croatia. The results showed that teachers use textbooks for lesson preparation to a great extent. Participants said that new material is mainly presented by the teacher at the front of the class followed by students working individually on the textbook exercises. So, the teachers consider the textbook to be an important source of practice exercises for students. The survey also showed that most teachers select a textbook mainly according to the quality of its examples and problems. The coherence between the textbook methodology and the students' age was also an important factor which proved to be relevant for 64% of teachers.

In this new study, we wanted to examine in a more in-depth way how mathematics teachers use the textbook in their teaching practice. Since the previous study encompassed a quantitative method, here we wanted to use a qualitative approach. The aim was to investigate how teachers use textbooks in mathematics classrooms and to identify potential factors that influence such use. The findings are observed in

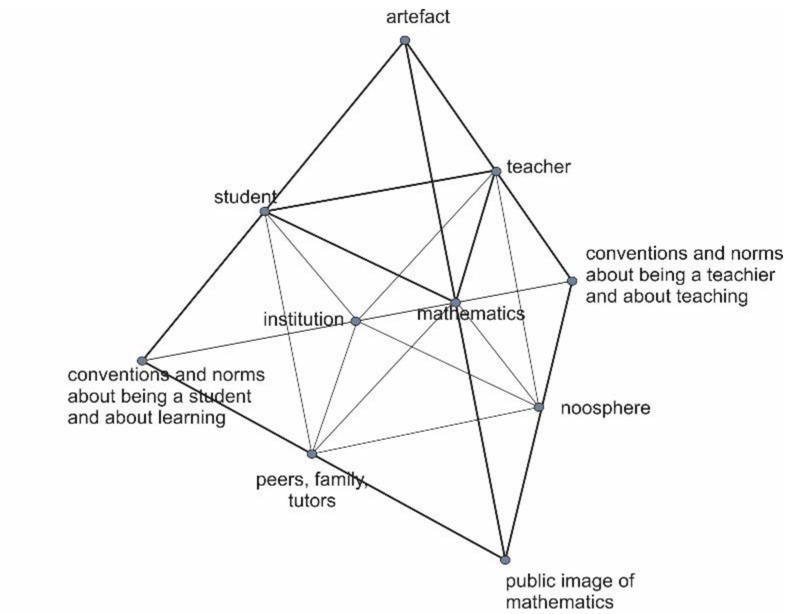

Figure 1: Socio-didactical tetrahedron

the light of the SDT, in order to better understand the teaching and learning of mathematics.

METHODOLOGY

Participants

The study involved two female mathematics teachers, Mrs. S and Mrs. D, from lower secondary education in Croatia (in our education system, this is a primary school, grades five to eight). The teachers chosen for this study are both experienced teachers: Mrs. S has 15 years of teaching experience and Mrs. D 20 years of teaching experience. Both participants have a degree in mathematics education and use the same textbook series. It is the most commonly used textbook series in Croatia, used by about 65% of the whole student population (data retrieved from the Ministry of Education, Science and Sport).The structure of this textbook can be described as the "exposition – examples – exercises" model. It has been found that this kind of model predominates in the structure of mathematics textbooks (Love & Pimm, 1996).

The Croatian education system

In the Croatian education system, primary school is compulsory and lasts for eight years. Secondary school is not compulsory, but the majority continues to go to school after finishing primary school. Secondary school lasts three or four years, depending on the type of school (i.e. vocational or grammar). One lesson unit lasts for 45 minutes in both primary and secondary school. Textbooks are compulsory and all textbooks used in schools are authorized by an official group of experts appointed by the Ministry of Education. As of 2010, teachers jointly select authorized textbooks for their school for the period of 4 years. Textbooks are usually purchased by parents, except for a short period from 2006 to 2008 when the Ministry of Education provided free textbooks for all primary school students in Croatia.

Method

In this study, we used qualitative strategies in the form of observations and interviews. During October 2013, we observed several lessons given by the participants. In that year, Mrs. S was teaching sixth grade, and Mrs. D grades five and eight.

For the purposes of observation, we designed three main observation categories. The categories were:

— *Minutes of textbook use* (How much time do the students and the teacher use the textbook?)

— *Impact of the textbook structure on instruction* (What is the influence of the textbook content and structure (title, language and symbols, order of worked examples, definitions and rules, didactic intentions) on instruction? Does the instruction follow the textbook page by page? What is taken from the textbook?)

— *Use of the textbook* (For what purposes is the textbook used during the lesson? How is new content introduced? Is the textbook used during the teaching of new mathematical content? What is a practice lesson like? Which sources are used for practicing and homework? Is the textbook used for practicing and reviewing? Did the teacher point out any specific figure, frame or picture from the textbook? For what purposes?)

Prior to each observation, we examined the structure of the mathematical content which was to be taught in that lesson. This helped us in making comments and answering the observation questions. After the classroom observations, we conducted a semi-structured interview with each of the participants. The interview questions come under three main categories, but the interviewer was able to ask additional questions based on the observed lessons or expand upon an interesting point arising during the interview:

— *Impact of the textbook structure on instruction* (Describe how you usually prepare for a mathematics lesson. Does the textbook, in your opinion, influence the structure of your instruction, e.g., using the same title as in the textbook for the lesson unit, using the same definitions, symbols, sequence, didactical approach, worked examples, figures? Explain.)

— *Use of the textbook* (Describe a typical lesson where new content is introduced. Describe a typical lesson with emphasis on practicing. Describe a typical revision lesson before a test. Describe how you select homework activities and from which sources. Do you significantly change your teaching style when you change the textbook?)

— *Strong and weak points of the textbook* (What do you find is lacking in textbooks? What do you like and what do you find helpful about textbooks?)

Data analysis was conducted using the constant comparative method (Corbin & Strauss, 1990). Data gathered from the observations and the interviews were coded thematically. This process allowed us to attend to, and report on, those aspects of textbook mediation that were common to both teachers as well as their differences.

RESULTS

Minutes of using the textbook

We observed four lessons of Mrs. S teaching grade six. The textbook was used intensively in all her observed lessons. Students had the textbook open on their desks all the time. In the first lesson, the textbook was used directly for 10 minutes when students worked on their own solving tasks from the textbook, and for the rest of the lesson the students and the teacher used it occasionally. In the other three lessons, the textbook was used for the entire 45 minutes.We observed three lessons given by Mrs. D. She used the textbook directly only in the first observed lesson for 15 minutes. In the other lessons, the textbook was not used by the students or the teacher at all.

Impact of the textbook on instruction

The textbook had significant impact on the lessons observed in Mrs. S's classroom. In the first lesson, the textbook was followed page by page for more than half of the lesson. The influence of the textbook was also visible in other parts of the lesson. The rules written on the blackboard were the same as the rules in the textbook. In the second lesson, to introduce and teach a new topic, the teacher used the motivational example from the textbook, as well as the worked examples and rules. The exercises for practicing were also from the textbook. In the third lesson, the textbook structure was heavily reflected in the lesson, since the textbook was followed page by page. The fourth lesson was preparation for the up-coming exam, where students solved problems from the textbook in the exact order as given in the textbook. In the interview, Mrs. S explained that she always uses the textbook in lesson preparation. The textbook structure influences her lessons and the textbook is the main source for practicing and for homework. Mrs. S explained that in this way she encourages the students to use the textbooks. She wants her students to use textbooks actively for two reasons. The first reason is "so that children can find at home what we did in class, especially if someone did not understand what I said in school". The other reason is so that students become independent and confident in using various resources, like books, encyclopedias or other curriculum materials. In this way she aims to prepare students for the active use of textbooks in upper secondary school, where the subject matter is more demanding than in the lower secondary grades.

Mrs. D did not follow the textbook page by page in any of the lessons observed. In the first lesson, rules were taken from the textbook, as well as some exercises for practicing. In another observed lesson, the textbook was not even open in front of the students; all the tasks were on a worksheet she had prepared, though some tasks were similar to those in the textbook. All of the lesson titles that she wrote on the board were the same as the titles in the textbooks. In the interview, Mrs. D said that the textbook was not her main resource for lesson preparation. Rather, she uses a variety of available materials such as the internet, a range of textbooks (old and new), professional journals, and ideas from colleagues.

The use of textbook

In the first of Mrs. S's observed lessons, the students used the textbook for learning new content. They were required to read the new unit from the textbook (Reciprocal fractions), become familiar with the new content, and work through the examples and exercises from the textbook. The teacher helped those students who had problems with understanding the textbook's content, thus she acted as mediator between the textbook and the student. The second observed lesson involved the division of fractions. The new content was presented through a teacher-led discussion with the class, where the teacher relied on the textbook, using the model of the chocolate bar (quadrilateral shape) as presented in the textbook. The discussion brought up some rules for fraction division, and the teacher also introduced the case $\frac{a}{b} : n$ which was not in the textbook, which some students remarked on. The practice tasks which followed were also from the textbook, as was the homework. The third and fourth lessons had a very similar structure. The teacher gave a long list of textbook exercises to be done, wrote the page number and exercise numbers on the board, and the students opened their textbooks and individually worked through the tasks. At the end of the lessons, the teacher assigned the homework, which was also from the textbook.

In the interview, Mrs. S said that she uses the textbook for teaching new mathematical content if she finds that the book covers the subject matter well. If it does, she does not devise her own exposition and examples. However, she says that she does not take all the definitions directly from the textbook:

> "I change a definition sometimes, not because my way is better, but so that students can see that the same thing can be said in different ways..."

At the beginning of the first lesson with grade eight, Mrs. D checked and went over the homework from the previous lesson (the homework was from the textbook).The teaching of the new content of powers was not related in any way to the textbook: the teacher used a story from the Rhind Mathematical Papyrus: "There are seven houses. In each house there are seven cats. Each cat kills seven mice. Each mouse has eaten seven grains of barley and each grain would have produced seven hekats. How many grains of barely will be saved?" The teacher pointed out the rules for the powers in the textbook and the exercises which students should do during the lesson. The teacher did not assign homework from the textbook, but gave a link to a web page with numerous tasks for practicing. The second and third observed lessons were in the fifth grade and in both lessons students worked in groups. In the second lesson, the students competed in a quiz. The tasks were prepared on a worksheet and were not the same as the textbook items. The third lesson was a revision of the topic of whole numbers. Here students participated in a game, which consisted of solving various tasks. The solution to each task was a piece of a puzzle that contributed to the solution of the overall puzzle. The tasks were similar to the items from the review section in the textbook. The game, however, did not come from the textbook.

In the interview, Mrs. D explained that she rarely introduces new procedures and concepts according to the textbook; she likes to use her own ideas. She uses the textbook for students to practice, but she uses other resources as well. For reviewing, she uses the textbook items, or composes similar ones herself. She considers that other textbooks do not greatly differ, having similar exercises.

Strong and weak points of the textbook

In the interview, Mrs. S described her attitude towards the official textbooks she was currently using in the classrooms. She was dissatisfied with the introductory sections of the lessons in the textbooks. However, she liked the selection of worked examples, that there are plenty of exercises from simpler to more complex ones, and that the exercises come right after the exposition.

> "I think it's right that when we learn something [a new concept], the exercises should follow on directly. Not be placed at the end of the chapter. This way parents can find them easily... Most of the parents aren't mathematicians and they don't always know what to give their children for practice, they might give them the wrong tasks."

Mrs. D said that she is satisfied with the textbook structure and exercises. But she also finds some textbook definitions and rules to be inappropriate for the students' age, so she rephrases them:

> "Definitions are sometimes unclear to students, so I translate them to be simple and clear".

She says that the main reason for choosing the current textbook series was financially and socially based:

> "Our school uses this textbook because... many of our students have brothers and sisters, we don't want them to have to buy new textbooks so we decided to continue to use this one and not to change it."

DISCUSSION AND CONCLUSIONS

Both participants consider their position as mediators between the textbook and students, in spite of the fact that they have different approaches to teaching mathematics and the use of textbooks. They both highly control what will be learned and practiced, how and when it will be learned. These intentions are related to the norms about being a teacher and about teaching because the teacher is supposed to prepare and shape the lesson actions. This is related to the SDT face *textbook-teacher-student* with the related social components placed on the bottom of the triangle: institution, conventions and norms about being a student and about being a teacher (see Figure 1).

Mrs. S uses the textbook as the central tool for teaching and encourages her students to use the mathematics textbook intensively. All the exercises done in the four observed lessons were taken from the textbook. Although she complained in the interview that she is not satisfied with the introductory sections of the textbook, in the observed lessons she used the material from the textbook. It may be that she relied on the textbook as a guarantee of stable quality (Pehkonnen, 2004) because the approved textbooks offer security and convenience for teaching (Love & Pimm, 1996). On the other hand, she claims that she encourages the use of the textbook because of the students. Learning how to use the textbook will help them when they attend the subsequent secondary school. Here we come to *institution* on the SDT. This also means that for her using textbooks does not mean just "learning mathematics from the textbook", but also "learning how to use a textbook, i.e. learning for life". Mrs. S mentioned another reason why she encourages the use of textbooks by her students – if the student was absent, or did not understand the subject matter in school, he/she is able to look at the textbook at home with the help of peers or parents. Here we come to *peers and family* on the other face of the SDT. The relationship *textbook-student-mathematics-peers and family* corresponds to the explanation given in the interview that the textbook helps parents to help the students at home. This is one of various reasons why Mrs. S follows the textbook so closely. This is also connected with the textbook being clearly organized – so that students and parents can catch up. The importance of the contents of the textbook being set out in a clear and simple way was mentioned by both participants.

The second participant Mrs. D prepares lessons using a variety of materials, the textbook being just one of them. She chose different and innovative ways both of presenting new concepts and practicing them. This is related to the norms and conventions of being a teacher and about teaching (Remillard, 2009). She likes the structure and the amount of exercises in the textbook, but she used it directly in only one observed lesson. The interview and the analysis of the observed lessons showed that she mostly used the same titles, symbols, definitions and rules as found in the textbook. For example, after a creative introduction to the idea of powers, her students opened the textbooks and copied the rule into their notebooks. The copying of rules and definitions into notebooks was also observed in Mrs. S's classes.

In the interviews, both participants said that they sometimes change the wording of the definitions and rules from the textbook to make them more appropriate for the students. This means that the teachers, during the lesson preparation, reflect on the didactics of mathematics in the textbook. This also corresponds to the norms about being a teacher, because the principle of compatibility of mathematical content with the students' age is one of the basic principles in mathematics education (Kurnik, 2009). The textbook content should be appropriate to the students' age, and at the same time it should be mathematically correct. The teacher should reflect on this interplay during the lesson preparation. This finding leads to the tetrahedron face with the vertices *teacher-textbook-mathematics*.

Mrs. D gave a reason of a social nature as to why the textbook is not frequently changed in their school. The same textbooks are used for a number of years, so that the younger generations can use the textbooks of their older siblings. This means that social and financial reasons are important factors in choosing whether to change the textbook or not. Such use of textbooks can be explained with the relationship within the SDT, *textbook-student-parents-public image of mathematics*. In Croatia, parents buy textbooks and this represents a great expense for them at the beginning of each school year. Also, from the public point of view, mathematics is concieved as a static discipline, with a long known set of concepts, principles, and skills (Cooney, 1985), and the learning of mathematics is concieved through practicing various exercises. Thus, from this persepective, there is no need to change textbook if the textbook contains a good amount of exercises.

All these findings lead to the conclusion that the reflection on the actions within the SDT model can help in understanding the teaching and learning of mathematics. The survey results obtained in Glasnović Gracin (2011) were not sufficient in comprehending the deeper reasons related to the teachers' use of mathematics textbooks. The qualitative approach presented in this paper confirmed and extended the survey results: Croatian teachers use textbooks for lesson preparation, exercises and homework. However, the findings of this qualitative study show in-depth how and why Croatian teachers use the textbooks in the classroom. One particular finding is related to the textbook characteristics. Teachers should have good mathematical knowledge for teaching, i.e. according to Ball and colleagues (2008), knowledge of content, students, curriculum and teaching, and to know the strong and weak points of the textbooks to be able to decide when to be the mediator between the textbook and students, and when to use other instructional resources for teaching beside the textbook. The study implies that teachers' use of the textbook is multilayered. This utilization is connected with the complex interaction between the STD components. Consequently, textbook use should not be examined separately from social and institutional influences.

Using the SDT model offers great potential and ideas for new studies. For example, the triangle *student-mathematics-textbook* is a very important face of the SDT. This aspect needs to be examined in more depth in order to better understand instruction and to improve instructional quality in the classroom.

Interdiscursivity and developing mathematical discourse for teaching

Reidar Mosvold

University of Stavanger, Faculty of Arts and Education, Stavanger, Norway, reidar.mosvold@uis.no

This paper aims at further elaborating on a redefined theory of mathematical knowledge for teaching in terms of participation in discourse. This redefined theory of mathematical discourse for teaching is used to analyze data from mentoring sessions in initial teacher education. The results indicate that the mentor teacher, who is a more central participant in the mathematical discourse for teaching, is able to more dynamically switch between the different discourses related to mathematics teaching than the pre-service teachers—referred to as interdiscursivity.

Keywords: MKT, discourse, teacher education, mentoring dialogues.

INTRODUCTION

Learning is often defined as a process of acquiring knowledge; this metaphor of acquisition is popular in education research (Sfard, 1998). Following this metaphor, an aim of education is for students to learn something (i.e. acquire knowledge), and the teacher's responsibility is to ensure that students gain the required knowledge. In order to handle the tasks that are involved in this work of teaching mathematics, teachers need a particular kind of professional knowledge. Ball, Thames and Phelps (2008) have proposed a theory of mathematical knowledge for teaching (MKT) that has become widely used. Ball and colleagues define MKT as "the mathematical knowledge needed to carry out the work of teaching mathematics" (p. 395). Following Shulman's (1986) theory of teacher knowledge, they describe several subdomains of MKT. These subdomains of knowledge are seen as distinguishable and measurable. Measuring particular subdomains of MKT is, however, challenging. When analyzing the connection between teachers' responses to multiple-choice MKT items and additional written reflections, Fauskanger and Mosvold (2013) found that teachers use knowledge from different subdomains of MKT when responding to items that were designed to measure one particular subdomain only. Sticking with the metaphor of acquisition, a quandary emerges: How can teachers use knowledge from different subdomains of MKT when responding to an item, if these subdomains are distinct and items have been developed to measure distinct subdomains only?

Instead of adhering to the acquisition metaphor to knowledge and learning, I follow the participation metaphor (Sfard, 1998; Skott, 2013) in this paper when I look at mathematical knowledge for teaching from a discourse perspective. In doing this, I adopt Sfard's (2008) commognitive framework and follow Cooper's (2014) suggestion of redefining MKT into "mathematical discourse for teaching". Cooper argued that such a redefinition of the MKT framework is useful for interpreting data from professional development of teachers. My aim is to extend this redefined framework further and apply it in analysis of example data from initial teacher education. With this theoretical framework, I will argue, the quandary with the distinct subdomains of MKT becomes obsolete.

THEORETICAL FRAMEWORK

Before Shulman (1986) presented his ideas about teachers' professional knowledge, classroom research often had a focus on observable behavior of teachers and/or students. His main contribution was to focus researchers' attention on the role of teachers' knowledge. Shulman, who adhered to an acquisition metaphor, suggested that the knowledge required by teachers could be divided into several distinct categories. Among the most well-known are subject matter knowledge and pedagogical content knowledge, and these two categories are often presented as import-

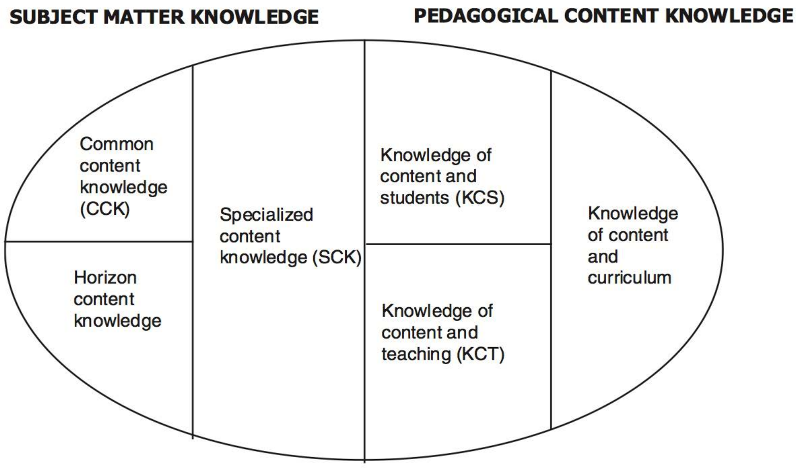

Figure 1: "The egg"—depicting MKT and its subdomains (Ball et al., 2008, p. 403)

ant aspects of teacher knowledge (e.g., Baumert et al., 2010). When Ball and colleagues (2008) presented their theory of MKT, they continued to scrutinize Shulman's initial categories. Subject matter knowledge and pedagogical content knowledge were divided into subdomains, and this model was depicted in a figure that has later been referred to with nicknames as "the egg" or "the oval" (Figure 1).

Sfard's (2008) theory represents a different view. A main idea is that cognition and communication are inseparable, and she combines the two terms into a new theoretical term: "commognition". She defines thinking as "an individualized version of (interpersonal) communication" (Sfard, 2008, p. 81). Knowledge is related to participation in discourse — not acquisition of an objectified entity — and learning is seen as a permanent change in discourse. This change can be either on an object level (where new words are introduced) or on a meta-level (where the rules of discourse change). For the researcher, then, the study of communication and participation in discourse(s) becomes pertinent.

Cooper (2014) applied Sfard's theory when he attempted to translate the MKT model into a discursive framework. He suggested redefining MKT as "mathematical discourse for teaching" (p. 338), and he substituted subject matter knowledge with a mathematical content discourse; pedagogical content knowledge was replaced with what he referred to as "pedagogical discourse for teaching" (ibid.). Building upon the ideas of Sfard (2008), he suggested that the following features could identify these discourses: 1) main *words* that appear in the discourse, 2) visual mediators that are commonly used in the discourse, 3) *routines* that are distinctive to the discourse, and 4) *endorsed narratives*. In this paper, I attempt to take Cooper's reinterpretation of MKT one step further and introduce the subdomains of MKT. I envisage this as a revised model consisting of several partly overlapping discourses (Figure 2).

Instead of following Cooper's approach and investigate words, mediators, routines and narratives in a discourse, I focus on participation in different discourses. I build upon the theories of Lave and Wenger (1991). They focused on how learners move from being peripheral participants to full or central participants in communities of practice. Instead of discussing communities of practice, however, I focus on communities of discourse (c.f., Sfard, 2008). I follow Sfard's (2008) definition of discourse as: "The different types of communication, and thus of commognition, that draw some individuals together while excluding some others" (p. 91). Instead of investigating how teachers increase their MKT, I attempt to study the process in which (pre-service) teachers move towards full participation in the mathematical discourse for teaching.

METHODS

In this paper, I do not investigate the complete process of becoming full participants in the mathematical discourse for teaching. Instead, I use data from mentoring sessions between three pre-service teachers and their mentor teacher as well as classroom data as an exemplification of one part of the process. The data material was collected as part of a larger project: Teachers as Students (TasS). An overall aim of this project was to investigate how pre-service teachers develop knowledge, skills and competence for teach-

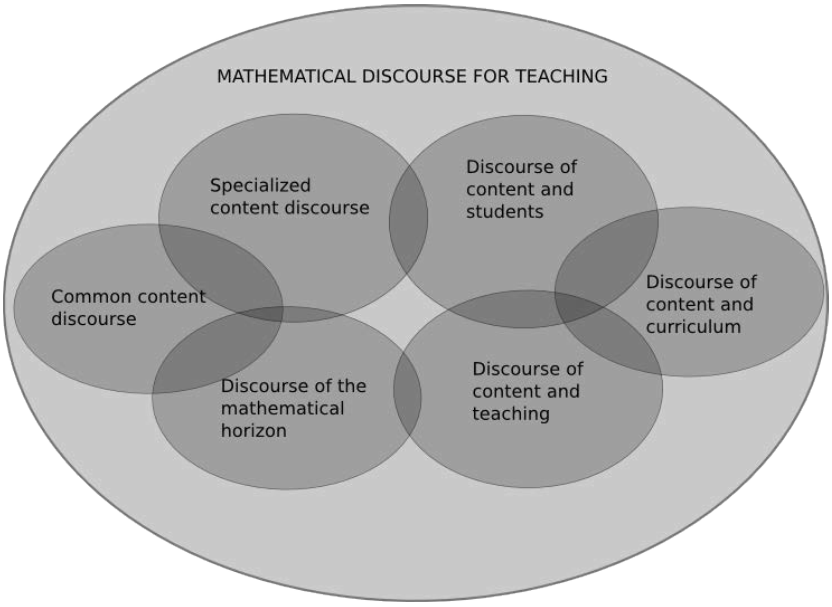

Figure 2: A tentative model of mathematical discourse for teaching

ing. In this paper, I use a discursive approach to investigate pre-service teachers' mathematical discourse for teaching.

In Norway, initial teacher education is organized as a four-year bachelor program. National curriculum guidelines require a total of 100 days of teaching practice, and teaching practice is supposed to be integrated in all subjects. The participants in this study were in the second year of their teacher education, and the data material was gathered in connection with a period of teaching practice. As example data, I use transcripts from two mentoring dialogues between a group of pre-service mathematics teachers and their mentor teacher before and after one lesson that was taught by the pre-service teachers. The group consisted of three pre-service teachers: Fiona, Rachel and Harry (all pseudonyms). The mentor teacher—who is a practicing teacher—is simply referred to as this in order to avoid confusion.

Recordings from the mentoring dialogues were transcribed verbatim, and these transcripts provided the foundation for my analyses. The analyses in this paper are meant to illustrate a possible use of an extended version of Cooper's (2014) redefinition of MKT into mathematical discourse for teaching as a framework, and I focus in particular on how the participants draw upon different discourses related to mathematics teaching in the mentoring dialogues.

RESULTS AND DISCUSSIONS

In the following, some excerpts from the data material will be presented as an illustration. A main emphasis will be on the mentoring dialogues before and after a mathematics lesson in 8th grade, but data from the actual lesson will be included in order to contextualize the mentoring discussions. The goal of the lesson was to enhance the students' understanding of the equal sign.

Pre-mentoring dialogue

When the three pre-service teachers met with their mentor teacher for a last mentoring session before teaching the lesson, their main focus was on discussing the lesson plan. They had discussed with the mentor teacher the day before, and they had agreed that they would have to adjust the level of the content they were going to present. In order to make it easier and more understandable for the students, they decided to start with a realistic problem. The context of the problem is that Fiona wants to go shopping, and she has to figure out how much money she could spend—given the various expenses that would be charged every month. With this problem as a starting point, Fiona explains how they are going to introduce the equal sign:

20. Fiona: And ask about how we are going to get that box (a), and what they did. Yeah, they subtract (b), and then you kind of take away 3500 from this side and that side, in order to balance [it]. And then we get to the

equal sign (c), and then kind of having scales and things like that, that kind of becomes a theme then, and work with the equal sign to really make them understand that it has to be balanced on both sides (d).

As we can see, Fiona has already included the unknown — the "box" — in this problem (a), but she is thinking of the equal sign as a main theme for the lesson (c). In this utterance, she navigates in a pedagogical content discourse. She describes how they will present the content for the students (d), and it can thus be interpreted as if she mainly draws upon a discourse of content and teaching. We can see that she anticipates a certain student response already (b), but her main focus is on the discourse of content and teaching. As a response to this, the mentor teacher goes into another discourse when she argues that they might be going too far too soon:

21. MT: Yes, what the equal sign really means (e). But isolating the box on one side, then you have really gotten far (f). Having something isolated on one side and move things, then you are really up there on the algorithm level right away (g). You might not have to talk about that at all, but I think they will see it when you say: "Okay, what's missing here?" They kind of see what is missing (h), and that is what the unknown is. It is something that is missing, and that you'll try to figure out. And then there are many ways of figuring it out. I mean, there are many ways of finding the unknown without rearranging and getting one box isolated, which is really the last part [in the process] perhaps. So try to hang in there as long as possible, only focusing on the understanding of what it is (i), and then one of the goals for the lesson is to understand the equal sign. Because then it is easier, and then you know what you want them to learn from the lesson. Being practical about it.

In the beginning of her utterance, the mentor teacher goes into a discourse of mathematical content. She starts by pointing at the true meaning of the equal sign (e), before shifting her focus to the mathematical horizon (f). Focusing on the mathematical implications of their choices in relation to the mathematical location of where the students are currently working, she claims that they have already moved to an algorithm level (g). I interpret this as an example of how the mentor teacher draws upon her experience from participating in a discourse on mathematical content in general and a discourse of the mathematical horizon in particular. The mentor teacher then draws upon her experience from the classroom and shifts into a discourse of content and students when she says that, "they kind of see what is missing" (h). Then she shifts again and moves into a discourse of content and teaching when she makes suggestions about how the pre-service teachers might present it to the students (i). The pre-service teachers still appear to be more peripheral participants in these discourses, and Fiona responds to the mentor teacher by drawing upon her experiences from the previous period of teaching practice instead (j):

22. Fiona: The equal sign is, in our last period of teaching practice (j), the equal sign and the understanding of an unknown was inseparable.

The mentor teacher follows up by confirming that the equal sign and the unknown constitute a sensible goal for the lesson. After this, they continue to discuss different aspects of the lesson plan until the mentoring session ends after 18 minutes.

Classroom discourse

In the lesson, the pre-service teachers start by presenting themselves, since this is the first time they are in that particular class in this period of teaching practice. After a round of presentations, Fiona starts teaching the lesson. "I have a problem that I want you to help me solve," she says. Then she explains that she wants to go shopping, but as a student in teacher education, there are certain expenses she needs to take into consideration. On the blackboard, she writes down the amount of money she gets from loans every month (6700 NOK), and then she writes down all the expenses below. The question is, "how much money is left for shopping?" After having given the students some time to think, one of the students presents 1200 NOK as an answer to the question. They spend some time discussing this before Fiona presents another similar problem: "It is the national day, and we have 200 NOK in our pocket. We want to buy ice cream, and an ice cream costs 20 NOK. How can we write down an expression that helps us calculate the number of ice creams we can buy?" The students come up with

Figure 3: Buying ice cream

different alternatives, and Fiona writes them down on the blackboard. She circles in the equal sign and asks if anyone knows the name of this (see Figure 3).

When a student responds, “is equal”, Fiona continues by asking what the equal sign actually means. A student responds: “what comes behind it is often the answer”. Fiona hesitates a bit before answering that it is partly correct, but that this is something they will come back to later in the week.

Post-mentoring dialogue

The day after having taught the lesson, the pre-service teachers meet with the mentor teacher for another mentoring session. The mentor teacher provides them with feedback, and they discuss different aspects of what they have observed in the lesson.

45. MT: And then you came to: What does the equal sign mean?
46. Fiona: Mhm
47. MT: “Behind it comes the answer”, said one of the students. And then another one said: “add together and insert [an] equal [sign] later”
48. Fiona: Yes, and then I thought...
49. MT: Andrew (name of a student) said it.
50. Fiona: (laughs)
51. MT: And you didn’t make much out of it really, and this was perhaps, you could have taken it further and shown: What does it become then? But you decided not to make much of it, and in this situation I think it was okay.
52. Fiona: Yes, I didn’t really≈
53. Harry: ≈I was thinking, when we were working with the cards, then he had the expression which is equal to, and the expression which is equal to, that’s what I meant.
54. Fiona: Yes, I was thinking≈
55. MT. ≈“If you have fifteen plus five equals twenty, and then minus three equals seventeen”, that’s how he said it.
56. Fiona: Mhm

The mentor teacher starts by referring to the question asked by Fiona in the lesson (45). The mentor teacher then follows up by presenting some of her observations from how students responded in the classroom (47). All of the pre-service teachers as well as the mentor teacher experienced the classroom discourse, but we see how the mentor teacher is the more central participant in the mathematical discourse for teaching (51) whereas Fiona and her fellow pre-service teachers are more peripheral participants. It can be argued that this relates to their different roles as mentor teacher and students in pre-service teacher education, but I argue that the differences can also be seen in how the participants navigate between different discourses. When evaluating Fiona’s response, the mentor teacher mainly draws upon a discourse of content and teaching, but then the focus shifts:

57. MT: Is this a correct use of the equal sign? (k) Because it is a very common thing to do for students, and it is a wrong use of the equal sign (l).

In this follow-up question (57), the mentor-teacher first draws upon a subject matter discourse (k), and then she combines this with a comment from a discourse of content and students (l): “it is a very common thing to do for students”. In the following, Harry tries to go back to the classroom discourse, but the mentor teacher interrupts him and continues:

58. Harry: He had≈
59. MT: ≈especially when it is multiplication and everything (m), then many [students] often add directly to the answer (n), and then the balance is really all wrong.

After having briefly drawn upon her experience from participating in a discourse of content and students (57), the mentor teacher is now back in a subject matter discourse (m), but she continues to draw upon the discourse of content and students (n) when saying that many students “often add directly to the answer”.

Fiona acknowledges the mentor teacher's statement with a "Mhm", before the mentor teacher continues:

60. Fiona: Mhm
61. MT: So you could have taken it further and shown: "Are both sides equal here?" and perhaps made them conscious about this already now, early on, to begin with (o). Because it is likely something many are going to have misconceptions about (p).

In this utterance (61), the mentor teacher draws upon both a discourse of content and teaching and a discourse of content and students. First, she reflects about how Fiona could have acted differently as a teacher (o)—which relates to a discourse of content and teaching—and then she adds a comment about this being something many students will probably have misconceptions about (p). The latter is part of a discourse of content and students. In this example, like in the other examples above, we clearly see that the mentor teacher does not stay within one of these discourses only, as if they were separate, but she continually switches between them—often within the same sentence. Throughout these examples, it the mentor teacher appears more dynamic in how she shifts between these different discourses—all related to a mathematical discourse for teaching—whereas the pre-service teachers are more caught in one discourse at a time.

CONCLUDING DISCUSSION

In the literature, researchers discuss supposedly distinct sub-domains of mathematical knowledge for teaching (e.g., Baumert et al., 2010). As a potential threat to the idea of the sub-domains of MKT being distinct, some studies indicate that teachers draw upon different aspects of knowledge when responding to MKT items (e.g., Fauskanger & Mosvold, 2013). When using a participation metaphor, however, it is unproblematic to consider that participants draw upon other discourses from which they have experience in participating. These discourses do not have to be completely separate, although they are different types of communication that include some participants and exclude others (Sfard, 2008).

In his attempt to bring mathematical knowledge for teaching under Sfard's (2008) discursive framework of commognition, Cooper (2014) distinguished between two components of what he referred to as mathematical discourse for teaching: a mathematical content discourse and a pedagogical content discourse. In doing this, he switched from an acquisition metaphor of learning and knowledge to a participation metaphor (cf. Sfard, 1998). Whereas Cooper used this as a framework for interpreting data from professional development, I have attempted to use it in the context of mentoring dialogues in initial teacher education. I suggest that the mathematical discourse for teaching is even more complex and compound than suggested by Cooper (2014), and indications of this can be found in the results presented.

Using a combination of Sfard's (2008) commognitive framework and the theory of learning as legitimate peripheral participation by Lave and Wenger (1991), I propose that the development of a mathematical discourse for teaching is related to the ability to dynamically draw upon different discourses for teaching mathematics. When discussing the planned and observed lesson on the equal sign, the mentor teacher uses a discursive move that can be referred to as interdiscursivity when she continually draws upon her experience from different parts of the mathematical discourse for teaching. The pre-service teachers appear to have less ability to use interdiscursivity, and this might be related to less experience from participating in the different parts of the mathematical discourse for teaching — or, put differently, that they are still peripheral participants in this discourse. There is a possibility, however, that this apparent difference can be explained by the different roles of the mentor teacher and the pre-service teachers in the mentoring dialogues. Cooper (2014) found that the learning situation in professional development is more symmetrical than what is often found in children's learning. In this study on pre-service teachers' learning in teaching practice, it can be argued that the situation is more asymmetrical. This issue of power relations could be investigated further in discussions among teachers with different levels of experience (but who do not have a mentor/student relationship). I have focused mainly on interdiscursivity in this paper, but this is only one of several issues that might emerge from analyses where the framework of mathematical discourse for teaching is applied. My discussion of this issue is meant to serve as an example, and I suggest that a redefinition of MKT in terms of participation in discourses should be further investigated.

With a discursive definition, a view of MKT — and knowledge in general — as some kind of object or hidden entity can be avoided. Discourse for teaching is not a latent or hidden trait, but something researchers can investigate and analyze more directly. I acknowledge that the framework of mathematical discourse for teaching is still in development, and further studies could for instance investigate a merging of this framework with Skott's (2013) framework of patterns of participation. Applying such a participatory and discursive approach to investigate MKT could then be seen as part of a larger initiative to develop a more coherent approach to understanding the work of teaching mathematics where acquisitionist terms are avoided.

ACKNOWLEDGEMENT

This study is part of the "Teachers as Students" (TasS) project, and it would not have been possible without the support from the Norwegian Research Council, grant no. 212276.

Teachers' initiating change in practice due to variation of progression of didactical time

Linda G. Opheim

University of Agder, Kristiansand, Norway, linda.g.opheim@uia.no

This study aims at identifying situations where time can act as a condition for change in teacher practice. A design based research methodology was applied and teachers where offered help designing mathematics tasks they would want to use in the classroom. All the discussions from this collaboration were analysed using timescales as analytical categories as described by Assude (2005). The findings show that in a diverse class, the difference in learning pace between students can condition change in the teachers practice.

Keywords: Teacher practice, change, diversity, time.

INTRODUCTION

This research report emerges from a PhD-study on teachers' perception of what makes a 'good' task in vocational school mathematics lessons. I have worked closely with different teachers over a school year designing tasks they would want to use in the classroom in order to learn more about the teachers' preferences for mathematics tasks. One of the concepts emerging from my research is 'time', and this paper focuses on how time can be a condition, i.e., a prerequisite, for change.

Time is a recurrent issue for many teachers, and time pressure is a real day-to-day classroom experience which teachers have to live with (Assude, 2005; Jordfald, Nyen, & Seip, 2009; Leong & Chick, 2011). Time can serve as an obstacle when implementing new reforms (Keiser & Lambdin, 1996), integrating new technology (Assude, 2005) and probing understanding through whole-class discussions (Black, 2004). A teacher might also make didactical choices in the classroom based on time triggers (Leong & Chick, 2011), and avoid lesson preparations that are too time demanding (Goodchild, Fuglestad, & Jaworski, 2013). As a summary, lack of time is often seen as an obstacle for change in teachers' practices.

In my research I have noticed that time is an issue that surfaces often in the conversations with the teachers, but not always negatively. This triggered my interest to explore the data using time as an analytical category. The research question addressed in this paper is: *When can time be a condition for change in teacher practice?*

I will, in the following, present my theoretical framework of timescales before I give a brief summary of the political ideas behind the Norwegian educational system. With this as a background, I present my methodology followed by results before I round off with a discussion of the results.

THEORETICAL FRAMEWORK

In this paper, I will look at how time is viewed by the teacher, and how time can be seen as a condition for change by the teacher. In order to do this, I need to identify different categories of experienced time. Lemke (2000) argues that all human activity takes place on at least one timescale and in complex systems more than one timescales. For instance, an utterance of a single word can be viewed as a timescale even if it takes less than a second to articulate. Also one school lesson or a year curriculum can be viewed as timescales. Every process that stretches out over time can be viewed as a timescale. In my work I study how time can be a condition for change and, given that change is a process, it will be helpful to identify timescales for analyzing my material. With the help of timescales it is possible to identify at which point time is a condition for change.

Assude (2005) describes three theoretical timescales, and I will present and use the same timescales with a slight modification. The three timescales are didactic time, time capital and the pace of a course. The concept of *didactic time* is related to the work of Chevallard, and is defined as "related to scheduling the teaching of some knowledge" (Assude, 2005, p. 185). However, Assude (2005) also makes the claim that: "Didactic time is used as a gauge of the advancement of knowledge, and, in this sense, it's a framework, which regulates the activity of the teacher" (Assude, 2005, p. 185). This last quote is referring to learning (advancement of knowledge) and not only the scheduling of teaching. As I see it, the concept of didactic time might be used as referring to a teacher's scheduling of some knowledge for a whole class of students, or the concept might be related to the scheduling of teaching with respect to individual students' learning. I will in my analysis use both of these interpretations of didactic time.

The second concept which Assude (2005) identifies is *time capital*. This refers to the 'objective' time available for classroom work, for example, the lesson is 45 minutes long. The third concept Assude (2005) applies is *the pace* of a course or a part of it, which is viewed as how didactical time is advancing with respect to time capital. This is demonstrated by showing different linear graphs of how courses can be fast-paced, moderate-paced or slow-paced. This last concept might be viewed slightly different in many Norwegian classrooms, and I will give some information of the Norwegian educational system to demonstrate this.

THE NORWEGIAN EDUCATIONAL SYSTEM

Education for all and equality are important concepts in the Norwegian educational policy across political party lines, with a goal to reduce social inequality. (Markussen, Frøseth, & Sandberg, 2011) In the Norwegian educational system we also have "the comprehensive school" as an important political concept (Department of Education and Training, 2006–2007). We do not have special needs schools in Norway, and every pupil is entitled to be in a normal classroom. As a result, a typical class in Norway will have children with high and low achievers, different diagnoses and handicaps. The Education Act (1998) specifies: "Education shall be adapted to the abilities and aptitudes of the individual pupil, apprentice and training candidate" (§1–3). All pupils are entitled by law to get adapted teaching according to their abilities, and this is the teacher's responsibility.

The political concept of the comprehensive school has also influenced upper secondary school, and since 1994 every teenager has a statutory right of secondary schooling regardless of abilities and academic results. As a consequence, near to every teenager is now starting upper secondary school and many of the low achieving students apply for the vocational programs (Department of Education and Training, 2006–2007). The Education Act also applies to upper secondary school, and adapted teaching is a requirement for all the courses in the vocational programs. As a result, many teachers take it personally when their pupils fail subjects or quit secondary school. They have as a goal to give adapted teaching to all of their pupils, but the classes are diverse and the pace of a course can be viewed quite different from student to student. It is therefore difficult to make a general claim about the course being slow-paced, moderate-paced or fast-paced.

Norway is a country where accountability systems have never been approved for use in the education sector, even if there are some accountability devices in local quality-assurance systems (Christophersen, Elstad, & Turmo, 2010). Still, the Norwegian Prime Minister said in a speech in 2008 that "Teachers should have a clear responsibility for what students learn in school" (Christophersen et al., 2010, p. 2). It has not been made clear how a Norwegian teacher can be made accountable for students' learning and Christophersen and colleagues (2010) argue that this is not possible. The Prime Minister's speech might indicate a political shift when it comes to accountability in the future, but as of today the main focus in Norwegian schools are still on adapted teaching and not on the pupils' test results.

In this paper, I focus on two teachers working at an upper secondary vocational school in Norway, which is a school with diversity and where adapted teaching is mandatory (the Education Act, 1998). Both of the teachers reported in this paper, have read and approved of the paper before it was submitted for the conference. I will, in the following, show how an analysis of the advancement of different timescales previously identified can act as condition for change.

METHODOLOGY

In the PhD-project I was collaborating with four teachers; however only two of them are considered in this paper. The reason is that the initial analysis revealed that the concept of time was much more seldom mentioned by two of them, in addition these two are working at University level where adapted teaching is not required by law. The two teachers considered in this paper teach mathematics at a vocational upper secondary school. They both volunteered to be part of the research, and the aim of the PhD-project is a greater understanding of the choices teachers make when it comes to mathematical tasks and not to change the teaching. Findings from the TIMSS advanced 2008 study, show that the most dominating activity in Norwegian classrooms is by far solving mathematical tasks similar to those in the textbook, and this is also a predominant classroom activity in other countries (Mullis, Martin, Robitaille, & Foy, 2009, p. 162). This is one of the reasons I view mathematical tasks as an important issue to research.

To accomplish a greater understanding of the choices teachers make when it comes to mathematical tasks, a design based research methodology (van den Akker, Gravemeijer, McKenny, & Nieveen, 2006) was applied in the PhD study, and the teachers were offered help designing tasks they wanted to use in the mathematics classroom and which they felt would improve their students' learning. The collaboration lasted a school year, and all conversations between the researcher and teachers were audio recorded. A total of 20 hours and 49 minutes of audio recordings with the two teachers have been used in the analysis; the recordings consist of interviews, and discussions about the tasks, refining tasks and evaluation of implementing the tasks.

All of the recordings have been imported into NVivo and data reduced concurrently with data generation. Data reduction entails writing down what is happening and what is being said without transcribing word for word. The data reductions are detailed facilitating retrieval of relevant data material at a later point, but they are also the first phase of analyzing, serving as a guide, focus and help when collaborating with the teachers. The data has not been transcribed; rather all analyses have been done using the original audio recordings.

The data has been analyzed using techniques from grounded theory (Corbin & Strauss, 2008), and time emerged as a recurring issue. As a consequence, I went back to the data and isolated all the parts where time had been mentioned. This data have then been analyzed according to Assude's timescales as analytic categories. I have in the analysis considered how didactical time advances with respect to time capital, and how this can be a condition for change. For instance, could there be a point where didactical time is advancing so slowly that it conditions changes in the teacher's practice?

As before mentioned, my research question is *when can time be a condition for change in teacher practice?* Given my research design, I have unique data for analyzing reasons for wanting change from a teacher's perspective. The teachers are offered help to design new mathematical tasks to use in their classrooms without the researcher trying to influence them, and the reasons provided for the new tasks are therefore a good gauge of what the teacher sees as important to change. The research was not designed to bring about big changes, just adjustments to what was already being done. Teacher change is mostly viewed as a slow and difficult process (Sowder, 2007), however, some of the teachers in this project expressed clearly that they participated in the research because they wanted changes and they wanted to improve.

The teachers participating in the project want some changes, but it might differ how important this is to them. In order to view if the changes are something that really are important to them, I am also looking at the time and effort the teachers are putting into this project and how they view this investment. We know that time to prepare lessons is a valuable asset for the teachers, and they are often protective of how this time is used (Goodchild et al., 2013; Jordfald et al., 2009). So if the teachers are expressing that they want to invest time into my project, I view this as changes being rather important to the teachers.

RESULTS

I will start this section by presenting excerpts which are related to the teachers wanting changes, as explained above. One of the teachers expressed at the very beginning of our cooperation that: "I am doing this (participating in the research) because I feel I can benefit from it. I'm not doing this because I have a heart of gold". This is a clear statement from the teacher seeing this cooperation as beneficial for him, and he is looking for help to make changes. The other teacher is open and honest about how he is struggling with time management in his job at the moment, and expresses:

> I am not happy with how I've been doing my job now. I am underperforming. It's not satisfactory. I have been stressed, but I don't have any more to do than everybody else in this world. This is resulting in me not being able to 'be present'; I forget things and have an extremely bad memory at the moment.

Given that I have spent a total of about ten hours of discussions with this teacher in my project, I feel bad for costing him so much of his preparation time and I express this, but he responds:

> Yes, but... no! I've never had a thought of that. I've been thinking it's been beneficial for me all the time. Because then I get the help, and if I didn't have the pressure to make the index task, the lesson would have been extremely boring. So for me it's only been good.

With a teacher expressing so strongly that he has been lacking preparation time, but still views our cooperation as beneficial and as an asset, speaks volumes of the need for help to change. This teacher actually ended our last conversation with: "You should just make contact if you need it again, and this year has been very good for me and a help, so no burden for me."

To summarize this part, the teachers are expressing that this is a research project they see as beneficial to them, and they do not mind that it cost them time. They view it as an investment to get help to make changes in their practice. When analyzing what might condition this change, I have used the analytical categories *didactic time* (with respect to the whole class or to individual students), *time capital* and the *pace* of the course. I will, in the two following sections, present results from the analysis of how the pace is viewed both with respect to the whole class and individuals, and how time capital and didactic time is relevant in these examples.

Pace of the whole class

I argue above that it is difficult to view the general pace of a course in vocational programs in Norway, but sometimes the teachers make references to it. In this section, I will present teacher comments related to the pace of the whole class, i.e. didactic time with respect to time capital, and identify how didactic time and time capital are being viewed by the teacher.

In my recordings I found three categories of comments related to the pace of the class as a whole. These were:

- The curriculum in general: These comments are related both to being ahead of schedule or being on time. "I have found out that I'm almost a chapter ahead of the others. So I wonder if I need to slow down a bit."
- Time needed for open tasks: The teacher comments on the difficulty in knowing how much time the students will need for an open task.
- Structure or chaos in a specific lesson: For instance a teacher is commenting on the need for better structure in a task because the students are spending too much time on irrelevant stuff for learning mathematics

None of the teachers I talked to expressed any concerns about having enough time capital for the given curriculum, so it doesn't seem like they view this as a fast paced course, especially since one of the teachers even comments that he is ahead of time. When it comes to the pace for the whole class, the only concerns of the teachers were related to smaller sequences, i.e. a lesson or a task, and they are making suggestions for adjustments to improve themselves. I am therefore not considering these as big issues for the teachers in my research project. None of the teachers have mentioned the pace of the whole class as reasons for wanting changes in the mathematics tasks.

Pace of individual students

As I have expressed above, the teachers did not seem very concerned about the overall pace for the class as a whole group, however they did express concerns when it came to individuals. These concerns could be divided into two different types of comments: one related to students not doing anything at all in the lessons, and the other one related to students not understanding from the teaching. Here is one example of a teacher expressing concerns of students not doing anything in the lessons:

> I think the idea [of the task] is good, but it requires that the students actually engage in the task... And that is kind of the roadblock. When

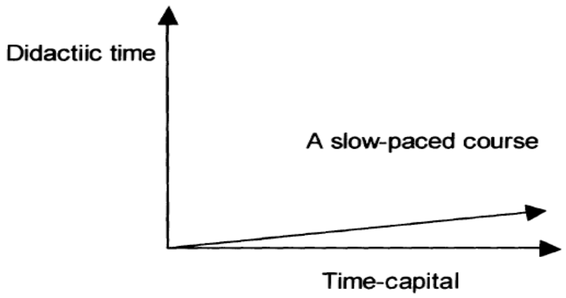

Figure 1: Diagram of a slow-paced course

> you asked me if we could cooperate, my idea was... What should I do to get the very lowest achievers of the students to have some kind of benefit? And what should I do to get them to do something?

These students are not only performing poorly, they are not doing anything at all during the lessons. The teacher talks about getting the students engaged as a roadblock and one of his main goals with this project is to get the low achievers to do something. Given that didactical time can be viewed as the advancement of knowledge, this teacher is here expressing that this is not happening at all for some of the students. This means that for these students, a graph of the pace of the course would look something like the diagram Assude (2005, p. 187) uses for a slow paced course (see Figure 1).

Students who are not doing anything at all during the lessons are the most extreme cases, but the teachers are also talking about students who are not benefiting from the teaching. This excerpt is from a conversation with a teacher where he is evaluating a ratio task we had designed and implemented:

> ...if I do it the "quicker" way which is: Hey, here is the formula, now do task one, two and three. And then there are those who manage to keep up with the explanations, they are done in five minutes. And then I use the rest of the time to explain to those who never get any of the things I explain (to the full class).

The teacher is here referring to a "quicker" way of teaching a formula, but where many of his students do not understand the explanation so he has to use the rest of the lesson trying to help them understand. This example shows how the teacher is struggling with students experiencing different levels of advancement of knowledge, or didactical time. Some of the students do not understand the mathematics from this type of teaching while others get it straight away.

The pace of individual students in a class is also what the teacher refers to when it comes to whether a new task is successful or not. Below is how a teacher is describing why he is happy with the task we designed:

> While here, here there is something everyone can do basically, and they have something tangible which they even can count if they need to. I even experienced that some of the low achievers seemed to have some Aha-moments, which they normally don't have. To sum up the benefits of the task: they get quickly started, everyone can manage something, they get active straight away.

Everyone being active and being able to manage something in the task, are success criteria according to this teacher. So didactic time is advancing at some level for all of the students, and these are the reasons the teachers are giving for the task being good.

DISCUSSION

Assude (2005) was, in her article, addressing the class as a whole when it came to the pace of a course, however I have shown that this is not necessarily sufficient for all classes. The teachers in this research project are mostly referring to individual students or a subgroup of students when they are talking about the pace of the mathematics course. The pace for the class as a whole does not seem to worry the teachers, but they are expressing concern when it comes to the pace of individuals or a subgroup of students.

I will argue that this difference in perspective is related to the diversity of a class. The more homogeneous a class is, the easier it becomes to talk about the general pace of the course. However, given the political ideal of the comprehensive school in Norway, there is great diversity in the classrooms of vocational schools. In addition to this, the teachers are obliged to give adapted teaching, which makes the differences in the pace of the course from student to student more obvious. In these classrooms there does not really exist *one* pace of a course, and the learning outcomes among the students might be very different.

This diversity of a class is, as explained by the teacher, a reason for their desire for changes in the mathematics tasks. Didactical time is not advancing for all of the students even if time is passing, so changes need to be made if they shall fulfill the requirements of the law when it comes to adapted teaching. If a student group is rather homogeneous and can keep up with the requirements of the curriculum, I assume the teacher will not worry much about didactical time. On the other hand, when a student group is very diverse, the teacher will be a lot more concerned about didactical time, given that it is so different within the same class.

If the student group is diverse, the teacher can choose to view this from two different perspectives. It is possible to have the perspective that the students will need to adjust to the teaching and the pace of the course, or you can have adapted teaching as a focus. The difference between these two perspectives comes from either a focus on the advancement of didactical time for each student as an individual or just an 'ideal' advancement of didactical time for the course. The teachers in this research projects were volunteers, and this might indicate a greater willingness to change, however the issues of diversity are present in the classrooms no matter the teachers' intensions.

The diversity of some of the Norwegian classrooms are extreme, however, there is some degree of diversity in every classroom. We might think that grouping students into ability groups in the form of setting, as they have been doing in England and Wales might give a more unanimous progress of didactical time with respect to time capital, but research shows that even in these classrooms, students feel the work they are given is either too hard or too easy (Boaler, Wiliam, & Brown, 2000). This shows that even if the problem might be more evident in the Norwegian comprehensive classrooms, there is evidence that this is also a universal classroom issue. Wilkinson and Penny (2013) argue that

> Within even the narrowest setting system, a set will contain students with considerable variations in attainment as well as learning style. It is therefore highly problematic to assume and treat setted students as intellectual homogenous. (Wilkinson & Penney, 2013, p. 10).

I have shown that some teachers feel the need to make changes, and I have argued that this is related to diverse classes where didactic time is not advancing for all of the students with respect to time capital, and this serves as a condition for change. Given that teacher change is mostly viewed as a slow and difficult process, identifying teachers who are so clearly expressing that they want change, can be of great value to further research.

Teaching actions conducting mathematical whole class discussions

Joana Mata-Pereira, João Pedro da Ponte and Marisa Quaresma

University of Lisbon, Institute of Education, Lisbon, Portugal, joanamatapereira@campus.ul.pt

The aim of this paper is to understand teacher practice conducting whole class mathematical discussions. Teaching practice is seen as an activity based on a motive and carried out through a set of actions. The study is carried out in a grade 9 classroom of an experienced teacher. Data is gathered by classroom observations (video and audio recorded), and by discussions with the teacher. Data analysis is carried out based on a model about teachers' actions. The results show that a central challenging action embodies all discussion segments and that teacher's actions are deeply related to students' knowledge about the situation being discussed.

Keywords: Teachers' practice, teachers' actions, mathematical discussions.

INTRODUCTION

Nowadays, inquiry based or exploratory learning is regarded as a fruitful learning environment in school mathematics. It differs from other environments by the ways in which challenging tasks are used and whole class discussions are conducted. However, proposing such tasks and providing students' opportunities to present and discuss their reasoning poses teachers many challenges (Stein, Engle, Smith, & Hughes, 2008). Organizing and conducting whole class discussions is particularly important to students' learning, being an important feature of teachers' professional practice.

In an exploratory setting, working on a task typically involves the students working on a task individually or in small groups (Ponte, 2005). That is not the case of the task presented in this paper, as it is proposed, discussed and solved within a discussion, making this a rather special whole class discussion. With this study, by analysing this particular whole class discussion, we aim to understand teachers' practice during whole class discussions, focusing on the teachers' actions and on the mathematical processes involved.

TEACHER'S PRACTICE IN WHOLE CLASS DISCUSSIONS

Teachers' practice may be characterized as the activity developed by the teacher (Jaworski & Potari, 2009) that unfolds in actions established according to an action plan (Schoenfeld, 2000). In traditional classes the teacher control is very high and students' interventions are very limited. In contrast, exploratory classes have many inquiry and divergent moments. In such learning environment, conducting whole class mathematics discussions is not only challenging for the teacher, but essential to students' learning.

Features of teachers' practice during whole class discussions have been highlighted by several authors. Wood (1999) states the relevance of involving students in presenting their solutions and in discussing those of their colleagues. Potari and Jaworski (2002) refer that the level of challenge of teachers' questioning during whole class discussion is an important feature of teachers' practice. Stein, Engle, Smith and Hughes (2008) point out that an essential feature of teachers' practice is to shape students' incomplete or poorly phrased ideas into more precise and powerful mathematical ideas. They argue that a productive mathematics discussion (i) is supported by students' thinking, and (ii) provides important mathematical ideas. They also present a model to prepare and conduct mathematics discussions that include actions of anticipating likely students' responses, monitoring students' responses, selecting students to present their responses, sequencing students' responses, and making connections between students' responses and key mathematical ideas. More recently, Cengiz, Kline, and Grant (2011) identify as main teachers' actions in whole class discussions aiming to extend students

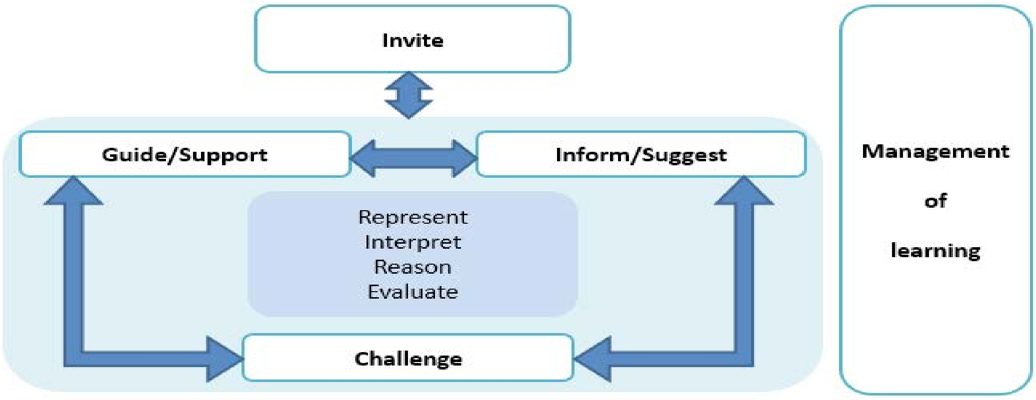

Figure 1: Framework to analyze teachers' actions (adapted from Ponte et al., 2013)

thinking: (i) eliciting actions that aims to elicit students' methods, (ii) supporting actions that aims to support students' conceptual understanding; and (iii) extending actions that aims to extend students' thinking. With a similar intent, Scherrer and Stein (2013) present a guide to analyze teachers actions (moves) during whole class discussion of cognitively demanding tasks that includes (i) begin a discussion, (ii) elaborate or deepen students' knowledge by furthering the discussion, (iii) elicit information, and (iv) other moves, like providing information and thinking aloud.

Teachers' actions during whole class discussions can be distinguished between actions directly related to mathematical topics and processes and actions that mainly relate to management of learning. Ponte, Mata-Pereira, and Quaresma (2013) identify four main categories related to mathematical aspects: (i) inviting actions – leading students to engage in the discussion, (ii) guiding/supporting actions – conducting students along the discussion in an implicit or explicit way in order to continue the discussion; (iii) informing/suggesting actions – introducing information, providing an argument or validating students' interventions; and (iv) challenging actions – leading students to add information, provide an argument or evaluate an argument or a solution. Guiding/supporting, informing/suggesting, and challenging actions, are the main support to develop whole class mathematical discussions, and involve key mathematical processes such as (i) representing – provide, revoice, use, change a representation (including procedures), (ii) interpreting – interpret a statement or idea, make connections, (iii) reasoning – raise a question about a claim or justification, generalize a procedure, a concept or a property, justify, provide an argument, and (iv) evaluating – make judgments about a method or solution, compare different methods. A model that relates teachers' actions in whole class mathematical discussions and these mathematical processes is presented on Figure 1.

RESEARCH METHODOLOGY

This study follows an interpretative and qualitative methodology. It is developed in a grade 9 class of a teacher with 13 years of experience. According to the teacher, the class has a very productive working environment and fruitful whole class discussions are possible because some of the students have a high performance and all of them are usually eager to participate. Data collection was conducted by the first author in the classroom and used direct observation (with audio and video recording of class) and document collection. Data analysis is based on the categories of the model presented in Figure 1, and is done with the support of NVivo software.

The situation analysed is a whole class discussion that aims to introduce how to solve incomplete 2nd degree equations generically represented as $ax^2 + bx = 0$. Before this situation, the students solved and discussed a problem that, implicitly, involves the zero product rule, but that was not explored with the aim of generalizing this rule to solve incomplete 2nd degree equations. Moreover, the teacher reminded how to solve incomplete 2nd degree equations as $ax^2 = 0$ and $ax^2 + c = 0$, that students had worked on in the previous lesson.

THE WHOLE CLASS DISCUSSION

We present some of the segments of the whole class discussion in order to analyse the teacher's actions to promote students' interpretation of the issues, reasoning and evaluation of solutions.

The first invitation

The teacher begins by writing down on the blackboard the equation $4x^2 - 12x = 0$ and, right after, she invites the students to solve this equation:

Teacher: . . . You have this equation, OK? An incomplete one, we are dismissing *c*. Who want to try to solve this equation with me? Just with what you already know. You already know how to solve 1st degree equations, how to solve some 2nd degree equations. I could tell you: Let's try to solve this equation. Irina, what would you do?
Irina: I would... Probably, I would get minus 12 to plus 12 in the other side [of the equal sign].
Teacher: So, I will write down [on the blackboard], $4x^2$ equals $12x$.
Irina: Exactly.
Teacher: It is true, this equation [$4x^2 - 12x = 0$] is equivalent to this one [$4x^2 = 12x$].

In this introduction, the teacher begins by inviting students to solve an equation. She also prompts students' answers by challenging them to make connections with their previous knowledge about equations. As Irina begins solving the equation, the teacher informs students by representing on the blackboard what she said. As this is the first time that students are solving this sort of equation, the teacher also suggests that Irina is going in the right direction by stating that both equations are equivalent. This suggesting action by the teacher leads Irina to keep going on her proposal to solve the equation:

Irina: Then, I would do the same procedure as usual. I would do squared *x* equals $12x$ divided by 4.
Teacher: [Writes down $x^2 = 12x/4$] Perfectly equivalent. Five stars. [Waits but Irina stands quiet.] Now the question is, when I am solving an equation, what is the aim?
Students: Find the value of the unknown.
Teacher: [Questioning Irina] Did you found the value of the unknown?

Once more, the teacher represents on the blackboard what Irina said and suggests that she is moving forward on her solving process. As Irina seems not to know how to continue, the teacher decides to highlight the aim of solving an equation, aiming to guide students on moving forward.

In this segment, the teacher's actions are marked by challenging the students on making connections between previous knowledge and this new situation. As students begin solving the equation, the teacher mostly uses guiding and suggesting actions to lead students to achieve the envisioned aim of using previous knowledge. Despite the aim of making connections, these guiding and suggesting actions are mostly representing actions, allowing students to stay focused on the solving process.

Overcoming misconceptions

As Irina does not know how to continue the solving process, the teacher selects Hugo from the students who want to participate:

Hugo: x^2 less x equals zero less 4 plus 12.
Teacher: Is that possible?
Students: No.
Teacher: Why? He would do this [writes down on the blackboard $x^2 - x = 12 - 4$]

Despite suggesting before that Irina was going in the right direction, the teacher does not suggest that Hugo is presenting an invalid proposal. Instead, she challenges the class to interpret Hugo's intervention and to further justify that interpretation. The teacher represents Hugo's proposal on the blackboard alongside with Irina's. Then, the teacher upturns the validation of Hugo's answer and, to do so, she suggests the students to establish connections with the monomial operations:

Teacher: Is this possible? This expression [$4x^2 - 12x = 0$] is equivalent to this one [Hugo's equation]? Remember that this is like a whole, a monomial, I cannot disconnect the coefficient from the literal part. I do not have something like this Hugo.

Towards this, Hugo presents another way to solve the equation, letting no time to his colleagues to justify why his first proposal was invalid:

Hugo: So... What if I add the x from 12 to x^2?
Teacher: So, first of all, can I add this two small monomials [x^2 and $12x$]?

Students: No!
Guilherme: You can.

Once more, the teacher challenges the students to interpret Hugo's statement, aiming to clarify the properties of operations with monomials. Most students seem to know that one cannot add two monomials with different degrees, but Guilherme states the opposite. So, the teacher promotes the analysis of this mistake, indicating that he can continue the solving process:

Teacher: So, do it.
Guilherme: $4x^2$ is the same has having $4x$ times $4x$.
Teacher: Is it?
Students: No.
Teacher: Guilherme asked if $4x^2$ is the same as having $4x$ times $4x$.
Students: No.
Teacher: Why not?

As Hugo, Guilherme proposes an invalid procedure, so, the teacher keeps challenging students to interpret his proposal and, to support students, she revoices Guilherme's statement. Again, the teacher challenges the students to justify their answer, but Guilherme realizes his mistake and corrects it right away:

Guilherme: But we could get, for example, $2x$ times $2x$, $4x^2$. And then, we would get $2x$ times $2x$ less $12x$ equals zero.
Teacher: OK, to that point it is OK. I will write down for you. $2x$ times $2x$, less $12x$ equals zero. It is also equivalent, OK?

With this new statement, the teacher suggests that Guilherme is doing a right procedure, arguing that this equation is equivalent to the previous ones. She also informs students about Guilherme's proposal by representing it on the blackboard. Then, despite being asked to keep going on his solving process, the student does not know what to do. So, in order to guide Guilherme, the teacher revisits the aim of solving an equation, which allows him to continue:

Guilherme: Not to stand again $2x$ times $2x$, after one would get... I do not know if I could divide by k. $2x$ less $12x$ equals zero divided by $2x$.
Teacher: This one here [$2x$] is multiplying the whole expression?
Students: No.
Teacher: When I divide, when I move to here dividing by $2x$, it means I divided the whole expression.

As the new proposal of Guilherme is not valid, the teacher suggests a reinterpretation of his statement and recalls the use of an equivalence principle of solving equations in order to show that he cannot do the procedure he is proposing.

In this segment, the students did several wrong procedures, highlighting that they do not have yet a mastery of monomial and polynomial properties. These wrong procedures led the teacher to challenge students to make connections with polynomial operations. As students have some knowledge about this topic, the teacher keeps using challenging actions instead of suggesting and guiding actions as she did in the previous segment. Nevertheless, when needed, the teacher uses suggesting and some guiding actions to move the discussion forward. All these actions are mostly around interpreting and reasoning about that interpretation.

An unexpected proposal

As before with Irina, Guilherme cannot move forward on solving the equation, so, the teacher invites another student to continue:

Teacher: Maria.
Maria: Teacher, getting back to that one [referring to $x^2 = 12x/4$].
Teacher: Getting back to this [pointing out the equation on the blackboard].
Maria: Is it possible to do x^2 divided by x equals 12 dived by 4?
Teacher: Oh, Maria did this... Have you seen what she has done?
Students: Yes.
Teacher: I am going to do what she has done, this x [on the left side of the equal sign]... She wrote this, I will continue [writes down $x^2/x = 12/4$].

As Maria begins where Irina stopped, the teacher guides students to focus their attention by revoicing and pointing out what Maria is referring to. As Maria presented her proposal, the teacher informs students by representing it on the blackboard. Before moving forward, a student states that Maria cannot separate 12 from x in $12x$, which leads to a segment of the discussion very similar to the segment *Overcoming misconceptions*. After clarifying some monomial properties, the teacher asks Maria to proceed with her way to solve the equation:

Teacher: And now what? Maria, I stopped here, what's next?
Student: x equals 3.
Teacher: In the other lesson we didn't get to this point. Now I am curious. Look here. If I would go this way, x^2 divided by x...
Students: It's x.
Teacher: Equals...
Students: Three!
Maria: So, it is possible!

Maria does not get to answer as there is a colleague that anticipates the response. The teacher asks again the question, suggesting students to develop the representation of the equation made by Maria. At this point, several students are following Maria's reasoning and completed solving the equation with no further support from the teacher. Thereby, Maria concludes that her way to solve the equation is valid. Nevertheless, the teacher explores the situation a little bit further by challenging the students to interpret the situation and then to justify their interpretation:

Teacher: Is it possible?
Students: It is.
Teacher: How can I see if the solution is correct?
Student: Replacing.

As a student readily answers how to justify that the value they found is a solution of that equation, the teacher suggests most of the computational procedures needed:

Teacher: So, let's do it slowly. Do it with me, slowly. Jorge, can you do it slowly? Here is 3 [referring to x]. x^2...
Lourenço: It's 9.
Teacher: 9 times 4...
Lourenço: 36.
Teacher: 36. 3 times 12...
Students: 36.
Teacher: 36 less 36...
Students: Is going to be zero.

This segment develops around Maria's proposal that emerge from the teacher's first challenge to solve the equation through making connections with previous knowledge. As students engage in the discussion about Maria's proposal, the teacher mostly suggests procedures that lead students to find a solution of the equation and, later, to justify that solution. In between, the teacher challenges students to justify that the value found is an equation's solution, which students easily do.

Comparing solutions

At this point, a student, by trial and error, figures out that zero could also be a solution, which led the teacher to introduce a discussion aiming the generalization of the zero product rule. This segment of the discussion had a first section where students factorized the proposed equation and a second section where the students figured out its solutions. Then, the teacher proposed some problems involving the zero product rule to students to solve in small groups. Previously to the discussion of those problems, the teacher recalls Maria's solving process:

Teacher: Earlier, I'll call it now "Maria's process". By Maria's process how many solutions have we found?
Student: That has one [solution].
Teacher: One solution. But when we did it by factorizing, we got two. My question is... We saw, we confirmed, that actually this equation has two solutions. The question is, what happened in this process, why zero does not emerge as a solution? This would be . . . x equals zero or x equals 3, two possibilities. Here [in Maria's process] only emerges x equals 3. Suddenly it looks like a solution has been hidden. Luís readily said that there was another despites this one . . . Why doesn't the solution show up here? [No student reacts.] Why did I found here x equals 3 and there I found out two solutions, zero and 3?

The teacher begins by saying what is going to be discussed, challenging students to evaluate the two processes of solving the equation. Mário says that solving using the zero product rule is the way to "obtain all possibilities", so the teacher guides the students to interpret Maria's process. But the students centre their attention on zero, referring to zero on the second member of the equation $4x^2 - 12x = 0$. At some point, Mário asks the following question:

Mário: Teacher, a question. Is zero the second solution in equation that... c equals zero [referring to c in $ax^2 + bx + c = 0$]

Teacher: That is a very good question. But my question... That is really a good question, it is very relevant. But my question here is why doesn't zero appear here? Before we go to that one. Why doesn't it appear here? And there it appeared.

Mário's intervention represents a very interesting generalization about zero being a solution of any 2nd degree equation like $ax^2 + bx = 0$. The teacher decides not to explore it but to move back to Maria's solving process, challenging students to get some justification on the lack of one of the solutions in Maria's process. A student gets back to the zero rule process' solution but the teacher guides students again to focus on Maria's process. Hélder intervenes:

Hélder: Because one cannot divide by zero.

Student: Yes you can!

Teacher: [Writes a huge 2/0] Question to the class...

Student: What a huge 2!

Teacher: It really is to be seen. Hélder said, here does not appear zero as a solution because Maria, when did this step, divides by x. And, if I place here a zero, what Hélder is saying is that it doesn't make sense to place here a zero. My question is, why? This equals to what?

Student: Zero.

João: Undetermined.

As Hélder's answer to the teacher prior challenge lead to a disagreement, the teacher challenges students to justify if Helder's statement leads to a justification or not. This discussion leads the students to conclude that it is not possible to divide by zero, as Madalena states ("Even so, no number can be divided by zero") and the teacher supports reinforcing ("No number can be divided by zero).

As the evaluation of the solving processes relies on the reason why Maria's process leads to just one solution, and that reason is justified, the teacher ends this whole class discussion.

In this last segment of the discussion, the teacher main action is challenging students to evaluate both solving processes. To promote students' activity towards evaluation aim, the teacher guides the students to focus on Maria's process and challenges them to justify the single solution it yields. In this segment there are few informing actions, and teacher's challenging actions lead to many students' reactions.

CONCLUSION

In this whole class discussion, we identify a variety of teachers' actions. We note that each segment is structured by a main action. As this class discussion aims to introduce new knowledge, one could expect that central actions would be mostly guiding, subtly or explicitly leading students to a solving procedure using the zero product rule. Nevertheless, attending this class characteristics, the teacher begins all four segments with a challenging action leading to quite unpredictable students' responses. This teachers' choice provided rich learning opportunities that would probably not occur if guiding would be the central action in each segment. We also note that, albeit marked by a main challenging action, all segments differ in their nature. Teachers' actions seem to depend on students' knowledge about the situation, as challenging actions are followed by other challenging actions when the students have the tools to embrace those actions and are followed by guiding or suggesting actions when the mobilization of students' knowledge needs further support.

Regarding mathematical processes, the teachers' central actions mostly rely on interpreting processes. Nevertheless, more demanding processes also occur as in *Comparing solutions,* where challenging evaluating actions assume great importance. As with the actions themselves, the mathematical processes addressed also depend on students' knowledge. New situations to students require a focus in representing and interpreting processes, while segments where students have some previous knowledge to rely on, reasoning and evaluating processes are more likely to occur, as in *Overcoming misconceptions* or *Comparing solutions*.

In summary, the model used to analyse teachers' actions (Figure 1), extending the previous models of Stein and colleagues (2008) and Cengiz, Kline and Grant (2001), contributed to better understand teachers' practice. Also, an interesting relationship between teachers' actions, mathematical processes and the situation itself emerged from the analysis with this model, which suggests the need of further research of teachers' practice during whole class discussions focusing on these features.

Conducting mathematical discussions as a feature of teachers' professional practice

João Pedro da Ponte and Marisa Quaresma

Universidade de Lisboa, Instituto de Educação, Lisbon, Portugal, jpponte@ie.ulisboa.pt

We analyse teacher's actions during whole class discussions in exploratory classes (in which students are asked to design their own strategies) and their relation to students' learning. Data is collected through participant observation, with videotaping of lessons. The results show that the exploratory approach favours the emergence of disagreements among students and their formulation of generalizations and justifications provided that the teacher intertwines guiding and suggesting actions and makes appropriate challenging actions at key points. In such whole class discussions, the teacher has to make important decisions in relation to problematic situations raised by students' difficulties or unforeseen responses as well as by the need to figure out productive ways of continuing a discussion.

Keywords: Teacher practice, mathematical discussions, communication, reasoning.

INTRODUCTION

An exploratory approach to mathematics teaching seeks to propose students situations where they have to deal with tasks for which they do not have an immediate solution method or in which a new representation, concept or procedure may be useful. This approach creates opportunities for students to build or deepen their understanding of concepts, representations, procedures, and mathematical ideas. The students are called to play an active role in interpreting the questions proposed, in representing the information given and in designing and implementing solving strategies which they are called to present and justify to the whole class. This teaching approach is based in the fundamental distinction between task (the objective to be achieved) and activity (the work to be done to achieve this goal) (Christiansen & Walther, 1986). The work on exploratory classes develops usually in three phases (Ponte, 2005): (i) presenting and interpreting the task; (ii) carrying out the task individually, in pairs, or in small groups; and (iii) presenting and discussing results and doing a final synthesis.

In this study, we focus our attention in the work of the teacher in leading whole class discussions, in which students present and justify their solutions and question the solutions of their colleagues. We do not seek to establish a normative framework, saying what the teacher "must" do, but rather to analyze the phenomena that take place in the classroom, in order to understand the situations that occur and the actions that the teacher can do to promote students' learning. As students carry out exploratory work, the diversity of situations that may arise is very large and depends on the age level of the students, their mathematics ability, the culture of the classroom, and the mathematical topics under study. In addition, one must keep in mind the influence of other factors such as teachers' and students' concerns about assessments, school guidelines on curriculum management, textbooks and other resources available, physical conditions of the room, etc. In this way, our study has essentially an analytical stance, aiming to examine the diversity of actions that the teacher is called to undertake in whole class discussion moments and their relation to student learning.

THE DYNAMICS OF DISCUSSION MOMENTS IN THE CLASSROOM

Teachers' practices have an important influence on students' learning (Ponte & Chapman, 2006). An important aspect of such practices is the nature of the tasks that the teacher proposes to their students. If a task only requires students to select and apply a solution method that they already know, they have just to identify and carry out this method. By contrast, a task with challenging features (Ponte, 2005) or involving a high cognitive demand (Stein, Remillard, & Smith, 2007; Stein & Smith, 1998) may lead to a diversity of strategies that can be compared and evaluated, resulting in interesting classroom discussions.

Another aspect that frames teachers' practices is the nature of the classroom communication (Bishop & Goffree, 1986; Franke, Kazemi, & Battey, 2007). A fundamental aspect of communication are the questions posed by the teacher. Among these, inquiry questions that admit a range of legitimate responses are particularly useful. In addition, another important feature of classroom communication is the process of negotiation of mathematical meaning (Bishop & Goffree, 1986), leading students to make new connections among mathematics ideas, and helping the teacher to recognize their sometimes unforeseen points of view. Franke, Kazemi, and Battey (2007) stress the importance of processes that support students' language development, like revoicing. Whole class discussions provide opportunities for particular forms of communication, such as explanations and argument and are attracting a growing interest of mathematics education researchers (Bartolini-Bussi, 1996; Cengiz, Kline, & Grant; 2011; Fraivillig, Murphy, & Fuson, 1999; McCrone, 2005; Scherrer & Stein, 2013; Sherin, 2002; Stein, Engle, Smith, & Hughes, 2008; Wood, 1999).

The teacher role is to prepare the moment of discussion, taking into account the work carried out by the students and the class time available. In order to do this, Stein, Engle, Smith and Hughes (2008) highlight the importance of anticipating how students might think, to monitor their work, to gather relevant information, to select aspects to note during the discussion, to sequence the students' interventions and to establish connections among the different solutions during the discussion. A preparation made under these conditions is an important support for conducting a discussion. However, the actual development of a discussion involves other issues beyond the establishment of connections. Many of these issues cannot be fully predicted prior to the discussion, but create problems that the teacher must be prepared to face. As Sherin (2002) indicates, the teacher needs to be able to balance aspects relating to mathematics knowledge, which requires filtering ideas focusing students' attention in fundamental ideas, and aspects related to mathematical processes that require a frequent attention.

Seeking to identify situations of particularly productive discussions, both Potari and Jaworski (2002) and McCrone (2005) emphasize the value of challenging students mathematically. Wood (1999) underlines the potential of exploring disagreements among students, as teachers lead them to justify their positions and encourage other students to join the discussion. Fraivillig, Murphy and Fuson (1999) and, subsequently, Cengiz, Kline and Grant (2011) developed a framework of analysis for the teacher's actions in conducting mathematical discussions that distinguishes three main types of actions: (i) eliciting actions, to lead students to present their methods, (ii) supporting actions, to promote their conceptual understanding, and (iii) extending actions, to widen or deepen students' thinking. In another study, Scherrer and Stein (2013) developed an intervention to support teachers in analyzing whole class discussions based in four main coding categories of moves: (i) those that begin a discussion; (ii) those that further the discussion by elaborating or deepening students' knowledge; (iii) those that elicit information; and (iv) other moves.

With a similar intent, Ponte, Mata-Pereira and Quaresma (2013) developed a framework that assumes that the teacher performs actions directly related to the topics and the mathematical processes as well as actions that have to do with management of learning (Figure 1). Focusing their attention on actions related to the mathematical aspects, they point out that inviting actions are used to start a discussion and guiding actions allow leading students on solving a task through questions or observations that implicitly point the way forward. In informing/suggesting actions the teacher introduces information, presents arguments or validates students' answers. Finally, challenging actions seek to lead students to produce new mathematical knowledge. In informing/suggesting, guiding, and challenging actions it is possible to identify fundamental aspects of mathematical processes such as (i) representing (constructing, using, or transforming a representation), (ii) interpreting, including the establishment of connections, (iii) reasoning, including formulating a strategy to achieve a goal, producing a statement, generalizing procedure and justifying, and (iv) evaluating, making judgments about a concept, representation, or solution. A generalization may concern a definition, a statement or a procedure and a justification may be informal and related to the context of the situation or more formal as is the hallmark of mathematical work.

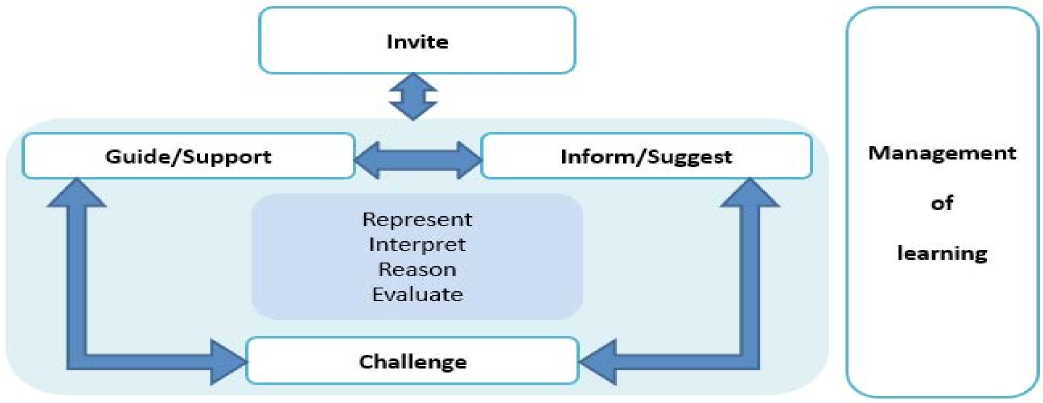

Figure 1: Framework to analyse teachers' actions (adapted from Ponte et al., 2013)

RESEARCH METHODOLOGY

This study follows a qualitative and interpretive approach (Denzin & Lincoln, 1989) using participant observation. Both authors assumed the role of teachers (striving to follow an exploratory approach) and researchers – as one conducted the class, the other acted as a participant observer. The grade 6 class, with 19 students, is in a rural elementary public school, in a deprived area. The students, usually, show little commitment to school activity and do not get themselves much involved in working in the mathematics class. The study involves five 90-minute lessons, in which students carried out several tasks presented in three worksheets. The first worksheet included diagnostic questions on comparing, ordering, adding and subtracting rational numbers, the second aimed to introduce the multiplication of a natural number by a fraction and the multiplication of two fractions, and the third was intended to develop the notion of operator in the context of problem solving. After the introduction of the task, the students began by working in pairs and the teacher monitored their work, helping them to move on, when necessary, but striving to not provide direct responses to the questions stated in the task. Finally, there was a whole class discussion, in a register of dialogical communication (Ponte, 2005).

The classes were recorded on video and the whole class discussions were integrally transcribed. Data analysis began by identifying the segments in the discussion of the solution of each task, coding the teacher's actions according to the categories shown in Figure 1. Then, we sought to establish relationships between these actions and specific events as regards interpretations, representations, and reasoning made by the students. For this paper, we selected two episodes that illustrate several aspects of these relationships.

DEALING WITH STUDENTS' DIFFICULTIES

In this episode we find two rather common situations in the classroom: (i) students with difficulty in understanding a written mathematical question and, (ii) students with difficulty in expressing their thinking. We show a first situation with several guiding and suggesting actions but where a challenging action proves to be critical and a second situation in which guiding and suggesting assume an identical role and there is a very low level of challenging. This takes place as students work on a task in a mathematical context (Figure 2) that asks to evaluate the validity of a statement involving two fractions. This task is a problem that requires the students to figure out that they either must find counterexamples or justify that the statement is always true.

Task 1. $\frac{2}{4}$ is larger than $\frac{1}{3}$, $\frac{4}{5}$ is larger than $\frac{3}{4}$. Do you think it is possible to make the following statement: "If we want to compare two fractions and we verify that one of them has the numerator and the denominator larger than the other fraction, we can immediately conclude that this is the larger fraction"? Justify your answer.

Figure 2: True or false? (task based on Lin & Tsai, 2012)

As students begun working individually, they immediately show difficulty in understanding what is asked in the question and the teacher realizes the need to promote a whole class interpretation of the statement and in helping students find a solution strategy:

Teacher: The two cases are true. (...) OK, this and this [$\frac{2}{4} < \frac{1}{3}$ and $\frac{4}{5} < \frac{3}{4}$] are true. May I always say that whenever the numerator and the denominator of a fraction are larger than the numerator and the denominator of the other fraction, then [the fraction] which has larger numerator and denominator is always larger than the second [fraction]? Does this always happen?

A student: No...

Teacher: How can you know if it always happens or not?

Daniel: Doing more fractions...

Teacher: Finding more examples... It may be a good suggestion from Daniel...

The teacher recalls the main aspects of the statement ("this and this are true") and then makes a more general statement ("when the numerator and the denominator of a fraction are larger than . . ."). The students realize that the statement is true in some cases but have difficulty in knowing what to do to know whether, in general, the statement is true or not. The teacher makes an inquiry question ("How can you know if it happens always or not?") and this leads Daniel to suggest a promising strategy. The teacher supports this idea and she revoices it formally in more appropriate terms.

In this first segment, as the students show difficulty in finding a strategy to answer the question, the first intervention of the teacher helps them to interpret the statement and is a guiding action, which is followed by an inquiry questiona challenging action. The final intervention, supporting the proposal of Daniel, is a suggesting action. The emphasis of the teacher's intervention is in interpreting (the task and its different elements) as a basis to support students' reasoning as the aim is knowing and justifying whether a given statement is mathematically valid or not.

In the sequence of this exchange, during the whole class discussion of the results, Guilherme, presents a counterexample for the statement, identifying fractions that satisfy the given conditions ($\frac{2}{4}$ and $\frac{3}{16}$) but which do not verify the inequality. To compare these fractions he converts them in percent. The teacher considers interesting that the whole class observe this solution, but some students do not understand it:

Teacher: So, Guilherme found... a way to transform fractions in percent and... He found that $\frac{2}{4}$ is 50%, right? And what did you find about $\frac{2}{4}$, $\frac{2}{4}$ was how much? Some of you discovered... Changed the fraction into a decimal...

Jaime: It was 0.5.

Teacher: Oh! It was 0.5. And so, 0.5 in percent is...

Guilherme: It is 50%.

Teacher: Oh! It is 50%. Oh, so that means that he arrived to the same conclusion as you did, but using a different representation . . . So Guilherme prefers to work with percent . . . So, he discovered that $\frac{2}{4}$ is 50% and $\frac{3}{16}$ is 18,75%... Why have you done this, Guilherme?

The teacher leads the students to compare the representations used by Guilherme (percent) and by the remaining students (decimal). With a final question, the teacher seeks to guide Guilherme, supporting him in explaining his solution.

In this second segment the teacher asks a student to present his solution, which she found to have a remarkable originality, but is faced with the problem that the student has great difficulty in explaining his reasoning. As many students are confused, the teacher's actions alternate between guiding and suggesting, with no challenging actions. There is much attention to representations and their transformations (converting between decimals and percent) but the focus of the teacher's interventions is in interpreting, revoicing the student's statements in a more understandable and correct way, in order to allow an interpretation and understanding of the other students in the class.

CHALLENGING STUDENTS

Next we show a situation that begins with a teacher challenge which is then followed by inviting, guiding and informing/suggesting actions, which lead the students to establish a first generalization connecting multiplication of an integer by a fraction with successive addition of fractions and a second generalization that highlights an understanding of equivalent fractions. It takes place when students work on the task shown in Figure 3 that asks for the value corresponding to seven repetitions of a certain magnitude in a contextualized situation. The students had not yet learned to multiply a whole number by a fraction. It was expected that they would solve the task through repeated addition, perhaps proposing by themselves a definition for the multiplication of a whole number by a fraction.

> **Task 2.** In the grade 6 class of the school Wide Horizon, the teacher made the following problem: "Every morning, Raquel drinks $\frac{1}{4}$ of liter of milk. How much milk does she drink in a week?" You must solve the problem yourself and justify your answer.

Figure 3: Task involving the multiplication of a natural number by a rational number

Two students solved the task using repeated addition of seven equal fractions. However, in their solution they wrongly indicate that $\frac{1}{4}+\frac{1}{4}$ is equal to $\frac{2}{8}$. During the whole class discussion, in a first segment, the teacher decides then to question how much is $\frac{1}{4}+\frac{1}{4}$. The students indicate several answers, some correct, such as $\frac{2}{4}$ and 0.50, and some incorrect such as $\frac{1}{8}$ and $\frac{2}{8}$. To guide the students in distinguishing among correct and incorrect answers, the teacher draws a pictorial representation (a rectangle divided in four equal parts) and asks again the students what will be the response.

Daniel, who had already presented a response to the question $\frac{1}{4}+\frac{1}{4}$ as $\frac{2}{4}$ and as a decimal (0.50), suggests a new answer, using the equivalent fraction $\frac{4}{8}$. The teacher notes that the student is thinking in fractions equivalent to , decides to validate his solution and asks for a justification (a challenging action):

Teacher: Exactly, $\frac{4}{8}$ would be also an answer. Why? Why is $\frac{4}{8}$ equal to $\frac{2}{4}$?...
Guilherme: Because it is 0.50.

Guilherme's justification is based on a change of representation. At this moment teacher decides to take the opportunity to recall equivalent fractions, emphasizing the relationship that exists among $\frac{2}{4}$, $\frac{4}{8}$ and $\frac{1}{2}$, and this leads to a new discussion segment.

Driven by the intervention of Guilherme and the suggestion of the teacher, Edgar suggests another equivalent fraction. The following dialog takes place:

Edgar: Oh! Teacher, I know another... 8 divided by 16 also does it!
Teacher: Also does it... $\frac{8}{16}$ also does it... Very good... Any other that also does it?

As two students (Juliana and Edgar), in the last class, had also made an interesting discovery related to this issue, the teacher encourages them to indicate it. Juliana corresponds to this invitation, stating a generalization:

Juliana: A number divided by its double will always yield its half."

The teacher challenges then the students to give more fractions equivalent to $\frac{1}{2}$, and they correspond in an enthusiastic way:

Teacher: Very well... $\frac{2}{4}$ is equal to $\frac{1}{2}$ that is equal to $\frac{8}{16}$... And I want another one!
Rui: So, now 16 divided by 32...
Teacher: $\frac{16}{32}$. And I want still another one...
Students: 32 by 64.
Teacher: Ah... Very good, $\frac{32}{64}$. Still another...?
Students: 64 and 128...

Other students join the discussion and suggest more fractions equivalent to $\frac{1}{2}$. The teacher supports this enthusiasm, revoices their suggestions using a correct fraction language and challenging them to find other fractions that satisfy the same condition.

In summary, at the beginning of this episode several students show that they do not recall the procedure to add two fractions with the same denominator. The teacher seeks to lead them to understand the rule to add two unit fractions, using for that purpose a pictorial representation. When all agreed that $\frac{1}{4}+\frac{1}{4}=\frac{2}{4}$, and assuming the opportunity provided by the fact that different correct responses were already provided, the teacher begun challenging the students to provide justifications regarding equivalent fractions and to find further equivalent fractions. In this episode, the teacher's most important actions are challenging, although one recognizes inviting, guiding and informing/suggesting actions as well. Starting from a simple procedural question, the teacher ends up leading an inquiry-oriented reasoning, with the establishment and use of a generalization to produce equivalent fractions.

CONCLUSION

This paper shows how teachers' actions may unfold during whole class discussions conducted within an exploratory approach. In the first episode the teacher seeks to support students in interpreting a written mathematical statement and leads those who solved a question correctly to explain it to their colleagues. The teacher provides some challenge but uses mainly guiding and suggesting actions, without indicating the solution to the students. Drawing on counter-examples, the teacher seeks to make the elements available to the whole class so that the students can figure out that the statement is false. In the second episode, after some work on pictorial representations to figure out a correct answer, the teacher challenges the students to present more answers, seeking the emergence of disagreements and, in response, the students produce a sequence of equivalent fractions. That is, in both episodes challenging is a critical action (Potari & Jaworski, 2002; McCrone, 2005) but needs to be underpinned by other types of actions. The way the teacher intertwines guiding and suggestion actions and makes appropriate challenging actions at key points is critical to foster students' involvement and to achieve the learning goals, notably, (i) when students present promising conjectures, (ii) when there is room for important justifications, and (iii) in situations that may prompt fruitful conjectures from the students. In addition, both episodes show how the teacher may promote the interconnection of representing and interpreting and create opportunities to foster students' reasoning, notably asking them for generalizations and justifications (Ponte, Mata-Pereira, & Quaresma, 2013).

These whole class discussion moments provide many opportunities for interpreting statements and using representations (Bishop & Goffree, 1986), for improving the students' language revoicing their claims (Franke, Kazemi, & Battey, 2007), for establishing disagreements (Wood, 1999), and formulating generalizations and justifications (Lannin, Ellis, & Elliot, 2011). However, whole class discussion moments also create many problems for the teacher, requiring the ability to deal with unforeseen situations and to notice opportunities for promoting students' learning (Scherrer & Stein, 2013). The discussion episodes presented in this paper include many moments in which the teacher needs to make decisions with respect to different situations, which are constituted as problems that she has to deal with in the course of the action. Some of these problems have to do with students' difficulties in understanding what they can do in a proposed task or in interpreting some aspect of a solution provided by another student. Other problems arise from unexpected responses from students, sometimes correct and other times incorrect. There are also problems which arise from the students' difficulty in explaining their reasoning. Finally, other problems arise from the need to manage, in a productive way, the range of students' responses and in keeping an appropriate pace for the classroom work. That is, besides planning the discussions and anticipating possible students' difficulties (Stein et al., 2008), the teacher must be ready to make important decisions in relation to problematic situations raised by students' difficulties in understanding the tasks, in figuring out strategies, in expressing themselves and by unforeseen students responses. In addition, at many points the teacher needs to figure out what is the most productive way of continuing a discussion. Such problems that conducting whole class discussions raise to teachers' practice creates an important agenda for research concerning mathematics teacher professional development.

Mathematics assessment, competition and professional capital

Nick Pratt

Plymouth University, Plymouth, UK

In this paper, I use interviews with two teachers, drawn from a small scale study of four schools, to illustrate the way in which mathematics assessment is used as a form of capital in teachers' wider professional lives and the effect that this is likely to have on teaching practices in mathematics. Assessment is high-stakes for English schools and outcomes are increasingly measured numerically in terms of annual 'pupil progress'. I use an analysis based on Bourdieu to illustrate how this affords competition between teachers for grades and potentially brings them into conflict with each other. I argue that the effect of this kind of professional capital is likely to be unhelpful in relation to what is known to be effective use of assessment in mathematics teaching.

Keywords: Assessment, Bourdieu, professional capitals, competition.

INTRODUCTION

The focus of this work is mathematics assessment from the perspective of teachers in English primary schools (5–11yrs) in relation to the significant part it plays in their teaching. This is set in the context of massive investment in mathematics education over the last 15 years, but with modest improvement and concern that English pupils are not keeping up with their international peers (e.g., Gove, 2013). Research (e.g., Boaler, 2005) is clear that one vital issue in effective learning of mathematics is that teachers, and pupils themselves, see the potential for learning as flexible and mutable; and that its opposite – perceiving it as objectified and immutable – leads to teaching practices which hold learners back. Pupils should be involved in understanding what they can and cannot *yet* do and involved in mathematics as a process of exploring interconnecting ideas. Despite this clarity, practices in English classrooms tend not to reflect it; a view of mathematical ability as a fixed characteristic of individuals, setting by such ability and teaching that is negatively differentiated so that weaker pupils (and the highest achieving) are not challenged mathematically, all prevail (Boaler, Wiliam, & Brown, 2000; Marks, 2014). This paper explores some of the reasons for this contradiction by trying to understand teachers' mathematics assessment practices from the perspective of professional status as a whole. In doing so it makes use of Alexander's definition of pedagogy as 'the act of teaching together with its attendant discourse' (Alexander, 2004, p. 11). Crucially, from this perspective, teaching practices can only be understood in relation to the politics of daily life within which teachers act; research which decontextualizes teaching and learning in this way is unlikely to affect practice in any significant manner.

THEORETICAL FRAMEWORK

Assessment judgments in the UK take place within a high-stakes environment of increasing competition at both school and individual level with quantified test outcomes being the key commodity for recognition of success and high status. Schools, and the individual teachers within them, are now judged on the basis of standardised numerical outcomes; ubiquitously referred to as 'data' by those who work with them. For anyone not associated with education in English schools it may be hard to appreciate just how much of a hold this assessment-driven culture has over the lives of those who work in them; to a large extent it dominates the way they think and talk about their work, with numerical assessment data being used as a proxy for the overall standard of education in a highly politicised landscape. The term 'progress' has been adopted by successive governments and policy makers to stand for the rise in pupils' attainment over time. Pupils' progress over stages of their educational life against subdivisions of National Curriculum levels has become the key measure by which schools are judged during inspection (Office for Standards in Education, 2012a) and schools can only be graded as 'outstanding' if the progress from Key Stage 1 (KS1 – 7 years old) to Key Stage 2 (KS2 – 11 years old) fits the approved pattern, regardless of the perceived quality of teaching during an inspection[1]. This means that the quality of teaching is understood to be validly and reliably represented by the measured progress. In turn this means that teaching *tends to get constructed backwards*; if the progress is not as much as it should be then teaching cannot be good, regardless of what is seen on the ground. Furthermore, the UK Coalition government has recently introduced new arrangements for performance-related pay for individual teachers (Hodgson, 2012) in which successful teaching gauged at an individual level is defined as all pupils making a specific number of points of progress across a year, regardless of circumstances. Assessment is therefore naturally very much part of teachers' everyday mathematics discourse and so, on the assumption that human activity is object-orientated (Vygotsky, 1978), this discourse and acts of teaching and learning mathematics will be mutually constituting in pedagogy.

To try to understand this relationship between assessment and teaching I draw on Bourdieu's notions of *field*, *habitus* and *capitals*. As Colley (2013) notes, though imperfect by Bourdieu's own admission the idea of the *game* as a metaphor is important in understanding how field and habitus interact with each other. The field (here the work of school assessment) is 'a space of conflict and competition constructed only through the human doings of human people' (p. 10) so that it 'is not only a set of external conditions which themselves have been devised or imposed ... [but] is also the agentic and partly subjective *playing* of the game through our *habitus*'. Field and habitus are not therefore separable, and certainly not representative of structure and agency respectively. Rather, they are mutually constitutive of each other, each produced through the other: habitus developed through repeated activity in the field; field developed through the playing out of activity through habitus. Thus, the question here is how the changing nature of mathematics assessment as a high-stakes, politicised element of schooling affects the ways in which teachers and pupils 'play out' schooling. In this respect, two other Bourdieusian ideas are relevant: *doxa* which refers to the dominant discourse of a field, separating what is thinkable from what is unthinkable; and *illusio*, a more conscious belief in the stakes (*enjeux*) of the game and the *belief that it is worth playing*.

METHODOLOGY

The project forms part of a wider study based in Plymouth University, UK, looking at the socially-constructed nature of teaching (see, e.g., Kelly, Hohmann, Pratt, & Dorf, 2013). It involves extended semi-structured interviews with primary teachers in four different schools (12 teachers in total) aimed at exploring their use and understanding of mathematics assessment (though inevitably, as non-subject specialists teaching the primary curriculum, teachers spoke about assessment in general too). In this sense it is a case study, exploring assessment as an aspect of the field of teaching and learning in the four case schools. Both teachers and schools were chosen purposively, the latter with different characteristics that might reasonably affect the way in which assessment takes place, including: inspection gradings; different arrangements of governance; and different proximities to competing schools. Data from all the interviews were analysed using a constructed, grounded approach following Charmaz (2006) and themes were developed. These themes are incorporated into the account that follows, but using examples from just two interviews, Tony and Sasha, to illustrate the claims, accepting that in such a short paper only a partial account of these themes is possible. Both interviewees are classroom teachers at the same urban school of 550+ pupils and have been teaching for 9 and 6 years respectively. Tony trained via a one-year postgraduate course and teaches Year 3 (7–8 yrs); Sasha trained on a four-year Bachelors course and teaches Year 5 (9–10 yrs). The school has had successful inspection outcomes over the last 15 years, based on attainment that is above the national average, but was recently downgraded from 'outstanding' to 'good' on account of progress not being consistent across the whole school. Such consistency, judged through assessment, is therefore a focus for all staff.

THE DISCOURSES OF SCHOOL ASSESSMENT

Despite the points about assessment used for institutional and professional monitoring made in the

1 At the time of writing the UK government is consulting on the removal of this system and its replacement by one in which pupils are judged against 'age-related expectations'.

introduction above, England has a long tradition of child-centred, progressive education and, more recently, assessment for learning in which the 'first principle of learning, is to start from where the learner is' (Hogden & Wiliam, 2006, p. 1). The inalienable nature of this as it relates to assessment is nicely exemplified by Tony who, right at the start of his interview is asked what 'role assessment plays in what you have to do to be a successful maths teacher'. He responds:

> Tony: Ok. For me the only [hesitating and thinking] thing assessment's for, obviously we're measured against it and the children are measured against it, but to be a successful teacher, for me, the only reason is to see what you need to teach the children and teach to their ability ... um ... and find those gaps and fill them and bring them on. ... what you want to do is only assess for what you are planning, what you are teaching.

But asked whether this is representative of how assessment is used in the school as a whole he declares:

> Tony: I think the trouble is that not everyone would agree with that. I think there would be some teachers who see assessment as a measure of progress, rather than assessment for learning. And I think all teachers would see those two things as part of assessment but where they put, where they see the emphasis might be slightly different.

In these two statements Tony describes the two contrasting discourses of assessment that were apparent in the data set, as well as the tension between old and new traditions. On the one hand assessment is formative, for teaching and learning; on the other it is a summative measure of progress. However, for both of these discourses there is also a question of who controls the information that assessment generates and therefore who makes use of it and what is expected from them. Children are certainly involved in this respect. Formative assessment is routinely used to set targets, usually in very systematic ways such that children know what they are meant to achieve next; and summative assessment outcomes are shared too so that my own son, for example, will routinely tell me that 'I am a level 5b'.

The language is interesting here as children are objectified 'as' their perceived ability level. Objectifying children in relation to 'their ability' has a considerable literature critiquing it (see, e.g., Boaler, 2008; Boaler et al., 2000; Cooper & Dunne, 2000; Muijs & Dunne, 2010), and the increasing emphasis on accountability seems to drive the need to become auditable, which in turn drives objectification of pupils as numbers on an assessment scale. Thus, in interviews we hear Tony describing the moderation of assessment, saying that the teachers in his year group 'looked at our level 4s'. Whilst this does not, of course, imply that teachers only see children in these terms, nor that there may not be benefits from doing so anyway, it does illustrate a creeping objectification of pupils in the discourse of schooling *as* their assessment level and runs counter to the research pointing to the value of a flexible view of learning potential. I argue that this is a necessary part of a system of high-stakes accountability since objectifying pupils as assessment levels enables them to be measured, and hence to create a narrative of 'progress' as also measurable. However, for this to be used to account for (and increasingly measure) teachers' work a second aspect of the narrative is necessary, which is the imposition of personal responsibility for this measure on teachers themselves. If one is to link pay to progress one must not only have a reliable measure of progress but must also believe that this is the result of the teacher's actions, so that these can be assessed and understood as the teacher-performance. So, for example, Sasha describes performance management meetings with the school's senior management team as 'a scary meeting', but says,

> Sasha: I've always quite looked forward to it. But again, I wonder if that's because I'm a successful teacher – it feels very strange saying that. If I'm a successful teacher, and if maybe I wasn't a successful teacher it would maybe be more worrying. And I know teachers in the past who've been hauled before heads or governors to kind of go 'your children have not made appropriate progress this year, why not?' ... the performance management cycle ensures that no-one's rubbish at their job.

In this light, aspects of the discourse that is created around school assessment include:

- The belief in a version of success defined in narrow, data-led terms
- The belief that progress is predictable and controllable across time
- The creation of official expectations of such progress
- Making individual teachers responsible for learning outcomes through their teaching

I argue that this discourse constitutes a *doxa* because as teachers spoke of their experiences in interviews these descriptions of assessment practice were generally 'granted [a] recognition that escapes questioning' (Bourdieu & Wacquant, 1992, p. 98). We see the attributes of control and predictability described here exemplified by Tony as he describes the typical shape of the graph of mathematics data for his class.

> Tony: Probably [the slope is] less gradual, very gradual, in the first term and then second term goes up a bit and then maybe curves over because you wouldn't go any higher than your SATs in May because you can't make any progress after that can you [laughs ironically]!

Note how the expectation on Tony and his own assessment practices constitute each other and control what is possible. Assessment does not just describe progress; it defines what is possible and what is not. Moreover, the doxa affords another shift, namely a move from assessment as a public good for the school, or more widely society as a whole, to also being a private good for the teacher. Teachers 'own' the data, in the sense that they both are made responsible for it and can make use of it as capital in their professional work. These are at work in the way Sasha describes mathematics assessment targets.

> Sasha: So the school target is something that everyone in the whole school is working towards. So whether that is a set amount of progress in a particular aspect of maths or just developing something, you kind of think about just that one thing. ... The class [assessment target] is progress of the children in your particular class or set and so again, obviously your assessment links up. And with the new pay and conditions thing, if you don't hit every one of your professional development targets you can't progress up the pay threshold...
>
> NP: Do you feel responsible for them [children's SAT scores]?
>
> Sasha: [immediately] Yes, really responsible, completely ... and some children you will be like, oh they were so close and then you feel a sense of disappointment for them and then you question whether or not you could have done more.

Moreover, this data is used and contested as capital by different parties.

> Tony: I mean like government need to be looking like they are doing a good job governing. It gets onto heads [headteachers] and they need to be monitoring that progress and they would say 'my school has made a lot of progress'. Deputies look at their key stage and say 'my key stage has done really well this year' [laughs]. And then teachers, 'my progress it is, it is' ... you're responsible for that data, so you have ownership over that data, but I suppose the stupid thing is ... is the children who are at the centre of it are the ones who are almost most removed from the talk of targets and data and .... Yes, it's ridiculous isn't it.

Again, Tony illustrates how the doxa of assessment works in opposition to the stated policy of assessment for learning with pupils at its heart.

ASSESSMENT: TEACHING AND MERITOCRACY

The culture of audit and accountability which promotes this doxa of assessment affords another idea; that teaching is meritocratic. The 'best' teachers are those whose children make the most progress, which, according to the doxa, can be reliably measured through assessment outcomes and attributed to individual teachers and their teaching. Thus, in describing herself as a successful teacher above, Sasha is not being immodest or arrogant. Rather, she is stating a fact since her outcomes are simply the right ones; though she seems aware of the possible social unacceptability of saying so ('it feels very strange saying that'). Habitus, the way actors are disposed towards the pedagogy of assessment, and field, the way they position themselves and are positioned by others in the professional setting, combine to normalize the practice of measuring outcomes and using these in particular ways. These outcomes can be understood as *les enjeux* (Bourdieu & Wacquant, 1992), the stakes in the meritocratic game of promoting one's professional status. That teachers adopt this position is not an example of either being forced to do so by structure or choosing freely to do so agentically. Instead it represents teachers' *illusio*, their sense of being caught up in the game and *committed to it in a belief that it is worth their investment*. Where doxa is a non-conscious participation in the dominant discourses of a field, illusio is a more aware sense of 'simply acting sensibly' (Colley, 2013, p. 11) in relation to the stakes of the game. By acting this way teachers implicitly say to themselves that they will be able to achieve things of value, and this may even outweigh acts of symbolic violence that they experience as a result.

Teachers therefore express their illusio in the manner in which they commit to the apparently meritocratic business of teaching and assessment because they believe it brings rewards, but also because the doxa within which pedagogy takes place appears to provide no alternative. It is important to understand that these work together. Just as it is not the case that teachers are unconscious of their actions, so neither do they exercise fully-conscious choice. The notions of doxa and illusio therefore try to represent the 'dance' of awareness that the teachers can move in and out of and, consciously or non-consciously, the way their actions are affected. For Sasha her illusio seems fairly straightforward and aligned with the doxa.

Sasha: and [my assessment] is all monitored really closely [in meetings with managers] in terms of percentages and progress in terms of points and any children who are flagged up as having regressed or not making as much progress as we'd have hoped, they're then flagged up and we put things in place, interventions and what-not. And similarly we do it to challenge [pupils] as well. Who do we need to challenge more?

In this instance at least, Sasha seems satisfied that assessment is valid, can legitimately be used to make decisions about teaching and that such decisions lead directly to outcomes such that teachers' work can be judged on a meritocratic basis.

In his interview however, Tony suggests a more arbitrary and political side to assessment, for example:

Tony: our stress is we should be recording children [with the grade] they are because then the [next] teacher could teach them effectively, and you feel like you are letting the children down if you don't record them accurately, but you know the stress of the school where it needs to look like a perfect gradual line. And we know that Ofsted would want that ...

Tony: Um, I don't think it [assessment] necessarily has an impact on progress on children. I think it helps people communicate the progress that people think children are making, but ... stress is necessary to some extent to perform to an optimum level, isn't it. But too much stress might tip people over, which... some people I know feel that way. And if the situation is where [pupils] are not moving, that's where the stress is bad, isn't it, but if they are succeeding then those meetings [about pupil outcomes] are usually quite rewarding, so it's usually quite ... it's never negative if you are jumping through those hoops.

Tony shows his awareness of, and challenge to, the doxa in his slight cynicism and way he seems to be questioning the effect of assessment for teaching and learning, but his comments still express his sense of illusio regarding the validity and use of assessment grades. Nonetheless, contrary to Sasha's view of assessment as supportive of learning, Tony describes his teaching practice as distorted by assessment in having to 'jump through hoops' with little 'impact on progress'.

ASSESSMENT: MERITOCRACY AND COMPETITION

Meritocracies, usually implicit in any neoliberal system, are essentially competitive. One rises up by being successful in whatever terms the dominant group in the system creates through the doxa; but as the stakes get higher obstacles to progress take on a greater significance. In a system where one's performance is judged mainly by being able to demonstrate a certain number of points of progress annually on an assessment scale, anything which makes this harder will be seen as a challenge; and since progress for one teacher starts where it left off for the previous teacher, end of year assessment has become a major focus and an issue of potential stress and anxiety for teachers.

> Sasha: … if you are in a position where actually you need that [grade] then it's very stressful because you then go 'but it's one child and it's one point and if I do it [alter the score] I'll get that' and you kind of go 'but professionally I can't do it, but I really need it …' it's that kind of whole, that real inner-turmoil about it.
>
> Tony: At the start of the year you look at data and you think how do I make progress with this lot and at the end of year you are stressing, I can't send them up like this they've done quite well, I'll put them down [laughs, but serious]. Every moment's stressful when you look at progress because you … I always found the stress of sending up children and how that would be perceived by [the next teacher] with the whole value-added thing, and I was always extremely careful that [it was] moderated *with* KS2. So sending up is incredibly stressful …and my stress at this moment is how my results which are relatively good are going to be perceived by the next teacher in year 4.

Despite the competition that assessment generates, Sasha's illusio suggests a stronger sense of investment in the practice of assessment. Perhaps because she is so successful within it and, regardless of the 'inner turmoil' described above, she notes that:

> Sasha: [The children] have no comprehension that you want to know how they've done and so you're stood over them [as they do tests] going 'yes, yes, yes, yes, nooo! Keep counting, keep counting' [laughs] and then you're like 'brilliant' or you're filling in their [marking] grids going 'amaaazing, look what they can do'. Very definite positives to it.

It seems that her habitus involves a strong commitment to these forms of high stakes assessment and despite her descriptions of stress she describes assessment as 'cathartic' because 'it confirms what I think about them' and 'it reassures you as a teacher'. This investment (illusio) requires a belief in the validity of the system of testing. For other teachers the illusio is just as strong, but is effected through other means, and where their pupils appear less successful the temptation to manage the system is clear. Indeed, more than just managing it, Tony claims that:

> Tony: I'd use the word manipulation! [laughs]. It is manipulated … for … for because of all the pressures. It's never manipulated up, it's certainly manipulated down. I've never manipulated up at all and that's, you know, I'm sure of that.

The best teachers were described above as those who made the 'most progress', but this is not quite the case. A better description is those who create the impression of having achieved the 'right progress'. Tony's manipulation is actually a *decrease* in the scores obtained at the end of the year and Sasha also reports 'moving their level back' so as not to be treated with suspicion by colleagues. However, whilst this seems altruistic, two further factors are important to appreciate. Firstly, Tony notes the robustness of the moderating system, saying that 'I don't know actually anyone who would send them up higher than you think because of the pressure of it being um [moderated]'. Similarly, Sasha claims that 'there is a tendency to perceive that a generous marker is bad'. End of year assessment appears well policed. However, progress is measured between two ends, and if you cannot move as far forward as you would like then you can simply start making progress from further back by challenging the judgements of colleagues.

> Tony: If you drop them [the previous teacher's transferred grades] four points [in your first assessment of the new year] then you are saying the other teacher's incompetent or a cheat and there is no other reason for doing that really. Some teachers, naturally … this thing really

> bugs me ... that some teachers don't trust other teachers and you see four points dip at the start of years. And they consistently do it.

Again, assessment is not simply the practice of recording mathematical achievement. It has the potential to distort teaching practices, requiring teachers to generate fictions to manage *their own* progress (not just that of pupils), and in doing so discover themselves in competition, even conflict, with each other.

IMPLICATIONS OF THE ASSESSMENT DOXA

As was noted at the start of this piece, research is clear about what we know to be effective mathematics teaching and the role of assessment in this; above all encouraging learners to treat mathematics as a network of related ideas and learning as flexible and mutable. Yet we also know that in England this is far from the case in practice and despite years of professional training and countless millions of pounds spent trying, pupils' experiences of mathematics are largely the same as they have always been; on average, these fail to extend those who are moving on with it and leave a long tail of those who are not (Office for Standards in Education, 2012b). Standing back and examining assessment from the perspective of teachers' wider professional lives offers some insights into this conundrum.

Teachers clearly work within a strong doxa surrounding assessment in mathematics and the evidence from the teachers here suggests that this doxa promotes a belief in a particular *epistemological* position: that mathematical knowledge is individual, not socially distributed; that it is largely propositional; and that learning is the business of its acquisition. This position then implies several implications for teaching: that acquisition should be predictable; that teaching should control and monitor this acquisition; that this takes place smoothly over time; and that teachers are responsible and accountable for it. No wonder then that whilst on the one hand teachers attempt to use assessment formatively to consider the learning of every child, on the other this is overlaid by practices that are designed to do professional work for themselves, as well as for the pupils. Whilst teachers still undertake assessment for formative purposes, ultimately the system requires them to objectify pupils' progress and to manipulate this into the 'right shape'. As we have seen, this is not a simple case of overinflating scores; it also involves downgrading them such that, potentially, 'the personal is used for the sake of the functional: students are included or excluded, valued or not, primarily on the basis of whether they contribute to the performance of the school' (Fielding & Moss, 2011, p. 52). Though this research has not observed these teachers' classroom practices directly it is not hard to speculate that, in general: teaching is likely to encourage pupils to see their mathematics learning as objectified and fixed rather than as constructed and mutable; and, rather than freeing children to explore the world of mathematics, teachers may well want to control mathematical thinking. Rather than simply being the business of evaluating pupils' mathematical achievements, assessment is a politicized process which alters classroom practice and through which *both* teachers and pupils are constructed as winners or losers.

Québec anglophone teachers' pedagogies: Observations from an auto-ethnography

David A Reid[1], Annie Savard[2], Dominic Manuel[2] and Terry Wan Jung Lin[2]

1 Universität Bremen, Bremen, Germany, dreid@uni-bremen.de
2 McGill University, Montréal, Canada

This paper describes some characteristics of the pedagogy informing the teaching of anglophone teachers in Québec, on the basis of focus group interviews conducted as part of a Canada-wide comparative study. The paper also illustrates research methods embedded in an enactivist methodology that permit researchers to take advantage of the observer dependence of interpretations to gain insight into phenomena, like pedagogies, that are not directly observable. The dependence of results on methods used is illustrated in the case of the anglophone Québec focus group.

Keywords: Pedagogy, methodology, comparative research, teachers' beliefs.

INTRODUCTION

Large-scale international and national assessments have revealed a considerable range of student achievement in mathematics across Canada. When compared to international results, some Canadian provinces, notably Québec, rank among the top countries, while other provinces, especially in the Atlantic region, are significantly below the Canadian average. There are also some difference by the language of the school system. Students from the francophone (French speaking) system in Québec and from the anglophone (English speaking) system in Ontario achieved a higher average than their peers in the other language group in the same province (Brochu, Deussing, Houme, & Chuy 2013). A number of factors have been suggested to explain these differences including curriculum, gender, attitudes, beliefs, aspirations, time spent working outside school, parents' education, involvement and socio-economic status and school resources (see, e.g., Anderson et al., 2006; Beaton & O'Dwyer, 2002; Schmidt et al., 2001; Wilkins, Zembylas, & Travers, 2002). Teaching, which might be expected to have the most direct effect on student achievement, is considered less often. In a comparative research project (see http://www.acadiau.ca/~dreid/OT/) we seek to account for some of these disparities through a focus on pedagogy.

The nature of pedagogy

We make a distinction between *teaching* and *pedagogy*. Teaching refers to the observable practices of teachers and their interactions with learners. Pedagogy refers to what Tobin and colleagues (2009) call the "'implicit cultural practices' of teachers [...] practices that though not taught explicitly in schools of education or written down in textbooks reflect an implicit cultural logic" (p. 19). As Tobin et al. note, these implicit practices are related to teachers' "knowledge in practice" (Anderson-Levitt, 2002, p. 109) and "embodied knowledge" (Anderson-Levitt, 2002, p. 8). Such knowledge is related to Bruner's (1996) concept of folk pedagogy, the "taken-for-granted practices that emerge from embedded cultural beliefs about how children learn and how teachers should 'teach'" (p. 46). We see pedagogy as characteristic both of communities of teachers (grouped linguistically and regionally in our research) and of the individual teachers in those communities, being both a 'domain' and an 'orientation' in Maturana's (1988) sense. The two key features of pedagogy are that it is implicit and that it guides practice.

METHODOLOGY

The data analysed here comes from a larger project comparing regional pedagogies in middle school mathematics in four regions of Canada that show significant differences in student achievement. The regions chosen for comparison are Atlantic Canada, Québec, Ontario and Western Canada. In most regions two focus groups of teachers were formed, one whose language of instruction is English and one whose language of instruction is French. This was done as large scale assessments have revealed that there are differences of achievement along linguistic lines in some regions of Canada (Brochu, Deussing, Houme, & Chuy 2013) and this suggests there may also be differences in pedagogy along linguistic lines. Data from the anglophone focus group in Québec is analysed here.

Recalling Maturana's (1987) statement that, "everything said is said by an observer", we study teachers' pedagogies by examining teachers' observations of teaching. Our approach is similar to the multivocal ethnography approach described by Tobin (1999; Tobin, Hsueh, & Karasawa, 2009; Tobin, Wu, & Davidson, 1989) and we have adopted their terminology to describe the phases of research. Tobin and colleagues (1989) describe a layered process of documenting the implicit criteria of members of a community. This process involves working with members to construct a visual ethnography, an auto-ethnography and an ethno-ethnography. At each stage the teachers in the focus groups observe either their own or others' practices, first by creating a video record of their own practice, then by commenting on video recordings of classroom teaching within their region, and finally discussing video recordings of classroom teaching from other regions.

Visual ethnographies: Each teacher was asked to choose three lessons to be video recorded: a lesson that the teacher judged to be a "typical" lesson in her/his classroom; a lesson the teacher considered "exemplary"; and a lesson in which a topic related to fractions is introduced. Each teacher with a researcher collaboratively selected segments to be included in an edited video. An edited video of 20 minutes or less was produced by a research assistant for each lesson recorded by each teacher. These edited videos provide the visual ethnography of the teacher's teaching.

Auto-ethnographies: The teachers in each focus group viewed the edited videos from their classrooms and attempted to identify three that they feel show "representative" teaching in their region. The recordings of these focus group discussions form the first data set: as responses of regionally and linguistically internal observers they provide an auto-ethnography of mathematics teaching in each region. The three representative videos were used as stimuli for the other groups in the ethno-ethnography phase.

Ethno-ethnographies: Each focus group viewed and discussed videos from other regions, and in some case from other language groups. Encounters with other pedagogies offer the participants a way to reflect on their own familiar beliefs and practices, by comparison with others. The recordings of these focus group discussions form the second data set and constitute the ethno-ethnography of the pedagogy revealed in the videos.

The overall methodology for our research is enactivist (Reid, 1996). As noted above a key element of this perspective is that "everything said is said by an observer" (Maturana, 1987). This insight allows us to overcome a limitation of other studies of teaching practice, such as the TIMSS video studies (e.g., Hiebert et al., 2003). Pedagogy cannot be studied using approaches that involve external observers, as they have no access to what is implicit to the teachers themselves. However, by positioning the teachers as observers, one gains insight through what they observe and how they observe it into the implicit criteria that guide their observations.

In addition the research design includes self-observation by the researchers. In an enactivist approach, the process of analysis of data is an interrelationship, in which researchers find themselves learning new things within a context which is partially of their own creation. The changes which can be triggered in us, that is, what we can learn about the research context, are determined by our theories, beliefs and biases. What we learn is determined by what we know (Reid, 1996, pp. 205–206). In this paper, the analysis of the data was done by the first author, and so it is important to take into account his background as someone who himself was once an anglophone teacher in Québec, and whose teacher education occurred in Québec. However, he did not himself go to school in Québec, and so he is unlike the teachers in the focus group who experienced the Québec schools first as students and then as teachers. His teaching experience in Québec is also now two decades old, and things are no doubt different now. And his perspective has no doubt been modified by his more recent experiences doing school based research in other parts of Canada, and working with colleagues on school based research in England, France and Germany, as well as his main research focus on proof and reasoning.

ANALYSIS

The data analysed in this paper is drawn from the auto-ethnography of the anglophone teachers in Québec. The four teachers in this focus group all teach in the same school, at the grade 7–8 level (called "secondary cycle one" in Québec). They recorded their videos in their grade 8 classes. All the teachers have at least five years of experience teaching mathematics. Their school population is low income and low-middle class, with mostly homogeneous ethnicity. The rate of diagnosed learning difficulties in the school is high. One teacher left the group because of a stress leave, but gave permission for her videos to be used by the remaining three teachers.

The focus is the transcript of one focus group session, in which the teachers discuss first what exemplary and typical teaching is like, and then select the video about fractions they will share. The transcript can be divided into episodes based on breaks imposed by T, the interviewer. These are described in Table 1.

The transcript was analysed by coding it for the topic of the discussion. Teaching is complex, and so any discussion of teaching necessarily addresses some

Episode	Transcript line numbers	Description of episode
1	5–201	Responses to the question "What do you think a typical class in Québec in the English system looks like?"
2	203–266	Responses to the question "You're saying wow this is a really exceptional lesson. What would you be looking at?"
3	269–290	Following a pause, reactions to "It's interesting. I don't know if you guys are interested."
4	296–354	Discussion following T's responses to being asked by S, "What do you think T? About exceptional-"
5	373–405	Discussion following viewing of the first part of Video 1
6	409–419	Discussion following viewing of the second part of Video 1
7	423–444	Discussion following viewing of the third part of Video 1
8	449–494	Discussion following viewing of the first part of Video 2
9	499–611	Discussion following viewing of the second part of Video 2

Table 1: Episodes

Teaching related topics	**Gr**	Grouping (groups or pairs, think-pair-share)
	I	Interaction (student involvement, teacher prompting, brainstorming, student feedback)
	F	Format (chalk and talk, lecture, modelling, tell me what you need, student-centred approach)
	B	Basis (problem based, skill based, language based, reform, multiple solutions, examples)
	Pa	Pacing (working at the pace of the student, pressure to get through presentation)
	T	Technology & materials (Smartboard, Powerpoint presentation, notebook, worksheet)
	A	Assessment (student accountability, summative evaluation, monitoring, competition)
	Go	Goals of teaching
Learning related topics	**E**	Emotion (motivation, engagement, anxiety)
	H	How learning happens (memorising, repetition, activity, representations, creativity)
	W	What is learned (organisational skills, study skills, real world applications)
	Pr	Prior knowledge and experience
	Co	Specific mathematical concepts (equations, fractions)
Institution related topics	**Cu**	Curriculum (order of topics, goals)
	Ct	Communication between teachers
	Q	Teacher qualifications and perceptions (generalists, specialists, reputation)
	S	Stratification (difference, weaker groups, enriched kids, the strongest kids)

Table 2: Topics used in coding transcripts

aspects of teaching and neglects others. The topics addressed reflect a teacher's pedagogy, even before a particular position is taken. For example, referring to how students are grouped indicates that the topic of grouping is significant, whether preference is expressed for pairs, small groups, whole class construction or some pattern of combining groupings. The topics used in coding the transcripts are listed in Table 2.

These topics were generated from the data in an initial reading of the transcript, asking "What are the topics of this utterance?" for each speaker's turn. The transcript was then read a second time, and each utterance was coded with as many topics as fit. After this reading, several topics were only rarely used, and a third reading was done to check if additional occurrences of those topics had been missed.

Visualisations were then created to assist in in seeing patterns in the topics. For example, Figure 1 shows the topics discussed at the beginning of Episode 1, when the teachers were asked to describe a "typical class". The main focus is on Grouping (Gr), Format (F) and later Stratification (S). Interaction (I), the Goals of teaching (Go) and How learning occurs (H) also come up. The main focus is on topics related to teaching.

Figure 2 shows the topics discussed at the beginning of Episode 2, when the teachers were asked to discuss what an "exceptional lesson" looks like. Again, the main focus is on Grouping and Format as well as Interaction, topics related to teaching. As in Episode 1, Stratification also comes up later. Communication between teachers (Ct) is also mentioned.

These two sub-episodes display a pattern, of focussing on teaching related topics, and stratification, with little or no mention of learning related topics. This pattern was observed in five sub-episodes (1a, 2a, 4a, 7b, and 8c). Of these sub-episodes, four of the five occur in reaction to prompts to describe a typical lesson or an exceptional lesson. This suggests that teaching related topics are the first to come to mind when these teachers describe lessons.

Other topics related to teaching are discussed in sub-episode 1b (focussed on technology use) and sub-episodes 2b, 2c, 3b and 8b, focussed on the basis of teaching.

Episodes focussed on learning

Figure 3 shows the topics discussed in sub-Episode 1c. The focus shifts ways from teaching related topics, although technology, the basis of teaching, assessment and format of lessons are all mentioned. Instead the main focus is on an aspect of learning, specifically what is learned. The teachers are discussing the importance of learning good organisational skills in this sub-episode. "What is learned" is also the focus of discussion in sub-episode 4b, where the topic is learning about real world applications of mathematics and episode 9, the discussion of the second part of Video 2.

In sub-episode 1d, the main focus is on learning about integers, and the students' prior knowledge (see

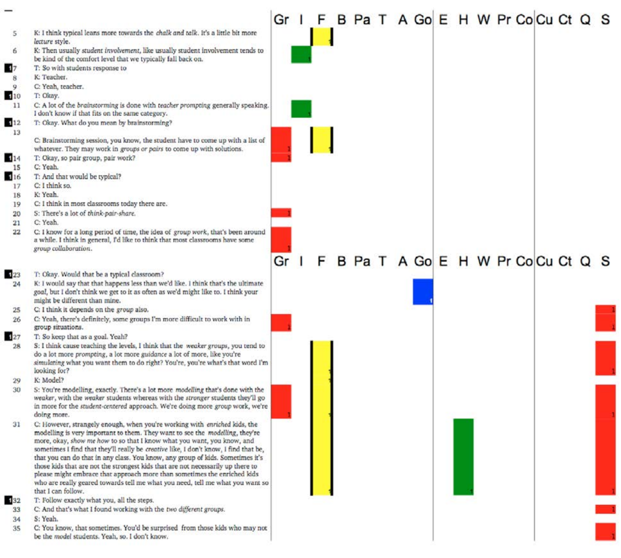

Figure 1: Topics discussed at the beginning of Episode 1

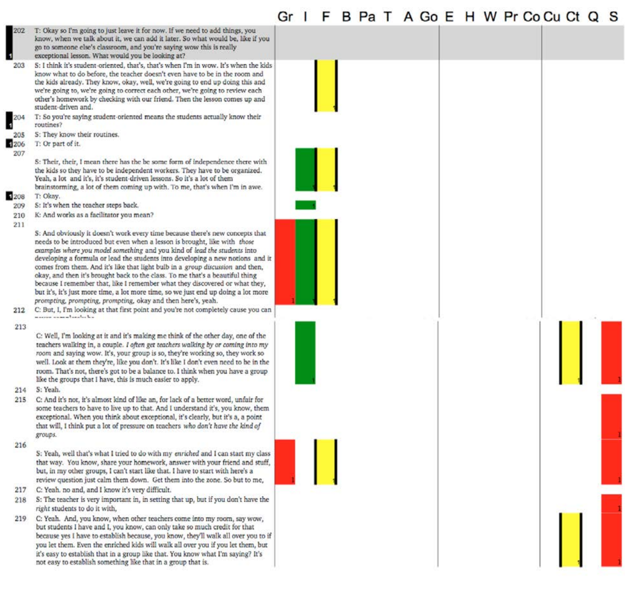

Figure 2: Topics discussed at the beginning of Episode 2

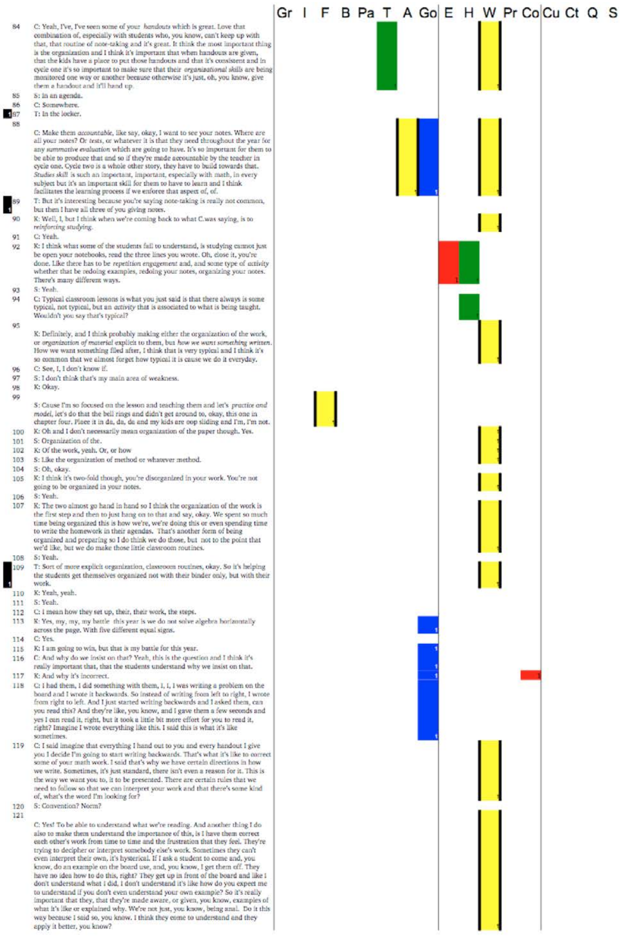

Figure 3: Sub-Episode 1c, focussed on what is learned

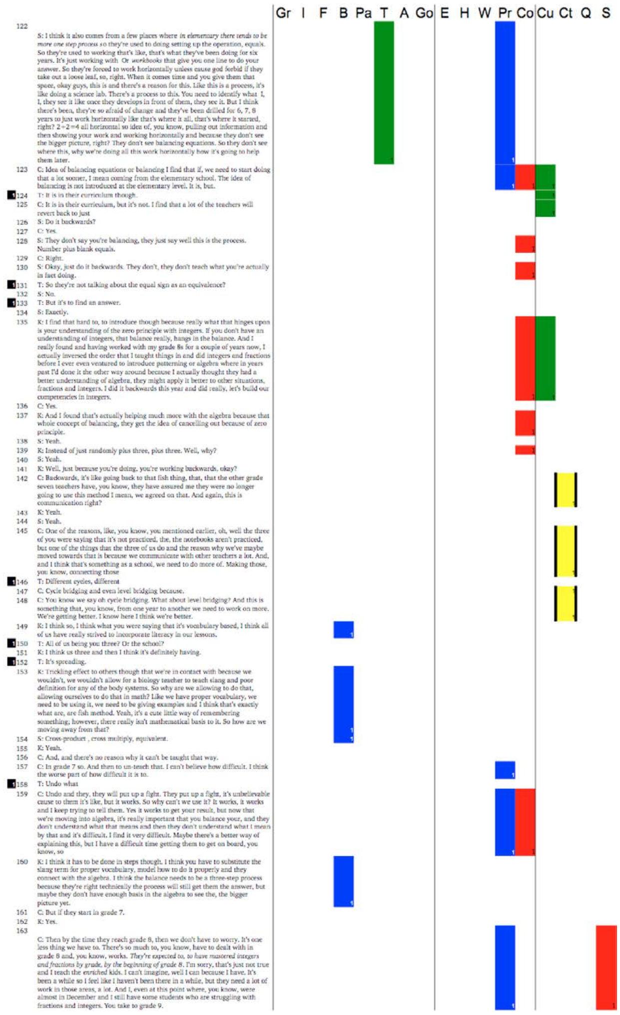

Figure 4: Discussion in sub-episode 1d, focussed on learning about integers and the students' prior knowledge, with a digression on communication between teachers

Figure 4). At one point the topic shifts to communication between teachers. The most extended discussion in which the focus is on specific concepts occurs in Episodes 5, 6 and 7, in reaction to watching Video 1. There the topics are the difference between negative numbers and subtraction in the context of algebraic expressions (in Episode 5), order of operations (in Episode 6) and equivalent fractions (in sub-episode 7a).

Other topics discussed related to learning include how learning occurs (sub-episode 8a) and students' prior knowledge (sub-episode 9b).

Other topics

In sub-episode 1e the topic of the intended curriculum came up very strongly. Topics related to learning, and assessment, also came up. Curriculum is also the topic of the discussion in sub-episode 4c. Again, topics related to learning (especially prior knowledge) and assessment also come up.

The discussion in episode 3 began with reflections on the experience of discussing teaching in the focus group, so the initial topics are emotions and communication between teachers. This shifts into reflections on the status of "Cycle 1" (grades 7–8) teachers compared to Cycle 2 (grades 9–11) teachers, who tend to be more specialised. The teachers returned to this topic at the end, in sub-episode 9c.

OBSERVATIONS

Table 3 shows an overview of the topics discussed. It makes visible a pattern in the teachers' discussions. In Episodes 1 and 2, when the teachers are first asked to describe typical lessons and exceptional lessons, they focus first on teaching related topics, especially format of lessons, student interaction, grouping, and the basis of teaching. The interviewer, T, also focusses on these topics in Episode 4 when the teachers ask her what she feels is exceptional. In Episodes 1 and

		1a	1b	1c	1d	1e	2a	2b	2c	3a	3b	4a	4b	4c	5	6	7a	7b	8a	8b	8c	9a	9b	9c	9d	9e

In	Cu					X								X												
	Ct				X		X		X	X																
	Q									X															X	
	S	X	X				X																			

Table 3: Overview of topics discussed

4 however, the focus shifts as the discussion goes on, to topics related to learning: prior knowledge of students, specific mathematical concepts, what is learned and how it is learned.

In Episodes 5–7, after watching the videos, there is a striking inversion. The first topics the teachers discuss are related to learning, especially, in the case of Video 1, learning specific concepts. It is only briefly at the end of the teachers' discussion of Video 1 that they mention topics related to teaching (in sub-episode 7b). The discussion of Video 2 (Episodes 8–9) also begins with the topic of how learning occurs and learning a concept, but it then turns to topics related to teaching, before returning to topics related to learning after watching the second part of the video.

A further observation is that the topic of reasoning does not occur. This is noticeable primarily in that the observer in this case (the first author) has a strong interest in reasoning and so would be likely to notice any discussion of it by the teachers. The absence of this topic is an example of a finding that arises out of our methodological awareness that everything said is said by an observer.

CONCLUSIONS

These results are interesting in several ways. They reflect on the topics teachers themselves find most relevant when describing and reacting to teaching, and on the research methods used and the nature of teachers' pedagogies revealed by them.

The topics the teachers discussed overall are unlikely to be very surprising to researchers who are interested in teachers' pedagogies, beliefs and identities. However, it may be valuable to compare these specific results with results from elsewhere, and to consider sources of differences in both research methods and regional differences. We have made one such comparison, between this anglophone Québec group and the francophone Québec group and found agreement on the format of the typical lesson, the importance of mathematical vocabulary as the basis for teaching, the use of multiple representations (at least in exemplary lessons) and a belief that a high level of knowledge of the curriculum is important in planning exemplary lessons. However, there were also differences related to questioning, synthesis, and attention to student ability (see Manuel, Savard, & Reid, 2014, for more details).

From a methodological perspective it is thought-provoking and important that the topics the teachers discussed were different when asked to describe typical and exceptional lessons, and when reacting to videos of lessons. The teachers do not simply say different things in these two contexts, they focus on different *topics*. This means that a research design that relies on a single way of ascertaining teachers' views of teaching will miss some topics and overemphasise others. Within our larger research project, the other focus group sessions were run somewhat differently in the different regions, and in most cases teachers reacted to videos without having any prior discussions of typical and exemplary teaching. It will be interesting to compare the topics discussed in those focus groups with the topics discussed by this group.

Teacher alignment of values in mathematics classrooms

Wee Tiong Seah[1] and Annica Andersson[2]

1 University of Melbourne, Melbourne, Australia, wt.seah@unimelb.edu.au

2 Stockholm University, Stockholm, Sweden

Teacher-student and student-student interactions in mathematics classrooms reflect what teachers and students value in mathematics teaching and learning respectively. These interactions shape and fine-tune developing values systems, which in turn affect the quality of the students' learning experiences. We propose that these teacher responses represent values alignment processes. We show three examples of teacher strategies, namely, redefining, reprioritising, and complementing. We will argue for the importance of teachers being able to develop strategies to facilitate values alignment in mathematics lessons.

Keywords: Values alignment, values, critical incidents, volition, teacher-student interaction.

INTRODUCTION

'When are we ever gonna use this maths?' (or its equivalent) must have been one of the most commonly posed questions by students all over the world. It seems that students find it important that there is utility in the knowledge or skill they are learning. They may be said to value *application* and/or *relevance* when learning mathematics.

It can also be assumed that the quality of students' mathematics learning will be affected by their teachers' responses to such a question, whether it is one in support of the student's valuing of *application/relevance*, one which implies a valuing of *understanding* ("this knowledge enhances your understanding of related mathematics content"), or one which reflects the valuing of *rationalism* (see Bishop, 1988).

Although it may generally be felt that teacher responses such as those above are guided by cognitive reasoning and/or affective dispositions, we argue here that importantly, these cognitive and affective functions are governed by the volitional variable of values. That is, what the teacher him/herself considers important – and indeed, values – concerning mathematics and mathematics pedagogies are embedded in the response offered to the students.

Accordingly, the teacher-student and student-student exchanges that take place in each and every mathematics lesson represent numerous negotiations of what the students and/or their teachers value, which may or may not result in agreements. Importantly, each of these represents an example of a critical incident (see Tripp, 1993) in that responses and outcomes affect the direction of subsequent classroom discourses and the extent to which planned lesson objectives are achieved. If successful negotiations about such critical incidents require that everyone concerned are satisfied with the outcomes of these negotiations, then the competing values would have become aligned in some way during the process.

This paper draws on empirical data to investigate what such values alignment incidents might look like in mathematics classrooms. We identify and categorise three values alignment strategies. To contextualise this discussion, we first review what is known about values as these relate to mathematics pedagogy and teacher-student / student-student interactions in mathematics classes.

THE ROLE OF VALUES AND VALUING IN MATHEMATICS PEDAGOGY

We consider values in the context of mathematics learning and teaching as a volitional construct. We have proposed elsewhere that:

> values are the convictions which an individual has internalised as being the things of importance and worth. What an individual values defines for her/him a window through which s/he views the world around her/him. Valuing provides the individual with the will and determination to maintain any course of action chosen in the learning and teaching of mathematics. They regulate the ways in which a learner's/teacher's cognitive skills and emotional dispositions are aligned to learning/teaching. (Seah & Andersson, 2015, p. 169)

The philosopher Ayn Rand wrote, "a being of volitional consciousness has no automatic course of behaviour. He [sic] needs a code of values to guide his actions" (1961, p. 97). Values guide decisions and actions (e.g., Park et al., 2011), and people and organisations defend or fight with passion for what they value. That is, values are expressions of will and convictions that provide us with a certain degree of 'stubbornness' to stay motivated and to persevere when we encounter barriers. This is not to say, however, that values are always expressed in the form of observable actions. Rather, the potential for action is the basis for valuing. Whether it is expressed in observable action or not depends on the context. This can be seen in Andersson's (2011) recent study, in which the upper secondary student participants indicated that they disliked – even hated – mathematics. However, Andersson's analysis show that their stories of mathematics learning experiences were connected to the context in which they were told. The students' stories and actions for learning mathematics changed as the contexts evolved.

As volitional variables, values have both cognitive and affective components as well. The cognitive components are visible through the choosing dimension of the valuing process (Raths, Harmin, & Simon, 1987). Valuing also has an affective dimension which can be seen in the way we often find ourselves embracing what we value in a passionate way, supported by associated emotions, attitudes and beliefs.

Considering any classroom interaction, then, what is conveyed (verbally or otherwise) and the subsequent responses would reflect what the teacher or student is valuing. These interactions represent negotiation attempts by all involved; students are aware of their capacities to adopt, resist or reject discursive positions. Given that there exists considerable within-class and within-school diversity of student cognitive and affective variables (Sullivan, 2015), the (mathematics) classroom discourses between teachers and their students – and amongst students – represent pedagogical spaces of contestation and conflicts. This is inevitable, and after all, the consistent domination of one particular (person's) goals and interests in any social gathering is very likely not desirable anyway, as discussed by Gutierrez (2007).

As a volitional variable, values (in mathematics education) not only motivate and guide decisions and actions; they also provide one with the will and determination to maintain courses of action in the face of competing actions and obstacles. In this way, values do more than what motivations do. In Kivinen's (2003) words,

> there is a distinguishing line between volition and motivation. Volition promotes the intent to learn and protects the commitment and concentration from competing action tendencies and other distractions. For example, a student may be motivated to read a book in the evening. He or she is more or less motivated to do so. The student takes the book and starts to read (motivation has done its work). Volitional processes (will) keep him or her reading, in spite of the fact that there is an interesting football match on TV. (pp. 26–27)

It is this sense of will and determination that is associated with valuing which would account for an individual bringing what s/he values to any interaction s/he is involved in. When such an interaction brings together different and potentially competing values that are embraced by teachers and students, this may involve resisting or rejecting decisions or actions representing the competing values. Thus, when a student asks when a particular mathematical concept or skill might be useful, the question reflects his/her valuing of, say, *application or relevance*. In the same way, the teacher's response will reflect particular values too, which demonstrate if these values are aligned with each other or not. In turn, anyone involved in the interaction can choose to pursue what s/he values with regards to the topic being discussed, although this will often be subjected to sociocultural norms and conventions such as power distance (Hofstede, 2011). We suggest that in order for a lesson to 'move forward' productively, teachers would have negotiated about the competing values such that there is achieved a certain level of alignment amongst the values concerned.

While values may indeed be stable when compared with variables such as interests and beliefs, we argue that the extent to which a value is embraced and prioritised is responsive to one's environment and is thus not fixed. In other words, opportunities for values teaching in mathematics education exist across all school years. Whereas values may be absorbed when one is young (Court, 1991), value priorities continue to be considered and evaluated throughout one's life in school and beyond. This may be seen in the valuing process conceptualised by Raths, Harmin and Simon (1987). Made up of three stages, that is, choosing, prizing, and acting, the first stage is related to choosing freely and amongst several alternatives, bearing in mind the consequences of adopting any one of these alternatives. We believe that it is this choosing activity that is periodically stimulated by phenomena that allows for one's value priorities to be monitored, assessed and fine-tuned.

VALUES ALIGNMENT IN THE MATHEMATICS CLASSROOM

Values alignment is a central feature of Senge's (2006) five disciplines of learning organisations (that is, personal mastery, building shared vision, team learning, mental models, and systems thinking). In particular, the discipline of building shared vision calls for aligned values in an organisation in order for the shared vision of the future to be co-created. The value of values alignment lies in the observation that

> all relationships – between one person and another, between the present and the future, between customer and product, a team and its goals, a leader and a vision – are claimed to be strengthened by aligned values. (Branson, 2008, p. 381)

Thus, for a teacher, being able to facilitate values alignment between what s/he values and what his/her students' value promises to strengthen the relationships, and is one of the keys to nourishing teaching and learning practices. Indeed, MacDonald and Shirley (2009) had proposed that the mindful teacher is one who, amongst other things, is proficient in establishing authentic alignment between his/her own values and professional practice, and is also successful in harmonising these values and policy. If some teachers are 'effective' in different classrooms whereas others perform well in particular classrooms only, this could be because the former have been successful in attaining values alignment in whatever classroom situation they find themselves in.

However, values alignment is not about ensuring that students' values are the same as their teachers'. It is thus different from values inculcation. Rather,

> building ... values alignment is about providing a cooperative and collaborative process whereby the members of the organisation can develop strategies, systems and capabilities that not only support those values that have previously been clarified as being essential for the ultimate success of the group as a whole but also are supported by the majority of the people within the group as acceptable guidelines for directing their behaviour. (Branson, 2008, p. 383)

That is, values alignment facilitates the co-existence of different values that are held by different people interacting together. In so doing, students can perceive that their knowledge, skills and dispositions are valued, and they can also feel inclusive in relation to their learning of mathematics.

IDENTIFYING AND INTERPRETING VALUES ALIGNMENT CRITICAL INCIDENTS

So, how do teachers and students negotiate the differences in what they value generally and in mathematics education in particular, so as to achieve values alignment in order to facilitate mathematics learning? In the absence of prior educational research on this topic, we referred to available data that were collected from a prior research involving values and valuing in the classroom (see Seah, 2005) as seen from the perspectives of classroom teachers of mathematics.

This prior research was conducted in secondary schools across Victoria, Australia. The methodology of the research then involved the identification of critical incidents (Tripp, 1993) in mathematics lessons when the teacher participants and their respective students were observed to be valuing different attributes of mathematics or of mathematics pedagogy. Lesson observations and teacher interviews were the methods employed. The research objective was to map out the range of strategies teachers employed to negotiate about differences in valuing between themselves and their respective students. The focus was on the various types of actions employed by the teachers, of which there were 7 (e.g., helplessness, amalgamation, appropriation). In the current study, however, the teacher responses to the episodes of values differences in the lesson transcripts were re-examined and re-analysed at a deeper level: instead of listing what the teachers did, here we have been attempting to interpret how the teachers' own valuing changed in the process of their negotiating about and aligning the value differences. The patterns observed amongst the 8 teacher participants suggested three such values alignment strategies, which we name redefining, reprioritising, and complementing. These are presented below.

Values alignment strategy: Redefining

> *Case 1.* Michael (a pseudonym), a mathematics teacher in a secondary school, noticed that his Year 10 students had been unwilling to work with concrete manipulatives such as geoboards and pattern blocks. "These are for young kiddies, sir!" they would say. Yet, Michael felt that learning is more effective when students are able to visualise the relevant concepts. Michael has since found a way round this issue, and his students are now exploring and understanding geometrical concepts using software programs such as dynamic geometry software, as well as online resources such as those hosted by the National Library of Virtual Manipulatives.

In this case, Michael's use of concrete manipulatives reflects his valuing of *visualisation*. However, this teaching approach was resisted by his students whose values were not aligned with the image of teenagers 'playing with blocks'. There was a potential here of a value conflict between Michael and his students, which could possibly result in the students being disengaged in his lessons. Michael resolved the potential value conflict through redefining what he and his students valued, coming to understand that in effect, his valuing of *visualisation* was underlied by a valuing of *exploration*. This was crucial, since the students' values were aligned with *exploration* as well; it was just that they did not want to feel like small kids playing with blocks and teddy bears. By redefining his valuing of *visualisation* with the use of digital learning technologies, Michael was able to plan and execute his lessons such that the dynamic geometry software and the online websites provided the students with opportunities to explore – and thus visualise – the relevant geometrical ideas and concepts in a form that was aligned with what the students value. Michael's valuing of *visualisation* had given him the will to resolve the value difference situation in ways which still allow for student visualising to take place, only that the means of actualising this valuing were now acceptable to the teenage students, who were understandably wanting to behave more adult-like and doing adult tasks. For his students, their positive response to the ICT use was an endorsement of their common valuing of *exploration*.

In this instance, values alignment was achieved through Michael's redefining what he values, such that its expression now is aligned with what his students value.

Values alignment strategy: Reprioritising

> *Case 2* Diane was an immigrant secondary school mathematics teacher from Canada, teaching in a small country town in Australia. When one of her students answered one of her questions about an algebraic equation by saying "just chuck in c, just chuck in the c", she responded that he was being too casual with his use of mathematical language. Diane's own mathematics learning experience in Canada had instilled in her a valuing of the *formality* in mathematics, a tradition that she felt needed to be upheld but which most students today would perceive as dry and boring. Thus she would have preferred her students to talk about "adding the constant, c".

Yet, Diane was deeply aware and concerned that she was teaching a class of mainly disengaged and underperforming students, and that meant that it would not be wise to get 'too caught up in those formal, scary things'. She was mindful that for these students, a valuing of *fun* would be a key motivator for them. In Diane's words,

> We see too many kids that's just, they come to the class and they are beaten already. Because they found it a difficult subject, and they don't enjoy it, they feel frustrated. It makes them, you know, they feel out of their depth, and that's just awful. If you're [i.e. the students] starting out that way, you know, I think we've got to really try. And if

> it's not [about] being so sticky about notations, then, you know, having a bit of fun with it then.

As such, she made a conscious effort to 'sacrifice 'plus c' for 'chuck in c' '.

Here, Diane realised that 'pushing' her students to share her valuing of *formality* and to use formal terminology would be counter-productive. This group of students needed first and foremost to be able to be interested enough in the subject, and to develop some confidence to acquire the skills and concepts required of them. The students' valuing of *fun* was a volitional force, which supported the cognitive and affective growth that they needed. Diane's understanding of this, and her subsequent reprioritisation of her valuing of *formality* and *fun*, resulted in values alignment between herself and her students. This reprioritisation of Diane's values is evident when she talked about the relative importance of notations/formality and fun/enjoyment, and how it would be her willing sacrifice to interchange the order of priority for the sake of facilitating her students' learning.

In this second case, values alignment was achieved when Diane in interaction reprioritised what she valued to achieve a common valuing with her students. Diane had not given up her valuing of *formality*. However, she also shared her students' valuing of *fun*, demonstrated through her provision of space for a different mathematical discourse in class. As a result of this reprioritisation between the two values within herself, Diane had achieved an alignment of what she and her students valued.

Values alignment strategy: Complementing

> *Case 3*. Amy taught Year 7 mathematics in a south-eastern suburb in Melbourne, in an area with a high concentration of Asian migrant professionals amongst its residents. Most of the students in her school were Asian, most of whose parents valued *competition* and *grades*. The school has also embraced the community's valuing of these two orientations. However, Amy had grown up valuing *co-operation* and (conceptual) *understanding*. For Amy, the need to confront the value differences between herself and the school/community was quite urgent, for she knew that she would not be able to teach mathematics effectively and professionally satisfyingly if she did not negotiate these differences soon enough. She talked to colleagues and some parents, and she referred to relevant literature. While she was not ready to give up what she had grown to value, she was also getting to understand how the students' and their parents' values were culturally powerful agents of engagement and motivation. At the same time, she felt that her students needed to learn to value *co-operation* too as a means of humanising competition, and that their developing meaningful understanding of (mathematical) concepts would further enhance their capacity to achieve even better grades in assessments. So in the last two years, Amy has developed mathematics lessons, which reflect the valuing of both *grades* and *understanding*, and more difficultly, *competition* and *co-operation*. Thus, her students strive to understand concepts while/before practising hard to attain proficiency. They are also able to work together and help one other, while enjoying pitting their mathematical skills against one another.

In this case, values alignment for Amy and her students was achieved through an acknowledgement of the different values, and a purposeful consideration of how they could co-exist and indeed, complement each other. Over two years, Amy developed pedagogical strategies that allowed for these pairs of potentially conflicting values to not just co-exist, but also to further support the inculcation of the other value in each pair. This complementarity reflects one of Hofstede's (2001) cultural value continua, *masculinity / femininity*. Here, the students' valuing of *masculinity* in the form of *grades* and *competition* has struck a balance through alignment with Amy's valuing of *femininity*, in the form of *understanding* and *co-operation*.

CONCLUDING IDEAS

In this paper, we have focussed on the day-to-day teacher-student and student-student interactions in mathematics classrooms, envisaging these as potentially critical incidents involving different and possibly conflicting values. We have drawn on empirical data to illustrate how teachers' facilitation of these critical incidents can actually be regarded as involving values alignment.

The examples listed above have been sourced from existing data given that there has not been any values alignment research study in our knowledge, an indication that values alignment in its various forms take place often enough during mathematics lessons. This highlights the importance for teachers' awareness of what they themselves value with regards to mathematics, to mathematics pedagogies, and to school education. With this self-knowledge, teachers are better empowered to respond to value differences/conflicts as critical incidents with effective values alignment approaches, thus maintaining a harmonious environment in the classroom. At the same time, such values alignment episodes also support students' cognitive and affective developments in a different way, that is, through the ways in which their own values systems evolve and mature.

Although it is not within the scope of discussion of this paper, it is also important to remind ourselves that not all values alignments attempt lead to productive learning/teaching. We observed in our data that despite the values being aligned and harmonious interactions being maintained, the aligned values might not support effective or productive mathematics learning/teaching. We also came across situations in which the values alignment attempts failed.

Although the values alignment strategies discussed above may well also take place in lessons other than mathematics ones, it is important that their deployment in mathematics lessons is highlighted to emphasise that the strategies can be as useful in mathematics pedagogy. The contexts within which Michael, Diane and Amy operated were uniquely mathematics educational. More importantly, the cases presented above relate values and valuing to mathematics pedagogies in very different ways. Indeed, the findings here which showcase the three values alignment strategies could well also address similar classroom tensions reported in Wester, Wernberg and Meaney (2015). The research reported here thus calls on the mathematics education research agenda to promote the need for a deeper knowledge of valuing as a volitional variable, and also of the values alignment process in the context of school mathematics pedagogy. Studies in this area represent cutting-edge, innovative mathematics education research; they promise to provide researchers and practitioners with a third, volitional approach to further understanding and improving mathematics learning in schools, complementing and strengthening existing cognitive and affective strategies.

A study for profiling mathematics teachers regarding factors affecting promotion of students' metacognition

Vuslat Şeker[1] and Engin Ader[2]

1 Middle East Technical University, Faculty of Education, Ankara, Turkey, vuslat.seker@boun.edu.tr

2 Boğaziçi University, Faculty of Education, İstanbul, Turkey

The main objective of this study was to describe mathematics teachers' profiles on factors affecting their promotion of students' metacognition through developing profiling tools. In the light of this aim, four factors from the Framework for Analysing Mathematics Teaching for the Advancement of Metacognition -FAMTAM- (Ader, 2009) were used. The factors were (1) teachers' conceptualization of metacognition, (2) teachers' perceptions of students' features and needs, (3) distribution of mathematical authority in the classroom and (4) the external pressure perceived by teachers. The sample consisted of 314 middle and secondary school mathematics teachers. In this study, descriptive, correlational and causal comparative research designs were used. The main findings indicated that most mathematics teachers were conceptualized what metacognition is. They were aware of students' features and needs. They supported a learning environment where mathematical authority was exercised by students. They perceived high external pressure from various factors influencing their promotion of students' metacognition.

Keywords: Mathematics, metacognition, teaching of metacognition.

INTRODUCTION

Metacognition is briefly defined as the regulation of and knowledge about cognitive activities (Flavell, 1979). It has an important place in mathematics education (Lucangeli & Cornoldi, 1997). It appears in early stages of problem solving process with accurate representations and the planning of problem solving (Desoete & Veenman, 2006). Metacognitive activities improve students' mathematical learning (Jacobse & Harskamp, 2012). Therefore teachers must arrange learning environments where learners are encouraged to learn mathematics through exercising metacognition (Lombaerts, Engels, & Athanasou, 2007).

There are various teaching practices for the development of students' metacognition by taking their needs and the learning environment into account. The promotion of metacognition should be examined in a broader sense in order to contribute the development of students' metacognition. For example, why teachers promote or not promote metacognition in their classrooms should be considered in order to help teachers to create effective learning environments (Lombaerts, Engels, & van Braak, 2009).

Several factors affecting teachers' promotion of metacognition or self-regulation has emerged in recent studies (Dignath-van Ewijk & van der Werf, 2012; Lombaerts et al., 2009; Lombaerts, Engels, & Vanderfaellie, 2007). Mainly three different determinants namely, teacher characteristics, school context characteristics and pupil characteristics were described as factors affecting teaching practices of teachers on promotion of self-regulation (Lombaerts et al., 2009). Teacher beliefs, previous teaching experiences and educational experiences are given as teacher characteristics that affect the introduction of metacognition in teachers' teaching practices. Furthermore, curricular changes, timetables, number of students, textbooks, the relationship among teachers are certain examples for school context characteristics. Lastly, pupil characteristics affecting teaching practices on stimulation of metacognition or self-regulation are cognitive and metacognitive abilities of learners.

Ader (2009) developed a framework for analyzing mathematics teaching for the improvement of metacognition of students. The reason for developing such a framework came from "the lack of emphasis on teacher's role and teaching practices within the efforts to incorporate metacognition into mathematics classrooms" (Ader, 2013, p. 7). The framework consists of four factors; (1) teachers' conceptualization of metacognition, (2) teachers' perceptions of students' features and needs, (3) distribution of mathematical authority in the classroom and (4) external pressures perceived by teachers FAMTAM was believed to be a good source for "exploring the teachers' approaches to promotion of students' metacognition" (Ader, 2009, p. 282).

The conceptualization of metacognition (Flavell, 1979) is defined as a factor in FAMTAM. Conceptualization of such complex and multifaceted phenomenon is important to investigate since the complex phenomena can be interpreted and implemented in a different perspective because of the structure (Ader, 2009). Secondly, teachers' perceptions of students' features and needs is another component of FAMTAM since it is an indicator of how teachers act with respect to the features and needs of students for effective mathematics teaching (Jaworski, 1992). Therefore, the perceptions give encouragement for students to use metacognition in their learning progress. Thirdly, the distribution of mathematical authority is a factor described as the way teachers encourage learners to use mathematics since mathematics or discipline of mathematics can be taken as authority where members of mathematical communities are working on mathematics (Schoenfeld, 1992). Boaler (2002) identified the members of a community of a classroom that lack mathematical authority (i.e. mathematical problem solving) as not contributors in each other's mathematical learning, not doing mathematics, but as only receivers of mathematical knowledge. Hence, metacognition can be conceptualized as a way of practicing mathematical authority because metacognitive and problem solving processes are intertwined (Ader, 2009). Lastly, external pressures perceived by teachers were given as another factor in FAMTAM. External pressures stemmed not from classroom practices, but from policies of educational system and demand or expectations of educational institutions that make teachers feel pressure on their teaching practices, such as curriculum content, national exam, time constraint and so on (Ader, 2013; Lombaerts et al., 2009).

The purpose of the study is to describe mathematics teachers' profiles on factors affecting promotion of metacognition through developing profiling tools which were developed and validated based on FAMTAM. It is aimed to explore mathematics teachers' approaches to promotion of students' metacognition considering the four factors in FAMTAM. This study is significant in a way the developed scales describe a teacher profile with regard to the factors affecting metacognitive implications or promotion in their classrooms. As a result of the study, such profile identification may help researchers and policymakers to make sense of the effects of teachers' promotion of metacognition for future actions. When the profile of teachers based on pre-determined reasons or factors are determined, this can also help teachers to tackle some of the issues that influence their promotion of metacognition by eliminating negative conditions and supporting positive ones.

METHOD

Three research questions were investigated; (1) What is the teacher profile on the factors affecting mathematics teachers' promotion of metacognition? (2) Are there significant correlations between variables derived from FAMTAM as conceptualization of metacognition, perceptions of students' features and needs, distribution of mathematical authority and perceived external pressure affecting mathematics' promotion of metacognition? (3) Is there a difference in the four variables derived from FAMTAM according to teachers' demographic variables?

Sample

For the description of profiles of mathematics teachers on the factors affecting promotion of metacognition, the main study was conducted with 314 (161 from middle school and 153 from secondary school) mathematics teachers from Turkey. There were 175 female and 139 male participants. Of these, 34 participants were from private schools and 280 participants were from public schools. Moreover, 116 of 163 middle and 43 of 153 secondary school mathematics teachers were graduates of faculties of education. 4 middle school mathematics teachers did not state the faculty they graduated. Remaining teachers graduated from faculties of science and got a teaching certificate. The sample of main study was chosen conveniently. 199 of 314 mathematics teachers filled out web-version of the instruments. 105 of 314 mathematics teachers filled out hard-copy version of the instruments.

Instruments

Four profiling tools addressing the four factors in FAMTAM were developed and validated for reaching the purpose of the study. The factors affecting promotion of metacognition within FAMTAM were supported by related literature as discussed in previous section. Within the process of development of four profiling tools, two pilot studies were conducted. The first sample was used in order to develop the four scales. The second sample was used for assessing psychometric qualities of the instruments that were revised after the pilot study.

The Teachers' Conceptualization of Metacognition Scale consists of 9 items. The teachers are asked to state to what extent they agree with the importance of addressing the statements given in the items in their teaching (e.g., "students' planning of their thought"). The individual total score for this scale indicated the level of fit between teachers' conceptualization of metacognition and what has been mainly documented in literature (e.g., Flavell, 1979). The Cronbach's alpha level of this scale is .91 for reliability and two structures as metacognitive knowledge and metacognitive skills were observed through factor analysis so there was an evidence for construct validity.

The Teachers' Perceptions of Students' Features and Needs Scale consists of 6 items (e.g., "Teacher should help learner to improve metacognitive skills and knowledge by using various teaching methods (e.g., modeling, think aloud, direct teaching"). The items of this scale asked to what extent teachers agreed with the statements in the items. Cronbach's alpha level of this scale is .81 for reliability. Experts agreed on the items that within this scale they covered important issues regarding content provided through literature on teachers' perceptions of students' features and needs. Therefore, it was an indicator of content validity for this scale.

The Distribution of Mathematical Authority Scale consists of 10 items (e.g., "A learning environment should be constructed where teacher and students reason together"). The questions in this scale asked teachers to code the items according to the following criteria: "by considering the power of determining what is right or wrong should be on mathematics; such a classroom environment, state to what extent you agree or disagree the statements below". Cronbach's alpha level of this scale is .65. Four factors were observed in factor analysis and this was accepted as evidence for construct validity of this scale since each factor was derived from the definition of where mathematical authority resides in.

The External Pressure Perceived by Teachers Scale consists of 9 items (e.g., "change in curricular and teaching approach"). The questions in the items asked for teachers to state to what extent they agree or disagree with the listed factors about their effect on their teaching practices. Cronbach's alpha level of this scale is .73. Two dimensions obtained from the exploratory factor analysis supported the construct so there was evidence of construct validity for this scale.

STATISTICAL ANALYSIS

Since the aim of the study is to determine mathematics teachers' profile on factors affecting their promotion of metacognition through developing profiling tools, descriptive and inferential analysis were used.

For descriptive statistical analysis, means, standard deviations and possible range for four scales were calculated in order to describe the data set. Furthermore, the distribution of data for each scale was demonstrated through histograms. For correlational analysis, Pearson Product Moment correlation coefficient was carried out in order to seek answers for to what extent four variables were related to each other.

Group comparisons were done in order to observe how the profiling tools discriminated between scores of groups of teachers according to certain variables as gender, age, years of experience, education level, teaching level, school type. It was aimed to explore different aspects of the profiling tools. For this reason, firstly, normality test was also conducted. When the assumption of homogeneity of variances was satisfied, a one-way Analysis of Variance (ANOVA) was used. When the assumption of homogeneity of variances was violated, Brown-Forsythe F- ratio was used. In order to explore effect size, partial eta squared was calculated.

FAMTAM Variables	N	Possible Range	Mean	Standard Deviation
Conceptualization of Metacognition	314	9–45	38.53	7.06
Perceptions of Students' Features and Needs	314	6–30	25.89	3.23
Distribution of Mathematical Authority	314	25–50	38.83	5.55
Perceived External Pressure	314	9–45	34.07	6.36

Table 1: Descriptive statistics

RESULTS

The results showed that most mathematics teachers conceptualized metacognition in accordance with the commonly accepted conceptualizations in the literature. They were aware of students' features and needs. They supported a learning environment where mathematical authority was exercised by students. However, they perceived high external pressure from various factors influencing their promotion of students' metacognition.

Secondly, it was seen that there was a significant correlation between conceptualization of metacognition variable and distribution of mathematical authority variable. Although there was a significant relationship between these variables, the correlation coefficient was relatively low. Therefore, it was a weak positive relationship, $r=.16$, $p < .01$. It was same with the relationship between conceptualization of metacognition variable and perceived external pressure variable, $r = .20$, $p < .01$. Perceptions of students' features and needs variable was significantly, but weakly correlated with distribution of mathematical authority variable, $r=.21$, $p < .01$. Furthermore, same situation can be observed in the relationship between perceptions of students' features and needs variable and perceived external pressure variable, $r=.23$, $p < .01$. Only non-significant correlation was found between distribution of mathematical authority variable and perceived external pressure variable. The relationship between conceptualization of metacognition variable and perceptions of students' features and needs variable was found as significant, but there was moderate correlation between them, $r= .43$, $p < .01$. The result indicated that when the teachers had high conceptualization of metacognition that they got high scores in The Conceptualization of Metacognition Scale, then they better perceived students' features and needs based on metacognition.

Significant gender differences were observed on teachers' claims about their distribution of mathematical authority, $F(1,312)=8.86$, $p=.05$, partial , perceived external pressure, $F(1,312)=18.052$, $p=.00$, partial , and conceptualization of metacognition, $F(1, 263.96) = 8.24$, $p= .00$, partial, in favor of female teachers. Significant differences according to age, $F(3,310)=15.127$, $p=.00$, partial , and years of experience, $F(3, 282.90)=6.57$, $p=.00$, partial, were observed only on teachers' distribution of mathematical authority in favor of teachers with 20–29 age group and 1–5 years of experience respectively. There were also significant differences on distribution of mathematical authority, $F(1,312) = 8.06$, $p=.00$, partial, and perceived external pressure, $F(1,148.78) = 1.76$, $p =.01$, partial, according to teachers' educational background. Teachers with a master's degree supported the distribution of mathematical authority more and perceived less external pressure than teachers with a bachelor degree. In addition, significant teaching level differences were found on each factor in favor of middle school mathematics teachers. Lastly, perceived external pressure, $F(1,312)=5.75$, $p=.02$, partial, and teachers' conceptualization of metacognition, $F(1,59.22)=.01$, partial, also significantly differed on school types. Teachers working at a public school perceived higher external pressure and their conceptualization of metacognition's scores were lower than teachers working at a private school.

Most participants were found to conceptualize metacognition as a multiphase phenomenon which include those commonly accepted principles in the relevant literature. It shows that teachers' beliefs about the presence of metacognition in their teaching are positive. Although the positive results might be a result of social desirability, it is important to keep in mind that the teachers are aware of the importance of metacognition in mathematics classrooms. The awareness of teachers might lead them to introduce and promote metacognitive activities within their teaching practices (Lombaerts et al., 2009). It can be stated that better teachers' conceptualization of metacognition parallel to those in the literature reflecting the details and sophistication might influence teachers' promotion of metacognition positively when hampering factors were diminished or eliminated. As a remarkable and significant difference on teachers' conceptualization of metacognition was observed on teachers working at different school types which could be a result of the fact that secondary school mathematics teachers are mostly graduates of faculties of science (111 out of 153), not of faculties of education (42 out of 153).

Secondly, most participants perceived students' features and needs in terms of metacognition. They mostly stated they were aware of metacognitive characteristics of students and acting upon it. In order to promote metacognition and self-regulation, learning environments should be arranged accordingly (Lombaerts et al., 2007). Teachers who give priority to students' characteristics in terms of their developmental milestones, their way of knowledge construction, and participation of the learning process, are described as the ones taking "learning needs and experiences of students as starting point" (Vandevelde, Vandebussche, & Van Keer, 2012, p. 1563). Therefore the results showed that there is a positive approach to promote metacognition with respect to this issue. Furthermore, in perceptions of students' features and needs variable, only significant difference was found according to teaching level in favor of middle school level. The reason might be the nurturing, parent-like nature of primary education (Louis, Marks, & Kruse, 1996). As they stated, the concerns in high school shift to a more academic plane.

Thirdly, mathematical authority is rather a new concept that provides a student-centered learning environment for teachers and learners (Wilson & Llyod, 2000). As Amid and Fried (2005) pointed out when authority in classroom is discussed, most people including teachers imagine the teacher as "the head of a classroom" (p. 145). However, mathematical authority in the classroom might exist within a classroom when teacher authority as expert authority is eliminated (Amid & Fried, 2005). The results of the study showed the majority of participants stated a distribution of mathematical authority in which mathematics teachers guide learners to use mathematical concepts and procedures in order to reach conclusions through creating an environment where learners share their knowledge, discuss their mathematical thinking and form communities of practices (Schoenfeld, 1992). The results might be interpreted such that most participants might provide learners with a learning environment where mathematical activities, processes or problems can be interpreted and conceptualized through multiple viewpoints and where learners share and discuss their mathematical ideas through taking responsibility of their learning (Wilson & Lloyd, 2000). When group comparisons were investigated on distribution of mathematical authority variable, there are remarkable results found with respect to gender, age and education level. Younger and less-experienced teachers distributed mathematical authority well since the reason might be that they have more positive towards integrating educational innovations into teaching practices (Ghaith & Yaghi, 1997). Furthermore, teachers' educational background also contributed their adaptation to new perspectives in their teaching practices through learning more about reform changes. Therefore, as a further investigation, it is important to examine teachers' varying backgrounds in (e.g. ,their age, career stage, generational identity of teachers) with respect to authority within the classroom to have an idea about the effectiveness of educational changes (e.g., student-centered learning) (Hargreaves, 2005).

Lastly, external pressure is highly perceived by most teachers in the sample. Especially change in curriculum, timing, content, and students' attitudes towards mathematics, classroom size, parental expectations and achievement test were found to be important factors affecting teaching practices such as promotion of metacognition. School context characteristics consisting of classroom size, curriculum, parental expectations, expectations from principal and timing creates occupational stress or pressure on teachers that affect promotion of self-regulation or metacognition negatively (Lombaerts et al., 2009). When group comparisons were taken into account in terms of perceived external pressure, on the contrary to literature (Karaköse & Kocabaş, 2006), public school mathematics teachers perceived higher external pressure than private school teachers in this study. Furthermore, the study indicated middle and secondary school mathematics teachers also differed with respect to perceived external pressure in favor of middle school mathematics teachers. The reason for this result could be given as the characteristics of age-group taught and primary learning environment (Kokkinos, 2007).

For this study, four instruments as the profiling tools were developed and validated. The data were gathered from 314 middle and secondary school mathematics teachers. The results indicated that most mathematics teachers' current thoughts on three factors namely as teachers' conceptualization of metacognition, teachers' perceptions of students' features and needs, the distribution of mathematical authority were positive. However, most mathematics teachers felt external pressures on their teaching practices. The results indicated that although most teachers have positive approaches towards promotion of metacognition, external pressure they perceived might have a negative influence on promotion of metacognition as an educational innovation. The negative factors created pressure or stress on teachers so especially teachers hesitating integrating educational changes in their classrooms may have problems with adjusting their learning environment for example with respect to promotion of metacognition (Lombaerts et al., 2009). One limitation of this study is the use of self-report instruments as the single data source. Group comparisons for factors affecting promotion of metacognition are significant, but effect sizes of the group comparisons were relatively small. The small amount of explained variances is a limitation for explaining the factors affecting promotion of metacognition (Lombaerts et al., 2009). It would be informative to describe such data in-detail through using qualitative methods (Dignath-van Ewijk & Van der Werf, 2012). The researchers would investigate FAMTAM variables based on the items of the scales through qualitative methods to check whether such variables included in these scales and teachers' statements on FAMTAM match with teachers' existing practices. For the further studies, it would be better to describe the profiles of mathematics teachers with a larger sample size in order to improve the generalizability of findings derived from the profiling tools. All in all, the study showed that mathematics teachers have already had positive approaches towards promotion of metacognition with respect to conceptualization of metacognition variable, perceptions of students' features and needs variables and distribution of mathematical authority variable. However, perceived external pressure might have negative influence on their teaching practices. As a possible next major step in research on teachers' promotion of metacognition, the investigation to what extent the variables affect promotion of metacognition can be suggested.

Characterizing a highly-accomplished teacher's instructional actions in response to students' mathematical thinking

Rukiye Didem Taylan

MEF University in İstanbul, Faculty of Education, İstanbul, Turkey, tayland@mail.mef.edu.tr

This paper is part of a larger study which investigates how a highly-accomplished teacher and two beginning teachers notice student thinking and respond to students' mathematical thinking as they teach concepts of multiplication and division in a third-grade classroom. The focus of this paper is on describing highly-accomplished teacher's instructional actions in response to student thinking which are different than that of the beginning teachers. The participant teachers' instructional actions were analysed utilizing a framework developed by Cengiz, Kline and Grant (2011). The results revealed that the highly-accomplished teacher challenged student thinking with counter arguments and introduced alternative representations more frequently, but complimented students less frequently than the beginning teachers.

Keywords: Instructional actions, responding to students' mathematical thinking.

INTRODUCTION

Creating instruction based on student understanding and thinking of mathematics is one of the essential practices underlying teaching for understanding (Ball, Lubienski, & Mewborn, 2001; Fennema, Franke, Carpenter, & Carey, 1993). Research shows that attending to mathematical thinking of students in professional development programs can help improve both teaching quality and student achievement (Carpenter, Fennema, Franke, Levi, & Empson, 1999; Kazemi & Franke, 2004). Although these findings establish the importance of mathematics teachers' understanding of student thinking and their pedagogical decisions based on this understanding, responding to student thinking in appropriate ways is a complex skill, which requires hearing and interpreting student thinking (Wallach & Even, 2005). Therefore, there is a need to understand this core practice of teaching and help teachers improve in their practices.

Due to the interactive and clinical nature of teaching, Grossman and McDonalds (2008) call for studies that investigate details of teachers' practices instead of their knowledge or beliefs. Grossman and McDonalds (2008) argue that research in teaching lacks "common pedagogies for helping novices learn to respond to student thinking in the moment," even though teachers' responses to students during interactive teaching is one of the major components of the teaching practice.

Berliner (2001) identified flexibility and adapting the lesson according to students' responses as one of the major skills that differentiate experts from novices. Among other studies, Borko and Livingston (1989) provided further evidence for this argument by observing and interviewing student teachers and their cooperating teachers before and after they taught lessons for a week. Researchers found that the cooperating teachers were much better than their student teachers at improvising the lesson according to unexpected student questions or comments.

There are relatively few studies that specifically focus on how teachers respond to student thinking during mathematics instruction (Even & Gottlib, 2011; Pierson, 2008). While many studies document different ways the way teachers respond to student thinking, these studies are either focused on classroom discourse (Even & Schwarz, 2003), teacher practices as they implement a specific curriculum (Fraivillig, Murphy, & Fuson, 1999), as part of an intervention program (Doerr, 2006), or in the context of a professional development program outside classrooms (Jacobs, Lamb, Philipp, & Schapelle, 2011).

Cengiz, Kline and Grant (2011) investigated how six elementary school teachers elicited, supported and extended students' mathematical thinking through classroom observations and interviews. The authors developed a framework building on the work by Fraivillig and colleagues (1999) that focused on instructional actions related to extending student thinking during whole class discussions. The authors conceptualized extending student thinking as "helping students move beyond their initial mathematical observations and further develop an understanding of a mathematical phenomenon" (p. 356). The most common instructional actions of extending student thinking were grouped under categories of encouraging mathematical reflection, going beyond initial solution methods, and encouraging mathematical reasoning. Using counter-speculation and introducing representations and contexts that are familiar to students were the least frequently observed instructional actions that supported or extended student thinking.

The purpose of this study is to describe characteristics of a highly-accomplished teacher's instructional actions, specifically in response to students' mathematical thinking. This kind of research may offer insights in teachers' learning as well as helpful learning experiences for novice teachers in improving their practices of building instruction on students' mathematical thinking. In this study, I prefer to use the term *highly-accomplished teacher* rather than expert teacher because the latter is not clearly defined and has many different connotations (Li & Kaiser, 2011). I draw upon Schoenfeld's (2011) definition of a highly-accomplished teacher as one who spends minimal time on classroom management issues and engages in diagnostic or responsive teaching most of the time.

METHOD

The case study methodology was used in the current study. Using this methodology allows the researcher to answer questions such as "how?" and "why?" while considering the influence of context on a phenomenon within which it is situated (Baxter & Jack, 2008). The purpose of the larger study (Taylan, 2013) is to characterize third-grade teachers' practices of noticing of student thinking and instructional actions in response to student thinking during teaching. Because the larger study explores noticing of children's mathematical thinking and teaching practices among three different third-grade teachers, one experienced and two in their first-year, it represents a multiple-case study which allows the researcher to explore differences and similarities within and among cases (Yin, 2003). The findings in this paper focus on the case of the highly-accomplished teacher.

The researcher observed and videotaped each teacher's mathematics classes for a week. Each third-grade teacher worked on topics of multiplication and division in the same school district during the time of data collection. The teachers wore portable cameras and selected moments of their instruction as they taught and reflected on the selected video clips during the interviews that followed each class. The interviews and teacher-selected video clips provided additional insights on the teachers' instructional decision making processes. The researcher's observation notes and transcribed video observations of each class together with teacher interviews and lesson plans allowed the researcher to have a robust understanding of teachers' instructional actions as they responded to student thinking in the context of each classroom.

Selection of case and background

Brooke was nominated for participation as a highly-accomplished teacher by the district mathematics coordinator and school principal, both of whom have observed her teaching before. Brooke has been teaching third grade for 6 years and she has 3 years experience of attending a contextualized and an intensive professional development program where she worked one-on-one with a prominent teacher educator and educational researcher.

Brooke taught at a school where many students came from low socio economical backgrounds. With regards to mathematics instruction in her classroom, Brooke aimed for her students to comfortably share their mathematical thinking and "think for themselves" (Brooke, the first interview) instead of seeking her approval. Brooke believed her students needed multiple types of opportunities in order to understand the content she planned to introduce.

The research project took place when Brooke's class was making a transition from learning multiplication to division. The activities that Brooke created and planned together with her colleagues involved different models of multiplication and division: students jumping on the number line taped on the floor to represent skip-counting situations, and cutting ribbons of equal length for wrapping gifts. Brooke described her teaching goals in the following way:

> One of our district objectives right now is having a variety of models for division and multiplication and make connections between multiplication and division and so we have done like discrete models and then we are supposed to introduce number line models. For some of my kids that have difficulties with number sense number lines are helpful, which we did in multiplication. Some of the things they used for multiplication might help them solve division problems more efficiently rather than having to repeatedly subtract and be inaccurate in their computation (Brooke, the first interview).

Brooke aimed to create meaningful experiences for her students so that they could make connections between the new topic of learning division and what they already knew in multiplication.

Data Analysis

Instructional actions examined in this study consisted of responses to student thinking (any spoken or written mathematics related ideas, justifications or generalizations) exhibited by teachers during instruction (Fogarty, Wang, & Creek, 1983). The nature of instructional actions as teachers responded to students' mathematical thinking was investigated by analyzing whole-class videos of classroom observations and field notes. Classroom talk pertaining to each lesson was transcribed, and instructional actions were analyzed only when they occurred as a response to student's mathematics related question, answer, comment or claim.

Guided by the frameworks of Fraivillig and colleagues (1999), Pierson (2008) in general and, Cengiz and colleagues (2011) in particular, teachers' instructional actions were analyzed in two steps. First, chunks were identified that indicated existence of instructional actions responding to a student idea or question. Second, these chunks of teacher responses were subdivided into more detailed segments.

By using the conceptual framework shown in Figure 1, teachers' instructional actions were categorized as supporting instructional actions, extending instructional actions and others. To ensure reliability, classification of instructional actions within one lesson was also checked by another educational researcher until reaching an agreement about the coding scheme.

RESULTS

The results of this study emerged mostly through the use of the conceptual framework (Figure 1) and observing instructional actions across teachers for different instructional actions. Apart from the analysis of individual instructional actions, observation of a phenomenon that was emphasized in previous research, flexibility of an expert (or a highly-accom-

Supporting actions	**Other**
Repeating student idea, claim, question	*Complimenting or evaluating*
Suggesting an interpretation	*Clarifying questions*
Introducing different representations	*Requesting basic information*
Reminding of the goal	*Redirecting to a peer*
Recording student thinking	*Providing hints*
Acknowledging student thinking	
Extending actions	
Inviting students to evaluate a claim	
Inviting students to provide reasoning and probing	
Challenging/providing counter arguments to student claims	
Pushing for alternative ways	

Figure 1: Instructional actions framework (Adapted from Cengiz et al., 2011)

Mrs. Paul has got this kid in her classroom named Sam. Here is the problem that she gave him: Mrs. Paul had 24 inches to wrap two presents. How long will each piece of ribbon be?

I want you to look at Sam's work and then I am gonna ask you whether you agree or disagree with Sam and to tell me why. Alright so here is his work. Sam wrote 24 + 24 =48 and 24 x 2=48.

If you agree with Sam's work you are going to go ahead and tell me why you agree. If you don't agree with Sam's work and his ideas, I want you to tell me why (Brooke, third lesson transcription).

Figure 2: A supplemental task after coming across a misconception

plished) teacher with regards to adapting instruction based on student thinking, deserved attention.

Although all three teachers provided evidence of noticing student thinking and employing instructional actions that supported student thinking, beginning teachers failed to introduce new tasks in modification to their lessons plans based on student strengths and weaknesses as they taught.

Brooke had the flexibility of changing the lesson plans by providing additional tasks she considered to be necessary. For instance, on the second day of observation some students used multiplication instead of division. On the third day, Brooke presented the following task given in Figure 2.

Most students who agreed with this misconception in the beginning of the lesson (more than half of the students in class) subsequently changed their thinking towards the end of the class as observed in student worksheets collected and teacher's assessment during interviews. Implementation of this task (Figure 2) could be considered as responding to student thinking based on the teacher's noticing.

In analysing classroom transcriptions of Brooke based on the analytical framework, several patterns emerged. First, Brooke exhibited instructional actions that had the potential to support and extend student thinking. In particular, *repeating a student idea*, *acknowledging student thinking* and *suggesting interpretation* were the most frequently used instructional actions that supported student thinking. With regards to instructional actions that had the potential of extending student thinking, the most frequently observed actions were *inviting students to provide reasoning and probing*, *inviting students to evaluate claims* and also *challenging/providing counter argument*s.

Brooke *introduced multiple representations of mathematical concepts* in her teaching and *challenged students* more frequently than the two beginning teachers did. On the other hand, Brooke did not *compliment student thinking* as frequently as the beginning teachers did in the study. Although most of the instructional actions were observed across both the highly-accomplished teacher's class and the beginning teachers' classes, some of the instructional actions almost solely occurred in Brooke's class. Therefore, it is important to provide details of how those instructional actions are enacted in order to understand the differences between the highly-accomplished and the two beginning teachers.

Challenging / providing counter arguments

Brooke challenged her students more frequently than did beginning teachers in this study, mostly by asking questions that helped students realize their own mistakes. Brooke specifically challenged her students in the first class, when she observed many misconceptions in her students' understanding of multiplication and division. Most of student misconceptions were revealed after Brooke introduced the task of finding the patterns between multiplication and division sentences. For example, the students worked on understanding the relationship between the two number sentences, such as 5 times 7 is 35, and 35 divided by 7 is 5. Several misconceptions came to surface during this discussion. For instance, some students thought that in division sentences, numbers are sequenced from the largest to the smallest number; such as in the example of 35, 7 and 5 (35 divided by 7 equals 5) while multiplication sentences go from the smallest to the largest numbers (such as 5 times 7 equals 35). Especially during the first lesson when Brooke observed that most students had this misconception, she challenged the students and provided counter explanations. The following excerpt from the first classroom observation transcription is a typical example of how Brooke challenged a student:

Student: I know that division starts with the big number and the first number in the multiplication sentence is the answer. And the multiplication goes from smaller to bigger.

Brooke: So is that pattern always true? What about this, what if I write 7 x 5 =35, is that number sentence true? Is it always gonna go from small to big? [*challenging, providing counter argument*].

As evident above, Brooke does not directly tell the student that his answer is problematic but instead she challenges his misconception by providing a counterexample in order for this student to arrive at this understanding himself. During the interviews Brooke noted that she avoided evaluative language such as "that is a wrong answer" because she wanted her students to think for themselves, independent of her approval or disapproval.

Introduction of multiple representations of mathematical concepts

Being aware of her students' weaknesses, Brooke used alternative representations to make the concepts more meaningful to them. Additionally, she believed that each student had a different way of learning and some models/representations made more sense than others to some students. Accordingly, she believed in using a variety of representations in her teaching, as evidenced in the following interview excerpt:

> The number line makes a lot of sense to some kids. It really helps them. For some kids it does not really make any sense. And some kids with the discrete model they are like "well, this is great." It makes complete sense, and for other kids it makes no sense. So sometimes that's why I like introducing a few ways to visualize it because I feel like different kids have different ways of thinking about it so it is nice to find something comfortable for them (Brooke, the first interview).

Further evidence of introducing different representations can be found in the following excerpt given below where Brooke helps two students by suggesting use of different representations when they have difficulties of cutting 45 inches of ribbon into 9-inch strips and finding the total number of strips.

Student: I know it is going to be 45 divided by 9 but I can't figure out the answer.

Brooke: Okay. What could you guys do, what tools could you use to figure that out? Could you use a meter stick or do you want to try number line that is erasable? [suggesting use of/introducing different representations] (Brooke, third lesson).

DISCUSSION

Analysis of the highly-accomplished teacher's instructional actions in responding to student thinking revealed distinct qualities. Although all teachers in the study worked towards building their instruction on student thinking via asking students to provide their reasoning, and restate and evaluate peer's thinking, the highly accomplished teacher's repertoire of instructional actions included challenging/providing counter arguments and introducing multiple representations, unlike novice teachers.

The highly-accomplished teacher's flexibility in building instruction based on her noticing of student thinking during teaching was a finding that was not surprising based on previous research findings (Berliner, 2001; Borko & Livingston, 1989). The task presented in Figure 2 was not included in Brook's weekly teaching plan. However, she developed and implemented this task based on what she believed students needed.

Some instructional actions were more common than others across all teachers. For instance, *inviting students to provide reasoning behind their answers and probing*, *repeating student answers*, and *inviting to restate peer's claims* were among the most common instructional actions that followed up student thinking. On the other hand, *challenging and providing counter arguments* to what students said was the least frequent instructional action for teachers. This result may not be surprising given the fact that it was observed rarely even among experienced teachers in Cengiz and colleagues' (2011) study. Lack of this particular instructional action, namely, *challenging and providing counter arguments* to what students said in beginning teachers' teaching was one of the most important distinctions compared to the highly-accomplished teacher's teaching. Challenging students' thinking with counter arguments is considered an important component of extending student thinking although it is not easy to come up with this type of arguments in the actual moment of teaching (Cengiz et al., 2011; Fraivillig et al., 1999). Being able to engage in this particular instructional action likely required Brooke to listen to students carefully and to be able to generate a counterexample in the moment that would confront their misconception by learning that it would not hold in every case. It may be the case that Brooke was able to challenge her students more frequently because her experience allowed her to develop certain schemata for providing responses when students had misconceptions (Borko & Livingston, 1989).

The instructional actions that require students to provide reasoning and evaluating peer's answers may not be enough to create discussions that would really benefit student learning if they do not take place during a well-planned math discussion. The selection and sequence of student ideas to be shared with the whole class are the key components to a quality instruction (Stein, Engle, Smith, & Hughes, 2008). The experienced teacher was confident in her choices as she selected particular students to share their thinking with the whole class and their sequence of appearance (Brooke, the third interview). This may be a difficult task for novice teachers.

Brooke *introduced different representations of the concepts* of multiplication and division frequently in her class. Brooke's experience in both teaching and professional development where she created curriculum materials and thought about appropriate models for student learning may have helped her to develop a larger repertoire of representations. According to Shulman (1986) being able to understand and present different representations of the same concept is an important component of teacher's pedagogical content knowledge.

CONCLUSION

Adapting instruction based on student thinking, challenging/providing counter arguments, and introducing multiple representations were characteristics of the highly-accomplished teacher's instructional actions in response to student thinking in this study. The findings have the potential to contribute to research in teachers' professional development, especially in creating schemata of instructional actions that novice teachers may learn from to become better teachers.

Providing illustrations of how experienced teachers employ a variety of instructional actions may prove valuable for novice teacher learning. Watching video cases of highly-accomplished teachers such as in this study, reading transcribed teaching or learning to provide hypothetical responses in the form of challenging students or providing multiple representations may be valuable tools for beginner teacher's learning of the profession of teaching.

There is a need for studies that investigate instructional actions of other experienced and highly-accomplished teachers as they teach different mathematical topics in different contexts. Considering future research, it may also be worthwhile to explore the relationship between specific instructional actions in response to student thinking and their impact on students' participation in mathematics discussions and achievement levels in mathematics.

Promoting the understanding of graph representations by grade 3 students

Isabel Velez and João Pedro da Ponte

Universidade de Lisboa, Instituto de Educação, Lisbon, Portugal, velez@campus.ul.pt

This paper aims to understand how two grade 3 teachers promote students' learning of graph representations. The conceptual framework addresses representations and teachers' actions as students work on a task involving graph comprehension. Data collection includes observation and video recording of two classes. The results show that to promote the understanding of the graph representation teachers supported students in reading the data and in reading between the data, mostly by questioning.

Keywords: Teachers' practices, graph representations, graph comprehension.

INTRODUCTION

Representations are a key element on students' learning. Several authors have been studying the role of representations in mathematics learning (Bruner, 1999; Thomas, Mulligan, & Goldin, 2002). The NCTM (2000) indicates that representations help students to interpret, organize and understand the information given in a problem statement, to figure out how to reach the answer, and to monitor and evaluate their work. Therefore, it is important that teachers provide students with opportunities to learn and understand different types of representations (Bishop & Goffree, 1986).

Research regarding interpreting and using graphs has been receiving more attention. According to Friel, Curcio and Bright (2001) graphs are "used for data analysis function as discovery tools at the early stages of data analysis when the student is expected to make sense of data" (p. 132). They also refer that this side of the use of graphs in the classroom is related to the school curriculum. In 2012 Portuguese teachers were starting to use a new school curriculum (Ministério da Educação, 2007), that emphasized for the first time, the importance of working statistics from the early ages. In this paper, we aim to understand how two grade 3 teachers promote students' learning of graph representations.

REPRESENTATIONS AND TEACHERS' PRACTICE

A representation is a mental or physical construct that describes aspects of the structure of a concept, and its interrelationships with other concepts (Tripathi, 2008). Bishop and Goffree (1986) say that, to foster students' understanding of representations, the role of teachers is to facilitate "the interpretation of the many representations commonly used [and] encourage the connections to be exposed, so that pupils can share that knowledge" (pp. 335–336). Stylianou (2010) refers the importance of understanding more than one representation related to the same concept and states that teachers may select those which they regard as more appropriate to promote their students' understanding. When students explain their solutions this provides the teacher with the opportunity to understand students' answers and to know how they interpret a representation. As students work or present their representations, teachers may ask them to explain such representations, thus supporting the establishment of connections between representations and making conversions and treatments (Duval, 2006).

Statistical graphs are an important kind of representation. Goldin (2000) says that graphs may promote new learning, providing students opportunities to build their own knowledge and to participate in discussions. According to Friel, Curcio and Bright (2001) although all graphs have a similar framework, each type of graph has its own specifications and its own language. When a student reads a graph he or she must be able to describe, organize, represent, analyse, and interpret data, and relate it to its context. They state that "graph instruction within a context

Students' activity regarding representations	Teachers' actions
Designing/Choosing	Promoting free choice Hinting through questioning Providing explicit suggestions or examples
Using/Transforming	Challenge students through open questioning Asking to explain in a structured way Suggesting alternatives
Reflecting	Guiding or challenging to establish further connections Guiding or challenging to find conversions or treatments
	Promoting the evaluation of the work done Promoting systematizations

Table 1: Teachers' actions regarding students' representations

of data analysis may promote a high level of graph comprehension that includes flexible, fluid and generalizable understand of graphs and their use" (p. 133). The authors also refer that students' difficulties in reading and understanding graphs are associated (i) to establishing connections between data, (ii) to the graph with known situations, and (iii) to the task, students, and class characteristics. To map students' understanding of graph representation, Curcio (1987) proposed a framework with three levels of graph comprehension: (i) reading the data, responding to simple questions that just require direct readings; (ii) reading between the data, finding relationships in the data and making simple inferences; and (iii) reading beyond the data, answering questions based on extensions, inferences or predictions based on the interpretation of the data. Friel, Curcio and Bright (2001) suggest that, when students work on a task, teachers may question them, in order to promote the different levels of graph comprehension.

Teachers' practices strongly influence students' learning, and in particular the way they use mathematical representations in the classroom (Stylianou, 2010). Saxe (1999) states that practices may be regarded as recurrent and socially organized everyday life activities. An important aspect of teachers' practice is how they use tasks in the classroom (Ponte & Chapman, 2006). Often this is done through three moments: introduction of the task (which can be made by teacher or by actively involving the students), students' work (individually or in small groups) and whole class discussion and systematization of representations results (Ponte, 2005).

Regarding whole class discussions, Ponte, Mata-Pereira and Quaresma (2013), identify four types of teachers' actions (inviting, challenging, supporting or guiding and informing or suggesting). They give special attention to challenging actions by which teachers support students in discovering new information. Based on this perspective, we analyse the students' work on a task and we connect their activity and teachers' actions, focusing on how teachers promote the understanding of representations (Table 1).

Students' activity may involve designing a representation, using and transforming a representation or reflecting about used representations. Teachers' actions are closely related to students' activity. To support the students' in designing a representation teachers may (i) promote the students' free choice about an adequate representation, (ii) give students some hints about a representation, or (iii) give a suggestion or example that students should use. To promote the use/transformation of a given representation, the teacher may (i) challenge students using open questions to promote students' thinking about transforming their representations, (ii) ask students to explain their solutions in a structured way, or (iii) suggest students an alternative to their representations. In the reflection phase teachers can guide or challenge students to (i) establish connections between the used representations or others that could be used as well and (ii) do conversions and treatments of representations. The difference between guiding and challenging depends on the questions that teachers make (in a more open or structured way). Teachers can also involve students into (i) evaluating the work that has been done and (ii) systematizing information.

RESEARCH METHODOLOGY

This study is part of a qualitative research on the practices of a working group of four primary school teachers that in 2013 were in a school cluster in the surroundings of Lisbon, all teaching grade 3. The teachers of this working group were striving to promote problem solving with graph representations in their classes. The participants in this paper are two of those teachers, Rui and Catarina. We choose them because in their classes we observed episodes illustrative of a wide variety of interesting situations. Both teachers had less than 5 years of experience and already knew the students in their classes from the previous school year.

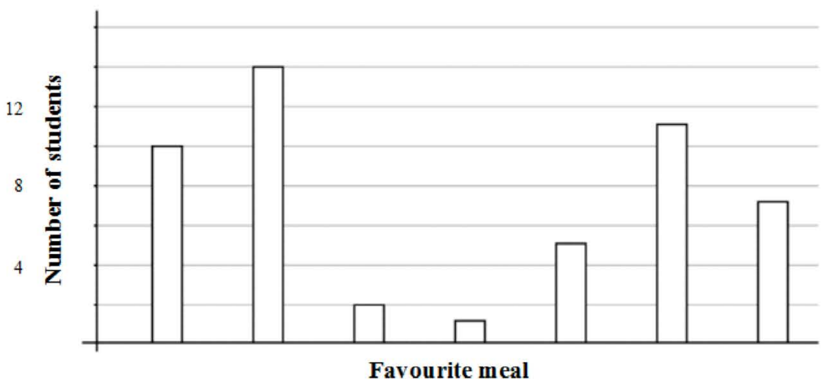
Data was gathered by video recording during class observations (whole class moments and individual teacher-student interactions). The first author collected the data and was a non-participant observer in the classes. Data was analysed trough content analysis regarding the different moments of classroom work on a task (Ponte, 2005), teachers' actions concerning the understanding of representations (Table 1), and the different levels of students' graph comprehension (Curcio, 1987). After transcribing all the audio and video data, we analysed teachers' and students' interactions and coded their actions with the categories of Table 1 and the levels of Curcio (1987). In this paper, we analyse the work carried out on a task on two different classes. The task was planned by the teachers' working group. At the beginning of the research, the teachers identified some topics that they wanted to teach (from January to June of 2013) and the first author suggested them some tasks. As the students had done some previous work with pictograms and graphs, the teachers chose a task involving a bar graph striving to address students' needs and difficulties in reading the data and reading between the data.

RESULTS

The task "The favourite meal" included a bar graph and a set of seven statements. Two questions (with sub questions) were made regarding the information provided in the graph and in the statements.

Interpreting statements a), d), f) and g) involve reading the data and interpreting statements b), c), e) involve reading between the data. As the information

Task – The Favourite meal



The schools' principal wants to know which students' favourite meal is. He received a report that included a graph and several conclusions:

a) The hamburger and fries were the most voted meal;
b) The number of students who chose the hamburger and fries were the double of those who chose roasted chicken;
c) The fish and chips had less 4 votes than hamburger and fries;
d) The spaghetti Bolognese was the second most voted meal;
e) The creamy codfish had 4 more votes than the baked fish;
f) 5 students voted on creamy codfish;
g) Some students voted in peas with eggs.

1) The principal received this little report with the graph but he was not pleased with it. He found the conclusions very confusing. After all, how many students voted? And how many voted for each meal?

2) Examine the graph that was done. What could be improved? What is well done?

Figure 1: Task presented to students (based in Martins & Ponte, 2010)

is already represented in a graph, the students do not have to design or choose representations – they are called upon to use, transform and reflect on given representations and on their own work.

Catarina's class

In the presentation of the task, Catarina begins by addressing the graph conventions (title, categories, vertical axis, horizontal axis) with her students, questioning them and providing some hints ("Why are graphs necessary?... What is the meaning of the numbers in the graph?..."). By doing this, she helps students in reading the data.

During the students' autonomous work, depending on their difficulties, Catarina walks around the room and asks students to explain their answers through open questioning or in a more structured way, seeking to understand their work. For example, regarding statement a), through open questioning, she challenges Jorge, a student who apparently does not have difficulty in solving the task, about his answer (he answers that the hamburger and fries matches to the second column). However, she is not sure how he read the data and continues questioning him about how many students chose this meal:

Jorge: Well... If this is twelve [points to the number twelve on the vertical axis], this should be thirteen...! Right?

That way Catarina could notice that although Jorge's written answer is correct, and his initial explanation seemed right, he does not have a proper understanding of the graph, assuming that the scale was of one element. The teacher continues to question him in a more structured way ("Let's look closer to the number of students...", "Where is the number zero?", "Let's complete the scale [in the vertical axis]"...). In this way, she leads the student to recall the graph conventions, focusing him in how to read the data, and guiding him to take a closer look at the graph scale on the vertical axis. Finally, Jorge discovers for himself his mistake.

In the whole class discussion, Catarina asks the students to present their solutions. She calls upon students according to their difficulties in reading the data and in reading between the data, especially reading the vertical axis scale and comparing graph bars that she had noticed in students' work. For example, Catarina had realized that António justified his answer to statement e) using just part of the information provided (if one column is greater than another one and if codfish has more votes than baked fish, codfish will be one column and baked fish another one). This prompts her ask him to present his solution to the class:

António: [as he points to the fifth column] [This is] the codfish...
Catarina: Why?
António: Because it has more than this one [he points to the third column].
Catarina: Hum... How many [votes]?
António: Two...
Catarina: But the codfish has plus four votes than the baked fish . . . How many votes does this has? [she points to the column chosen by the student]
António: Two...
Catarina: You have two votes...? So two plus four ... How much is it?
Antonio: Six...
Catarina: Do you have any [column] with six? . . .
António: No... Just five...!!

With this sequence of structured questions Catarina leads the student to read between the data, and António realizes that his answer was wrong. Afterwards, she continues to question him, focusing in how to read the data, and reviewing some elements of the graph representation that are necessary to solve the task, such as analysing the value of the remaining columns (reading the data) and comparing the with the scale of the graph.

In the discussion of the second question of the task, Catarina focuses in how to read the data, guiding students in reviewing the conventions of graphs. She uses open questioning, challenging students to find what they could improve ("What's missing?"). Some students say that "the graph is incomplete" and identify the two missing elements. Vanessa points to the missing categories on the horizontal axis ("It does not say the name of each meal (...) Here!") and another student refers to the missing title of the graph. At this point Catarina decides to challenge students, testing them about the size of the columns with a "bad example". On the black board, she erases some of the original columns and enlarges their width. As the students respond negatively to what she did, the teacher asks them: "Why are you reacting like that?! Why can't I do it like this?" The students' answers ("Because it would seem like a super meal", "It is occupying too much space!", "They must have the same width!") show that they know that all columns must have the same width. In the end the whole class discussion, Catarina systematizes with the students the information discussed and writes it on the board.

Rui's class

During the presentation of the task Rui provides some examples of how to read the data and questions students in a structured way. The teacher talks with them about graph conventions (role of horizontal and vertical axis) and states that it is important to understand what the axes represent ("This graph has . . . It has two axes... This axis here [points to the vertical axis] is the number of students that voted, right? And that [points to the horizontal axis], indicates the favourite meal").

During the students' autonomous work, most of them show great difficulty in understanding the graph representation and in reading the data. They have trouble in identifying the scale on the vertical axis and in relating the data on the graph to the sentences. As Rui realizes those difficulties, he decides to solve the task in a whole class discussion, asking students to explain their answers in a structured way. This decision motivates the class, prompting the students to reflect on the task and to participate in the discussion. Some of them start to read between the data. For example, on statement a), Bernardo justifies his answer saying that if the hamburger and fries is the most voted meal, then the corresponding bar would be the higher one ("The first [statement] indicates that the most voted meal was the hamburger and fries... So [the bar] that is the uppermost is this [meal]).

At this point, Rui invites all students to participate in the discussion and to present their solutions, and he challenges them through open questioning. For example, in statement b) he inquires a group of students that are talking about their solution:

Rui: Double of roasted chicken... What does it means? Explain me that!
Ulysses: The number of students who chose hamburger and fries was twice... Of those who chose roasted chicken... . . .
Rui: ... So what can I take from this? ... How am I going to do that?
Carolina: We have to go to the other [column of hamburger and fries]...
André: We have to see the numbers in this table [graph]!
Rui: We have to see the number in the graph, how?
André: Well... We have to see what number is [in each column]... We have to [compare columns and] see if [which] is twice of the roasted chicken . . .
Carlos: It's [the column] standing next to the hamburger with fries!
Rui: Come here to explain me how do you see that...

Carlos [as he goes to the black board]: I am telling you that... This [the second column] is the hamburger with fries and [the roasted chicken] is this [the first] one... Because...This [the first column] is eight and eight is the half of the double [the column that values fourteen]...

Rui begins by challenging students to read between the data and interpret the statement, namely the meaning of "double". Through open questioning ("Explain me that!", "How?", "What does it mean?...") he realizes that there were two strategies for dealing with statement b): comparing column size, such as Carolina suggests, or comparing column values, as André indicates. Prompted by Rui, André explains his answer.

Almost at the same time, Carlos insists that the first column is the right answer and Rui decides to question him in a structured way. For Carlos it is clear that he has to find the column which value is half of the hamburger and fries column ("half of the double") and he knows that half of fourteen is seven. However, as he could not find the column that corresponds to seven meals (because the number seven it is not identified on the vertical axis), he tries to compare column sizes and chooses the one that he thinks it is closer to seven. That way, he chooses the first column that he thinks it worth eight meals. Rui notices that Carlos is having difficulties in reading the data, and he promotes a comparison between the two strategies trying to make everyone understand why only one of them is reliable. Using Carlos as a representative of the users of the first strategy, Rui challenges him to explain how he can be sure that the value of the column that he chose is half of the column corresponding to the hamburger and fries. The student tries to read between the data, not acknowledging that he is not able to read the data. As the vertical axis does not have all the numbers identified, Carlos tries to compare the size of the columns, measuring them with his hands. Rui continues to challenge him through open questioning and asks Carlos and his classmates ("Do you think that column [first column] is half of the one of hamburger and fries?"). With this question, all the students begin talking at the same time, trying to pick the right column.

As Catarina did, Rui also realizes that the class is struggling to read the data (namely the vertical axis scale). He decides to explore the graph with his students making questions in a structured way. He points to the intersection between the two axes ("Which number is this one?") and that guides students to look at the scale of the vertical axis and to read the data. Leonardo, says "Oh! It's two by two!" and Miguel completes the answer of his colleague saying "It is two, four, six, eight, ten and twelve!" which makes the whole class understand the scale and therefore the graph representation. As a consequence, Rui decides that students can return to work autonomously. As the work goes on, the teacher analyses students' solutions and questions some of them through open questioning and structured questioning. Afterwards, during the whole class discussion of results, the students have no difficulties in explaining their answers.

In the second part of the task, Rui challenges the students through open questioning and they easily indicate what could be improved in the graph. For example, Bernardo states that the given scale (that he considers incomplete) made the graph difficult to read ("Because it had not all the numbers!") and André indicates that the graph should have a title ("The title!! It is missing the graph title!").

After the whole class discussion, Rui systematizes with the students the relevant information related with reading the data and reading between the data (title, scale, y-axis and x-axis, categories, size of columns) and he promotes the evaluation of the work done as well as what students have learned.

CONCLUSION

Teachers' actions as the students seek to use and transform the information provided on the graph and the statements mainly involved open questioning and questioning in a structured way to lead students to explain their answers. They also questioned students in a structured way to discuss the graph conventions and rules in order to lead them to understand the main characteristics of that representation.

As the students identified the relevant graph conventions they could read the data. This also allowed them to read between the data (Curcio, 1987). When the students were having trouble in reading between the data, the teachers decreased their questioning level in terms of graph comprehension (Friel, Curcio, & Bright, 2001), and sought to make sure that students could read the data by questioning them in a structured way about the graph conventions. When the students were able to read the data, the teachers increased the questioning level and challenged them through open questions. Rui and Catarina had to decide how and when to intervene, and how and when to increase or decrease their questioning level, helping students to understand the graph representation without jeopardizing the activity on the task, making it too easy or too hard.

During the discussion phase the teachers tended to guide and challenge students. Both of them systematized the most important information at the end of the discussion. As Bishop and Goffree (1986) suggest, the teachers chose students with right and wrong answers depending on what they wanted to explore. For example, Rui picked a situation when a student had a different solution from everyone else.

In conclusion, to help students to read the data teachers tended to question in a structured way and to help students to read between the data teachers tended to use open questioning. Both teachers used the whole group discussion in which students presented their solutions as an important learning moment in which they challenged and guided the students to explain their solutions, so that all of them could understand their colleagues' solutions. As the teachers recognized the students' answers, it was easier to help them to identify and correct their mistakes. The teachers used mostly open questioning and questioning in a structured way during the introduction, the students' autonomous work and whole class discussion, with very little resource to suggesting alternatives. The results that we present in this paper supports idea that the teachers' choice of tasks and handling classroom communication are crucial aspects of their practice (Ponte & Chapman, 2006), providing the required opportunities to develop students' mathematical learning.

Students' perceptions of Norms in a reformed classroom

Richard Wester[1], Anna Wernberg[1] and Tamsin Meaney[2]

1 Malmö University, Sweden, anna.wernberg@mah.se

2 Bergen University College, Norway

This paper explores tensions between the teacher's intention and the students' interpretation of a reformed classroom practice. Focus for this paper is particular on the social and socio-mathematical norms. The example presented in the paper is connected to the use of resources, such as manipulatives, to catch both explicit and implicit tensions between the students' perceptions of existing norms and teacher´s intention of supporting norms. These tensions could form and cause a barrier to students' opportunities to learn. Reform teaching is likely to fail if students do not share a similar understanding to that of their teacher in regards to their contribution to mathematics learning.

Keywords: Reformed teaching, tensions, social norms, socio-mathematical norms, students' perspective.

INTRODUCTION

School Inspection's quality review (Skolinspektionen, 2009) of Swedish mathematics teaching reveals that teaching in general is strongly connected to the use of textbooks. Students working individually in textbooks dominate Swedish mathematic teaching practice (Bergqvist et al., 2010; Kjellström, 2005). Alrø and Skovsmose (2002) term such teaching as the *exercise paradigm*. In the exercise paradigm, students are expected to learn how to master tasks by executing a series of procedures in order to gain the correct answer. According to Alrø and Skovsmose, an alternative to the exercise paradigm is *a landscape of investigation*. In that setting, students are encouraged to ask questions and to work together to investigate issues. The starting point is the students' previous understanding and that students are active seekers of learning.

In Sweden, a new syllabus (Skolverket, 2011) for mathematics education was implemented in 2011. It focuses on developing students' mathematical competences. The idea of mathematical competences in syllabus originates from the Adding Up report (Kilpatrick, 2001) and the KOM-project (Niss & Højgaard Jensen, 2002). Competencies provide another way to explain what it means to master mathematics. Both of these previous projects had the intention of changing teaching practice in schools (Boesen et al., 2014), by creating a broader view of what school mathematics means.

As a consequence of the introduction of the new curriculum and the reports such as the one by School Inspection, professional development in Sweden has concentrated on supporting mathematics teachers to adopt teaching practices which are less-textbook focused and require students to be more actively engaged. Although many teachers have been involved in extensive professional development of the kind advocated as best practice by mathematics education researchers (Rodgers et al., 2007), the impact on classrooms seems to be minimal. This follows a worldwide indication that changing mathematics teaching is challenging. For example, since the publications of NCTM's standards at the end of the 1980s, there has been a world-wide push to reform teacher-directed mathematics classrooms but this has met with limited success (Jacobs et al., 2006).

In trying to understand why this is the case, much research has focused on teacher change (see, for example, Clarke & Hollingsworth, 2002). There has been little research which investigates students' perspectives on reform teaching practices and whether their perspectives might contribute to the status quo remaining. One of the few studies is that of Graue and Smith's (1996), who investigated students and their parents' perceptions of reform mathematics classrooms. Graue and Smith showed that different students in the same class described the new teaching practices in various ways, almost as if they had experienced different things. There were often strong similarities between the students and their parents' stories. Graue and Smith concluded that when the students interpreted the teaching practices, they related them to their previous experiences of mathematics, some of which were shared with their parents. The students' stories also showed links between their perceptions of the reform classrooms and how they succeeded with the earlier practices. Those who considered that they were successful with the previous practices seemed averse to accepting the new teaching practices whereas those who had previously performed poorly talked more positively about the possibilities with the new practices.

THEORETICAL FRAMEWORK

There are many rules and routines that guide and frame the classroom practice (Jablonka, 2011). Without these, teaching would not be possible. Some rules are explicit, while others are unspoken and thus hidden. The hidden rules, you learn by participating in the practice. The rules are not fixed, but are changing continuously by the participants. To succeed as a student in school mathematics, it is not enough to know the mathematics thought. You must also cope with what it means to be a student in a mathematics classroom. One must be able to follow the rules of the classroom, both explicit and hidden.

To successfully reform a teaching practice means that there is a change in the prevailing teaching culture available in the mathematics classroom. Old understandings about teaching of mathematics are shattered and needs to be renegotiated in different ways. Cobb and Yackel (1996) describe the agreed rules that operate in a mathematics classroom as norms; social norms and socio-mathematical norms.

Social norms operate in all classrooms to regulate and frame the social interaction between teachers and their students. These norms are established, often implicitly, as agreements in the group, rather than by a single individual. However, individuals may have their own ideas about how the norms operate. Examples of social norms are expectations about explaining and justifying solutions, listening and trying to understand others' thoughts, etc.

In mathematics classrooms, there are ways of doing things that are specific to mathematics teaching and these Cobb and Yackel labelled socio-mathematical norms. Some examples of socio-mathematical norms are what is valued as an effective mathematical solution or what should be included in an acceptable mathematical solution. From participating in classroom practice the individual's perception are influenced by these socio-mathematical norms. The individual's perceptions will then affect the group's socio-mathematical norms.

In the examples scrutinised for this paper, Cobb and Yackel's (1996) framework provides as the analytical tool. Originally, this framework was used to analyse mathematics classroom interactions so that the taken-as-granted ways of behaving, *norms*, could be recognised and their role in determining what occurred in the classroom better understood (see, for example, Kazemi & Stipek, 2001). Cobb and Yackel found the framework had great potential for systematically structuring an examination of an otherwise complex and messy classroom. This framework therefore seemed relevant for exploring tensions between students and teachers.

DATA COLLECTION AND ANALYSIS

The data examined in this paper come from a larger study (Wester, 2015), investigating students' interpretation of their reformed classroom practice. The study was situated in a classroom where the teacher had made a major effort to change her teaching as suggested by the Swedish National Agency, defined earlier. Data from the students' perspective were gathered through semi-structured focus group interviews. These groups consisted of three or four students and were put together randomly. A round of interviews occurred during the spring semester of grade 8, the autumn semester of grade 9 and the spring semester of grade 9. The students were part of the first cohort to experience a new curriculum and a grading system which were implemented to support teacher change.

The extracts should be considered as illustrations, which exemplify how students from this classroom talked about their new teaching practice. Students' perceptions were compared with teacher's intensions. The different ways the issues were discussed were compared in order to identify tensions. These differences identified tensions operating. Three kinds of tensions occurred: *explicit tension*, *tension inside a norm* and *tension between different kinds of norms*.

Explicit tension

The explicit tensions are easy to get hold off. When discussing classroom practice, students express that they have a different opinion than the teacher about the practice in the mathematical classroom. That is an explicit tension.

The students described how they experienced the mathematics teaching had changed from previous school years. Working in textbooks was no longer seen as the obvious activity connected to a mathematics lesson. Instead, using manipulatives had become increasingly prevalent.

> Student 1: Yes, it's *very practical subject* at the moment, which I think is wrong. So those blocks and so, even drawing and so, which I think is wrong. It's really very practical. And then it's too little, there is very little with books. It's *not so much calculating in books* nowadays. And then it's very much like visualizing the numbers in front of you (2012-05-31). [*Ja, det är väldigt praktiskt ämne just nu som jag tycker är fel då. Så de med klotsar och så, även rita och så tycker jag är fel. Det är väldigt mycket praktiskt. Och sen är det för lite, det är väldigt lite med böcker. Det är inte så mycket man räknar i böcker nu för tiden. Och sen är det väldigt mycket vi ska se talet framför oss.*]

Students stated that teaching was no longer just about calculating in textbooks. The student gave examples of various practical activities. The first sentence in the quote shows explicitly that there is an explicit tension between the student's view about mathematical teaching and the new practice. The student draws on his previous experiences about mathematical teaching, working individually in textbooks (Kjellström, 2005; Skolinspektionen, 2009) to criticise the new practices. The student was not convinced about the value of a new teaching practice towards learning mathematics.

Potential tensions

The hidden tensions that are not expressed explicitly by the students are more difficult to detect. Just because students do not express tensions, do not impose they do not exist. We call these, *potential tensions*. Two kinds of potential tensions were found in the data; *potential tensions inside a norm* and *potential tensions between different kinds of norms*.

Potential tensions inside a norm

In next extracts, students discussed a task where they could use manipulatives. The task instructions were:

> Student 4: *You get to understand exactly how big a cubic decimetre is.* And you realize it can have different shapes. [*Man förstår hur stor en kubikdecimeter är. Och att den kan se ut på olika sätt.*]
>
> Student 1: It is *rather basic in the beginning*. You start with number one. Do one thing. [*Det är en rätt grundläggande början. Alltså att man börjar med ettan. Gör en sak.*]
>
> Student 2: It will take some time to cut and paste. [*Det tar ju tid också att klippa och klistra.*]
>
> Student 4: Yes. It takes a lot of time to put the whole thing together. Folding and taping. [*Ja. Det tar mycket tid att hålla ihopa den. Vika och massa tejp.*]
>
> Student 3: I think this is rather good, when you are supposed to make different shapes, to get *to know which sizes are possible* to have making a cubic decimetre. You have to understand how big or small a cubic decimetre really is (2012-12-19). [Sen är det rätt bra tycker jag när man ska börja göra olika former på dem att man lär sig *vilka mått man måste ha* för att få just en kubikdecimeter. Så man förstår hur stort eller litet en kubikdecimeter är.]

Students indicated that they knew what it was they were supposed to understand from participating in the activity; getting to visual the actual size of a shape which could hold a cubic decimetre. They also have to understand how the shape could vary. Seeing the different representations of a cubic decimetre is valued by the students, at least early in the group discussion. As the discussion continued, the interpretation of the task above changed. The given task was now discussed in relationship to its teaching context by the students.

> Student 1: That was what it was about in our *lesson before. How to do to make a correct*

calculation. How to get a cubic decimetre. All connected to this task. [*Det fick vi hela lektionen innan. Hur man skulle räkna ut det. Få fram en kubikcentimeter. Se vad det var till uppgiften.*]

Student 2: You have it all *in the textbook*. [*Och det stod ju i matteboken.*]

Student 4: Yes, but this is of course rather ... basic. [Ja men det här är ju väldigt ... grunden.]

Student 1: Actually. This task is connected to exactly what we were discussing in the lesson before. We had a whole lesson on how to calculate it. How to calculate volume of 1 cubic decimetre, and others. And the next lesson was about this task. [*Egentligen. Det här är en uppgift på det vi gick igenom på hela den lektionen. Så vi hade fått egentligen en hel lektion på hur vi skulle kunna räkna ut kubikdecimetern. Eller hur man skulle räkna ut kubikmetern, och massa sånt. Och sen efter det kom uppgiften.*]

Student 4: This task is typical at the beginning of a new chapter (2012-12-19). [*Den här uppgiften är vad man gör i början av ett område.*]

The students now connected the task to what they had done in the previous lesson, which had been about how to calculate volumes. The manipulative activity now shifted into a task about supporting to calculate volume of objects, even though calculations are not mentioned in the task instructions. Understanding the need to visualise the decimetre, discussed by the students in the first part, is now something you just need to do in order to do the calculation properly. The existing *socio-mathematical norm* expressed by the students is to be able to do the calculations (see Table 1). The students experience calculations are easier to do when they have produced representations of the different objects with manipulatives. They thus interpret the purpose of the manipulatives to support calculations and not the understanding of concept of volumes. The students´ beliefs about what school mathematics is about do not allow such an interpretation. In students´ beliefs and values, concepts have a secondary importance in relationship to mathematical procedures. Manipulatives are thus tools doing the mathematics (see Table 1).

The teacher's intentions with the specific task are not in the interviews with her. However, the teacher had expressed elsewhere how she considers manipulatives to support students´ understanding of mathematical concepts.

Teacher: I was teaching multiplication of fractions. The given task was 1/3 multiplied to 3/4. It is really handy if you know how to do it. 1/3 multiplied to 3/4 is just multiplication straight ahead and it will be 3/12. It is easy to rewrite as 1/4. That´s the way. Super easy. But I didn´t stop there. *Why does it works*? Then we used paper strips. (The teacher explained how the multiplication of fraction will be *represented* through the paper stripes). We *visualized*, made it *concrete* and explained. Yes it was not so smooth, if you compared it to the procedure (2013-02-01). [*Vi skulle köra multiplikation av bråk. Då ville jag att vi skulle titta på 1/3 gånger 3/4. Det är ju jättelätt att ställa upp ju. 1/3 gånger 3/4 är ju bara att gånga varandra. Det blir ju 3/12. Det kan man snabbt och enkelt göra om så blir det 1/4. Så gör man ju. Det var ju supersmidigt. Men så försökte jag liksom varför blir det så då? Och så tog vi pappersremsor. (Läraren förklarar hur man kan illustrera uppgiften med pappersremsor) Vi visualiserade, gjorde konkret det det var. Men det är klart lite krångligare. Det andra är bara att ta och gånger varandra.*]

In this quote, the teacher compared the learning of the procedure with explaining and understanding the concepts behind the multiplication of fractions. For the teacher the manipulatives is a tool helping students to gain mathematical understanding of concepts. Developing understanding requires more effort from the students than memorizing a procedure. As the teacher wanted to develop students' mathematical understandings, memorizing procedures was considered a contradiction to this. The *socio-mathematical norm* intended by the teacher is that mathematics is much more than calculating. School mathematics also aims to develop mathematical understanding and thinking (see Table 1).

The socio-mathematical norm suggested by the students and confirmed by the teacher, is that manipulatives are useful tools in mathematical teaching as they can represent and visualize mathematical concepts. But there is a tension in relationship to this norm. Students considered manipulatives useful as a primitive form for solving tasks, and thus less valuable than calculating. The teacher on the other hand, considered them to be a tool for gaining understandings. This is an example when both students and teacher talks about the same norm but give this norm different meaning. There is an example on a *potential tension inside a norm* (see Table 1; tension between students and teacher inside socio-mathematical norm).

Potential tension between different kinds of norms

Teacher's intentions of new socio-mathematical norms described above require a different teaching approach. The new socio-mathematical norms need supporting social norms containing teacher's role, students' role and general activity (Cobb & Yackel, 1996). The teacher wants students to be active seekers of learning through discovering and discussing while working with manipulatives in groups.

> Teacher: From there I put up different kinds of tasks that *used manipulatives*, we try to use the computers part because they actually have their own computers, *much discussion* and *group tasks* so they should learn to *communicate mathematics*, is also trying to get away so that math does not become a writing topic (2012-06-13). [*Och därifrån lägger jag upp olika sorters uppgifter med laborativa övningar, vi försöker använda datorerna en del eftersom de faktiskt har egna datorer, mycket diskussion och gruppuppgifter så dom ska lära sig att kommunicera matematik, försöker också komma ifrån så att matte inte blir ett skrivämne.*]

The students' own thinking challenged and developed through reasoning and discussion. The teacher wants *social norms* containing a student role, teacher's role and a role of activity adapted to a learning landscape (see Table 1; teacher's intensions of new social norms).

In the interviews, students easily express different ways of their new teaching practice. But they never talk about changes in their role as students or the teacher's new role. Instead they keep suggesting traditional roles to the teacher, which they believe make their learning more efficient.

> Student 3 It is better, I think, to work with exercises from the textbook instead of blocks and stuff like that. I think they are hard to learn from. Instead I *want somebody to show me how to do it. Then I have to practice on my own.* [*Det är bättre tycker jag att arbeta med uppgifter man får och inte hålla på med klossar och sådant. Jag lär mig heller ingenting utav det, utan jag vill ha någon som visar så här gör du så får jag träna själv.*]
>
> ...
>
> *Math should be something to calculate.* If you manage to do it in your head it is good. *It should not be necessary to lay it out.* (2012-06-06) [*Matte ska vara någonting du räknar ut. Tänker så blir det bra. Du ska inte behöva lägga ut det.*]

In these quotations, the student is talking about what mathematics is about (socio-mathematical norm). From their socio-mathematical norm the students suggest a supportive social norm; the role of the teacher is to show them how to calculate. Since they keep repeating the supportive social norm it could be seen as an indication of their awareness of the non established social norm.

In the same way have manipulatives has a role supposed to help students to calculate. Students believe using manipulatives is a good method if you do not know how to calculate. For instance, if you are on your way learning something new. But you are later supposed not to use manipulatives if you are able to calculate. This kind of value is an example on a socio-mathematical norm (see Table 1).

Students' suggestions of traditional social norms are heavily connected to their view of socio-mathematical norms. There is a *tension between students' view of*

	Students	*Teacher*
Socio-mathematical norms	School mathematics is about mastering calculations. Manipulatives are tools doing the math.	Math is more than calculating. School mathematics aims to develop mathematical understanding and thinking
Social norms		Creation of a learning landscape contains certain roles.

Table 1: Patterns of potential tensions

socio-mathematical norms and teachers intention of new social norms (see Table 1).

CONCLUSION

Changes in mathematics teaching from a traditional setting toward reform practices give rise to changes in social and socio-mathematical norms. However, it appeared hard for students to understand teacher's intentions of new classrooms norms. Hence a new curriculum and grading system, the change from mastering procedures to developing competences is not discerned by the students. They still believe that school mathematics is mainly about learning procedures. There is a tension between students' interpretation, and the teachers' intention of the reformed classroom practice. This teacher wanted her students to develop mathematical competences and not just learn the procedures. Nevertheless, for the students it is not yet a norm that conceptual understanding should be learned from teaching. This will affect what it is possible for students to learn from using different teaching resources. Students consider the use of manipulatives as interfering with their learning of mathematics. The resources are somehow able to do what the students are supposed to learn from activities. Thus, the students think it is better if they can do the mathematics without them. This is in contrast to the teacher, who is using these resources to support students developing mathematical thinking (Table 1, tension between socio-mathematical norm and social norm).

Students' interpretation of operating socio-mathematical norms interfere students' possibility to catch up teacher´s intention of new social norms. When students are not aware of new student roles and new teacher roles, they are hindered to participate in practise. Even if it looks like they are participating, tensions of this kind works as resistance. Without students are able to understand, there cannot be any agreement which provides new classroom's norms. This might be one explanation to limited success of reform teaching (Jacobs et al., 2006).

Understanding the inherent differences between viewing these resources as part of a social or a socio-mathematical norm, or conceptions of a socio-mathematical norm, provides an indication of why some students might resist reform teaching practices in their mathematics classroom and this will have an impact on the reality of their mathematics learning. This difference could be an explanation to why students do not learn from these resources what teachers aiming for.

Relating arithmetical techniques of proportion to geometry: The case of Indonesian textbooks

Dyana Wijayanti

University of Copenhagen, Science Education Department, Copenhagen, Denmark, dyana.wijayanti@ind.ku.dk

The purpose of this study is to investigate how textbooks introduce and treat the theme of proportion in geometry (similarity) and arithmetic (ratio and proportion), and how these themes are linked to each other in the books. To pursue this aim, we use the anthropological theory of the didactic. Considering 6 common Indonesian textbooks in use, we describe how proportion is explained and appears in examples and exercises, using an explicit reference model of the mathematical organizations of both themes. We also identify how the proportion themes of the geometry and arithmetic domains are linked. Our results show that the explanation in two domains has different approach, but basically they are mathematically related.

Keywords: Proportion, arithmetic, geometry, textbooks, Indonesia.

INTRODUCTION

Trend of fragmentation of the school curriculum makes students visit a theme after the other, but somehow the rational for visiting them or the way they are related to each other does not become clear. Chevallard (2012) defined this trend as "visiting monument" in which students are encouraged to admire and enjoy without knowing about its *raisons d'être,* now or in the past. Thus, relation among themes is necessary, particularly for an important theme such as proportion. This theme appears in many different domains, such as arithmetic and geometry. When it goes across domain, the relationship is important because it is easier to relate a theme within a domain than across domains or across grades. Making those links could help students having the experience that mathematics is a connected body of knowledge not just a collection of tricks that teachers play out to satisfy the children.

The notion of "proportional reasoning" is often used to indicate what is needed to fully operate with a variety of mathematical objects and models such as scales, probabilities, percentage, rates, trigonometry, plane geometry, linearity, fractions, etc. The so-called "missing value problems" are a common way to introduce proportion problems to the students. For example, if it requires two hours of work to make 3 puppets, how many hours are needed to make 25 puppets? Here we can find three values in the task (2, 3, and 25) and one missing value to be found. In general, proportion is considered as a relationship between quantities. More abstractly, proportion is about two n-tuples of quantities related in the same way to each other (constant ratio), for instance the ingredients in two recipes of the same cake or the sides in two similar triangles.

The mathematical notion of proportion is antique and goes back as far as to Euclid (about 300 BC). In book V, definition VI it is said that magnitudes having the same ratio are called proportional (Fitzpatrick, 2008). In book VI, Euclid also defines the geometric notion of similarity. It is also said that similar figures are those which have their corresponding angles equal and the corresponding sides about the equal angles proportional. This definition is still used in the elementary curriculum, although it adopts a more modern formulation. In particular, according to Miyakawa and Winsløw (2009), it can be said that Euclid's notion of proportion is static (about a property of given quantities) rather than dynamic (in terms of a functional relationship between variables). The dynamic definition is common in the algebraic domain which has become dominant in scholarly mathematics over the past four centuries and has been conceived in terms of linear functions between real numbers.

In the Indonesian school, the proportion theme in arithmetic is introduced as ratio equality: given four numbers a, b, c and d, the equality $(a, b) \sim (c, d)$ indicates that *a* and *b* are in the same proportion as *c* and *d*. At the beginning of the seventh grade, students start to work with missing value problems. However, proportion also appears in the geometry and statistics domain and mostly in upper secondary school, in the introduction of functions.

The fact that proportion is found not only in arithmetic, but also in geometry, makes it interesting to investigate how textbooks introduce and treat the theme of proportion in geometry (similarity) and arithmetic (ratio & proportion), and especially how these themes are linked to each other. To formulate and investigate this phenomenon with more precision, we use the anthropological theory of the didactic (ATD) by (Chevallard, 1999, 2002) in particular the notion of *praxeology*. It is not our aim to address the issue of how proportion in arithmetic and geometry should be taught in lower secondary education (in Indonesia), or how it should be treated in textbooks. However, we expect that our research into the approaches chosen in textbooks will contribute to this discussion and give it more precision.

PROBLEM BACKGROUND

The research about how teachers use resources for teaching is increasing. Gueudet and Trouche (2012) point out that documentation work where teachers interact with resources, selects them and work on them is a central in teachers' professional activity. Considering textbooks as an example of resources, this study implies that the textbooks are not only seen by teacher as a text to follow, but also it can be used as a resources for teacher learning. However, Pepin (2012) argues that it is still less clear what kind of textbooks that can help teacher learning. In her study she used tool analysis for reflection and feedback to help teachers develop further understanding and enrichment of mathematical tasks. Pepin's study inspired me to use another tool to analyse task in order to enrich teachers' point of view of quality materials for teaching.

A textbooks analysis developed by González-Martín, Giraldo, and Souto (2013) who consider the case of the introduction of real numbers in Brazilian textbooks and found an unintegrated mathematical organization as knowledge to be taught. Furthermore, Hersant (2005) conducted a historical study of how the arithmetic of proportion appears in the French compulsory education from 1884 to 1988. Based on an elaborate reference model, she demonstrated how the teaching approach is changing over time. Finally, García (2005) proposed a reference epistemological model in terms of a sequence of *praxeologies* to study linear systems and linear functions, and he used it to identify proportional relations, both in arithmetic and in the study of functions, showing a quite poor coherence between the two as they appeared in school mathematics. Our proposal to look at proportions as they are treated in the arithmetical and geometrical domain has to be considered as an extension of Hersant's and Garcia's work relying on González-Martin and colleagues' methodology.

THEORETICAL APPROACH

According to ATD, knowledge is produced, communicated, learned and used in institutions, and depends on them. The relationship between knowledge in scholarly institutions and school institutions is described using the notion of *didactic transposition* (Chevallard & Bosch, 2014). Even though our study does not aim at analysing the full transposition problem, the notion of reference model enables us to analyse specific textbook transpositions of scholarly knowledge in a wider framework, without assuming this scholarly knowledge as a universal or fixed measure.

In ATD, mathematical activity is identified into two blocks. First, there is *practical block (praxis)* which is made of the type of task and technique to solve. Second, there is *knowledge block (logos)* formed by technology and theory to explain and justify the *praxis*. We refer to Barbé, Bosch, Espinoza, and Gascón (2005) for more details on these notions. The aim of this paper (and my thesis) is to develop a textbook analysis method based on ATD.

Our analysis of textbooks mainly considers *mathematical praxeology*, but the textbook itself is also a rich resource for developing *didactic praxeology*. Specifically, textbooks contain a wealth of explicit mathematical tasks, demonstration of techniques using specific technologies, and also *theoretical discourse* which explains, relates and justifies the technologies.

Reference model

Proportion appears as themes (collections of mathematical *praxeologies* that are unified by a common technology) with different theoretical frameworks (sectors) that appear in different school mathematical domains; we consider here mainly the domains of arithmetic and geometry, while related themes appear also in other domains, especially algebra and probability. We now present parts of our reference model to analyse the two themes separately. We mainly use a categorization of techniques which are sufficient to explain *praxis* (as the types of tasks are also evident) in this model.

Proportion in the arithmetic theme is defined as follows, for pairs of numbers: $(x_1, x_2) \sim (y_1, y_2)$ if $\frac{x_1}{x_2} = \frac{y_1}{y_2}$. More generally, $(x_1, ..., x_n) \sim (y_1, ..., y_n)$ if $(x_i, x_j) \sim (y_i, y_j)$ for all $i, j = 1, ..., n$. There are three main types of task that are categorized:

T_1^{Ar}: given $(x_1, ..., x_n)$ and $(y_1, ..., y_n)$ decide if $(x_1, ..., x_n) \sim (y_1, ..., y_n)$

T_2^{Ar}: given $(x_1, ..., x_n)$ and $(y_1, ..., y_n)$ compare $\frac{x_i}{x_j}$ for $i = 1, ..., n$

T_3^{Ar}: given $(x_1, ..., x_n)$, y_1 find $y_2, ..., y_n$ so that $(x_1, ..., x_n) \sim (y_1, ..., y_n)$

The actual tasks in textbooks are usually given through the description of a daily situation, such as using scales on a map, buying and selling goods. technique that is used for T_1^{Ar} is to calculate the ratios of related terms and conclude about the proportionality. In T_2^{Ar}, the technique consists in comparing ratio of corresponding numbers or magnitudes. For T_3^{Ar}, the detail technique can be categorised as proposed by Hersant (2005). We illustrate these types of tasks with typical textbooks task:

T_1^{Ar}: The price of 2 kg rice in shop 'A' is Rp. 5.000,- and the price of 5 kg rice in shop 'B' is Rp. 12.500,- . Do both shops have the same price of rice?

T_2^{Ar}: In Bu Ina's grocery, the price of a package containing 2 kg of sugar is Rp. 9.400,-and the price of a package containing 5 kg of sugar is Rp. 22.750,-. Which package is cheaper?

T_3^{Ar}: Two students can carry 15 books. How many books can 8 students carry?

In geometry, proportion is connected to the notion of "similarity". Two polygons of the same kind (triangles, quadrilateral, etc.) are defined as similar if the corresponding angles have the same measures and the ratio of the lengths of corresponding sides are equal. Common types of tasks in the textbooks treatment of similarity include the following which are closely related to T_1^{Ar} and T_3^{Ar} respectively:

T_1^{G}: Given two polygons with the same angles and also given the side lengths of two polygons, decide if the polygons are similar.

T_3^{G}: Given similar figures with corresponding sides $(x_1, ..., x_n)$ and $(y_1, ..., y_n)$ with $x_1, ..., x_n$ and y_1 known. Find the unknown sides $y_2, ..., y_n$.

There are some textbooks examples of the types of tasks T_1^{G} and T_3^{G}, together with corresponding techniques:

T_1^{G}: One rectangle is 12 cm in length and 8 cm in width. Another rectangle is 6 cm in length and 4 cm in width. Are they the similar?

T_3^{G}: Quadrilaterals *ABCD* and *LMNO* are similar. The side of *ABCD* are 6 cm, 10 cm, 12 cm and 14 cm in length, respectively. The shortest side of *LMNO* is 9 cm. Find the length of other side of *LMNO*.

To analyse the *praxeologies* proposed in the textbooks, we will mainly use the categorization of types of tasks explained above (the basic reference model).

CONTEXT AND METHODOLOGY

Indonesia is a big country with 252 million people inhabitant. It is a big market for publishing companies and makes among them are competing with each other. Furthermore, the fact that Indonesia still lacks of teachers and some of them have a weak educational background makes them dependent on the textbooks. Thus, it is the reason why the quality of textbooks should be controlled or become a priority for the ministry of education.

The proportion theme in arithmetic (Ar) is introduced in grade 7. In Indonesian, proportion is called "perbandingan" which literally means proportion. Proportion in geometry (G) is introduced in grade 9 as "kesebangunan dan kekongruenan" (similarity and congruence). We study two themes in three different textbooks for each of the two grade levels. We refer to the textbooks as shown in Table 1 and 2.

Code	textbook title	Authors, year of publication
Ar_1	Book for studying mathematics 1	Wagiyo, Surati, and Supradiarini (2008)
Ar_2	Contextual teaching and learning mathematics	Wintarti and colleagues (2008)
Ar_3	Mathematics 1: concept and application	Nuharini and Wahyuni (2008)

Table 1: Lower secondary textbooks grade 7, analysed in this paper

Code	textbook title	Authors, year of publication
G_1	Book for studying mathematics 3	Wagiyo, Mulyono, and Susanto (2008)
G_2	Contextual teaching and learning mathematics	Sulaiman and colleagues (2008)
G_3	Easy way to learn mathematics 3	Agus (2007)

Table 2: Lower secondary textbooks grade 9, analysed in this paper

To analyze the data, we studied how the above mentioned themes in the arithmetic and geometry domain were introduced in the textbooks (that is in the main text, rather than in the collection of exercises). We considered how proportion is introduced through examples (*praxis*), with explanations of techniques and use of theoretical justifications (*logos*). This way we identified the main elements of the mathematical organization to be developed by students in both themes, according to the textbooks. Furthermore, we were also interested in how much student autonomy was foreseen in solving tasks; for this, we considered the variety of tasks that are proposed for student work (in the exercise sections of the textbook) and also their degree of similarity to examples given in the main text. Obviously, the analysis of exercises as tasks is incomplete because there are no given techniques, unlike in the working examples. Furthermore, we identified how the proportion themes in arithmetic and geometry are linked, based on the characteristics of mathematical organization and the presence or absence of explicit cross references in the text.

RESULTS AND DISCUSSION

How proportion is introduced in the arithmetic theme

We first provide some informal remarks about the theoretical structure of the relevant chapters. The title of proportion theme was different in each textbook: application of algebra (Ar_1), ratio and proportion (Ar_2), proportion and daily life arithmetic (Ar_3).

There were three subchapters in the Ar_1: 1. linear equations with one variable; 2. problem solving in daily life arithmetic; 3. proportion. Between these three subchapters we find connecting sentences such as: “we often use algebra to solve economic activity' and 'in the daily activity a lot of things correspond to proportion” (Wagiyo, Surati, & Supradiarini, 2008, p. 108 & 115). Furthermore, the authors also relate proportion to fractions with a brief sentence. In Ar_3, there were two main subchapters: daily life arithmetic and proportion, and there was no explicit connection between them. However, the authors use fractions as a tool to introduce proportion: “in the last chapter you already learned that a fraction can be considered as a proportion of two numbers” (Nuharini & Wahyuni, 2008, p. 152). In contrast to Ar_1 and Ar_3, the authors in Ar_2 did not relate proportion with linear equations and daily life arithmetics. They directly discussed a new terminology called *'ratio'* to introduce proportion. Due to the focus of research, we will only consider the proportion subchapters.

To explain what proportion is, the authors tried to avoid formal explanations. For example:

$$\frac{\text{the price of one book}}{\text{the price of fives books}} = \frac{500}{2500} = \frac{1}{5}$$

> Comparison between the amount of the books and the prices give the same numbers, so that the amount of the book and the price are proportional (Wagiyo, Surati, & Supradiarini, 2008, p. 120).

The authors used daily life situations to introduce proportion, for example, selling and buying price. Furthermore, the technologies that cover proportion in these three textbooks were very similar. For further explanation, the following table shows the number of examples in three textbooks, given to the two figures of task T_1^{Ar} and T_3^{Ar}.

Type of task	Ar_1	Ar_2	Ar_3
T_1^{Ar}	2	1	1
T_3^{Ar}	5	4	7

Table 3: Number of examples in the main text

From the table above, we noticed that the textbooks have more T_3^{Ar} than T_1^{Ar}. Also, we found a considerable number of techniques related to T_3^{Ar}. For example: reduction of unit, multiplication by ratio, proportion, graph and etc. (for further study, we refer to Hersant, 2005, techniques).

Task type T_2^{Ar} appeared in the two textbooks (Ar_1 and Ar_2), but it was only as an exercise. In the exercise section, we also found a variation of T_3^{Ar} that is symbolised as $T_3^{Ar'}$. The example of this type of task is:

> $T_3^{Ar'}$: A contractor estimates a bridge to be completed within 108 day, if it is done by 42 workers. After working 45 days, the work is stopped for 9 days for some reasons. Determine how many workers, which must be added to finish on times (Nuharini & Wahyuni, 2008, p. 159).

To solve this type of task requires considerate student autonomy. They should master in mathematics modelling before they apply technique from T_3^{Ar}.

We can point out four important observations from the discussion above: 1. proportion is located in one subchapter with a connecting sentence to the previous subchapter and there is a large variation in the titles of chapter where proportion is explained; 2. the authors tend to use informal examples (daily activity case) to introduce the notions of proportion; 3. there are two types of task that are provided by textbooks in the main texts (T_1^{Ar} and T_3^{Ar}); 4. to work with exercises, students sometimes require to develop new variations of techniques demonstrated in the main task (T_3^{Ar}).

How proportion is introduced in the geometry theme

Proportion was introduced as similarity in the geometry domain. Similarity was always explained together with congruence. Due to the focus of research, we will only consider the similarity theme. We found connecting sentences in G1 and G3 which support students to relate arithmetic techniques to geometry techniques. G1 tries to connect similarity with proportion using scale , whereas this theme is also discussed in arithmetic domain. For further explanation, see the example bellow:

> We already studied about scale in the seventh grade. Pictures that are of same scale can be found by magnification or reduction. So that scaled picture has the same proportion as the real picture. We can say that the scaled picture and real picture are similar (Wagiyo, Mulyomo, & Susanto, 2008, p. 7)

However, G3 used plane geometry to introduce similarity and there was no connecting sentence in G2.:

> We already learned about triangles, rectangles, squares, trapezoids and kites. In this chapter, we will discuss about the similarity of those figures (Agus, 2007, p. 1).

To explain similarity, the authors of three textbooks used more formal definitions such as:

> Two figures are similar if the corresponding angles have the same measure and the ratio of the leghts of corresponding side is equal (Sulaiman et al., 2008, p. 10).

We counted the number of examples of the two types of task T_1^G and T_3^G:

Type of task	G_1	G_2	G_3
T_1^G	6	3	4
T_3^G	4	1	4

Table 4: Number of examples in the main text

From Table 4, we can see that the number of T_3^G was smaller than T_1^G, because in many examples T_3^G is explicitly given that the two figures are similar. Therefore, students only need to compute the unknown side. On the other hand, student need to consider the property of similar figures to solve T_1^G. Furthermore, there is also T_4^G whereas students need to develop their own technique:

T_4^G: A rectangular frame of photographs is 40 cm × 60 cm, and a rectangular photograph is 30 cm × 40 cm. Are the frame and the photograph similar? Suppose we modify the size of the frame so that the frame and the photograph are similar. What is the size? (Sulaiman et al., 2008, p. 8).

Students need to elaborate new techniques to solve task T_4^G because they face a new type of task which is different from the example.

From the above, we can conclude four things: 1. similarity is introduced together with congruence; 2. to explain similarity, the authors use formal definitions; 3. there are two types that appear as examples in the textbooks (T_1^G and T_3^G); 4. students sometimes require autonomy to develop new variations of techniques demonstrated in the main task T_4^G in the exercise.

How the arithmetic and geometry themes are connected to each other

Based on the discussion, we can see the relation between two themes, especially the use of arithmetic techniques as a part of geometry techniques. There are two types of tasks in arithmetic (T_1^{Ar} and T_3^{Ar}) which correspond to geometry type of task (T_1^G and T_3^G).

There is a relation between arithmetic and geometry themes, but we consider it to be relatively weak. From the data, there is only one textbook (G_1) in the 9th grade which refers explicitly to 7th grade proportion. The other textbooks discuss about plane geometry (G_3) and there is not even a connecting sentence in G_2.

CONCLUSION

We have identified the main types of tasks related to proportion in the domain arithmetic and geometry as they appear in the textbooks. The introduction of proportion in arithmetic theme is more informal than for the geometric theme. For example, in arithmetic the authors use daily life activity as a tool to explain what proportion is. While in geometry, the definition of similarity is based on formal definition. However, we also found that both themes have varied types of tasks, including tasks with a considerable variety as concerns the student autonomy required: from tasks that require techniques to be reproduced from an example to main tasks that require a technique to be developed independently by the students.

We found that textbooks establish two mathematically related types of tasks in each of two themes within different domains, and found that the explicit link between these types of tasks is relatively weak. Making this link is seen explicitely by students could help them experience mathematics as connecting body knowledge. Furthermore, we point out that methodology of this study can contribute as a new approach to analyse textbooks or a new approach to choose a textbook.

Posters

Investigating the voice of two Swedish mathematics teacher guides

Linda Ahl and Tuula Koljonen

Mälardalen University, School of Education, Culture and Communication, Västerås, Sweden, linda.ahl@mdh.se

This poster presents a study on the voice of two Swedish mathematics teacher guides. We have made a content analysis of teacher guides to the two most commonly used mathematics textbooks in Swedish lower secondary school Grades 7 to 9. Our theoretical stance is that curriculum resources can support teachers pedagogical design capacity. Our analysis shows that the voice of both guides speaks through the teacher with narratives and scripted instructions, instead of making visible the strengths and weaknesses with different teaching design considerations. The results could be used to further elaborate on how the teacher guides can be designed to support the pedagogical design capacity for a range of different teachers.

Keywords: Sweden, teacher guides, voice.

RESEARCH TOPIC

Mathematics curriculum resources are teachers' most important tools in mathematics education all over the world (Fan, Zhu, & Miao, 2013). Emerging research shows potential in curriculum resources to support teachers' pedagogical design capacity (PDC), i.e., support teachers to find productive ways to adapt curriculum resources to reach instructional goals (cf. Brown, 2009; Davis & Krajcik, 2005). This poster presents one piece of a larger study where the support for the teachers in their teacher guides' is investigated. Our research question is: *What characterizes the voice of two dominating Swedish mathematics teacher guides?*

THEORETICAL FRAMEWORK AND METHOD

Davis and Krajcik draw on the work of Ball and Cohen and present five high-level guidelines for how to design educative curriculum materials, i.e., with the intention to promote teacher as well as student learning. We used these guidelines to develop an analytical tool to analyze the content of mathematics teacher guides (Hemmi, Koljonen, Hoelgaard, Ahl, & Ryve 2013). In this poster, we focus on one of five categories in that framework, namely to make the developers pedagogical judgments visible to the reader. This category is manifested by the *Voice of* the teacher guide; how the authors communicate with the teacher. They can speak either *through* the teacher or *to* the teacher. The difference in addressing the teacher by through or to is nicely explained by Remillard (2012) in the following quote:

> Despite the invisibility of the authors, curriculum resources have a voice that is manifested through the way they communicate with the teacher. Most curriculum resources place primary emphasis on what the teacher should do. I think of this as talking *through* teachers. That is, the authors communicate their intent through the actions they suggest the teacher takes. Few resources speak *to* the teacher by communicating with teachers about the central ideas in the curriculum. (p. 112)

RESEARCH RESULTS AND IMPLICATIONS

Our analysis shows that the voice of the investigated guides mostly *speaks through* the teacher as narratives and scripted instructions, and only occasionally *to the teacher* about the strengths and weaknesses with different teaching designs that could facilitate teachers to make choices and to keep their autonomy. The results could be used to further elaborate on how the teacher guides can be designed to support the PDC for a range of different teachers.

Formative assessment in Swedish mathematics classroom practice

Catarina Andersson and Erika Boström

Umeå University, Umeå Mathematics Education Research Centre, Umeå, Sweden, catarina.andersson@umu.se

Using formative assessment has woken interest in many countries because of the potential effect on student achievement. To investigate Swedish teachers' use of formative assessment in mathematics, this study used classroom observations and teacher interviews of 38 mathematics teachers. The teachers used formative assessment, but additional formative activities could support teachers to better take advantage of the potential in using formative assessment.

Keywords: Formative assessment, mathematics education.

BACKGROUND

Several studies have demonstrated that substantial learning gains are possible when teachers introduce effective formative assessment (e.g., Black & Wiliam, 1998; Hattie, 2009). Despite many reform initiatives concerning formative assessment taken in different parts of the world (Tierney, 2006) a more extensive use of formative assessment is still desirable (Cizek, 2010). To be able to estimate possible learning gains for Swedish students in mathematics, and need for additional content in teacher education and in-service training we need to know the characteristics of current Swedish mathematics teaching in relation to formative assessment.

Effective formative assessment can be conceptualized as practice based on an adherence to the fundamental idea of using evidence about student learning to adjust instruction to better meet student needs, and a competent use of the following five key strategies (Wiliam, 2010):

1) Clarifying, sharing and understanding learning intentions and criteria for success;

2) Engineering effective classroom discussions, questions, and tasks that elicit evidence of learning;

3) Providing feedback that moves learners forward;

4) Activating students as instructional resources for one and another;

5) Activating students as the owners of their own learning.

PROJECT DESCRIPTION

The study is a part of a larger research project on professional development in formative assessment in mathematics. Participants were 38 randomly selected primary and secondary school teachers. Using interviews and classroom observations, we investigated those teachers' classroom practices to answer the following research question: *How do mathematics teachers in the municipality use formative assessment in their classroom practices?* Using the framework of one fundamental idea and five key strategies in the analysis, we identified actions of the teachers that we called formative assessment activities.

RESULTS

The findings show that most teachers use 11 to 15 formative assessment activities, distributed over the five key strategies as well as the fundamental idea of formative assessment. There are only minor differences between the primary school and secondary school teachers in the extent and the ways the teachers use formative assessment. The overall picture of the mathematics teachers' current use of formative assessment shows both strengths and weaknesses. For example, the teachers adjust their instruction in several ways as a consequence of information about students' learning. However, the potential of the adjustments are not fully utilized since the teachers often collect such information rather seldom and not from the whole class. In addition, the teachers do not use questions or tasks consciously connected to specific learning intentions.

DISCUSSION

The study shows that the mathematics teachers use formative activities in their classrooms and that similarities predominates differences between the two groups of teachers. However, additional formative activities could support teachers to better take advantage of the potential in using formative assessment. For example, the teachers could use more goal-target questions and tasks that all students answer on mini whiteboards. The identified room for improvement implicates the need for formative assessment to be included in teacher education and in-service training for teachers.

Teaching trigonometry based on the meaningful learning theory and the conceptual field theory

Marjúnia Edita Zimmer Klein

Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, marjunia.klein@gmail.com

The present study sought to identify the previous knowledge a group of students possessed about trigonometry so that educational activities could be developed in order to teach, clarify and help students comprehend the related concepts. As an educator, I delved into Ausubel's and Vergnaud's theories in an attempt to help my students with conceptual and procedural difficulties to relate trigonometry to real life. Results show that identifying the students' previous knowledge and making the knowledge-in-action explicit results in a change of attitude both on the part of the student and on the part of the teacher.

Keywords: Mathematics education, high school, knowledge-in-action.

RESEARCH TOPIC

This applied study focused on the possibility of promoting learning in trigonometry by using a method based on the theory of meaningful learning and the theory of conceptual fields.

THEORETICAL FRAMEWORK AND METHOD

Ausubel and colleagues (1980) in his meaningful learning theory emphasizes the knowledge the learner possesses. According to it, teachers can identify the knowledge learners have in order to draw a map and outline a plan of how to teach them in an appropriate and significant way. Thus, meaningful learning is a process by which new information interacts with a structure of existing and specific knowledge, and as a result, there is a new piece of information, with new meaning. Vergnaud (2007) proposed a theory to provide a coherent structure and some basic principles to the study of the development of complex skills. Conceptual field is the set of situations, problems, relationships, contents, thoughts, and procedures that the learners use to give meaning to a given topic to comprehend the real world. In this realm, both theories contribute to comprehend how empirical knowledge evolves into scientific one as well as how pedagogical activities support the process. A group of students from the 2nd year high school of a private institution answered a questionnaire with 6 questions aimed at clarifying the students' prior conceptions of trigonometry. The answers helped developing educational activities about (1) the definition of the trigonometric ratios; (2) the contextualization of the trigonometric ratios for the construction of an instrument capable of measuring heights; (3) the definition of the number π; (4) the definition of the trigonometric functions in the trigonometric circumference; (5) the relationship between the congruous arches and the reduction to the first quadrant; and (6) the construction of plots for the sine, cosine and tangent functions. Right after the completion of each activity, there was a class discussion and the teacher intervened.

RESEARCH RESULTS AND IMPLICATIONS

Outcome analysis reveals that identifying the students' previous knowledge and making explicit the knowledge-in-action result in a change of attitude both on the part of the student and on the part of the teacher. The activities engaged the students, favored concentration as well as the clarification of doubts. They represented a possibility for the debate of ideas, an opportunity for reflection. Conceptual and procedural aspects of knowledge evolved from empirical knowledge into scientific knowledge.

Attitudes of teachers towards the external evaluation system for the assessment of mathematical learning

Giulia Signorini

University of Pisa, Department of Mathematics, Pisa, Italy, signorini@mail.dm.unipi.it

The external evaluation systems for the assessment of mathematical learning are increasingly widespread in the educational context, nationally and internationally. They actually affect the teachers and their teaching practices with different effects. The poster shows a qualitative research in order to explore teachers' attitudes toward the external evaluation in Italy, with particular attention to their emotions.

Keywords: Teachers' practices, assessment, affective factors.

INTRODUCTION AND THEORETICAL PERSPECTIVE

Research in mathematics education has focused its attention on teacher education rather recently: mathematics teacher education is considered "an emerging field" (Adler et al., 2005). In this emerging but growing field there has been little space for study about the teachers' attitudes towards the external evaluation systems for the assessment of mathematical learning.

In the present age, the issue of evaluation system has become central in the discussions on education and external evaluations are increasingly present in many school systems. Therefore we believe that it is crucial to give voice on this important educational issue to one of the main actors of the educational process, the teachers, collecting their beliefs, emotions and attitudes. As a matter of fact, these affective reactions seem deeply to affect the emotions of teachers, also influencing their educational choices. In this perspective we believe that understanding teachers' attitudes towards the external evaluation of students' mathematical competencies can be the first step in order to exploit at the best from a didactical point of view the important feedback that an external evaluation can return to teachers and students.

In our theoretical framework, we assume a multidimensional definition of attitude where attitude is characterized by emotions and beliefs towards the object and their mutual interactions (Di Martino & Zan, 2010).

FOCUS OF THE POSTER

Our research focuses on the Italian teachers' attitudes towards the evaluation system for the assessment of mathematical learning promoted by INVALSI (National Institute for the Assessment of the Educational and Instructional System). In the Italian context, the impression is that many teachers suffer this kind of evaluations also because they feel the external evaluations as something "ready-made", far from "real school" and imposed from above without listening to teachers' opinions. This impression is largely perceived in many unofficial occasions but not scientifically analysed in Italy until now.

To understand the range, but above all the causes of the sometimes strongly negative reactions by the Italian teachers to this external evaluation, we have planned a research in two stages. A first stage based on the elaboration of an on-line questionnaire addressed to all teachers of every school level and a second stage that foresees the development of personalized interviews to the teachers who voluntarily share their e-mail for that in the online questionnaire.

The focus of the poster will be the first stage. We will introduce the methodological choice at the basis of the development of the questionnaire and discuss the first analysis of the data collected.

Concerning the methodological choices, they are in line with recent studies about teachers' attitude (Coppola et al., 2013): the survey was voluntary and anonymous, formed mostly by open questions in order to allow everyone to choose what he feels is the most important to say, with the words he feels as the best. Regarding the analysis of the data, the research is now in its first stage but we are developing what Demazière and Dubar (2000) call *analytical* approach: the text is analyzed in order to systematically produce sense starting from people's words. The final outcome of this process is the construction of a set of categories, properties, relationships: what Glaser and Strauss (1967) call *grounded theory*. A first result is surely the participation of Italian teachers beyond any expectations: in less than 2 months, about 2 thousands of teachers have filled our open questionnaire, confirming the teachers' desire to express their view about the current external evaluation of mathematical competencies. Among the first results of the data analysis, we have seen the differences between teachers' attitudes according to the school level, but also some different motives that origin a negative attitude toward the external evaluation.

CONTENT OF THE POSTER

The poster was divided in two sections: in the first we illustrated the argument, the conceptual framework and the methodological choices at the basis of the development of the used questionnaire; the second section was focused on the conducted analysis, providing the first results of the data analysis.

Formative assessment: Teacher knowledge and skills to make it happen

Charlotta Vingsle

Umeå University, Umeå Mathematics Education Research Centre, Umeå, Sweden, charlotta.vingsle@umu.se

The study investigates a teacher's use of activities, knowledge and skills when conducting formative assessment during interaction in whole-class. This formative assessment practice includes eliciting information about student learning, interpreting the responses, and modifying teaching and learning activities based on elicited information. Results show that the teacher used activities that help students to engage in common learning activities and take co-responsibility for their learning. Furthermore, while orchestrating the activities the teacher used knowledge and skills that are complex, demanding and difficult.

Key words: Formative assessment, teacher knowledge, mathematics.

BACKGROUND

Several studies have demonstrated that substantial learning gains are possible when teachers use formative assessment in their classroom practice (Black & Wiliam, 1998; Hattie, 2009). At the heart of most definitions of formative assessment lies the idea of collecting evidence of students' thinking and learning, and based on this information modifying teaching to better meet students' learning needs. Such regulation of learning processes would require skills to elicit the thinking underlying students' oral and written responses, and the capacity to make suitable instructional decisions based on this thinking. Sufficient knowledge about the character and use of mathematics teachers' knowledge and skills when practicing formative assessment is lacking (Heritage, Kim, Vendlinski, & Herman, 2009). The aim of this study is to identify activities, and characterize the knowledge and skills, that a teacher of mathematics uses in her formative assessment practice during whole-class lessons. The definition of formative assessment by Wiliam (2010) was used as analytic tool to identify the formative activities. A framework based on Shulman (1986), and Ball, Thames and Phelps (2008) was used to characterize the knowledge and skills used by the teacher.

METHOD

The study is a case study of a teacher's formative assessment practice during mathematics lessons in year 5. This teacher is one of 23 teachers that participated in a professional development program in formative assessment during spring 2010. The students of these teachers significantly outperformed a control group at a distal post-test in the end of the school year compared with a pre-test in the beginning of the same school year (Andersson, Vingsle, & Palm, 2013). The lessons in mathematics was observed and audio-recorded for 2 months. In the study a number of examples of situations involving formative assessment have been analysed. The situations were chosen from interactive whole-class lessons from three different time cycles. The examples represent situations where the teacher elicits information of student thinking and learning in different ways.

RESULTS AND CONCLUSION

The main result of the study shows that the formative assessment practice is a very complex, demanding and difficult task for the teacher in several ways. For example, during short-cycle minute-by-minute formative assessment practice the teacher used knowledge and skills to elicit, interpret and use the elicited information to modify instruction to better meet student learning needs. In the minute-by-minute formative assessment practice the teacher handled new mathematics (to her), unpredictable situations and made decisions about teaching and learning situations in a matter of seconds. In addition, she also helped students' to engage in common learning activities and to take co-responsibility of their learning. Specialized content knowledge and Knowledge of students and teaching where the most useful characters of teacher knowledge used when the teacher searched to understand students' answer and to formulate questions based on incorrect answers.

Distinct mathematics teaching practices: Patterns of argumentation

Jana Zalska and Veronika Tumova

Charles University in Prague, Faculty of Education, Prague, Czech Republic, jana.zalska@pedf.cuni.cz, veronika.tumova@pedf.cuni.cz

This analysis of several mathematics lessons in two teachers' classrooms looks for characteristic patterns of argumentation and justification, specifically at the presence and types of warrants required, provided, and accepted – in the social environment of the classrooms – for mathematical claims. A question is posed whether these could be useful as descriptors of distinct justification-related teaching practices.

Keywords: Argumentation, teaching practices, middle school, warrant types, participation.

THEORETICAL FRAMEWORK AND RELATED RESEARCH

The process of mathematical argumentation, explanation and justification in mathematics education has long been an important subject of study. Toulmin (1969) proposes a framework of analysis for arguments in general, and his model of argumentation has been successfully adopted, adapted and accepted as a useful tool in analysis of qualities of (students') mathematical argumentation itself as well as of the collective learning experiences in a classroom (e.g., Yackel, 2002; Rasmussen & Stephan, 2008; Krummheuer, 1995, 2007; Tabach, Hershkowitz, Rasmussen, & Dreyfus, 2014), helping to shed light on students' learning in a social context.

Yackel (2002) points out two different roles that teachers play in collective argumentation (in an inquiry-oriented environment): that of using it as a means to start introducing new concepts and that of carefully supplementing either data, warrants or backings for claims that would otherwise not be explicit to all students, and/or that help students make connections between mathematical concepts.

Krummheuer (2007) analyses argumentation in a mathematics classroom and adds the criteria of participation. He is then able to reconstruct "different grades of autonomy according to the interactional contribution of a student" (p. 60) as well as his status as a participant in the argumentation process.

Our own study also looks at the use of argumentation and justification in a mathematical classroom as a whole, i.e. a closed learning community, but through the lenses of two teachers' distinct beliefs and their respective teaching practices.

THE METHOD

Data were collected from two different classrooms: a cycle of teacher interview-lesson observation-interview was conducted for a sequence of 5 lessons in two lower-secondary classrooms with different teachers (the lessons were about percentage in one classroom and operations on fractions in another). The two teachers were selected as professing distinct beliefs about mathematics teaching and learning, one characteristically leaning towards an inquiry-based conception of the norms for mathematics teaching and learning (as described in Yackel, 2002).

Data collected from observations (transcripts of collective interaction) were analysed for episodes involving the justification of mathematical claims. Cases of argumentations were further characterized using Toulmin's model (especially for data, warrants, and backing) and analysis of participation on warrants and backing.

RESULTS AND IMPLICATIONS

While pupils' participation in providing warrants was proportionally similar in both classrooms, the differences that emerged concerned especially the types (forms) of warrants. Those varied more in the inquiry-oriented classroom, while argumentation in the other classroom was typically centred around procedures. There is evidence that backing for warrant forms and relevance (although not always correctness), is provided by the teacher in both classrooms. These results show that patterns of argumentation are partly useful as descriptors of a teacher's practice, however, more investigation is necessary in the connection between teacher's beliefs about the role of argumentation and the socio-mathematical norms of argumentation as well as the impact of mathematical tasks on argumentation patterns in a particular classroom.

TWG20

Mathematics teacher knowledge, beliefs, and identity

Introduction to the papers of TWG20: Mathematics teacher knowledge, beliefs, and identity: Some reflections on the current state of the art

Miguel Ribeiro[1], Fatma Aslan-Tutak[2], Charalambos Charalambous[3] and Julia Meinke[4]

3 University of Cyprus, Nicosia, Cyprus

4 Georg-August University of Göttingen, Göttingen, Germany

In this introductory chapter for the Thematic Working Group "Mathematics teacher knowledge, beliefs, and identity" (TWG20) at CERME9, we address the main issues discussed during our working sessions. We aim to provide a critical and broader view on the work being done, including the work undertaken at previous conferences, although not extensively. We also seek to take a new look at areas of potential improvement with regard to the focus of, discussion about, and problems inherent to research in the area of teacher knowledge, beliefs and identity, all with the goal of improving teacher education and practices. This paper brings to the forefront some critical features of this area of research and aims to contribute to the genesis of a new focus on our research and a new vision of our own roles as researchers and teacher educators.

Keywords: Teachers' knowledge, beliefs, identity, teacher practices.

INTRODUCTION

In considering possible theoretical and analytical perspectives with regard to teacher *knowledge, beliefs,* and *identity*, a long list emerges that includes different aspects and foci. Even so, having a TWG dedicated exclusively to these areas allows the simultaneous amplification and synthesis of such a list—both in depth and on a broader scale—in terms of theoretical and analytical approaches, as well as the goals of the research presented.

A broader and deeper view of the multitude of possible perspectives on teacher *knowledge, beliefs,* and *identity* is facilitated by an in-depth discussion of, and reflection on, different contexts, such as the variety of knowledge frameworks and conceptualizations among different teachers, evaluating versus understanding teacher knowledge, belief changes, and the existence of a mathematics teacher identity and its content. Focusing on the content and on the aims of such a multitude of approaches to these three areas, gives a deeper awareness of possible potentialities and misunderstandings within the area of mathematics education. The existence of a multiplicity of ways to perceive the same aspect is in itself a potential area for improving research (and education), and should also be a focus in order to better understand each of the three factors addressed in the TWG. The misunderstandings come, for example, from the different contexts and cultural heritage of the researchers themselves, which leads to the use of different interpretations of a notion (e.g., teacher knowledge) being linked with the aims of the research itself (e.g., understanding versus evaluating teacher knowledge). Examples are the discussions presented by Kuntze, Dreher, and Friesen (2015); Vasco, Climent, Escudero-Ávila and colleagues (2015); and Pizarro, Gorgorió, and Albarracín (2015) around teacher knowledge in different contexts and using different theoretical and analytical approaches. Overcoming such misunderstandings allows a broader view of the landscape, leading to a better understanding of where we are coming from and where we envisage going in the future. Obviously, diverse paths can be taken, and we consider this beneficial; but the different ways such approaches can contribute to the end goal should always be explicitly considered.

The creation of a unified understanding of the work being developed around the three focuses of the TWG requires evidence of how the multiplicity of theoretical and analytical approaches might contribute to the ultimate end point — the (student) teachers' learning. Knowing where we are heading — as well as where we are coming from —, this introduction will present and reflect upon the core aspects discussed in the TWG, expanding upon the content of the papers included in the proceedings and the already developed work. We note that although theoretical and analytical perspectives are perceived as intertwined, and thus incapable of being considered as two disjointed sets, we opted to deal with them in separate sections for operational purposes. In doing so, we advocate the need for more careful attention to the importance of attending to different perspectives and the roles they can play in research (process, findings, recommendations, and implications). Additionally, the large predominance of current research focusing on teacher knowledge also influenced the discussions we elaborate on here.

With this introductory chapter, the work developed in the TWG (focus upon problematic and core aspects of/for discussion when working in the area of teacher *knowledge, beliefs,* and *identity*) is discussed with some clarifications, and we call attention to the need for a further step forward in research in this area and its impact on education. We will also discuss the possible structure of future research.

SOME CORE THEORETICAL ASPECTS

When looking at the theme of our TWG, three areas of study are considered to deeply influence teacher practices: *knowledge*, *beliefs,* and *identity*. These can be considered as the core of a teacher's practices, with each area influencing and being influenced by the others (Ribeiro & Carrillo, 2011a). In doing so, our aim was to shed some light on the paths that still need to be devised to allow for a better understanding of teachers' *beliefs, identity,* and *knowledge*.

Beliefs

When teachers became a focus of research, one of the first attributes studied was their beliefs (e.g., Pajares, 1992), along with the inconsistencies that could be found between discourse and practice. Afterwards, the interest shifted to the ways teachers change their beliefs, leading in turn to a change in their teaching methods and awareness of their own practices—all influenced by their own experiences as students (e.g., Ebbelind, 2015; Sayers, 2013). Going a step further, another relevant point addressed was the development of teacher awareness about how and why they teach what they teach (e.g., Schueler, Roesken-Winter, Weißenrieder et al., 2015), making this transparent through the analysis of beliefs and thus making change possible.

Although a large amount of research has focused on beliefs and their manifestations in teacher actions, questions, or answers (e.g., Ribeiro & Carrillo, 2011b; Sayers, 2013), it is important to consider in conjunction with this the competencies and practices of teachers. Although beliefs have been a focus of research for a long time, there remains a lack of information leading to better and deeper understandings of the role, impact, and connection between teacher beliefs and the remaining core aspects of mathematics teacher practices (e.g., Potari, Berg, Charalambous et al., 2013) in order to improve student learning, understanding, and results. When addressing research being done on teacher beliefs (as well as their *knowledge* and *identity*), a core aspect of discussion in the TWG was the need to re-emphasize the human aspect of mathematics in the classroom—humanizing without de-mathematizing. Such foci would bring mathematics to the front, and is one of the core ways to bring more consistency (both internal and external) to the area, eradicating the question "Where is the mathematics in this mathematics education research?".

Identity

In researching identity, the particular aspects focused on within this multifaceted notion must be made explicit. In particular, the transformations involved in moving from student to teacher have to be taken into consideration. And, in an intertwined manner, the changes that occur over time in teacher practices, goals, and levels of awareness must also be examined, especially because some authors argue this leads to the development of a teacher identity (e.g., Adler, Ball, Krainer, Lin, & Novotná, 2005). Assuming the existence of such an identity, research on its development must consider the need to move from dealing with mathematics as a scientific discipline (as it is traditionally presented at university) to understanding it as primary and secondary school mathematics and the diversity of processes involved; or, in other words, teacher professional development as a learning process. In that process, the concept of teaching and its dynamic nature plays an essential role in the development of a mathematics teacher's identity (e.g., Rø, 2015). Thus, when attempting to contribute to the study of teacher identity development as a learning process, our own practices and knowledge as educators should also be examined (e.g., Mellone, Jakobsen, & Ribeiro, 2015; Superfine & Lin, 2014) in order to allow for placing the scientific discipline into a primary and secondary school context. Such inquiry can lead to an expansion of the notion of awareness as perceived by Mason (2002), taking into consideration the possible focus on differences and similarities between the identity of mathematics teachers and those of teachers of other disciplines. It is of special importance to consider the specificity of the content being taught and how that influences teacher identity, particularly when a teacher must teach several disciplines, as is often the case for elementary school teachers. This once more brings mathematics and its specificities in and for teaching to the front.

When thinking in terms of mathematics teacher identities, and considering research as a way of making us stop and think (Kilpatrick, 1981), some questions naturally emerged during discussion and reflection in the TWG. Some of these discussions and reflections are concerned whether identity is a self-concept, leading to a broader question about the concept of identity itself, particularly what identity is and what comprises it[1], as well as its dynamic versus static nature. Taking a broader view of our own practices as teacher educators and researchers (as if looking at our own work from a distance), the need is evident to address the importance and helpfulness of the concept of identity(ies), clarifying its content as well as its developmental process(es).

Knowledge

Research of teacher knowledge began, and in some cases remains, in the domain of identifying lack of knowledge—assuming a deficit. In order to overcome such a deficit perspective and, further, contribute to the creation of improved education (Potari et al., 2013), research should be done that works with teachers to develop and expand upon what they already know. Although the papers in the TWG mainly adopted this perspective, it is clearly one area where research, and a rethinking of the foci of such research, is still most needed. Thus, a step forward is still required when rethinking the foci to lead away from the deficit perspective and toward an understanding of what teachers know and how they know it (nature and type) (e.g., Fauskanger & Mosvold, 2015; Montes & Carrillo, 2015). This can then lead to the development of practices that enrich the levels of awareness and connections that contribute to improved education and, ultimately, practice. Bridging theory and practice is essential for such improvement, and core to building such bridges is defining the nature and goals of proposed tasks (e.g., Jakobsen, Ribeiro, & Mellone, 2014; Tirosh & Wood, 2008) for enhancing teacher acquisition of ideal knowledge that would allow them to foster fruitful mathematical understanding in their students.

A large number of teacher knowledge conceptualizations—visible in the different papers of this chapter—are grounded in Shulman's (1986) seminal work. The discussed conceptualizations also assume the Subject Matter Knowledge (SMK) and Pedagogical Content Knowledge (PCK) domains, but with different interpretations of its content. Such interpretations associated with the devised focus of attention lead the research being done in different directions. Examples of such are the Mathematical Knowledge for Teaching (MKT) (Ball, Thames, & Phelps, 2008); the Mathematics Teachers' Specialized Knowledge (MTSK) (Carrillo, Climent, Contreras, & Muñoz-Catalán, 2013), the Knowledge Quartet (KQ) (Rowland, Huckstep, & Thwaites, 2005) and the multi-layer model presented by Kuntze (2012). The use and development of such diverse conceptualizations can be perceived from one side as a richness of the field, and from another side as a constraint when discussing the core aspects of teacher knowledge. Such diversity contributes to enriching views on the content and factors that influence the development of teacher knowledge, contributing scaffolding for the necessary bridges to improving student results. But they can also be problematic from the viewpoint of the language used —the same wording with different meanings (Bardelle, 2010) — making it difficult to find a common ground when discussing the core aspects of teacher knowledge.

1 This same question can be asked concerning knowledge and many other concepts we work with and sometimes take for granted. Indeed, in a TWG focusing on teachers, this was one of the problems discussed (see part of the proceeding with TWG18 papers).

Although the conceptualizations of teacher knowledge have different points of views and foci, as well as different elements at their cores, what they all have in common is considering teacher knowledge as too complex to be examined on its own, as well as the impossibility of considering the different subdomains in an isolated manner. In that sense, the existences of subdomains are justified for analytical reasons — facilitating description and a deep understanding of teacher knowledge and practices. The subdomains are also considered to be a core element for devising and conceptualizing teacher education tasks that are focused on improving teacher knowledge and awareness (Jakobsen et al., 2014).

The existence of such a diversity of concepts of teacher knowledge, as well as the diversity of dimensions as core elements, is one of the reasons for the continued lack of consensus on what comprises ideal knowledge. In the TWG discussions, such lack of consensus led to reflection and research on a number of topics. These included the advantages and disadvantages of considering different subdomains in teacher knowledge conceptualizations (subdomains versus global knowledge); whether or not there is a need to measure teacher knowledge, and if so, how to best do so (effectiveness of instruments designed and the nature of the knowledge measured); the nature of the claims the researcher makes about teacher knowledge and the learning outcomes with such a foci of analysis (e.g., deficit, descriptive, understanding, measurement perspective); and the potentialities and constraints of each conceptualization in and for analyzing teacher practices.

SOME CORE ANALYTICAL AND CONTEXTUALIZED ASPECTS

In practice, the theoretical aspects focused on cannot and should not be taken separately from the analytical approaches considered. In that sense, in accordance with the different theoretical perspectives explored in this chapter's papers, a diversity of analytical approaches was used. Such diversity was linked not only to the different frameworks considered, but also to the specific aim of the particular research. In this section, rather than discussing the type and nature of the analytical approaches used in the papers (e.g., different nature of the case studies – what concerns the cases; different foci of analysis and instruments used; the nature of the research aim – evaluate or understand knowledge/practices, contribute for change, understand awareness), we will address and reflect upon some of the more crucial aspects that emerged when discussing research focused on teacher *knowledge*, *beliefs,* and *identity*, including sharing the processes and results.

One of the most pertinent topics is the content of analytical and contextualized aspects, commonly termed methods or methodology. On the one hand, this section should include the description, justification, and explanation of the methods used in the research (with or without an example of how they were used). On the other hand, it should also include other contextualized information that would allow the reader to better understand the hows and whys of the decisions made and the specific context in which these were made (minimizing misunderstandings). Although this has already been a topic of discussion in previous conferences (e.g., Potari et al., 2013), it still remains an underinvestigated area. In that sense, there are some essential, though often unmentioned, aspects needing to be addressed and taken into account when thinking and writing about analytical and contextualization options. Among these, we can consider aspects from (i) why a certain analytical process was chosen over any other, (ii) the particularities of the method used (e.g., taking into consideration the theoretical perspective used or developed), and (iii) the different analyses done (e.g., qualitative, quantitative, particular case study, or going beyond the particular case study).

With regard to (i), the reasons for selecting a certain analytical process must be made explicit, including not only justification for the process chosen, but also factors that led to the exclusion of other approaches. This allows for building common ground. Some of the aspects to take into account are the minimal requirements for writing about the analysis and results obtained so others effectively understand them and the degree of detail needed for describing the context, assumptions, and each theoretical perspective.

For (ii), the particularities of the specific analytical processes used and the implications of a descriptive versus analytical approach must be made clear. Such particularities and implications are linked with the potential for, or limitation of, work being done to impact education and steer toward a change in teacher *beliefs* and *knowledge*, allowing the development of teacher *identity*, and thus its impact in practice. See, for example, Ferreira and Ponte (2015) for teacher learning after a teaching experience or Zoitsakos, Zachariades, and Sakonidis (2015) for teacher difficulties in conceptualizing and suggesting mathematically correct instructional practices for an issue at hand. With regard to different subdomains in teacher knowledge, the subdimensions one might encounter and their impact (potentialities and limitations) on research, as well as for education and practice, must be taken into consideration. For example, what impact would they have in the elaboration of mathematics teacher identities? How can they be used as a resource to conceptualize tasks for teacher education? How can they refine the theoretical concept assumed? Keeping these questions in mind would contribute to an awareness of the need for developing further both theoretical and/or analytical methods used as well as ways to bridge research and practice, explicitly fulfilling the already identified gap concerning the need for clarification of the context and analytical procedures.

Concerning the different focus and processes of analysis (iii), and its impact on future research and knowledge generated, at least two perspectives must be kept in mind. One is how to feed back the research findings to inform the theoretical and analytical framework(s) used/developed. The other concerns a focus on what aspects can be brought into the discussion in order to go a step beyond merely describing the particulars of the situation(s) under study. When aiming at taking a step forward through the research to have a more effective impact on education, practice, and ultimately on student learning and understanding (e.g., Ebbelind, 2015), the previously mentioned two components need to be assumed in an intertwined manner. Considering the need for such an intertwined approach leads to reinforcing the connections and filling the gaps between such dimensions. Such reinforcement, and the associated step forward, seem to be crucial to clarifying the role, impact, and importance of case studies and large qualitative studies in improving education and promoting a deeper understanding of what seems to happen, and why, in the context of each study.

Thus, a need exists to clarify the choices made in research, keeping in mind the requirement of a balanced way of doing so, considering the broad range of research foci and analytical processes—all while also being aware of the different information required and the results obtained.

CONCERNS, POSSIBILITIES, AND FUTURE NEEDS

There is a diversity of theoretical and analytical approaches in the chapter's papers associated with different contexts and research aims. In this introductory paper, our aim was not merely to address the issues discussed during the working sessions. Rather, starting from these and thinking backward, our foremost concern was the possible horizons we could envisage moving toward at that time. With such an approach, we hope to lead the reader to think and reflect on the role of the diversity, depth, lenses, and aims associated with each of these studies. In doing so, we ultimately hope to contribute to thinking outside of the box in order to break the chains that constrain us, which ultimately restrict the effective potential of the work being developed.

During the TWG discussion of the papers and possible content and structure for this introductory chapter, a lot of questions for future research emerged. This provides evidence of the need for more focused attention to the what, how, and why of what we do, leading to envisioning potential impacts of the work with teachers and students to foster a more literate and numerate society globally. In that sense, addressing the different aspects and foci of needs (theoretical, analytical, and of context) is essential in order to allow a broader impact on the work of teaching (rather than merely remaining with particular successful cases). Such needs are of a diverse nature and associated with different aims, and therefore are associated with different target groups. When analyzing the papers and the questions raised from its discussion (e.g., the need for emphasizing teacher potential rather than deficiencies; bringing teachers and the mathematical content to the front; attending to teacher voices in the research being done — see, for example, Takker, 2015; Toor & Mgombelo, 2015) reflection on the researcher's role in the research and education process arises. There is thus the need for rethinking our own role—our own beliefs, knowledge, and identity — in the research being developed. Have they influenced the choices made and, necessarily, the path followed and results presented? We must consider ourselves and the work we develop not only as part of the possible solution to the problems addressed, but also as part of the challenges.

Possible points of focus for future research can be, for example: (a) having a profound understanding of a specific mathematical content (its meaning — core aspects of its content, ways to measure/develop it, analytical approaches and its implications); (b) connect the mathematical content knowledge (e.g., university mathematics) to the mathematical knowledge in primary and secondary school (changes and impact on teacher education — including their educators); (c) meaningful communication among communities with different professional identities (communicate findings to practitioners and policy makers to steer change); (d) development of theoretical and analytical tools to break some of the chains that constrain us (leave the known space of solutions and bring novelty to theoretical and methodological aspects, both as objects of and for research).

Having an open mind, developing an awareness (Mason, 2002) to pay attention to granular aspects, and making connections to better perceive and understand the big picture allows us to take a further step toward freeing research from the description and interpretations of particular cases (even when quantitative research is considered).

Systemic Functional Linguistics as a methodological tool when researching Patterns of Participation

Andreas Ebbelind

Linnaeus University, Department of Mathematics Education, Kalmar, Sweden, andreas.ebbelind@lnu.se

This study highlights the role, if any, that teacher education programmes and experiences from other practices play in influencing generalist student teachers' tales of themselves as emergent primary mathematics teachers. The conceptual framework Patterns of Participation, PoP, is used when theorising and interpreting student teachers' becoming, and analysing the processual and dynamic character of immediate social interaction related to practice on a macro level. Therefore, this paper evaluates whether Systemic Functional Linguistics, SFL, can be a methodological tool used on the micro level. This paper shows that SFL structures the data in a way that makes interpretations through PoP possible.

Keywords: Methodology, Patterns of Participation, Systemic Functional Linguistics, teacher education, student teachers.

INTRODUCTION

Methodology can be understood as methods used for gathering information and the specific reasons for using such methods. Furthermore, methodology should concern aspects of how gathered information is transformed into data and why the transformed data are relevant in relation to a framework (Skott, 2014). The process of transforming gathered information into data is done in steps. Gathered information needs to be structured. Structured information is used when generating data. The generated data is then interpreted by using a conceptual framework. This means that there is a relationship between methodology and theory (Gee, 2014). This paper focuses on the first step of this transformation, the choice of methodological tool in relation to a conceptual framework, and on how this methodological tool is used for structuring information on a micro level in a study concerning student teachers at the primary level. Microanalysis allows access to finer details of gathered information (Jarowski & Potari, 2009), in this case highlighting the functionality of language.

In this study, concerning primary student teachers, the overall aim is to contribute insights about the role, if any, that teacher education programmes and experiences from other relevant past, present and future practices play in influencing generalist student teachers' tales of themselves as emergent primary mathematics teachers. Tales refer to stories teachers tell about themselves and can imply more creative or imaginative storytelling. Other relevant practices include those related to the teaching and learning of school mathematics, but they may also be non-mathematical and not institutionalised. Furthermore this study seeks to understand how these different practices and experiences are related, if at all, to each other.

This means that the methodological tool needs to disentangle elements of teacher education and relevant practices in relation to different entities, experiences related to these elements of teacher education and relevant practices, the tense in which these experiences are described, what role these experiences play in terms of degree of certainty and the relationship between these different practices. This interest draws on the highlighted concern that primary generalist teachers within their first years in the profession may not prioritise, or may have no opportunity to prioritise, the subject of mathematics itself (Palmer, 2013).

Emergent student teachers at the primary school level are typically generalists, expected to teach a range of different subjects in the future. Consequently, their level of education in each of the school subjects is modest, and their professional background is less linked to the teaching of specific subjects than to the profession as a whole. In Sweden, for instance, the combined course in mathematics and mathematics education for primary school student teachers is a 30 ECTS point course in the four-year teacher education programme (240 ECTS).

Recently, there has been extensive interest in student teachers' image of teaching mathematics, their knowledge gained during teacher education and how their image of themselves as teachers evolves in relation to practice. Standard procedures for assessing these have involved research about student teachers' beliefs, mathematical knowledge for teaching, and identity (Skott, 2013). The first two research fields have generally interpreted human behaviour as something enacted within a person and it is generally explained by acquisitionist research perspectives. The last research field has generally interpreted human behaviour as situated in practice and explains it using participatory research perspectives (Sfard, 2008).

However, in all three research perspectives attention to student teachers themselves as the unit of analysis has decreased over the years. The main focus is not on the student teacher. Instead, the focus is on, for example, the domain-specific beliefs, the knowledge needed for practice and the specific community of practice. In contrast, this study intends to focus on the student teacher as the unit of analysis and therefore uses the PoP framework. This is because PoP intends to describe the pre-reified processes that are said to precede the so-called construction of beliefs, knowledge and identity (Skott, 2013) and, above all, PoP places the student teacher at the centre of the analysis (Skott, 2014).

PATTERNS OF PARTICIPATION

When theorising and interpreting the role that teacher education programmes and experience from other relevant past, present and future practices play in influencing generalist student teachers' tales of themselves as emergent primary mathematics teachers, the conceptual framework Patterns of Participation, PoP (Skott, 2013) is used. PoP "seeks to understand how a [student] teacher's interpretations of and contributions to immediate social interaction relate dynamically to her prior engagement in a range of other social practices" (Skott, 2013, p. 549). Lerman (2013) highlights the need for frameworks that emphasise emergence and regards PoP as such a framework. He implies that Skott, through the PoP framework, tries to go beyond the demarcation of the acquisitionist and participatory perspectives.

PoP provides the researcher with thinking tools (Gee, 2014) to use when planning and designing a study, and also when interpreting the patterns in the immediate emerging social practice on a macro level. The conceptual framework is therefore used to go beyond the micro level in order to focus on the social practice and situation (Jarowski & Potari, 2009). PoP draws on two main theoretical sources, symbolic interactionism and social practice theory. Symbolic interactionism views humans as actors and reactors in situations, and it positions meaning as something that one engages in when experiencing things in the situation. Humans respond to the situation by interacting with others and with the self, and by taking the role of others (Prus, 1996). In social practice theory, student teachers' identity formation and learning results from shifting participation in relevant practices (Skott, 2013). Identity is viewed as imaginings of selves expressed in actions and created in immediate social interaction. Identities develop and are expressed in social practice (Holland, Skinner, Lachicotte, & Cain, 1998).

PoP focuses on immediate emerging social interaction. Immediate social interaction is concerned with the relationship between a social practice and a text produced within it. A text is considered any instance of language used as part of a situation. The situation is regarded as the "environment in which meanings are being exchanged" (Halliday & Hasan, 1989, p. 12). Individuals' interpretations of the situation emerge as they interact symbolically in past, present and future practices (Skott, 2013), intra-personally as well as inter-personally (Sfard, 2008), and this interaction contributes to the production of texts (Halliday & Hasan, 1989). This means that every situation is unique and the gathered information is situated in time and place.

Skott (2013) and Palmer (2013) use a qualitative approach inspired by grounded theory to disentangle prior engagement in immediate social interaction. Inspired by social semiotics, this study turns the disentangling of immediate social interaction in a different direction, that of linguistics (Ebbelind & Segerby, 2015). It does so for several reasons, for example, to focus the analysis on the functions of language while highlighting the uniqueness of the situation, and to incorporate a systemic way of structuring the gathered information on a micro level that specifically focuses on the text itself while highlighting the relations between different experiences in terms of language as functional.

To conclude, PoP has an interpretive stance that implies that human behaviour is different from objects that can be measured statistically. An interpretive stance also implies that there is no intention, in this study, to discuss cause and effect through different variables in relation to teacher education. However, questions of validity and trustworthiness need to be addressed. According to Gee (2014) and Skott (2014), validity in this kind of social research concerns the relation between theory and methodology, how they work together. This recognises that the macro level includes the micro level (Jarowski & Potari, 2009).

Therefore, the specific aim with this paper is to evaluate whether Halliday's Systemic Functional Linguistics, SFL (Halliday & Hasan, 1989) can be a proper methodological tool for disentangling the information gathered for this study. The reason for exploring SFL is that SFL is suggested and regarded as a powerful tool for visualising context in text (Herbel-Eisenmann & Otten, 2011; Morgan, 2006). To explore SFL, a short transcript will be analysed with this tool and then related to PoP in the discussion.

METHODOLOGY

The present study adopted a theory driven, multi-sited ethnographic approach. It involved three student teachers and followed them before, during and after different situations such as lectures, seminars, internships, study groups and examination work related to mathematics education.

The study was theory driven (Walford, 2009) because PoP (Skott, 2013) guided the choices made during the ongoing project. The study was multi-sited because the mode of construction was not a single site; instead, the mode of construction was a process, the emergent generalist teacher, that took place in multiple sites (Pierides, 2010). The ethnographic approach implies the use of multiple methods for gathering information, including field notes, interviews and the collection of other text material. The reason for using multiple methods is based on the assumption that different types of material contribute different types of information.

The gathered information needed to be structured in relation to the aim and conceptual framework. For this purpose SFL was used. Among research that has been conducted internationally in mathematics education studying the role of language, Morgan's (2006) use of SFL to visualise experience in school mathematical assessments is the most well known. Another example is Herbel-Eisenmann and Otten (2011), who set out to reveal mathematical meaning potentials construed in discourse and used SFL to visualise semantic structures of mathematical content. SFL views language as a resource that people use to accomplish specific purposes through the functions of language (Halliday & Hasan, 1989). The functions can be analysed at the clause level to understand how contexts are reflected in the linguistic choices that participants make in their text production.

Systemic Functional Linguistics

SFL states that every speech act is about something (ideational meta-function), is addressed to someone (interpersonal meta-function), and is presented and connected in a specific way (textual meta-function).

The ideational meta-function relates to the main verb and concerns how actions or experiences are articulated through the transitivity system. The transivity system illustrates how actors are connected to actions or objects (Halliday & Hasan, 1989). The main verb can either be a material process, in which there is an actor that does something; a mental process, where a senser is addressing a phenomenon; a verbal process, expressing something that has been said; or a relational processes, emphasising relations between objects.

The interpersonal meta-function relates to voice, tense and modality. Voice highlights the personal pronoun and entities visible in the text. Tense highlights whether the proposition is valid for the present, past or future. Modality relates to the degree of certainty in an utterance. This function answers the questions: What persons and entities are visible in the text and how are persons and entities connected to the text?

Finally, the context and language structures used to carry the meanings of the text are components of the textual meta-function. This function concerns the process of structuring the way information is conveyed. By looking at the theme and rheme one can view how clauses follow each other in thematic bindings. When several of these thematic bindings occur, a lexical chain is created. One can also view the use of conjunctions. Conjunctions show how different experiences are related to each other. For an extended description of the meta-functions see Ebbelind and Segerby (2015).

Background of the student and the text

The texts selected for analysis in this paper come from a semi-structured interview with a student teacher during her second internship, after two years and three months of study in the programme. The student teacher, who was in her early 20s at the time of the interview, began the teacher education course immediately after high school. During the first internship and the later 30-credit course in mathematics education, she did not talk much. When she did speak, her tone was low and her body language withdrawn. This was also observed during several interviews and observations. During the second internship the researcher was present, attending lessons and meetings. The observations made on these occasions marked a major shift in the student teacher's participation related to the mathematics classroom, from shy and quiet to straightforward and self-confident. The selected text from this interview, presented below, was then analysed through SFL.

The transcript

Researcher: So, in some way, you felt more secure. [Yes] Or if you were not secure, then you were at least much more determined. [Yes (content in intonation)] How do you experience this? Secure or determined, or the difference from last time.

Evie: I have got more training to stand in front of pupils and speak. More teaching hours on this internship than the other, that is probably the biggest difference.

Researcher: But have you spoken much about [the changes in] your voice? That you use your voice in a totally different way now than you did before. Is that something you have been speaking about or something that you have been trained in?

Evie: No, I think that a lot of this is from my soccer referee career and from different referee courses and refereeing at different levels. That comes naturally, how one uses one's voice for speaking to the players on the field in the same way one speaks to pupils in the classroom.

Researcher: But when did you begin this referee initiative?

Evie: I began refereeing at a senior level during the summer of 2010, but then the initiative began during the winter when I found out, found out that I was nominated to the next level in connection to the "elite camp for girls" this summer.

Researcher: Has anyone besides me pointed this out, about your voice?

Evie: No, no one from the course, but the inspectors when I referee (laughing), they point out that I speak well and distinctly when I speak with the players.

ANALYSIS

Ideational meta-function

The transcript is a sample of an interview between two people where the researcher guides the conversation. The student teacher makes linguistic choices when discussing her engagement in past, present and future practice. The researcher asks the student teacher about the perceived change through the mental processes *felt* and *were* and opens the interview and addresses this perceived change with the mental process *experience*. When describing the origin of this experience, the verbal process *speak* and the material processes *got* and *stand* are used. The researcher's sensing is answered with examples from the physical world. The researcher tries to identify the origin of the changed *voice*, or relationship, through the verbal process *spoken* and the material process *trained*.

The student teacher then uses the mental process *think*; however, *think* is used to describe the relation between *"soccer referee career"* and the researcher's utterance *"you use your voice in a totally different way"* and is therefore regarded as a relational process. Furthermore, the student teacher uses the material processes *referee* and *use* in relation to the first relational process *think*. The choice of saying *"one speaks to pupils"* is important in this transcript. Here, *speak* is a relational process between the management of a soccer field and a mathematics classroom. Speaking with soccer players and pupils learning mathematics can, through this choice of words, be interpreted as equal ways of communicating.

The researcher then uses the material process *begin* to locate the tense of the *"referee initiative"*, and the student teacher answers twice with the same word; however, *began* in the answer is considered a relational process. In the last interference by the researcher the verbal process *"point this out"* is used to see if someone else has registered the change. The student teacher emphasises that no one from the educational side has highlighted this change, but uses the verbal processes *point out* and *speak* in relation to inspectors from the Swedish Soccer Association.

Interpersonal meta-function

The researcher poses questions with prompts such as *"do you experience"*, *"have you spoken"* and *"when did you begin"*, and the student answers the questions. The student teacher's prior and present internships, the change as perceived by the researcher and soccer referee career appear in the interview as entities.

In the first section two questions and answers are concerned with this change that the researcher has recognised. In the third question, the researcher uses the mental process *experience*. When answering this question, the student teacher uses *I* and draws on her past and present experience through internship. In the second section the researcher uses the personal pronoun *you* five times. The first two *you* are related to the verbal process *spoken* and involve the internship supervisor, and the last three address the student teacher. In the answer, the student teacher uses *I* and relates to the fact that *one* needs to use one's voice both as an referee and as a teacher in the classroom. *They* is used to emphasise that the inspectors are the ones that have highlighted her way of behaving, *"I speak well and distinctly"*.

As already indicated, the modality is strong at the beginning when the student refers to having *"got more training"*. The tense is used to refer to the difference between the present and the past internship *"on this internship than the other"*. When the student teacher first mentions the "referee initiative", the validity becomes low through *think*; however the validity becomes stronger and ends with strong linguistic validity with *"they point out"*.

Textual meta-function

The researcher links the first and second questions together with the disjunctive conjunction *or* and the interrogative *if*. The comparative conjunction *then* is used to relate the two internship experiences to each other. The additive conjunction *and* is used to turn the low validity of the clause to provide the clause with stronger validity. The conjunction *but*, used in the last answer, is used to exclude the teacher education from the discussion and promote the inspectors. This is an adversative conjunction, which means that there is something contrary to what one might expect.

Looking at the theme and rheme in the transcript reveals that the feeling promoted by the researcher is followed up by the student teacher in relation to the different internship experiences (first and second internship). The researcher uses this rheme to formulate a question, theme, about whether the student teacher has articulated this difference. In the rheme the researcher asks if it might be something the student has been trained in (during internship). At this point the lexical chain is broken by the student teacher when adding the *"referee initiative"*.

DISCUSSION

This paper focused on methodology and the transformation of gathered information into data, more specifically on the use of Systemic Functional Linguistics as a methodological tool for structuring gathered information on a micro level, enabling interpretations using the conceptual framework Patterns of Participation on a macro level.

PoP seeks to understand how teachers' interpretation of and contribution to immediate social interaction relate dynamically to what Skott (2013) calls prior engagement in a range of other practices. This is in line with the aim of the study, which problematises the role, if any, that teacher education programmes and experience from other relevant past, present and future practices play in influencing generalist student teachers' tales of themselves as emergent primary mathematics teachers and how these different relevant practices and experiences are related, if at all, to each other.

As indicated in the first section, the methodological tool needed to: disentangle elements of teacher education and relevant practices in relation to different entities; identify the tense of these experiences; disentangle the role these experiences play in terms of degree of certainty; and visualise the relationship between these different practices and experiences.

Through the voice, interpersonal meta-function, persons, entities and social practices became visible in the text, for example, the referee inspectors *they*; the student teacher herself, *"I speak"*; the *"referee initiative"*; and the student teacher's participation in *"different referee courses"* and *internship* related to mathematics education.

The transivity system, ideational meta-function, indicated how actions or experience were related to persons, entities and social practices. This was done through the main process verb, for example, the verbal process *speak* when describing the origin of the experience indicated by the researcher, the mental process *think* when relating to the *"referee initiative"* and the material process *referee* relating to refereeing soccer games and how to act in classrooms.

The tense highlighted whether the proposition was valid for present, past or future time. An example of this is when differentiating between the present and the past internship *"on this internship than the other"*.

When disentangling the role that persons, entities and social practices play in terms of degree of certainty, modality was used. One can see, for example, that modality is strong in the utterance *"have got more training"* and low through the mental process *think*.

Finally, the methodological tool needed to visualise the relationship between these different practices and experiences, if any. This was done by looking at the relational process, ideational meta-function, through the use of conjunctions and theme/rheme. For example *speak* was used to describe the relation between the management of a soccer field and a mathematics classroom. Another example was the adversative conjunction *but* that was used to promote the referee inspectors instead of teacher education. Looking at the theme and rhyme in this transcript it can be seen that the lexical chain was broken by the student teacher when adding the *"referee initiative"*.

CONCLUSION

On a theoretical level Morgan (2006) highlights that SFL is a systemic way of visualising the relation between text and practice. Through the structuring of the information it is clear that the student teacher's *contribution* to an *interpretation* of immediate emerging social interaction can be linked in a fine-grained manner to the "*prior engagement in a range of other social practices"*, for example, internship (past and present) and the current referee initiative. It is also clear that the fine-grained analysis highlights small but important parts in relation to the aim of the study. However, PoP does not highlight relevant practices, but sets out to highlight the way the re-engagement is conveyed and connected. In this perspective, the textual meta-function models links between practices, experience and entities, but maybe more important, the relational process links do not just go forward in chronological order. The relational process also indicates links back in the patterns that are created in the emergent social immediate interaction. These different links combine the re-engagement in prior and present practices into patterns.

I hold that I am coordinating two different perspectives. Prediger, Bikner-Ahsbahs, and Arzarello (2008) make a distinction between coordinating and combining theories. They define coordinating as a term for bringing theories together that contain interpretations of notions that are compatible, whereas combining is when theories are only juxtaposed. In both PoP and SFL, immediate social interaction is central; more important, PoP set out to describe practices that are within the text produced in the immediate situation. SFL not only visualises the practices, it clearly shows how the different practices, in Skott's terminology, are linked together.

To conclude, SFL used as a methodological tool allows a text analysis on the micro level of the text, and PoP allows an analysis on the macro level related to practice. In this sense the theory and method seem to work together. The validity in Gee's terms is, from this perspective, strong.

Why are Laura and Jane "not sure"?

Janne Fauskanger and Reidar Mosvold

University of Stavanger, Department of Education and Sports Science, Stavanger, Norway, janne.fauskanger@uis.no.

The mathematical knowledge for teaching (MKT) measures have been widely adopted by researchers. This paper reports on a case study of two mathematics teachers. The aim of the study was to investigate challenges regarding extensive use of "I'm not sure" as a suggested solution in the multiple-choice items. The connection between teachers' responses to multiple-choice MKT items, their written responses to corresponding open-ended questions (long responses) and group discussions are analyzed. The findings indicate that teachers' responses to multiple-choice items do not always correspond with the understanding revealed in responses to open-ended questions and in group discussions.

Keywords: MKT, measuring teachers' knowledge, multiple-choice items.

INTRODUCTION

This paper has a focus on measuring teachers' mathematical knowledge for teaching (MKT), and it builds upon the practice-based theory of MKT that was developed by researchers in the US (Ball, Thames, & Phelps, 2008). In connection with the development of this theory, sets of multiple-choice items were developed to measure MKT (e.g., Hill, Sleep, Lewis, & Ball, 2007). These items—which are often referred to as MKT items—were developed in the Learning Mathematics for Teaching project (LMT).

A multiple-choice item includes a correct answer—referred to as the key—and several wrong answers or distractors. In order to reduce the possibility of guessing, "I'm not sure" was included as a suggested solution in MKT items formatted yes/no (see Figure 1) in 2001 (Hill, 2007). In 2002, the researchers who developed these items were required to include "I'm not sure" on all number and operations content knowledge items that were piloted. To avoid changes in item parameters, "I'm not sure" was also included in the forms from 2004—which were later translated and adapted for use in the Norwegian context (Fauskanger, Jakobsen, Mosvold, & Bjuland, 2012). "I'm not sure" is always coded as incorrect, and teachers who are experienced with such tests would therefore immediately know that this suggested solution is a distractor. Some teachers would thus avoid this suggested solution, whereas other teachers might select it to avoid giving a wrong answer or to avoid guessing. In his often-cited handbook of development and validation of multiple-choice test items, Haladyna (2004) recommends that all distractors in multiple-choice items should be plausible, and, as a consequence, the suggested solution "I'm not sure" should be avoided. Many issues regarding the MKT items have been investigated already, but possible challenges related to the use of "I'm not sure" have not received much attention.

Previous studies conclude that teachers seem to have different reasons for selecting this alternative solution; some select "I'm not sure" based on uncertainty, whereas other teachers reveals instrumental and even relational understanding of the content of the items—but still select this alternative (Fauskanger & Mosvold, 2014). In this paper, we analyze data from a collective case study in an attempt to approach the following research question:

> What differences can be found between teachers' arguments for choosing the suggested solution "I'm not sure" in multiple-choice items?

This question is important in order to reveal challenges of extensive use of "I'm not sure" as a suggested solution in multiple-choice items developed to measure MKT. We focus in particular on two teachers' written long responses and discussions in group interviews regarding MKT items where they selected the alternative "I'm not sure". Cross case displays were constructed from teachers' long responses and their multiple-choice response supplemented with data from the interviews.

MEASURING TEACHER KNOWLEDGE

Teacher knowledge is imperative to high-quality teaching (e.g., Davis & Simmt, 2006), and it is thus relevant to gain insight into methods used to access and assess different aspects of teachers' knowledge (e.g., Hill et al., 2007). At the University of Michigan, researchers have developed a practice-based theory of mathematical knowledge for teaching (MKT). Hill, Rowan and Ball (2005, p. 373) define MKT as "the mathematical knowledge used to carry out the work of teaching mathematics". In the LMT project, considerable resources were invested in developing and validating sets of multiple-choice items in order to assess and access teachers' MKT (e.g., Schilling, Blunk, & Hill, 2007). Based on these efforts, Hill and colleagues (2004) suggest that the MKT measures can be used to measure growth in teachers' knowledge. The teacher knowledge that is measured by the MKT items further relates to the mathematical quality of instruction (Hill et al., 2008) and—to a certain extent—to student learning (Hill et al., 2005). Inspired by these promising results, researchers have adapted the measures for use both in and outside the US (Blömeke & Delaney, 2012).

Responses from multiple-choice items are expeditiously analyzed and they can be used at scale. Developing multiple-choice items that are intended for measuring something beyond procedural skills is, however, both tedious and demanding (e.g., Haladyna, 2004; Osterlind, 1997). When discussing measurement of teacher knowledge, researchers have argued that use of multiple-choice items might result in trivialization of the complexities of teaching and thus threaten validity (Beswick, Callingham, & Watson, 2012; Haertel, 2004). In his critical discussion of the MKT measures, Schoenfeld (2007) argued that these measures might test something other than they are supposed to. He further suggested that the multiple-choice format might complicate the content for the test takers, and confirming evidence of this was found in a Norwegian context (Fauskanger, Mosvold, Bjuland, & Jakobsen, 2011). An additional aspect of Schoenfeld's (2007) criticism was that the items actually measure a type of knowledge that is more procedural than intended, and more recent studies in Norway support this criticism (Fauskanger & Mosvold, 2015).

A standard multiple-choice item consists of two parts: a problem (often referred to as stem) and a list of suggested solutions. In the MKT items, the stem is typically situated in the context of the work of teaching mathematics. The list of suggested solutions contains a key and one or more distractors (often incorrect alternatives). Some MKT items differ from more standard multiple-choice items in that mathematically incorrect alternatives are not always included; the correct solution might then be: "all of the above" or "none of the above". The use of such items are often discouraged (Haladyna, 2004); if used, they should at least be used with caution (Osterlind, 1997). Another way in which MKT items differ from more standard

3. Imagine that you are working with your class on multiplying large numbers. Among your students' papers, you notice that some have displayed their work in the following ways:

Student A	Student B	Student C
35 x 25 125 +75 875	35 x25 175 +700 875	35 x 25 25 150 100 +600 875

Which of these students would you judge to be using a method that could be used to multiply any two whole numbers?

	Method would work for all whole numbers	Method would NOT work for all whole numbers	I'm not sure
a) Method A	1	2	3
b) Method B	1	2	3
c) Method C	1	2	3

Figure 1: MKT testlet including "I'm not sure" as a suggested solution in all three items (Ball & Hill, 2008, p. 5)

multiple-choice items is the extended use of the suggested solution "I'm not sure" (Fauskanger & Mosvold, 2014)—first included in items that were formatted yes/no and later for all number and operations content knowledge items (Hill, 2007).

Different approaches have been made to distinguish between different categories of teachers' knowledge and understanding of the mathematical content; Skemp's (1976) distinction between instrumental and relational understanding is an archetype. Rote memorization of algorithms for two-digit multiplication (Figure 1) is an example of instrumental understanding, whereas relational understanding encompasses a deep, conceptual understanding. Skemp argued that students cannot develop relational understanding from instrumental teaching. Recent research has investigated this connection empirically and concludes that teachers' knowledge of facts and procedures have less positive effect on the quality of instruction and students' achievement relative to knowledge of concepts and connections (Tchoshanov, 2011). For this reason, the importance of exploring teacher knowledge accessed by measures as well as possible challenges regarding the use of multiple-choice items to investigate something as complex as teacher knowledge, becomes evident. It is relevant to carefully investigate these challenges—in particular the challenges revealed from extensive use of "I'm not sure" as a suggested solution.

METHODOLOGY

This study is part of a collective case study (Silverman, 2006), and two in-service teachers were chosen as cases to investigate the topic under investigation. When adopting a case-oriented approach, we considered the case as an entity and first looked for configurations and characteristics within the case before we searched for similarities and patterns across cases. The two teachers, who have been assigned the pseudonyms Laura and Jane, were participants in a professional development course. A total of 38 in-service teachers participated in the course, and 30 of these teachers agreed to submit multiple-choice responses to 28 MKT items (including the testlet in Figure 1). All of these items had a focus on number concepts and operations, and 18 of the items included "I'm not sure" as a suggested solution. In addition to submitting their multiple-choice responses to the items, the teachers also agreed to submit long responses related to each item and to discuss the items in groups afterwards. The questions prompting long responses were developed to tap into teachers' instrumental and relational understanding (Skemp, 1976) and varied across the 28 items. The group discussions were based on the same 28 items.

In a previous publication, we have reported on results from analysis of multiple-choice responses and long responses for all the teachers who selected "I'm not sure" as a response to a particular item (Fauskanger & Mosvold, 2014). Those analyses revealed that three groups of teachers could be distinguished between (see Table 1).

Laura and Jane both responded "I'm not sure", but their long responses indicated that Jane did so due to insecurity (group 1), whereas Laura indicated relational understanding in her long response (group 3). In our attempt to investigate different arguments for selecting "I'm not sure" as a response to MKT items, we therefore selected these two teachers as contrasting cases.

According to the official coding manuals from the LMT project, the suggested solution "I'm not sure" should be coded as incorrect. An underlying hypothesis would then be that teachers who select this response do not have the proper level of MKT to identify the key; they select "I'm not sure" to avoid guessing. In order to learn more about what challenges are revealed from extensive use of "I'm not sure" in multiple-choice items, we focus on what types of understanding could be found in teachers' long and oral responses when they select the answer "I'm not sure" on a multiple-choice item.

The unit of analysis is the individual teachers' multiple-choice responses, their long responses and their

Group	Group 1: not sure	Group 2: instrumental understanding	Group 3: relational understanding
Name of teacher	Erna, Frøya, *Jane*, Jan, Ada and Nina	Pia, Mons, Harald, Ola and Are	Sara, Inge, Ragna and *Laura*

Table 1: Teachers grouped according to their long responses

individual voices as revealed in group discussions. The group discussions were recorded and transcribed. We have applied an iterative strategy weaving back and forth between the empirical material and theories (Alvesson & Karreman, 2011).

We used Skemp's (1976) categories for our coding of the textual data. Excerpts from teachers' written and oral responses reflecting memorization of facts or rules, procedural computations or other aspects related to instrumental understanding were coded as instrumental, whereas excerpts reflecting understanding of concepts and connection between them, multiple solutions to non-routine problems or other aspects related to relational understanding were coded as relational. A third code, low/no MKT, was used to code excerpts where teachers' explicitly wrote or said that they did not know the content of the item(s) or excerpts revealing low level of MKT. In order to increase the reliability of the coding, the two authors coded the data independently and reconciled. In the few instances where there was a mismatch between our initial coding, we discussed and reached agreement.

THE CAse of Jane

Jane's long responses indicated insecurity related to the content in focus, and she responded "I'm not sure" to all three items in the testlet in Figure 1 (6a, 6b and 6c in our form). When asked how she would approach students who used methods like A, B and C, Jane wrote: "It is difficult to know when you do not understand the methods [the students have] used." This long response—along with the other long responses written by Jane—thus seems to support the hypothesis that the selection of "I'm not sure" implies lack of knowledge or insecurity. Coding her responses to the multiple-choice items in this testlet as incorrect thus seems reasonable. It can also be argued that the inclusion of "I'm not sure" has reduced the possibility of guessing with Jane, and that was the intention of including this suggested solution in the MKT items (Hill, 2007).

In the interview, Jane explains that she wants to teach an algorithm she is more comfortable with herself:

Jane: There is a point to explaining that your own way [of calculating it] is all right, in a way. I have used it for calculating for years, so it is natural to me. But, then again, we are different. Some like this and some like that. And it is similar to subtraction, when you borrow 10, if you say for instance 15 minus, or if you say three minus and then add the 5. We have shown both ways, and then it is up to them [the students] what they... Then we have said that it relates to what they, some like this and some like that, and≈

Ragna: ≈Open for all [to choose]≈

Inga: ≈And then, many [students] have the parents show it to them in a different way than the one they have been taught. Yes, that is difficult.

Interviewer: But do you experience that the parents have a common [algorithm]?

Jane: No. I haven't asked about that, but I know that many [parents] help their children setting it up, and with subtraction it is quite similar – with borrowing (...)

Interviewer: Anything else you want to say in relation to the items that were concerning different algorithms?

Jane: No, and we have been taught that there isn't only one standard algorithm (laughter)

As displayed in this excerpt, the reason why Jane selected "I'm not sure" seems to be that she is insecure about the mathematical content, and she wants to teach the students an algorithm with which she is familiar. The excerpt thus indicates that Jane's knowledge related to multi-digit multiplication is instrumental (Skemp, 1976). She reveals, however, that the professional development course has made her aware of the existence of multiple algorithms, and she seems to agree that different algorithms might be useful for different students.

THE CASE OF LAURA

Laura also selected "I'm not sure" as her response to several multiple-choice items. In contrast with Jane, however, Laura's long responses indicates that this was not due to low level of MKT or insecurity. On the contrary, Laura's long responses indicate deep conceptual knowledge (Skemp, 1976). In her long response related to a particular testlet — with a content focus related to place value and non-standard ways of decomposing three-digit numbers (items 1a-d in our form) — Laura argued that the stem could be interpreted in different ways and that the choice of key for each item would depend on this interpretation. The following is an excerpt from what Laura wrote: "Item a) is wrong by all means. Items b), c) and d) are wrong if it [the problem presented in the stem] is a closed problem, but they are correct if it is an open problem." By "closed problem" Laura seemed to have in mind the standard decomposition, and by "open problem" she meant "open" to non-standard ways of decomposing three-digit numbers. When highlighting testlet 1 as mirroring knowledge important for her as a teacher Laura wrote:

> To be able to do arithmetic one has to think flexibly when it comes to decomposing a number. 574 is not only 500 + 70 + 4. It could also be 400 + 170 + 4. 500 is 5 hundreds, 50 tens or 500 ones, etc. The students need to be familiar with this [non-standard ways of decomposing numbers] in order to be able to understand the four arithmetical operations [addition, subtraction, multiplication and division] and in order to develop flexible strategies for multi-digit arithmetic.

Laura is one of the teachers whose long responses—by relating the decomposition of numbers to understanding of "the four arithmetical operations" and "the development of flexible strategies"—indicate relational understanding (Skemp, 1976) of the content. In her long responses, Laura relates multiple decompositions to arithmetic, and multiple decompositions seem to be just as important for her as standard decompositions (cf., Jones et al., 1996). Her incorrect multiple-choice responses are thus inconsistent with her long response, and she responds "I'm not sure" despite of a high level of MKT. Laura seems to have responded "I'm not sure" due to the wording of the items included in this testlet. This brings forth issues related to item development and translation (cf., Fauskanger et al., 2012).

When analyzing Laura's utterances from the interviews, it also appears that she has a deep understanding—both in terms of mathematical content knowledge and pedagogical content knowledge. The interview data thus, seems to support the long responses from Laura.

Laura: I want to argue that these items are very much about understanding. (...) You have these [MKT items], which relate to understanding what the students actually do. And being able to identify it. And it is what they were able to divide into, I mean, normally we divide into all the hundreds, all the tens and all the ones. That is how to do it. And then they don't remember that they can change into ones and tens, and then they are stuck there. So this is very relevant.

(...)

Laura: It relates to what grade level it is in. So you could say, now I work in third grade, and we have approached the bigger numbers. The first point then is that they know that the numbers have different value if they are in the one, ten or hundred place. Then they know this, and this is the first thing they have to know. And then they know the place value system. But if they are not able to calculate, for instance 200 minus 4, because that doesn't work since there are no ones there [to subtract from in 200]. Then there is something they don't know after all, about knowing that they have different value. That is the first point. And then it is concerning the flexibility that this item implies. To see if they have [this]. This also has to become natural eventually. But I think it is important to know that there and there and there [points to the digits in the three-digit number] the values are different.

As displayed in these excerpts, Laura selected "I'm not sure" despite being secure about the mathematical content. The voice of Laura in the group discussion thus seems to support findings from her long responses and the reason why she responded "I'm not sure" in the multiple-choice items does not relate to her low level of MKT but rather her relational understanding (Skemp, 1976) of the content.

CONCLUDING DISCUSSION

In a previous study, we analyzed 15 teachers' long responses related to a set of multiple-choice items from the LMT project (Fauskanger & Mosvold, 2014). Based on those results, two teachers were chosen as contrasting cases in the present study. We analyzed the teachers' responses to multiple-choice MKT items, written long responses as well as discussion of the items in group interviews in order to learn more about the challenges related to extensive use of "I'm not sure" as a suggested solution in the MKT multiple-choice items.

The results from our analysis indicate that we need to be careful about how we interpret it when teachers select "I'm not sure" as a multiple-choice response. "I'm not sure" is always coded as incorrect, and our analysis of teachers' long responses as well as their interview discussions reveals that this alternative was indeed selected by some teachers who explicitly indicated that they could not identify the key due to their low level of local MKT (as Jane, see Table 1). This seems to be in line with the intention of introducing "I'm not sure" to the items, and the suggested solution reduces the possibility of guessing for these teachers (Hill, 2007). Other teachers, however, selected "I'm not sure" as a response to multiple-choice items although their long responses as well as their discussions in group interviews indicated that they had relational understanding (e.g., Laura). Teachers might draw on deep conceptual or relational knowledge (Laura), procedural or instrumental knowledge (Schoenfeld, 2007), or their lacking knowledge (Jane) when responding "I'm not sure". Our results thus indicate that the knowledge teachers utilize in long responses or discussions does not necessarily mirror the knowledge (that seems to be) used when selecting a certain multiple-choice response. The assumption that the multiple-choice response "I'm not sure" is correctly coded as incorrect should therefore be subject to further scrutiny, and the inclusion of this alternative response in MKT items should also be critically discussed.

Our analysis of teachers' long responses as well as their discussions in group interviews indicate that none of the 30 participating teachers were guessing—thus conforming to the intention of including "I'm not sure". This suggested solution is still problematic, however, since one cannot conclude whether the choice of this suggested solution is based on lack of knowledge as one extreme point or deep conceptual knowledge as the other extreme. One might advocate removal of the "I'm not sure" option from the items, but this would change item parameters and should not be done hastily. Instead, we call for cross-cultural studies that investigate teachers' motivation for selecting a suggested solution like "I'm not sure" when responding to MKT items. Recontextualizing the MKT items into scenarios for use in qualitative studies related aspects of teachers' MKT as done by Adler and Patahuddin (2012) might be a fruitful approach. These researchers argue that the carefully constructed MKT items provokes teachers' mathematical reasoning in relation to practice-based scenarios.

Exploring pictorial representations in rational numbers: Struggles of a prospective teacher

Nadia Ferreira and João Pedro da Ponte

Universidade de Lisboa, Instituto de Educação, Lisbon, Portugal, nadiadferreira@gmail.com

We aim to identify the knowledge that a prospective teacher, Maria, uses in practice, focusing on her struggles and what she learned from her practical experience teaching rational number multiplication. Data was collected from lesson plans, observations, written reflections and semi-structured interviews. Maria developed her knowledge for teaching when anticipating solutions and errors and selecting representations. Reflecting on her practice, she realised that she was able to solve some tasks with symbolic procedures but could not represent them pictorially.

Keywords: Knowledge, practice, rational numbers, representations.

INTRODUCTION

The knowledge for teaching mathematics that prospective teachers need to develop and the way they develop it are controversial issues (Ball, Thames, & Phelps, 2008; Ponte & Chapman, 2015; Shulman, 1986). The practicum is a particularly important site to study such knowledge since prospective teachers are faced with circumstances that allow noticing important weaknesses and strengths.

To foster students' understanding of mathematics concepts and procedures, teachers are called to engage them in making connections among representations (NCTM, 2007). They need to support students' fluent use of symbols, grounded in informal representations (Ball et al., 2008; Ma, 1999; Ponte & Chapman, 2015). Rational numbers raise many difficulties for students and challenge teachers to promote conceptual learning (Lamon, 2006; Ma, 1999). Research has brought attention to prospective teachers' knowledge of rational numbers in different ways. For example, Isiksal and Cakiroglu (2011) studied prospective teachers' pedagogical content knowledge of fraction multiplication. Findings indicated that teachers have different perceptions of children's mistakes and employ different strategies including using multiple representations, using problem solving strategies, making clear explanations of questions, and focusing on meaning of concepts. However, no study has been found focusing on the use of informal and formal representations in teaching fraction multiplication and the struggles prospective teachers may experience in providing representations that enable students to develop their knowledge on this topic. The aim of this study is to identify the knowledge of a prospective teacher in the teaching and learning of rational number multiplication, with a focus on the use of informal and formal representations, analysing the knowledge mobilized in teaching practice, the struggles, and the knowledge built from the first practical experiences.

PROSPECTIVE TEACHERS' KWOWLEDGE

Teachers' knowledge includes mathematical and pedagogical content or didactical knowledge, both of which are of critical importance for teaching practice (Ball et al., 2008; Ponte & Chapman, 2015; Shulman, 1986). Mathematics knowledge involves conceptual and procedural aspects (Hiebert, 1988; Rittle-Johnson & Schneider, 2012). Conceptual knowledge is a network of concepts and procedural knowledge consists in rules or procedures for solving mathematical problems (Bartell, Webel, Bowen, & Dyson, 2012). Procedural knowledge may be part of conceptual knowledge. Procedures may be performed without understanding or may be performed knowing why and when, in which case we have mathematical conceptual knowledge. Conceptual mathematical knowledge of rational numbers involves knowing different representations and meanings and in order "to create one representation first we have to know what to represent" (Ma, 1999, p. 135). Conceptual knowledge allows us to connect topics (e.g., seeing multiplication as repeated addition).

Didactical knowledge concerns with how teachers teach (Ponte & Chapman, 2015). Teachers must anticipate students' common mistakes and misconceptions (e.g., generalizing addition procedures in multiplication), to anticipate students' solutions in specific tasks, and also know what students will find challenging, interesting or confusing. Teachers also have to be able to sequence tasks, to recognize the value of using certain representations, to pose questions, and to explore students' strategies. In addition, they need to understand the main ideas of current curriculum documents, identifying principles of teaching (e.g., NCTM, 2007).

Ponte, Quaresma and Branco (2012) characterize teacher's practice into two main aspects: the tasks proposed to students and the communication established in the classroom. In respect to tasks, teachers may choose to offer just simple exercises or also propose challenging exploratory tasks, problems and investigations in which students need to design and implement solution strategies based on their previous knowledge (Ponte, 2005). Classroom communication may be univocal or dialogic, depending on the roles assumed by the teacher and the students and the types of teachers' questions, including inquiry, focusing or confirmation questions (Ponte et al., 2012). Representations are an important feature of tasks, and may be categorized as pictorial (images), iconic (points, lines, circles), and notational (number line, arrows, vertical columns, symbols) (Thomas, Mulligan, & Goldin, 2002).

RESEARCH METHODOLOGY

This study takes a qualitative and interpretative approach (Erickson, 1986), using a case study design. The participant is Maria, a prospective elementary school teacher. She always wanted to be a teacher but is in a higher education program at a late stage of her life. In school she had mathematics up to grade 9. Maria reflects with ease, addressing her difficulties in an explicit way. She said that she had to study hard to know the content that she was going to teach and to figure out how to implement the didactical ideas that she had learned at university. During teaching program, she experienced exploratory learning and she wishes to provide such approach to her students. Maria already knew the grade 6 class with 28 students, in which her practicum took place. She interacted informally with her school mentor to discuss who would teach the different topics, deciding that they would give a total of six classes on rational numbers, three of each taught by each one of them, with Maria introducing the concepts and the school mentor providing practice.

Maria's lesson was observed and videotaped (Li). In addition, data was collected and analysed from initial (II) and final (FI) semi-structured interviews, and before (BIi) and after lesson (AIi) interviews. We also analysed the documents that she produced (lesson plans and reflections) and the field notes written by the first author during data collection. The interviews and videos were fully transcribed. The analysis is descriptive, seeking to characterize Maria's teaching. The transcribed conversations were first analysed according to four dimensions (conceptual/procedural mathematical knowledge and didactical knowledge about tasks and students). At a second moment the analysis was based on categories built from data. The intersection of the four dimensions enables us to highlight communication moves (Charmaz, 2006). We consider knowledge to be conceptual when there is evidence of understanding the reasons for using procedures and for knowing different representations and meanings of a situation. We consider knowledge as procedural when the teacher cannot relate informal and formal representations or when she cannot explain in the interviews why she did it. We also give attention to didactical knowledge in practice, focusing on knowledge about tasks, students and communication that takes place in the classroom. For example, teachers must design appropriate tasks, know what they will explore and relate the representations, anticipate student's solutions and plan how to orchestrate them. In addition, teachers should anticipate questions to help students understand the concepts in the context of productive classroom communication.

THE PRACTICE OF MARIA: LEARNINGS AND STRUGGLES

Despite her willingness to follow an exploratory approach and carry out considerable planning, Maria did not anticipate how to relate different representations. Comparing her agenda with her teaching practice, she realized that she did not clearly explore the concepts. That is, Maria is a case of a prospective teacher seeking to perform exploratory teaching but with trouble in preparing and carrying it out as intended.

Mapping the topic and anticipating practice

Maria taught three lessons on rational numbers. She wanted to introduce fraction multiplication with an emphasis on understanding: "I'm more interested that students understand the why of the result and the meaning of the result. What it represents..." (BI3). She made decisions about the tasks to propose, considering their nature and value, and chose a pictorial rectangular representation and different symbolic representations of rational numbers. She intended to promote discussions with inquiry questions. Next Maria had to negotiate the tasks with the school mentor who wanted her to use the textbook. She used the tasks of the textbook, but felt that her choices were limited. She also read articles and documents about rational number multiplication. She reviewed procedures and solved several tasks: "I saw everything always supported what was in the textbook" (BI1). She tried to include ideas that represent "good practice". In the end, she decided to explore first the multiplication of a natural number by a fraction and then the multiplication of fractions. However, she still had some unresolved questions and sought out the professors from her teacher education college: "It was only when the professor began making pictorial representation that it occurred to me! Only when I looked at this representation did I associate pictorial and symbolic representations" (BI3).

In her lesson plan, Maria anticipated students' solutions, errors and explanations to prepare her to help students overcome these errors. She thought, "If they ask this, what will I say? If I ask this, what might they say?" (BI). And she added:

> I consider students' possible solutions (...) in the multiplication of fractions, whether they follow the rule denominator times denominator and numerator times numerator (...) multiply denominators and maintain the numerators, [or generalize ideas from] addition, finding common denominator ... (BI).

In her view, pictorial representations might serve as a useful support for solving the tasks because "sometimes... I think we do the mathematics, we give the results, but what are we talking about? Which unit? What part? Part of what?" (BI3). As she explored the tasks, she encountered difficulties and said: "It's very difficult to imagine students' thinking, what will happen... Imagine them... It is a difficult exercise but very necessary for further practice" (BI2). In the lesson plan, she solved all tasks with fractions and pictorial representations except in the first task.

Maria used didactical knowledge when she considered the kind of tasks to propose, established a sequence of tasks, and anticipated students' potential solutions and common mistakes. However, when anticipating the solutions of the tasks she did not fully realize how challenging and powerful they could be. As a result of a learning experience with her university professor, she recognized the value of using pictorial representations; thus, it seems that she had developed didactical knowledge. Yet when she anticipated different symbolic solutions for the tasks and some pictorial representations, her procedural knowledge became evident. However, her conceptual knowledge would only show up in the practical experience.

Instructional practice

Maria began the lesson reviewing the homework. Then, she told a story to engage students in solving a problem: "With the candy that came in a box, Luís separated 6 bags of 2/5 kg each. Does the box weigh more or less than 3 kg?" This task combines discrete quantities (6 bags) and continuous quantities (weight of the bags). Dealing with these quantities requires suitable representations. Maria invited students to present their ideas, saying "How can we solve this problem? Who wants to help? Pedro!" The student proposed immediately "add 2/5 six times". She recorded Pedro's idea and asked the result. After 5 seconds she wrote the sum with the students' help "2/5+2/5+2/5+2/5+2/5+2/5=12/5". Immediately Pedro said "12/5 isn't more than 3 kg". Maria again recorded this on the board and posed inquiry and focusing questions to help others students to understand it:

Maria:	Pedro said that 12/5 is not more than 3 kg. Pedro, how did you think?
Pedro:	Because 5/5 = 1; 5/5 + 5/5= 10/5=2; 15/5=3.
Maria:	Exactly! And what do I have (pointing to 12/5)?
Pedro:	12/5.
Maria:	Then we know that we have at least 2 kg! Because 5/5 more 5/5 are 10/5! And there is 2/5 missing to one [more unit]. But how can we see that? Is there

another way of seeing this? And if we tried… (Turns to the board) How many bags do we have?

To illustrate Pedro's answer, she began the explanation with the support of a rectangular representation (Figure 1) and said:

> Let's suppose we have here a rectangle and each part of the rectangle is a bag. How much does each bag weigh? (…) 2/5 kg. And with the second bag? (…) 4/5. So we have… (Together with the students) 4/5, 6/5, 8/5 and the result is 12/5. (L3)

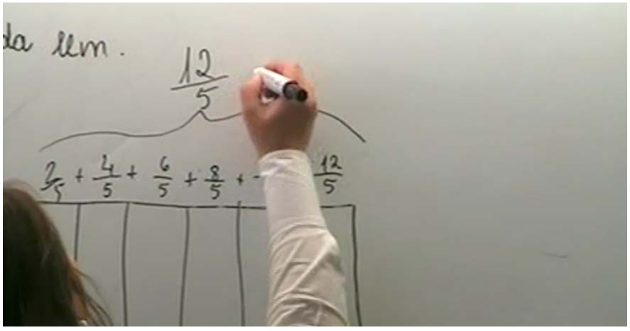

Figure 1: Representation of the first problem

This representation is rather confusing and students began complaining that they did not understand. Figure 1 illustrates that Maria was saying one thing and symbolically representing another. On a second trial, she divided each part in five parts unsuccessfully. Then she erased the figure and explained symbolically "we have to do 2/5+2/5+2/5+2/5+2/5+2/5=12/5". The teacher did not relate the pictorial and symbolic representations. She went on posing focusing and inquiry questions:

Francisco: Ok! And what if we do… Six times two and the five stays the same?
Maria: Ok! How can we do it?
Francisco: Six times two is twelve and the five stays the same.
Maria: Why don't you multiply the 5 too? And what if I do like this (6/1×2/5)? Now we have the numerator!
Pedro: Five times one is five…
Maria: And if I said that I multiply the (…) numerator and keep the denominator. Can I always do this? (L3)

The students rejected the rule and Maria, attempting to convince them, used another example with another denominator, stressed the rule comparing the procedure with the result, and moved to the synthesis and final answer:

> The problem said that Luís has six bags and each bag has 2/5 of a kilo. Then we do 2/5+2/5=4/5 and 4/5+2/5= 6/5 (…) 12/5. Then Francisco said it would be faster to do 6 times 2/5 which gives 12/5. And, finally, we see that we can multiply numerator and numerator and keep the denominator. (…) Pedro said in the beginning that the answer is less than 3 kilos because 12/5 isn't as much as 3 kilos… (L3)

In the sequence, Maria proposed a second task: "Rita cut a cake into 4 equal parts. But one quarter of the cake seemed to be a very big slice! After all, she only wants half a slice, or half of one quarter. Which part of the cake does Rita eat?"

Immediately a student explained that "1/2 represents half and one quarter is the final measure when we divide in 4 pieces. One half of a quarter is half of 1/4". Again, Maria asked how to represent this situation and drew a rectangle divided in four parts (Figure 2). She went on asking confirmation and focusing questions:

Maria: Is this what Rita eats? (Pointing to half of a quarter of the cake)
Francisco: It is half of a quarter! (…) She only wants half!? Since all the pieces were the same… I have to divide everything in the middle…
Maria: Oh! Interesting, Francisco! (…) What Francisco is saying is very important! But maybe it is better to divide in columns! It's the same reasoning! (L3)

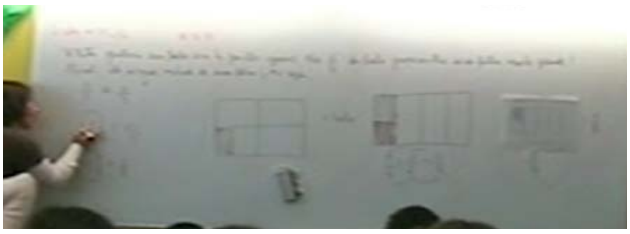

Figure 2: Different representations of the second problem

At this point, using the projector, Maria illustrated Francisco's idea. A student said:

> She eats one eighth. Rita divided the unit and only ate one part... The cake was divided into four parts and then divided in eighth parts... Halves that gives eighths... She ate one out of eight parts! (L3)

In her teaching practice Maria mobilized mathematical and didactical knowledge and showed weaknesses in both. When she explored the first problem, she used fractions and she did not consider the pictorial representation of multiplying a whole number by a rational number. She showed a procedural nature of mathematics knowledge and revealed some weaknesses in her conceptual knowledge when she was not able to pictorially represent the operation. In the second task she anticipated the pictorial representations and showed conceptual knowledge. However, she did not explore the connections between the pictorial and symbolic representations. Her discourse had changed. In the beginning, she had a dialogue with three students (one at a time) and tried to focus the attention of all students on the emerging ideas. She posed different types of questions, including inquiry, focusing and confirmation questions. In the second moment, she posed fewer focusing and confirmation questions.

Evaluating, reflecting critically, reviewing, and restructuring knowledge

In her reflection, Maria considered that this lesson had presented unexpected difficulties with the pictorial representation of the task and regarding the exploration of mathematical ideas related to the representations and their connections. This aspect caused her great anxiety at the end of the lesson:

> I shouldn't have used this kind of representation because they [the students] weren't used to it (...) Although I think that this representation helps explain why. The goal is for them to realize why in that case the result 12/5 appeared. It didn't fall from the sky! (AI3)

Maria recognized the value of using certain representations but considered giving up on the use of pictorial representation, which reveals some insecurity regarding her didactical ideas. She did not notice the mistakes that she had made on the board (shown in Figure 1) and merely felt that she had not handled the situation well and the students did not understand. After visualizing the lesson video she said: "I think this approach [using pictorial representations] is better for everyone, I am convinced. (...) The problem is not in the explanation of the problem! It's in me!" (AI3). She identified her mistakes in the first task: "What I wrote was not the same as what I was saying! And maybe that was the confusion! I caused the confusion because, in fact, what they are seeing is 2/5+4/5+..." (AI3).

During the interview, Maria tried to explain why she should not use this pictorial representation. She agreed that the reason was that she did not recognize the differences between quantities and that the result was an improper fraction. These difficulties raise questions about her conceptual mathematical knowledge.

Confronting the plan and the practice in the second task, Maria realized that she used different pictorial representations and different symbolic representations of the proposed problem (Figure 3). At the end of this lesson she evaluated her practice recognizing that: "I knew the procedure, I mastered the procedure! I memorized the procedure back and forth and not how to represent the concept [multiplication]!" (AI3).

Reflecting on her agenda and comparing it with her teaching practice, Maria concluded that the end result was positive but could have been better. She recognized that, although she had invested heavily in planning the lesson, she had not achieved her desired result. She noticed that in order to prepare these lessons she had mobilized her mathematics content knowledge that she learned in the teacher education program:

> I see rational numbers in a different way (...) Before I had fractions and decimals arranged in

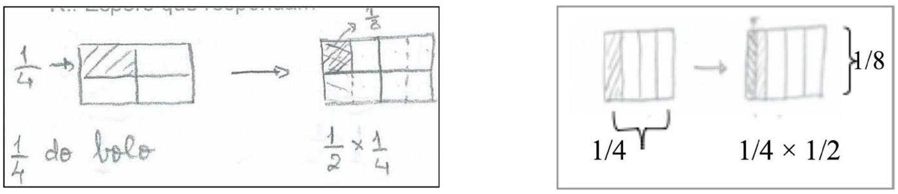

Figure 3: Representation of the second problem in the plan and in practice

different drawers (...) Now I see that they are different representations of the same number (FI).

When she studied the literature, she learned the relations between operations and said "when we multiply a whole number with a fraction we are simplifying repeated addition (like in 6×2/5, when I work with students starting from 2/5 +2/5 +...)" (FI). She did not explore the relationships between representations and she was able to see, during the interview, that the arithmetic expression that she wrote on the board did not represent the problem proposed.

Maria recalled general didactical ideas and these became meaningful for her. She realized the importance of planning and that her lesson plan was better after each practical experience. She realized that in order to be successful in her practice "the plans have to evolve (...). In the first plan [lesson before], I thought that it was perfect and then I went to practice and I realized that it could have been better..." (FI). She developed knowledge when anticipating solutions, errors and representations. Maria knew that a teacher must "lead students to understand the why of something" (FI) and that is why she knows that it is important to "unpack the pictorial representations" (FI). After the teaching practice, she continued to believe that good teaching leads to learning with understanding. She assumed that the teacher must support students in learning, by listening, asking good questions and helping them to build their knowledge.

CONCLUSION

Maria felt that she developed significant aspects of her knowledge about rational numbers during these lessons. Regarding her mathematics knowledge, she become more aware of the concepts related to rational number multiplication in fraction representation. Early in the lesson, her weakness in conceptual knowledge led her to take a procedural approach (Ma, 1999). However, she showed conceptual knowledge when she said that rational numbers may be represented by fractions and decimals and related addition and multiplication. However, she struggled to connect these with pictorial representations. As in other studies, we see issues related to connecting real-world situations and symbolic representations and connecting different representations of a concept (Ponte & Chapman, 2015). At the end of this teaching experience, Maria had learned about: how to represent improper fractions; the complexity of using both discrete and continuous quantities; connecting pictorial and symbolic representations; and the meanings of different expressions.

Concerning didactical knowledge, Maria was able to sequence tasks using ideas of several articles and recognized the value of using pictorial representations as tools to develop mathematical ideas. She mentioned that she had become more aware of anticipating students' questions, common mistakes, and solutions (Bartell et al., 2012). She also became more aware of when she needed to explain. In her instructional practice she posed questions and explored students' strategies, seeking to lead them to connect pictorial and symbolic representations. As in other studies, we see issues related to conceptual understanding, using multiple representations and curriculum materials and textbooks, planning, assessing students, and analysing mathematics teaching (Ponte & Chapman, 2015).

This study illustrates the struggles and learning that prospective teachers may experience when they strive to engage in an exploratory approach that requires strong mathematical and didactical knowledge (Ponte & Chapman, 2015). In order to propose challenging tasks and to use different representations, they need to develop a deep understanding of rational numbers. They must engage in analyzing students' strategies, offering student-focused responses, anticipating practice by solving the tasks and discussing common mistakes (Son & Crespo, 2009). This study shows how anticipating practice in a careful way is essential for prospective teachers.

These results show us that some aspects may only become explicit in practice. Teachers have perceptions of children's mistakes and different strategies that may be used including using multiple representations, using problem-solving strategies, providing clear explanations and focusing on the meaning of concepts (Isiksal & Cakiroglu, 2011). In this study we focused on the use of informal and formal representations in teaching fraction multiplication and on the struggles that a prospective teacher experienced in providing representations to help students to develop their knowledge about this topic. For example, Maria anticipated the solutions of the tasks in symbolic and pictorial representations but in class had trouble relating the two representations. In another words, practice was an appropriate context to see what she could do and the nature of her knowledge. These issues are important to know how teacher educators may prepare and support prospective teachers who are learning to teach for meaningful conceptual learning.

“Responding to student ideas” as an indicator of a teacher’s mathematical knowledge in teaching

Oguz Koklu[1] and Fatma Aslan-Tutak[2]

1 University of Georgia, Athens, USA

2 Bogazici University, İstanbul, Turkey, fatma.tutak@boun.edu.tr

This paper describes and analyses two 8th grade mathematics instructions, delivered by two teachers on the slope and its algebraic representation. The focus of analysis is on teacher content knowledge which was analysed with Knowledge Quartet model (Rowland et al., 2005). The study examined whether teachers’ responses to students’ comments indicate the quality of teachers’ content knowledge. Findings indicated that teacher’ reaction to students’ comments would significantly reflect teachers’ depth and breadth of mathematics content knowledge.

Keywords: Teacher knowledge, knowledge quartet, contingency, slope, responding to students’ ideas.

TEACHER KNOWLEDGE AND TEACHING

Enhancing students’ mathematics thinking and learning is the utmost aim of overall mathematics education. One of the most important influences on students’ learning and mathematics thinking is the teachers and their professional knowledge (Even, 1993; Darling-Hammond & Ball, 1998). Teachers’ knowledge is crucial since teachers’ effectiveness is influenced by that knowledge (Gilbert & Gilbert, 2011; Wagner et al., 2007). In addition to its effect on students’ learning, teachers’ knowledge is influential in shaping their practices (Borko & Putnam, 1996; Even, 1993; Fennema & Franke, 1992; Rowland & Ruthven, 2011; Sherin, 2002; Shulman, 1986).

Shulman’s study (1986) opened a way to understand teachers’ complex and multi-dimensional character of knowledge. Shulman suggested seven knowledge categories. Among them, the first four were content-free and the last three ones were on content-specific knowledge (Rowland & Turner, 2007). Subject-matter knowledge (SMK), curricular knowledge (CK), and pedagogical content knowledge (PCK) constitute the content-specific knowledge that teachers have (Shulman, 1986). The work of Shulman (1986) suggested that content-specific knowledge becomes important in studying teachers’ knowledge.

Shulman’s conceptualization on teachers’ knowledge has been heavily used by mathematics education researcher community. Almost all study on mathematics teacher knowledge assumes Shulman’s categorization and conceptualization of teacher knowledge that is why we do not present a detailed account of Shulman’s ideas in this paper.

Researchers have studied mathematics teachers’ knowledge from several perspectives. While some researchers conducted research on teachers’ understanding of various concepts in mathematics (e.g., Ball, 1990), others have focused on investigating the relationship between SMK and PCK and teaching (e.g., Even, 1993; Rowland, Huckstep, & Thwaites, 2005; Hill, Rowan, & Ball, 2005).

Apart from the perspectives summarized above, discussions on the nature of teachers’ knowledge deserve an exclusive attention. The discussion on the nature of teachers’ knowledge yield a consensus that the knowledge employed in teaching is dynamic, more visible through practice, and should be studied in actual classroom setting (Fennema & Franke, 1992; Hodgen, 2011; Rowland & Ruthven, 2011; Wagner et al., 2007). Conceptualizing a mathematical knowledge for teaching would unlikely to be successful unless it carefully takes the classroom context of teachers’ professional work into account (Hodgen, 2011; Rowland & Ruthven, 2011; Sherin, 2002). The reason behind this failure may originate from the de-contextualization of teachers’ knowledge (Hodgen, 2011). Focusing the use of teacher knowledge in the practice of teaching may lead more sound results in investigating teachers’ knowledge (Hodgen, 2011; Rowland & Turner, 2007).

Considering our concerns on the nature of teachers’ professional knowledge, one framework which may provide studying teachers’ content knowledge during instruction is the Knowledge Quartet (KQ) (Rowland et al., 2005). The framework suggests four broad units in investigating teachers’ mathematical knowledge in teaching. These are (i) foundation, (ii) transformation, (iii) connection, and (iv) contingency.

The first unit of the KQ is rooted in the foundation of teachers’ knowledge, beliefs and understanding of mathematics and teaching. The remaining three units originate from a foundational underpinning. The second unit of the KQ, transformation, is knowledge-in-action which is visible throughout planning and teaching. The unit includes a teacher’s capacity in transforming the content knowledge into pedagogically powerful forms. Connection concerns the depth, breadth and coherence of relationships demonstrated in a lesson or between lessons. The fourth unit of the framework, contingency, encompasses to responding appropriately to the events and ideas which occur in classroom during instruction. It is about contingent action of teachers in the classroom (Rowland et al., 2005). Each of these KQ units is represented with codes. For example, there are three codes for contingency (responding to students’ ideas, use of opportunities, and deviation from agenda). There are eight-teen codes in total for four units (Rowland & Turner, 2007). Within its current form, the units of the framework are not directly linked to Shulman’s conceptualization of subject matter knowledge and pedagogical content knowledge. However, within the units, the framework aims to cover those knowledge types. The KQ has been grounded in classroom practice, and the findings have been open to enhancement and revision in the case of new research data. In this sense, the KQ can be effectively used to investigate the way content knowledge enacts during instruction. A detailed account of the framework may be reached from the researchers previous studies (Rowland et al., 2005).

THE TEACHING AND LEARNING SLOPE OF A LINE

In order to examine and evaluate teachers’ knowledge on a topic, it is important to address crucial mathematical ideas for the topic and literature on teaching and learning of it. Therefore, in this part of the paper, we will highlight mathematical importance of the topic ‘slope’ and some literature on teaching and learning of it. Slope is a deep and multi-faceted concept (Stump, 1999). Learning slope requires proper comprehension of important concepts such as ratio, rate of change, proportionality, covariation, and synthesis of different representations. Hence, understanding slope of a line in early grades is especially crucial for future learning. Comprehension of slope through algebraically, geometrical or by other representation as well as the connections between them requires conceptualizing an important set of concepts.

Slope is a fundamental but a conceptually complex concept for students in learning algebra (Lobato et al., 2003; Stump, 1999, 2001). Rasslan and Vinner (1995) investigated that majority of the nine graders did not realize that “the slope is an algebraic invariant of the line and therefore does not depend on the coordinate system in which the line is drawn” (p. 264). In addition, Saldanha and Thompson (1998) suggested that it may be challenging for students to understand “graphs as representing a continuum of states of covarying quantities” (p. 7).

Lobato and Bowers (2000) provided that students have various difficulties in learning quantitative complexity of slope. For example, majority of the participants in the study showed difficulty in understanding the role of change in rise and run on steepness of a line. In addition, students have difficulties in regarding slope as a ratio (Bell & Janvier, 1981; Leinhardt et al., 1990; Lobato et al., 2003).

The previous studies showed that there exist a number of misconceptions among learners on slope concept. Some of the incorrect ideas mentioned in the literature were: the quadrant where the line is located is related to slope value, changing slope alters y-intercept of the line, slope is the scale of the x-axis, and slope is the difference in y-axis (Lobato et al., 2003). Among them, slope-height confusion is very common. Being aware of those misconceptions is crucial in teaching slope.

THE STUDY

The aim of the study was to investigate teachers’ responses to students’ unanticipated questions as an indicative of their content knowledge. In other words, in this paper, findings about teachers’ knowledge of contingency (as defined in KQ) will be examined. Therefore, the research question is that *How does mathematics teachers’ responding to students’ ideas indicate their content knowledge in teaching slope of a line?*

The original study focused on two pre-service, two early novice (0–2 years of experience), and two more experienced novice (3–5 years of experience) middle school mathematics teachers` content knowledge on slope at 8th grade in Turkey. One of the researchers conducted individual pre-interviews, recorded 1–2 lesson hours of slope instruction, and finally conducted post-interviews. Pre and post interview data were used for triangulation but main data source was video-tapes of classroom instruction and researchers’ observation notes of the instruction. Instruction data were transcribed and open-coded. In data analysis, the researchers attempted to reach themes for the open coded data. Then, for each theme, one of the eighteen codes of the KQ has been assigned. Since assigned KQ codes belong to the units, we were able to categorize each significant episode of instruction in terms of the KQ framework units. Lastly, findings were compared between groups and similarities and differences were discussed. A detailed account of the framework, methodology, and findings may be reached from the thesis study (Koklu, 2012).

The aim of the current paper is to discuss teachers’ responses to students’ unanticipated questions to examine their knowledge on students` mathematical thinking. For the purpose, *contingency* episodes were used to investigate research question. Furthermore, data from two teachers (Akif and Merve, pseudonyms) was used because their instruction had clear contingency episodes; they encouraged students to share their opinions in the classroom. For each teacher, first, the instructions will be summarized briefly then one contingency episode will be provided. It should be noted that there were more contingency instances for teachers but because qualitative research findings report less raw data but more interpretation, we will give only one example for each teacher. Further examples and detailed information about the analysis can be found in Koklu (2012).

A PRE-SERVICE TEACHER’S CASE: ALGEBRAIC REPRESENTATION OF A VERTICAL LINE

Akif was a pre-service teacher in senior year who was practicing in 8th grade mathematics course. He described the aim of the lesson in the lesson plan as “*Students will be able to explain the relationship between slope and equation of a line.*” Akif segmented lesson into three phases. In the first phase, Akif introduced the slope concept. The second phase based on a task. The task included a scenario and a numerically represented tabular data and asked students to; (i) graph a line, (ii) write its equation in slope-intercept form, (iii) compute slope on graph, and (iv) investigate that slope and the coefficient of x are same in a slope-intercept form of line equation. The lesson followed by a computation on a series of exercises in which students were asked to match line equations and graphs of lines in coordinate plane. The line equations given for the exercise were as follows: $y = 8 - 4x$, $y = 2x - 2$, $y = 3x + 6$, and $y = -x + 2$. The teacher preferred first to find slope of lines on the equations. Then, he found the slope of lines on the graphs and related these slopes to the equations by using the relationship discussed.

The below episode was coded as *contingency* because of the teacher’s reaction to a student’s comment. The teacher applied the algebraic relationship between slope and the coefficient of x in slope-intercept form of line to compute slope. Then, a student raised an important idea.

Teacher: We said that the coefficient of *x* would be the slope, okay the coefficient of *x* since *y* stands separately [in one side of the line equation].

Student: If there would be a number instead of *y* what would be the answer?

Teacher: If there would be a number [he repeats student’s idea and waits a second] you mean no *y* [he meant the case in which no y appears in line equation].

Student: Yes.

Teacher: When we are write such an equation [he indicates the graph of $y = 2x$] we need to write in terms of *x* and *y*, think when we graph a linear equation you should remember that [he graphs a line which has a negative x-intercept and positive y-intercept] let’s x-intercept would be a and y-intercept would be b. When we write it, we were saying x over a plus y over b equals to 1 [he wrote $x/a + y/b = 1$].

Student: I do not know it.

Teacher: Okay, let’s skip it. Why there should be y here [thinks a second] if there was not a y, then how can we indicate the number of goods produced [he refers to the activity of the lesson] based on the number of employees.

Student: Right.

Teacher: One variable needs to depend on the other there is a relationship between the variables there is a combination of two hence I cannot assume that one [indicates the variable] is missing. Two of them [indicates the variables] have to exist at the same time. As a conclusion we write in this way.

This episode indicated that even though the teacher tried to respond student’s idea in multiple ways, he was *unable to suggest a correct explanation.* In other words, Akif was unable to recognize that a line equation does not need to include two variables. A vertical line, for example, is expressed by one variable. The data suggested that in the first explanation the teacher was unable to address student’s comment because his explanation already necessitates the existence of two variables. The teacher’s second explanation referred to his activity. According to his activity, a case such as the student proposed would not be possible. The explanation made by the teacher seemed to satisfy the student even though the explanation does not address the student’s question.

The data suggested that the teacher responded to student’s idea willingly even though his responses did not address the question. It seems that the teacher was not able to remember vertical lines. It was remarkable that the teacher did not resort to slope concept. The basic idea that the teacher should know is that slope is a concept which is defined on non-vertical lines. Mathematically, slope of a vertical line is undefined.

During data analysis we labelled the above case and the similar ones as our themes. Then, for each theme, codes of the contingency unit of the KQ have been assigned. Since assigned codes belong to the units of the KQ, we were able to categorize each significant episode of instruction in terms of the framework. To illustrate, the above episode suggested a student involvement to instruction hence we assumed that “responding to student ideas” code from the contingency unit of the framework would be an appropriate coding. Revisiting the episode several times suggested that the other two codes of the unit, “use of opportunities” and “deviation from agenda” might also be involved to the episode. As a result, this single episode suggested a very fruitful conclusion for our data analysis. Teacher’s inability to respond student idea refrained him using it as an opportunity and deviate from his plan. Even though, the data does not yet allow us to claim that the observed teacher lacks necessary knowledge on vertical lines and their representation, our finding in this part helped us to speculate the teacher’s current state of knowledge on vertical line, its connection to slope, and the necessary skills and professional knowledge on how to teach it in such a context. Overall, we claimed that the episode of a student asking a question and the way the teacher reacted enables us to say more about the teacher’s content knowledge on teaching slope.

A NOVICE TEACHER’S CASE SELECTING TWO POINTS ON A LINE IN ANY ORDER

Merve started instruction with the graph of y=2x and yield the slope by first forming a right triangle on the coordinate plane and second by creating a table in which x and corresponding y values are inserted from the points got from graph. She showed that the slope of the line is same as the coefficient of x in the equation. As a second phase, the teacher provided four lines that pass through origin in the same coordinate plane. The teacher formed a whole class discussion on the inclination of the lines and the *sign* of the slope. She used slopes of lines graphed ($m = 1$, $m = 4$, $m = -4$, $m = -1$) to help students compare lines. The teacher summarized the findings. Then instruction on finding slope from the graphs was given. For the next phase, Merve asked students to find the equation of a line which given graphically. Merve indicated that the slope value and the coefficient of x are same. Then, the teacher asked further exercise questions to apply the newly learned relationship on $y = 3x$, $y = -2x + 1$, $y = 12 - 3/4$, $2y = 12x + 6$, $5y = 10 - 7x$, $3x + 4y - 8 = 0$ and $8x + 2y = 9$. In these examples students reached the slopes by using the relationship. Lastly, Merve asked students to find slope of a line in which only two coordinate points are given, (1,2) and (3,6). The students had difficulties in reaching both the intercept points of the line and its equation. The teacher reminded that they knew how to write equation of a line from its intercept points. The last exercise question was about finding slope of a line which passes through (-2,4) and (-1,-5) and write the equation of the line by using the points and calculated slope.

To compute slope, the teacher used the tabular data (Table 1). Merve told that students should be careful in considering the first point. According to her, between two selected coordinate points, students should take the point as first if its x-value is smaller than the other point's. In brief, Merve chose (0,2) as the first and (3,0) as the second point in computing slope.

x	y
0	2
3	0

Table 2: Tabular data used for coordinate points of the line

A student objected to Merve by claiming that it is not necessary to fix a point as first or second. The below episode indicate the teacher's reaction to a student's comment.

Student: If we did not take 2 as the first value for y [in the formula]
Teacher: Every time from left [teacher indicated to the left side of the graphed line which has smaller apsis]
Teacher: Hey kids Ali again asked a good question he said that if I would write (3,0) at first what would be the conclusion he said that he found the inverse hey kids if you recognize I start writing with smaller x values from this side [pointing from (0,2) to right side] in writing the change I start with the smallest x values.
Student: The point where x is smaller.
An. student: From left to right.
Teacher: Got it. I start where x is smaller.
Student: If we had written it would turn out the same thing since we again would write y's first.
Teacher: Let's try [the teacher applies the slope formula again and reaches the same conclusion]
Student: Yes same
Teacher: Okay good
Student: I already did in this way [the student indicates that he used the last way]
Teacher: Okay good, yes we have reached the same conclusion.

The episode indicates that though the teacher did not suggest the rationale explicitly, she showed it procedurally on an exercise question. It was particularly interesting that the teacher did only resort to a procedure that may be regarded as a pure idea in teaching slope concept. To check whether the student's idea is correct she only applied the procedure. There is a fundamental knowledge that two arbitrary points on a line may possibly give its slope. Lines are not as vectors though there is a resemblance in shape. A vector is a directed quantity so it has initial and ending points. In contrast, lines do not start or finish anywhere. All of these arguments suggest that we are not restricted to behave a point say A, as the first point and B as the second. In either order, the slope will be equal. All of these important ideas may be showed through slope formula. This episode reminded Saldanha and Thompson's (1998) suggestion that it may be challenging for students to understand "graphs as representing a continuum of states of covarying quantities" (p. 7). There is some evidence here that teacher's overall knowledge of line and skills for teaching slope of a line has some slightly weak parts. However, she was also able to use students' ideas as teaching opportunity. Though this single episode does not indicate a big problem, it helped us to put more attention on the issue throughout the full video recorded data.

CONCLUSION

To conclude, responding to students' ideas, first of all, requires active and careful listening of students' content related expressions (Davis, 1997; NCTM, 2000). The study supports Sherin (2002) that students' behaviors such as elaboration of their ideas may be regarded as a chance for teachers to revise their content knowledge. Knowledge of students ideas is regarded as pedagogical content knowledge (Shulman, 1986, Ball et al., 2008) however teachers' responses to student ideas also indication of their subject matter knowledge too. Using Knowledge Quartet as the framework for analysis, we were able to focus on episodes of *contingency* which reflected teachers' knowledge on slope. Teachers may effectively use those episodes to increase their and students' knowledge (Franke et al., as cited in Sherin, 2002). The results are very consistent with the claims made by Rowland, Thwaites, and Jared (2011) that teachers' contingent action provide valuable information on the effect of teachers' content knowledge in teaching. Furthermore, as authors addressed *contingency* episodes are not isolated from other units rather includes them. The contingency episodes that were discussed in this paper not only show teachers' way of responding to students' ideas but also their knowledge of the subject too.

Teachers' resources in analysing mathematical content and classroom situations: The case of using multiple tepresentations

Sebastian Kuntze, Anika Dreher and Marita Friesen

Ludwigsburg University of Education, Ludwigsburg, Germany, kuntze@ph-ludwigsburg.de

Using multiple representations for mathematical objects in the classroom is a key for fostering students' understanding. As teachers have to analyse both mathematical content and classroom situations in order to effectively accompany learning processes, they need corresponding professional knowledge and resources. As specific empirical research is scarce, this study aims at collecting first evidence about whether and how different samples of pre-service and in-service teachers analyse content against the idea of using multiple representations and whether these content-related resources interdepend with their awareness of the role of dealing with representations in classroom situations. The findings indicate expected differences in resources and interdependencies between CK and PCK.

Keywords: Teachers' analysing, PCK, CK, multiple representations.

INTRODUCTION

Teacher expertise is related to personal resources in various domains of content knowledge (CK) and pedagogical content knowledge (PCK, cf. Shulman, 1986). A reservoir of such CK and PCK is needed in particular when teachers have to analyse learning opportunities and subject matter on the one hand or specific interaction situations with learners in the mathematics classroom on the other hand. Making connections with professional knowledge in these two contexts belongs to the core of what is required from mathematics teachers in their profession. This holds in particular for being able to analyse content matter and classroom situations against criteria related to the use of multiple representations, as abstract mathematical objects can hardly be accessed without any representations (cf. Duval, 2006).

Consequently, there is a high interest in investigating whether secondary teachers from different school types are able to analyse (A) how mathematical content affords using multiple representations and (B) how problems for learners may emerge from a non-optimal use of multiple representations in classroom situations. To our knowledge this is the first study with a quantitative empirical scope on the potential interrelatedness of these domains of teachers' profession-related analysing.

In order to clarify our focus on teachers' analysing, we will in the following introduce into the theoretical background of this study, derive the research questions from these thoughts, inform about sample and methods, present results and discuss their implications for the theoretical and practical contexts.

THEORETICAL BACKGROUND

As mathematical objects are only accessible through representations (Duval, 2006), representations play an important role in the process of mathematical learning and its support in the classroom. Different representations can stand for a mathematical object (Goldin & Shteingold, 2001), so using multiple representations may support learners in learning more about the mathematical object behind these different representations (Lesh, Post, & Behr, 1987) and in distinguishing the mathematical object from its representations. As different representations mostly emphasise different aspects of the corresponding mathematical object, the use of multiple representations enables learners to build up a rich concept image (Tall, 1988; Ainsworth, 2006). Connecting different representations as well as changing between representations provide thus crucial learning opportunities (e.g., Ainsworth, 2006; Duval, 2006; Lesh, Post, & Behr, 1987; Ainsworth, 2006).

Using multiple representations for mathematical objects in the classroom is hence a key for fostering students' conceptual learning (see also Dreher & Kuntze, 2013). Accordingly, teachers need professional knowledge so as to foster their students' learning – and they have to be able to *use* this knowledge in analysis processes. Analysing mathematical content against the background of multiple representations (A) is probably as important as analysing related to ways of dealing with representations in the learning process (B). In the following, we will concentrate on the teachers' analysing and the underlying professional knowledge they refer to.

As a framework, this study uses a multi-layer model (Kuntze, 2012), which combines Shulman's (1986) domains with the spectrum between knowledge and prescriptive convictions/views (Pajares, 1992), which are considered as individual professional knowledge as well. As a third dimension, the degree to which professional knowledge is bound to content or classroom situations is used to distinguish different levels of globality (cf. Törner, 2002), resp. situatedness (vertically ordered layers in Figure 1). The cells of the model in Figure 1 should not be seen as completely separable – indeed, the extent to which components of professional knowledge are consistent across different cells may even be interpreted as an indicator of teacher expertise (cf. Doerr & Lerman, 2009). A more detailed description of this theoretical background is given in Kuntze (2012) and Dreher and Kuntze (2015a).

Professional knowledge related to using multiple representations is a resource (Schoenfeld, 2011) for teachers, which is the base on which they can draw when they analyse content matter related to learning opportunities or the interaction with students in classroom situations. By *analysing* we understand *an awareness-driven, knowledge-based process which connects the subject of analysis with relevant criterion knowledge and is marked by criteria-based explanation and argumentation.* The subject of analysis can be for instance an area of content knowledge (A) or a classroom situation (B). Both of these are in the focus of this study.

Analysing mathematical content with respect of criterial knowledge related to using multiple representations (A) means in particular that teachers can identify and connect different representations of mathematical objects, but also that they can think of examples of content in which the use of multiple representations plays an important role for example, for gaining in-depth conceptual insight or for simplifying problems (cf. Kuntze et al., 2011). Such analysis steps draw above all on content knowledge (CK). An example of a question which requires analysing content in such a way is given in Figure 2 (in the methods section): For answering this task, teachers have to be able to review examples of content matter according to criterial knowledge related to using multiple representations and hence to make connections between examples of content matter according to this criterial knowledge.

Analysing classroom situations against the background of dealing with representations (B) is more based on aspects of pedagogical content knowledge (PCK). In particular, the following processes play a role which are also connected to aspects of teacher noticing (cf. Friesen et al., in this proceedings book): 1) Identifying relevant situations concerning the use of representations, which marks the "starting point" of an analysis, 2) evaluating such situations in a critical way which is based on connecting relevant situations and arguments to corresponding elements of theory regarding the use of representations, and 3) presenting/articulating the results of the analysis. These processes should not be considered as ordered or completely

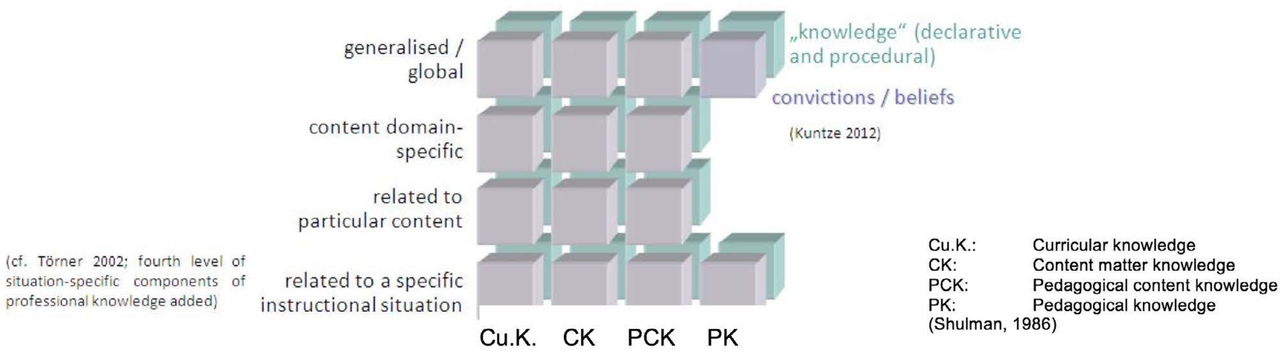

Figure 1: Multi-layer model for components of professional knowledge

separable, as there may be jumps or simultaneous processes.

In both cases, the analysis needs an initial awareness of criteria linked with using multiple representations. Moreover, making connections between this criterial knowledge on the one hand and specific content or characteristics of a specific classroom situation on the other hand is needed. Drawing on criterial knowledge affords explaining the subject of analysis and identifying arguments for the conclusions which are necessary for an appropriate answer. For this reason, potential interdependencies between teachers' personal resources in analysing merit attention.

Despite a clear relevance of the requirement of analysing the use of multiple representations in content matter and classroom situations for teaching mathematics, research focusing on teachers' analysing related to these aspects is scarce (cf. overviews in Dreher & Kuntze, 2015a, 2015b). More specifically, to our knowledge this is the first quantitative empirical study which focuses on interdependencies of teachers' analysing related to these domains of professional knowledge. For exploratory insight and against the background of differences (cf. Dreher & Kuntze, 2015a, 2015b), it is also necessary to explore whether there are differences between teachers from different school types and between in-service and pre-service teachers.

RESEARCH QUESTIONS

Against the background outlined in the previous section, there is a need of research exploring teachers' analyses of content matter (A) and of classroom situations (B) related to using multiple representations. Using multiple representations is thus an overarching concept (cf. Kuntze et al., 2011) which affords analysing and making connections between professional knowledge and the subjects of analysis, namely examples of content and classroom situations.

This study hence aims at answering the following research questions:

— To what extent do in-service teachers have professional knowledge necessary for analysing whether content matter can be connected with the overarching concept of using multiple representations?

— Are there differences between in-service teachers from different school types?

— How big are these differences in comparison with the knowledge and analyses of pre-service teachers?

— Does the quality of analysing content matter regarding the use of multiple representations interdepend with the in-service teachers' analysis of classroom situations based rather on PCK?

SAMPLE AND METHODS

The in-service teachers participating in this study belonged to two sub-samples: There were in total 58 German in-service teachers which consisted of:

— 34 teachers from academic-track secondary schools (20 female, 14 male; mean teaching experience 14.8 years, SD=13.4 years)

— 24 teachers from secondary schools for lower-attaining students (9 female, 15 male; mean teaching experience 10.7 years, SD=9.5 years)

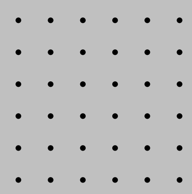
Moreover for answering the third research question, 117 German pre-service teachers were included (78 female, 35 male, 4 without data; mean age of 22.33 years, SD = 3.56 years) who had been studying on average for 2.19 semesters (SD = 1.12). Within this sub-sample of pre-service teachers, 61 were preparing for being teachers in primary schools, 32 in secondary schools for lower-attaining students (HSWRS), and 15 for working in schools for students with special needs (9 without data). An additional sample of 42 Austrian pre-service teachers preparing for teaching in academic-track schools were included for exploratory comparisons.

In order to tap the teachers' analyses of contents, a test was conceived with a focus on analysing contents and perceiving links across contents according to overarching concepts. The instrument concentrated on CK-related analyses connected with the overarching concepts *using multiple representations*, *dealing with infinity*, and *giving arguments/proving*. (cf. Kuntze et al., 2011). This study only focuses on the teachers' answers to two tasks related to using multiple representations, a sample task is presented in Figure 2. The answers were collected in an open format, the

On the right, there is a graphical representation of the definition of "square number". This representation affords an additional access compared to the symbolic definition ("if $q=n^2$ for a positive integer n, the q is called a square number").

Can you think of other mathematical concepts, for which a symbolic definition can complement with a non-symbolic representation in a similar way?

Please give as many examples as possible.



„A number that can be visualised like shown here in the form of a square is called a square number."

Figure 2: Sample task for analysing and connecting content according to the overarching concept of using multiple representations (Kuntze et al., 2011, p. 2722)

teachers were given as much time as they required to complete the test.

The answers were coded according to a top-down coding method (see Kuntze et al., 2011, for details and sample answers). Among others, the coding categories *existence of a codable answer*, *quality and transfer level of the examples*, and *embedding of examples provided* were used. An indicator score was generated in the following way: If the teachers gave at least one appropriate example, their answer was coded with 1 point, if at least one of the examples was from a different content area than the example given in the task, the full score of two points was assigned to the corresponding answer, as in this case we can assume that the teacher had shown awareness of criterial knowledge related to using multiple representations and analysed successfully at least one example of content matter.

In classroom situations, the quality of the use of multiple representations often depends on how carefully teachers link different representations and whether they accompany the students' understanding with this respect. For tapping the teachers analyses in this area, we used an instrument which is described in detail in (Dreher & Kuntze, 2015a). In this instrument, the teachers are given fictitious transcripts of classroom situations (related to the content area of fractions) in which the teacher changes the representation register unnecessarily and without explicitly providing help or explanation for linking the corresponding representations. In the situation in Figure 3, this is the case for the teachers' change to the pizza representation. The participating teachers were asked to evaluate how the given teacher's reaction supports the student's understanding in this situation and to give reasons for their evaluation. According to the design of the classroom situations, the participating teachers' analyses of these situations based on their PCK related to using multiple representations should hence lead to a critical evaluation of the way how multiple representations are used (Dreher & Kuntze, 2015a). A

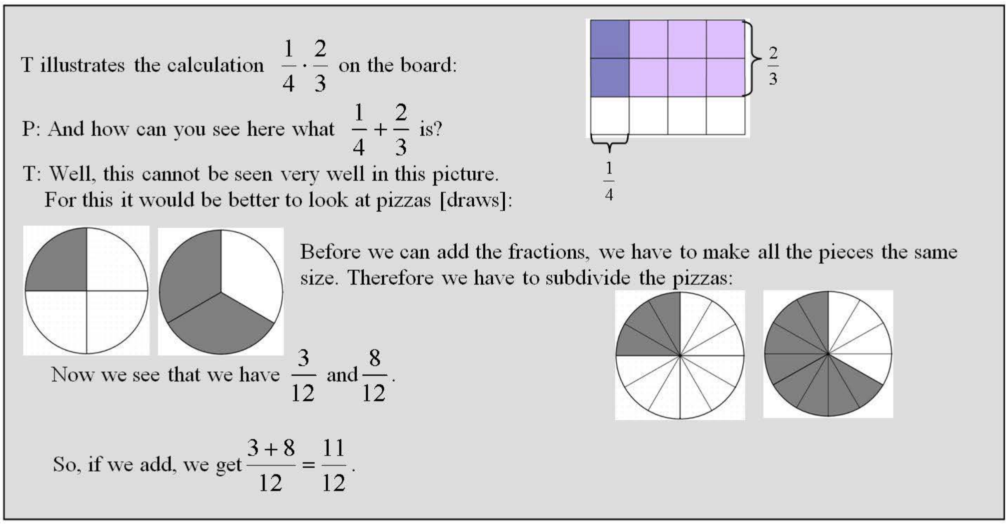


Figure 3: Classroom situation to be analysed according to the use of multiple representations (Dreher & Kuntze, 2015a)

corresponding top-down coding was consequently done with the teachers answers which were collected in an open format. Based on these codes, a score was calculated by counting successful answers. As there were four classroom situations, these scores ranged from 0 to 4 points (Dreher & Kuntze, 2015a).

For answering the fourth research question which focuses on interdependencies between the two analysis scores, correlations (Pearson) were calculated. As there was the possibility of controlling for specific CK related to changing between representations of fractions (for details about this additional instrument see Dreher & Kuntze, 2015a), this variable could be included in a regression model which affords describing the interdependencies in the focus of the fourth research question.

RESULTS

The first, second, and third research questions focus on the extent to which different samples of in-service and pre-service teachers analyse content matter against the background of the overarching concept of dealing with multiple representations. Figure 4 shows an overview of these results. The in-service teachers working at academic track secondary schools reached on average about two thirds of the full test score related to analysing and connecting content matter through the concept of using multiple representations. In contrast, the in-service teachers from HSWRS secondary schools were significantly less successful in these analyses (T-test; T=3.40; df=56; p=.001, d=0.90). However, each sub-sample of in-service teachers scored significantly better than the corresponding sub-sample of pre-service teachers (academic-track teachers: T=3.32; df=74; p=.001, d=0.76); HSWRS teachers: T=4.75; df=54; p<.001, d=1.23). The values of Cohen's d indicate that these are strong effects. The average score of the academic-track pre-service teachers was very similar to the score of the HSWRS in-service teachers.

As the data in Figure 4 is rather connected to the teachers' CK it may be of additional interest that we found in a corresponding study (Dreher & Kuntze, 2015a, 2015b) that there was a relatively similar pattern for teachers' analyses of classroom situations against the background of dealing with multiple representations, which is rather based on teachers' PCK. This points to the fourth research question, which concentrates on connections between CK-related and PCK-related variables.

CK, especially CK related to the particular content, is probably important for analysing classroom situations. For this reason specific CK (in this case related to the use of multiple representations with fractions) was also included in the study as an additional variable. Table 1 shows correlations, which suggest that for academic-track teachers the more overarching CK-related variable has played a more important role than the more specific CK variable (fractions) which is more close to the classroom situations the teachers had to analyse.

Deepening this insight, we included the variables in regression analyses (cf. Table 2). The results show that analysing contents according to the overarching concept of using multiple representations (B) interdepended more strongly with the quality of the analyses of classroom situations (A, i.e., the corresponding score as independent variable), than specific CK related to using multiple representations of fractions – and that in particular it plays a significant role even if the data is controlled for the fraction-related "local" CK component, as far as the in-service academic-track teachers are concerned.

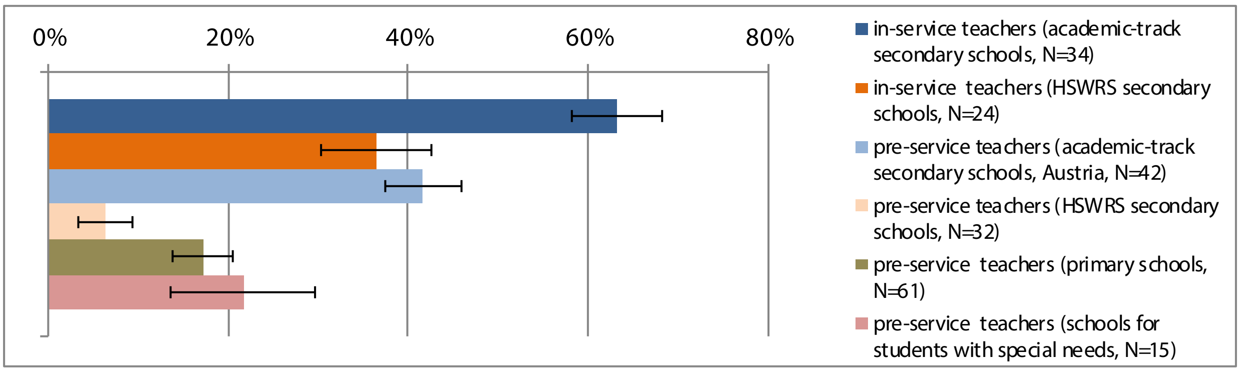

Figure 4: Analysing contents against the overarching concept of using multiple representations: Means and their standard errors

Correlations with score related to analysing classroom situations with respect to using multiple representations (B) (Dreher & Kuntze, 2015a)	Subsample of all in-service teachers (N=58)	academic-track in-service teachers (N=34)	HSWRS in-service teachers (N=24)
CK-related score „using representations in the content area of fractions" (Dreher & Kuntze, 2015a)	,128 ,333	-,031 ,863	,217 ,309
Score "analysing content matter with respect of using multiple representations" (A) (Kuntze et al., 2011)	,319* ,014	,365* ,034	-,021 ,922

Table 1: Correlations (Pearson) and significance values (2-sided)

		B	St. error	Beta	t	p
HSWRS in-service teachers	(Intercept)	,235	,077		3,046	,006
	CK-related score „using representations (fractions)"	-,206	,197	-,238	-1,050	,306
	Score "analysing content matter with respect of using multiple representations"	,028	,105	,061	,269	,791
academic-track in-service teachers	(Intercept)	,201	,132		1,523	,138
	CK-related score „using representations (fractions)"	-,146	,195	-,129	-,752	,458
	Score "analysing content matter with respect of using multiple representations"	,300	,130	,396	2,318	,027

DISCUSSION AND CONCLUSIONS

Before discussing the results in detail, it is important to recall that the study has clear limitations, as the findings hardly allow for generalisation. For instance, the samples are not representative for German teachers, and the research instruments should be extended in follow-up research. However, the findings afford answering the research questions and call for further investigation in related empirical studies.

The following key findings can be summarised:

— The results related to the first research question indicate that many of the academic-track secondary teachers were not able to connect the overarching concept *using multiple representations* to at least one example of mathematical content. Analysing content against this criterial knowledge appears hence to be very difficult even for in-service teachers from academic-track secondary schools.

— Teachers from HSWRS schools showed, however, even less elaborated analyses and a significantly lower professional knowledge related to connections with the overarching concept of using multiple representations. In line with findings from Dreher and Kuntze (2015b), the findings related to the second research question thus suggest that the culture associated with different school types or selection effects of teachers might play an important role and that there are school-type-specific professional development needs.

— As appropriate answers of the pre-service teachers were – as expected (cf. Kuntze et al., 2011) – even less frequent, the findings associated with the third research question point to a substantial need for teacher education.

— As far as the fourth research question is concerned, the results related to interdependencies may be seen as consistent with corresponding findings from the COACTIV study (e.g., Kunter et al., 2013), suggesting that there might be general interdependencies between CK and PCK. This study can add preliminary, but more specific insight by focusing on the teachers' analysing.

Follow-up questions arising from the findings open up several directions for further research: First of all, there is a clear relevance for the development of theory: What status does analysing related to overarching concepts (cf. Kuntze et al., 2014) have as a component of mathematics teacher expertise and to what extent do different contexts of profession-related analysing interdepend? But there are also more practice-related follow-up questions, such as: How can CK and PCK related to overarching concepts be supported best in professional development programs? When and how can growth in the corresponding domains of professional knowledge take place? Which role may be played by classroom experience or curricular knowledge? Finally, also aspects of the further development of the test instrument are in the focus (e.g., extensions to more overarching concepts, other test formats) and may contribute to a deepened understanding of the findings and teachers' profession-related analysing.

ACKNOWLEDGEMENT

The data gathering phase of this study has been supported in the framework of the project ABCmaths which was funded with support from the European Commission (503215-LLP-1-2009-1-DE-COMENIUS-CMP). This publication reflects the views only of the authors, and the Commission cannot be held responsible for any use which may be made of the information contained therein.

We further acknowledge the support by research funds of Ludwigsburg University of Education (project La viDa-M) during the data analysis phase.

What does it mean as a teacher to "know infinity"? The case of convergence series

Miguel Montes and José Carrillo

University of Huelva, Huelva, Spain, miguel.montes@ddcc.uhu.es

This paper aims to explore the knowledge of infinity that three teachers deploy in making methodological suggestions for dealing with the convergence of a geometric series in a secondary level lesson. We will also illustrate the potential of the model of professional knowledge known as Mathematics Teacher's Specialised Knowledge (MTSK) as a tool for analysing the knowledge of infinity underpinning the three proposals. The mathematical knowledge revealed is considered, alongside suggestions for further exploration of the pedagogical knowledge of the three teachers regarding infinity.

Keywords: Infinity, professional knowledge, MTSK, series, secondary teacher knowledge.

INTRODUCTION

It is widely acknowledged that the nature of a mathematics teacher's knowledge of the subject is different to that of other people involved in mathematics. To this end, Ball, Thames and Phelps (2008) specifically identify the sub-domain *Specialised Content Knowledge* within their analytical model, MKT, in contrast to that of *Common Knowledge*, with the aim of underlining the kind of knowledge about certain topics required of a teacher, but not necessarily required of others who habitually draw on mathematical knowledge. An alternative model was recently presented, *Mathematics Teacher's Specialised Knowledge*, henceforth MTSK (Carrillo, Climent, Contreras, & Muñoz-Catalán, 2013), the premise of which is that the specialisation derives not from the unique nature of the teacher's knowledge in itself, but from the use to which this knowledge is put in teaching. It is from this perspective of specialisation, following Montes, Carrillo and Ribeiro (2014), that we consider the concept of infinity and its significance to the teacher's store of professional knowledge.

The concept of infinity is an interesting case because it touches many areas of the secondary curriculum, and is hence especially relevant to analysing teachers' mathematical knowledge. From our perspective, a teacher's knowledge of infinity is specialised by virtue of the fact that, as practitioners, they need to know how to deploy their knowledge in contexts of teaching and learning. This paper applies this perspective to the question of how this knowledge influences the methodological considerations involved in planning a lesson on the convergence of a series generated by successive powers of ½. In doing so, it hopes to illustrate the effectiveness of the MTSK model in revealing the specialised knowledge underlying teachers' decisions.

THEORETICAL FRAMEWORK

The MTSK model (Figure 1), which provides the theoretical background to this paper, consists of six sub-domains divided between Shulman's (1986) original dichotomy of *Subject Matter Knowledge* and *Pedagogical Content Knowledge*.

In terms of purely mathematical knowledge, it proposes three sub-domains. The first of these, *Knowledge of Topics*, brings together all topics involved in the teaching-learning binomial, including many aspects which are seldom made explicit to students, but can nevertheless be understood as fundamental to the teacher's knowledge. The second, *Knowledge of the Structure of Mathematics*, concerns the connections between areas, such as concepts which range across the curriculum (as in the case of the concept of infinity). Finally, *Knowledge of Practices in Mathematics* encompasses ways of doing and proceeding with mathematics. There are likewise three sub-domains within *Pedagogical Content Knowledge*, which aim to enhance the specifications proposed by Ball and colleagues (2008). The first of these, *Knowledge of*

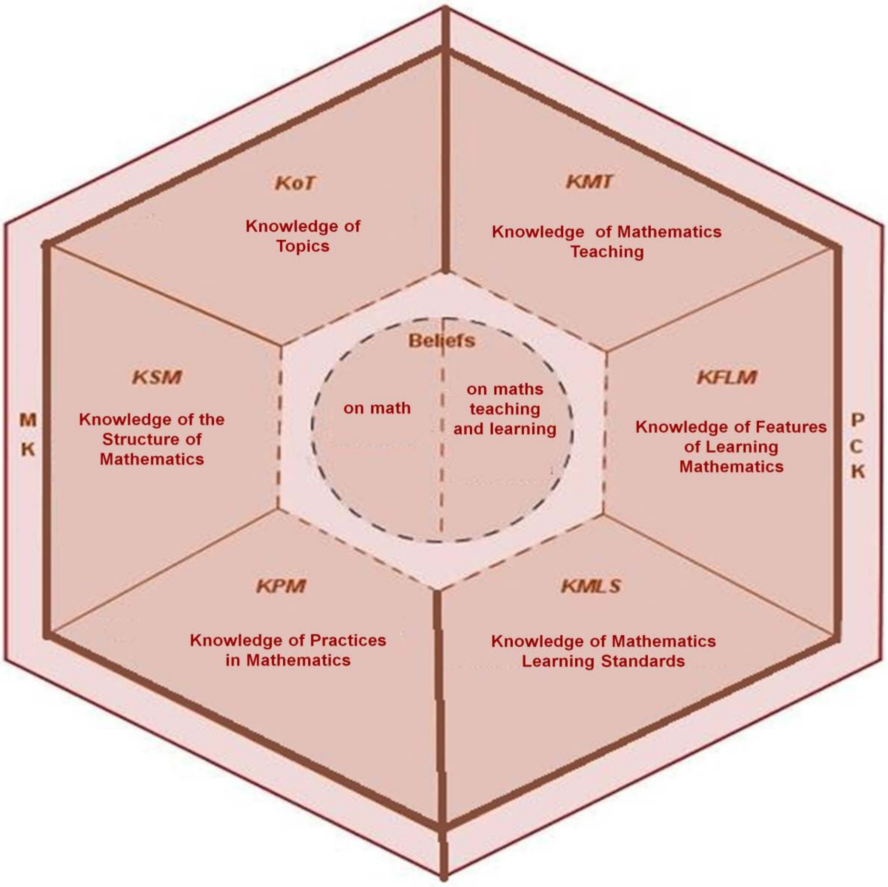

Figure 1: Mathematics Teacher's Specialised Knowledge

Mathematics Teaching, refers to knowledge about ways of presenting mathematical content in the classroom. The second, *Knowledge of the Features of Learning Mathematics*, concerns knowledge about how pupils learn, understand and interact with mathematical content. The last, *Knowledge of Mathematics Learning Standards*, includes knowledge relating to the curriculum and learner expectations in respect of year group, age and educational stage.

A professional understanding of infinity

The concept of infinity, as an item of human knowledge, has been widely studied over the centuries and at the present time is understood as a property of various sets (Moreno & Waldegg, 1991). With respect to research into infinity and learning, studies have considered the *intuition of infinity* (Fishbein, Tirosh, & Hess, 1979), the relation between conceptions of infinity and understanding the notion of limit (e.g., Sierpinska, 1987), how infinity is dealt with in class (e.g., Hannula, Pehkonen, Maijala, & Soro, 2006; Roa-Fuentes, 2013), and the development of students' understanding of situations closely associated with the concept (Arnon, Cottrill, Dubinksy, Oktaç, Roa-Fuentes, Trigueros, & Weller, 2014). Nevertheless, the concept of infinity has received scant attention as a component of professional knowledge, that is as something useful for education as opposed to a mathematical item to be studied in depth.

Efforts to research teachers' knowledge of infinity have thus tended towards regarding their subjects as "possessors of advanced knowledge" on account of their training background, including mathematics training, and their familiarity with the various concepts pertaining to school mathematics. But interest in teachers' knowledge also derives from their capacity to satisfy their students' curiosity and provide valid responses to their questions. As Hannula and colleagues (2006) state, "Most primary children are very interested in infinity, and they enjoy discussing the concept, if the teacher is only ready for it" (p. 1). Any such responses must be founded on mathematics; the teacher needs to be aware of what to say and why this is valid. In this respect, there have been numerous studies into the misconceptions about infinity of different groups of teachers, focusing on the epistemological basis for their thinking (e.g., Kattou, Michael, Kontoyianni, Christou, & Philippou, 2009), the nature of the misconceptions themselves, including taxonom-

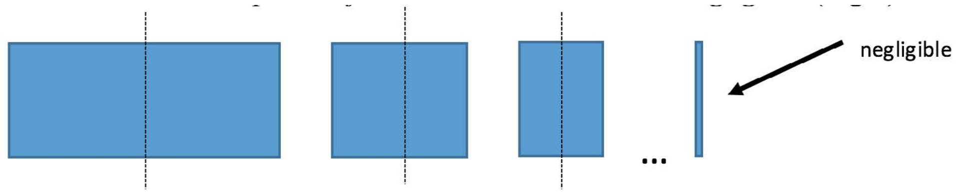

Figure 1: Graphical reconstruction of the explanation of Sandro

ical analysis (e.g., Yopp, Burroughs, & Lindaman, 2011), and the degree of cognitive development in relation to concepts associated with infinity (e.g., Weller, Arnon, & Dubinsky, 2009). Finally, some studies give special emphasis to how such misconceptions can be transmitted to students (Tall & Schwarzenberger, 1978). However, we would argue that the mere fact of being in possession of a valid response does not account for the full range of knowledge that a teacher mobilises when they construct an example, as shall be seen in the following section.

The potential of various models has recently been illustrated in relation to teachers' knowledge of infinity (Montes, Carrillo, & Ribeiro, 2014). In this paper, we consider the use of one such model, MTSK, in revealing the impact of the teachers' understanding of infinity on their planning for a lesson on the addition of geometric progressions.

METHOD

The data used in this paper are drawn from two separate but related case studies (Montes, 2011; Montes, in press), studying the knowledge of infinity of three teachers by means of an interview structured around the question, "How would you approach the addition of successive powers of ½ with a class of 16-year-olds?"

Here, we consider the different approaches adopted by the three teachers in response to this question. The first two, Sandro and Aaron, are mathematics graduates with 5 and 8 years' teaching experience behind them respectively, whilst the third, Manuel, also a mathematics graduate, was following a teacher training course at the time of the study. As noted above, all three were taking part in studies into their knowledge of infinity, and this meant that all of them took for granted that the interview about successive powers was concerned with the notion of convergence of an infinite series. Their suggestions for dealing with the concept in class are given below:

Sandro: *The usual thing is you say that they have a cake* [draws a rectangular cake], *and you eat half, and then half of the remaining bit, and then half again, and carry on like that a few times, and you see [...] You can also do it with a piece of paper, which you cut again and again, and each time you are left with a smaller piece, and they see that there comes a moment when the piece left over is so small as to be negligible* (Figure 1).

Aaron: *I'd take a piece of paper a metre wide as reference, and then one of half a metre, which I'd place on top. After that, another of a quarter of a metre, which I'd place on the right, and then one of an eighth, which I'd also lay on top. At some point, I'd get them to see that if you zoom in on the process, you get back to what was essentially the starting point, making a comparison between the piece left over and the original half-metre piece. I'd continue a few more times in the same way and get them to see that you can never get beyond that, however close you get* (Figure 2).

Manuel: *I'd get them to cut a sheet of paper in half, and then one of the halves in half again, and carry on like that five or six times until they see that you could continue with some 'super-sharp scissors' as many times as you like. Then I'd get them to write on each piece the fraction it represents, put all the pieces together*

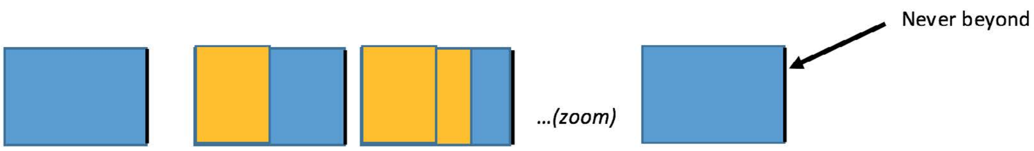

Figure 2: Graphical reconstruction of the explanation of Aaron

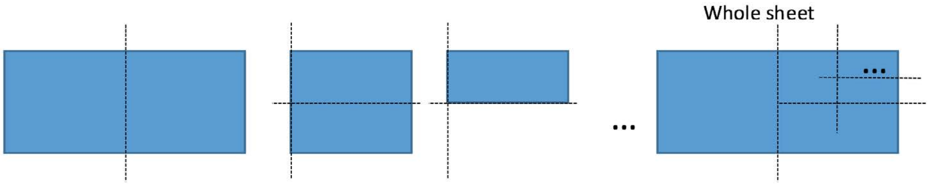

Figure 3: Graphical reconstruction of the explanation of Manuel

> *and imagine them all together, including the ones we could have cut but didn't, so that they became aware that all the pieces together comprise the whole sheet, which has an area of 1* (Figure 3).

ANALYSIS

This section takes the examples of three teachers talking about the same exercise and suggesting ways of dealing with it in class, and illustrates the potential these situations offer for exploring the knowledge displayed by the teachers beyond the strictly mathematical.

The three teachers take the same methodological approach in that they all recommend cutting paper in half, albeit that two – Sandro and Manuel – suggest the pupils themselves do the cutting, whilst in Aaron´s version it is the teacher who does this. In terms of the mathematical knowledge deployed, all three responses show understanding of the proposed scenario, predicated on convergence when adding a geometric series. However, the three scenarios reflect different understanding of the concept of infinity.

In the case of Sandro, his argument is based on the fact that after repeatedly cutting the sheet in half (in order to represent division by two) and putting the resultant pieces together, there comes a moment when the remaining piece "is so small as to be negligible." This alludes to a significant property of the remaining item in a series, underlying which is the idea of the infinitesimal. The knowledge revealed by the answer is a clear example of *Knowledge of Topics*, in which the topic in question is 'convergence of series'. Nevertheless, the concept underlying the solution and making it coherent, although not actually explicitly articulated, is that of the tendency to zero of the remainder in a series. This suggests a potential understanding of infinity (as the process is unfinished) which, given that the concept ranges across topics, is most appropriately located in the sub-domain *Knowledge of the Structure of Mathematics*.

Turning now to Aaron's answer, we can see that the mathematical foundation of his answer concerns the limiting effect of adding successive halves. Aaron diverts attention away from the total value of the addition towards the impossibility of this total ever reaching the total dimensions of the sheet. In mathematical terms, the element underlying this procedure is the concept of convergence of a sequence (of partial additions). Aaron makes the process a recurrent one so as to illustrate the fact that, however many times one cuts the paper in halves, there will always be one half lacking to complete the whole. The completion point constitutes a limit, which can be approached as closely as one wishes, but which can never actually be reached. This process view reflects a process-oriented and iterative perspective of infinity, again also associated with a potential understanding (Lakoff & Nuñez, 2000). Once again we are in the domain of *Knowledge of Topics*, in this case the topic being convergence of series. Aaron's familiarity with the definition of convergence means he puts the emphasis on the possibility of choosing any term and recognising that it never goes beyond the established limit, although it might be *very close*. This familiarity, rooted in his understanding of infinity, is likewise associated with *Knowledge of the Structure of Mathematics*.

Finally, Manuel's answer is suggestive of elements which are different from the previous answers, less in terms of the knowledge mobilised as the nature of this knowledge itself. It follows the same dynamic as the previous two in that it generates the $(½)^n$ series via the expedient of dividing a sheet of paper in two. During the procedure, Manuel introduces the idea of 'super-sharp scissors' to achieve the required degree of abstraction suggested by being able to cut the paper indefinitely, beyond the physical limitations. To the extent that this approach illustrates awareness of potential difficulties in the students' capacity for abstraction, the extract pertains to the sub-domain *Knowledge of Features in Learning Mathematics*. Afterwards, Manuel introduces an element which diverges significantly from the previous suggestions. Instead of centring attention on the process of repeatedly dividing in two, he pieces the sheet together again. This helps the students to make sense of the final result, graphically illustrating that the process of addition has a finite result equivalent to the surface area of the original sheet. The knowledge involved in this instance is that of *Knowledge of Topics*, which enables him to construct an example based on the meaning of the convergence of a series, and to take into consideration the implicit role of infinity in the expression 'all the pieces together', which provides an objective correlative for the notion of convergence of a series.

In each case, the proposed activity is underpinned by an understanding of the role of the concept of completion in demonstrating convergence, which is most pertinent to the sub-domain of *Knowledge of Practices in Mathematics*. Sandro makes use of the characteristic of series that if the remainder tends to zero, then the series is convergent. Aaron, for his part, draws on the fact that the annotation of partial additions implies convergence. On the other hand, Manuel bases his approach on the result of the addition, and as such it does not constitute a demonstration in the strictest sense of the word, although it is an interesting strategy to use with students.

Opportunities for further research

The analysis above is concerned chiefly with the purely mathematical considerations brought into play by the three teachers. Nevertheless, this is not the only kind of knowledge we believe they mobilise. The fact that the three suggestions are significantly different, in terms of both the mathematics involved and the manner of understanding infinity alerts us to the presence of *opportunities for further research* (Flores *et al* 2013), specifically into the responses which these three teachers might give to different questions about the appropriateness of their suggestions for dealing with this topic. With a view to developing teacher training materials such as vignettes for discussion, we think that further research into other aspects of these three teachers' knowledge is of interest as it will enhance the consistency of analysis. Some of the areas we feel would reward study are indicated below.

We think it would be interesting to ask the three teachers about the effectiveness of their approaches in terms of the students' potential understanding of the scenario. In this respect, although the first two approaches demand an understanding of the concept of limit if they are to be successful, they imply a potential understanding of infinity, something usually expected amongst students. By contrast, the third scenario implies considering the process as a whole, given that it demands an actual understanding of the infinite process, which is a more difficult concept to acquire. Exploring with teachers the use of the paper-cutting technique as a means of approaching the task also has the potential to reveal useful information about mathematics teachers' knowledge, going beyond the purely manipulative dimension of the technique towards understanding how it might help pupils to understand the concept in question. Finally, it would be interesting to go into greater depth regarding the suitability of the lesson plans in relation to the pupils' age, previous learning experiences of the topic, and syllabus expectations regarding the concept of infinity.

CONCLUSIONS

Infinity matters for teaching certain concepts, many associated with the area of mathematical analysis. For certain items on the syllabus, its importance to mathematical procedures at a conceptual level, such as the calculation of limits, is explicit. In the examples above, each teacher's consideration of infinity leads them to tackle the same question from different mathematical perspectives, each of which provides the epistemological underpinnings for the chosen approach, specifically the infinitesimal of the remainder, the iterative and recurrent elements of the limiting process, and the conceptualization of a sequence as a whole. We are aware that the examples covered in this paper offer nothing more than an initial consideration of the knowledge of infinity brought into play by teachers when they plan a lesson around the concept at an epistemological level. Nevertheless, we believe that they demonstrate the involvement of infinity in the teaching process, and explore a little further the big idea of *'dealing with infinity'* (Kuntze, Lerman et al., 2011). The examples also enable us to map the contours of the knowledge of infinity which the teachers bring to bear in their classes, which is extremely closely related to how they conceive of infinity, and complements studies of a purely cognitive nature (e.g., Weller et al., 2009).

Nevertheless, beyond purely mathematical considerations, we would argue that it is necessary to further explore those aspects of infinity which come under the auspices of *Pedagogical Content Knowledge*, as it is these that make the mathematical content relevant to the classroom. There are, too, the questions of the potential of different methodological approaches for different concepts, and the features of the pupils' learning of concepts involving infinity, as well as those of a curricular nature or associated with the performance expected at a particular age or level, all of which are also important for the teacher to be aware of.

In this paper, we have outlined some of the areas of pedagogical content knowledge associated with infinity which we believe merit further attention and which are of special interest to our work. The understanding and awareness of infinity which a teacher is required to acquire is necessarily one which takes a specialised perspective of mathematics teaching. The role of PCK is relevant from this perspective in terms of opportunities for further research beyond the purely mathematical aspects of the concept, such as understanding which features of the concept are involved in the process of learning. It is in this respect that the MTSK model is especially useful.

The different aspects arising from analysing teachers' professional practice with regard to infinity or related items should also be taken into account in the training of both primary and secondary teachers. For example, paradoxes could be used to nudge teachers to develop their understanding of key mathematical concepts, especially those associated with infinity, or could be a "vehicle for raising their pedagogical awareness of the development of mathematical knowledge" (Moshovitz-Hadar & Hadass, 1990).

Primary teacher' approach to measurement estimation activities

Noemí Pizarro, Núria Gorgorió and Lluís Albarracín

Universitat Autònoma de Barcelona, Barcelona, Spain

Estimation appears as a relevant aspect to the new Curricular Guidelines of year 2012 of the Chilean Ministry of Education. In this paper, we analyze the mathematical knowledge for teaching of 112 Chilean teachers of Primary Education to deal with a classroom activity of discreet measurement estimation proposed in governmental curricular orientations. The qualitative-descriptive analysis developed in our study is supported by a reconstruction of the concept of measurement estimation. The results show that the knowledge of a significant part of the participant teachers presents some deficiencies, since they either propose to develop the activity without including perceptive abilities or they propose an action limited to a measurement exercise. Only 13.1% of the teachers state that when using the example given for estimation a perceptive-type exercise is required.

Keywords: Mathematical knowledge for teaching, measurement estimation, perception, referent.

INTRODUCTION

At the beginning of the 80's, the teaching of measurement gained emphasis in the curricula of some schools that answered to the guidelines of international organizations linked to the teaching of mathematics (Cockcroft Report, 1982; ICMI, 1986). These orientations were included by the Chilean Ministry of Education in the Curricular Guidelines of the year 2012, in which measurement has become the new curricular axis in primary education. In order to complement these guidelines, the Ministry itself has published some activity proposals in its study program.

The new Chilean curriculum considers estimation in more than twelve learning objectives in measurement and geometry. However, previously to this reform, measurement estimation hadn't had its own space in Chilean study programs. For this reason, probably, current teachers have never received training in this respect, neither in their school years nor in their further professional training. Therefore, we are facing a situation in which a mathematical concept bursts into the classrooms without any specific training being provided to the educators.

Considering the shortcomings identified by international mathematics studies regarding the teaching skills of teachers on the estimation of measurement (Chamorro, 1996, 1998; Joram et al., 2005; Forrester & Pike, 1998), estimation measurement is a concept that has not been investigated in depth, and in which difficulties have been detected in the learning of the students (Jones, Forrester, Gardner, Grant, Taylor, & Andre, 2012). At the same time, there are studies that claim that teachers work in estimating measurement is superficial and that they do not feel confident about working with students (Lang, 2001)

If to this we add that Chilean teachers have not had training in this respect, we consider it important to focus on how teachers interpret the estimation measurement activities proposed in government documents and official textbooks. Developing different learning objectives for the Chilean curriculum should be the main reference point for this.

As an orientation for our work we ask ourselves: How are measurement estimation activities treated by primary school teachers? In order to answer this question we take the Mathematical Knowledge for Teaching (MKT) proposed by Ball, Thames and Phelps (2008) as a theoretical referent and we carry out a qualitative-descriptive study in Santiago de Chile with 112 in-service Primary School teachers, who have taught or will be teaching measurement estimation to their pupils at a certain point in time.

Our aim is to investigate the possible treatment of measurement estimation activities in the classroom. Conversely, we intend to study which MKT will be needed by the teachers when introducing the new content in the mathematics curriculum. Our final aim is to establish guidelines that may back up future improvement actions of initial and continued training of teachers.

MATEMATHICAL KNOWLEDGE FOR TEACHING

The work of Ball and colleagues (2008), rests on Shulman (1986), emphasizes the use of knowledge in teaching and for teaching. They focused on the analysis of knowledge for teaching from the observation of the teacher's work in the classroom and outside, thus introducing the line of research of MKT. In the current study, we focus only on one component of MKT, Knowledge of Content and Teaching (KCT), which combines knowledge of mathematics and knowledge of its teaching. Examples of this type of knowledge are found in the ability to sequence content, propose starting, deepening and closure examples, and knowledge of the advantages and drawbacks of representations used to teach a specific idea.

MEASUREMENT ESTIMATION

When revising the literature on measurement estimation we often observe that different definitions of estimation include a wide range of tasks related to different fields of mathematical knowledge. These tasks may include mentally assigning a value to a magnitude measurement, an agile mental calculation of an arithmetic operation, or the calculation of the likely value of a statistical measurement, amongst others. Table 1 shows different definitions of estimation proposed by different authors.

Segovia and colleagues (1989) establish that measurement estimation differs from computational estimation due to methodological reasons. Hogan and Brezinski (2003) differentiate three types of estimation, according to the abilities they develop:

— Numerosity: refers to the ability to visually estimate the number of objects arranged on a plane within a limited amount of time.

— Measurement estimation: is based on the perceptive ability to estimate different magnitudes in common objects.

— Computational estimation: refers to the process by which an approximate value is rapidly determined for the result of a mathematical operation.

For Hogan and Brezinski (2003), computational estimation is a skill which evolves together with the rest of mathematical abilities. On the other hand, numerosity and measurement estimation are abilities that develop independently from that of estimating a calculation and are not grouped in the category of usual mathematical abilities. These authors explain that

	Definition	Relevant aspects
1	"A process to reach a measurement or measure without the help of measuring tools. It corresponds to a mental process that includes visual or manipulative aspects." (Bright, 1976, p. 89).	Mental process used to obtain a measurement. Visual perception or use of sense of touch.
2	"the ability to judge whether the result of a calculation which has been carried out or a measurement which has been taken seems to be reasonable and ability to make subjective judgements about a variety of measures" (Cockcroft Report, 1982, pp. 22–23).	Evaluation of the adequacy of results of calculations or measurements. Subjective evaluation of a measurement.
3	"assessment of the value of the result of a numerical calculation or of the measurement of a quantity, as a function of the individual circumstances of who forms it" (Segovia et al., 1989, p. 18).	Subjective evaluation of the results of calculations or measurements.
4	"the skill of making an educated guess as to the value of a distance, cost, size, etc. or arithmetic calculation" (Clayton, 1996, p. 87).	Conjecture on measure-ments and arithmetic ope-rations.
5	"Refers to a number that is a suitable approximation for an exact number given the particular context" (Van de Walle et al., 2010, p. 241).	Adequate approximation of a number.

Table 1: Definitions of estimation

in terms of the human brain, we have an accumulator that stores quantities in an approximate way. For instance, we know what a meter is, we can identify this concept in an object or in part of it and we can describe it using our body. This is possible due to the fact that we are aware of the adequate measurement of the length of a meter. This quantity "accumulator" may contribute to the development of people's visual perception by relating measurement estimation and numerosity with spatial abilities. We understand that this "acquisition" of the unit of measurement in use when performing estimations does not appear in the definitions shown above.

ESTIMATION IN EDUCATION

An important part of teaching measurement is focused on the development of their estimation. In the first place, this is due to the fact that estimation will further develop perceptive abilities (Inskeep, 1976; Cockcroft Report, 1982; Hogan & Brezinski, 2003). In addition, estimation comprises the foundation of the teaching of physical magnitudes such as length, surface area, volume or weight, amongst others (Hogan & Brezinski, 2003; Joram, Subrahmanyam, & Gelman, 1998; Joram, Gabriele, Bertheau, Gelman, & Subrahmanyam, 2005). When working on measurement estimation numerical abilities are also exercised (Boulton-Lewis, Wils, & Mutch, 1996; Joram et al., 1998; Sarama & Clements, 2009), in the sense of measurement (Clements, 1999) and in the numerical and spatial senses (Lang, 2001).

Despite the emphasis mathematics education attributes to measurement estimation, there are few studies that refer to the way estimation is developed in the classroom. Forrester and Piké (1998) observed that in the teachers' speech in the classroom there was a significant separation between measurement and estimation. Estimation was treated as a predictive hypothesis, in a vague and superfluous way, as a process failing to produce satisfactory answers to solve situations that only a measuring tool would be able to answer.

These authors observed that estimation was treated as a means of "thinking reasonably" that included riddles more often than value judgments based on referents, without the requirement of evidence of concept understanding. This outlook suggests mathematics is a synonym of rigor and exactitude. Therefore, an estimate should always be checked with a measuring instrument. Segovia and Castro (2009) explain that in most dictionaries the meaning of mathematics is characterized by exactitude and rigor. Following these criteria, estimation would be far away from "real mathematics", since the results it provides are not exact.

In our literature revision we have found few studies on teacher training related to measurement estimation. However, Joram and colleagues (2005) suggest the use of the estimation strategy of the reference point, as a seemingly appropriate didactic strategy.

GOAL OF THE STUDY

Since the Chilean Curricular Guidelines of the year 2012 include measurement estimation, it would be desirable to for Chilean teachers to have the adequate knowledge to use the activities proposed in the study programs provided by the Chilean Ministry of Education. In this context, the aim of our study is the following:

— To characterize the Knowledge of Content and Teaching (KCT) on measurement estimation to allow teachers to apply the activities proposed by the Ministry's guidelines in their classrooms.

THE STUDY

As a data collection tool, we have elaborated a questionnaire of ten open questions that were oriented by the different categories of MKT (Ball et al., 2008). The questionnaire was answered by 112 in-service Primary School teachers in Santiago de Chile. In this presentation we only analyze the answers to a question based on a task proposed in the guidelines for the curriculum of 7-year-old children (Figure 1).

The task proposed in the guidelines is an example of a measurement estimation activity for the teachers to develop in the classroom. The aim of this activity is estimate quantities up to one-hundred in concrete situations using a referent. With this question, we try to collect information about Knowledge Content and Teaching, because it can show how the teachers manage the content and activities in the classroom, and consider that the referent is a strength of the activity and that students should not be permitted to measure using the square as the unit of measurement.

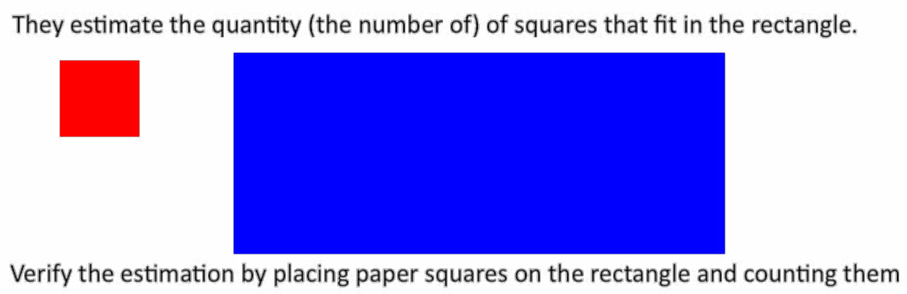

Figure 1: Estimation activity

In our questionnaire we ask teachers to explain how they would approach the activity shown in the classroom

DATA ANALYSIS

Since we are interested in identifying aspects of teachers' MKT around measurement estimation, the analysis of the data collected is qualitative. Therefore, based on the different views teachers have of activity 4, we have created several categories to characterise the knowledge of measurement estimation detected. When making a first reading of the answers, we prove the need to establish elements that determine if a task is actually about measurement estimation in order to back up our analysis. For this reason, we decided to elaborate a definition of the concept that included the fundamental elements identified during our literature review.

Our definition of measurement estimation is the following:

To perceptively assign a value, or an interval of values, together with a unit that corresponds to a discrete or continuous magnitude, by means of previous knowledge or by an indirect comparison to an auxiliary object.

This definition is based on three essential elements:

— Assigning a numerical value (V): in order to consider the task an estimation, the assignment of a numerical value is required; otherwise, the task only requires perceptive work. For instance, if when touching the water of a swimming pool we state that it is pleasant to swim in, the task is exclusively perceptive, given that we have not assigned any value to temperature and measurement units do not play a part in the activity (Bright, 1976; Informe Cockcroft, 1982; Segovia et al., 1989; Joram et al., 2005).

— Executing the task perceptively (P): in order to estimate it is necessary to use the senses, avoiding counting or the direct use of any measurement tool, standardized or not. When a measurement tool is used and a direct comparison is made, the action taking place is measuring, not estimating, even though the result may be expressed approximately (Bright, 1976; Hogan & Brezinski, 2003; Joram et al., 2005; Sarama & Clements, 2009).

— Relating perception to previous knowledge or to the mental image of an auxiliary object (R): In order to estimate referents are required, or to ideally possess a mental notion of a measurement unit; otherwise the activity would only require to guess or give a random result (Clements & McMillen, 1996; Hogan & Brezinski, 2003; Joram, 2003; Sarama & Clements, 2009).

Given that in the activity used in our question, the referent considered in the estimation has been given in the formulation, in our analysis we consider only how this referent has been used, the main analysis aspect of which is the perceptive component (P). Below we give an example of the analysis process and we introduce the different categories that organize the different ways teachers suggest approaching the activity in the classroom.

Use of the activity based on providing tools

Some teachers limit themselves to answering to what type of material will be used during the activity, without reporting particularly how these resources are planned to be used. For instance, one of the teachers answers: *"The students will be given both shapes (1 of each) made of paper card."*

We observe that the teacher's attention is focused on the material he will use in the activity instead of what is going to be done with it, which makes it impossible to guess how the teacher is going to develop the activity in the classroom.

Use of the activity as evaluation

Some of the answers given by the teachers suggest using the activity described as an evaluation exercise without a backup of mathematical processes associated to estimation. For instance, one of the teachers answers: *"First I would show the children this rectangle and after that I would hand in a piece of colored paper to each of them and would ask them to estimate how many squares can fit into the rectangle."*

We observe that the teacher is focused on the amount of squares that fit into the rectangle (V), but without offering any didactic instructions nor any other type of information that may allow us to understand how he plans to direct and develop the activity in the classroom. Therefore, we have no evidence that perceptive aspects may be included in the activity (absence of P).

"*Children: I invite you to estimate the area of the rectangle using the little square as the unit of measurement*". The teacher does the same as the teacher above, both give space for students to measure, estimate or guess.

Use of the activity as measurement

In the proposals of some of the teachers, we observe that they intend to go about the activity as a measurement task, with the use of non-conventional tools, explaining the way these are going to be used for the activity. This allows us to see that their proposal corresponds to a measuring activity. Answers in this category evidence a misunderstanding between the use of a referent to carry out an estimation and the use of a non-conventional measuring tool. Into this category we included answers such as: *"We need to know how many squares we need to cover the rectangle. After constructing the rectangle we should place squares of equal size on top of the former."*

We see that the teacher points out that the surface area of the rectangle should be covered by squares of the same size as the one given, suggesting a counting activity. Based on this idea, the referent then becomes a non-standardized unit of measurement. In this case, the students would reach an evaluation (V) that is not supported by a perceptive act (absence of P) but by a measurement.

Another example is this answer: *"Place the square on the rectangle to complete the rectangle with squares. The rectangle with the superimposed squares will be presented by the students"*

In this task, there is no perceptive work (absence of P) because the students must complete the rectangle with squares, perhaps drawn on it, to count how many squares fit. As with the teacher above, the square was used as a non-standardized unit of measurement.

Use of the activity as a measurement estimation

Some of the teachers regarded the evaluation of the amount of squares that fit into the rectangle as a perceptive activity, by using the square shape of the problem's formulation as a referent. We consider that answers of this type suggest using the activity as a measurement estimation exercise. Among them we find: *"Boys and girls, on the blackboard you can see a red square and a blue rectangle. Without standing up or leaving your seats, or as you prefer, please estimate how many times the red square fits into the blue rectangle, by placing the squares next to each other."*

We have identified that the intention of reaching an evaluation (V) is supported by a perceptive action (P), since the teacher does not allow a physical interaction between the students and the representations of the figures on the blackboard. In this case, the students would be obliged to carry out a visual perception exercise.

Another teacher answer: "*Without making any movement, think about how many squares you estimate will fit in the rectangle"*

We observe that when the teacher says "making any movement", s/he indicates that the student must not handle the square, thus steering the student away from measurement and supporting the perceptive action (P). In this way, the evaluation (V) rests on the perceptive action.

RESULTS

Table 2 shows the answer frequency for the different categories.

We see that only 16 of the 112 surveyed teachers have made a proposal that includes the development of per-

Category	Frequency	
Use of the activity based on the supply of tools.	4	(3.6%)
Use of the activity as an evaluation with a possible estimation or measurement.	38	(32.7%)
Use of the activity as a measurement.	25	(22.3%)
Use of the activity as a measurement estimation.	26	(13.1%)
Other answers	5	(4.5%)
No answer	23	(20.5%)

Table 2: Frequencies and categories of teachers' answers

ception and evaluation. Given that the referent used is found explicitly in the formulation, their proposal corresponds to an estimation task. These teachers show an adequate Knowledge of Content and Teaching for the development of the activity in the classroom.

On the other hand, 38 of the teachers make a proposal in which estimation is a synonym of evaluation of a magnitude, without justifying how the task is carried out. This makes us think that in the concept of estimation used by these teachers, perceptive processes are not relevant and estimation is not supported by mathematical processes. The development of the activity proposed is incomplete, presenting an incomplete Knowledge of Content and Teaching regarding measurement estimation.

A third group of 25 teachers considers that estimating a measurement is a synonym of measuring, using the referent as a unit of measurement. For these teachers, measurement estimation seems to be the same as measuring with a non-standard tool. In this last category, we include the answers to the questions that are exclusively based on providing the students with measurement tools without specifying their didactic use. This group is comprised of 4 teachers, who we may also consider to confuse estimation with measurement. Finally, the categories that include other answers and empty answers represent 28 of the 112 teachers, which represent a non-negligible percentage (25.0%) of the teachers surveyed.

General research results

This research is part of a wider study. We have used a variety of questions focused on different aspects of MKT estimation of measurement. In this way, we have found that there are gaps at different levels, e.g., teachers confused estimation of measurement with measurement itself, using non-standard units of measurement; teachers consider that the estimate of measurement is a superfluous task, like a guess; teachers do not observe the weaknesses of estimation measurement activities.

CONCLUSIONS

In the present study we have observed large differences in Knowledge of Content and Teaching on measurement estimation between Chilean teachers. Based on one of the activities proposed by the Chilean Ministry of Education to exemplify measurement estimation work in the classrooms, we note that a large part of the teachers do not possess an adequate specific knowledge to use these activities with the purpose for which they have been designed.

Specifically, only 13.2% approaches the activity with the required conditions to work on estimation in an effective manner. A significant part of the group does not acknowledge the importance of perception when estimating and do not mention perception explicitly. This allows the student to handle the activity both directly or indirectly, which would not be considered estimation. It should be noted that a large part of the teachers confuse measurement estimation and measurements based on the use of non-standardized measurement tools. This type of confusions can be related to the absence of estimation in the curriculum to this date. The surveyed teachers have not received any training that allows them to distinguish these two types of tasks.

In order to solve this situation of lack of knowledge, we consider that measurement estimation should be included in teacher-training curricula. It would be interesting for pre-service and in-service teachers training to include activities that required for them to carry out their own estimations and compare them to measurement processes It would also be useful for teachers to observe mathematical processes that distinguish the different types of estimation presented in our literature review, as a way of reinforcing their specific mathematical content. On the other hand, a revision of current curricular guidelines is paramount, in order to avoid creating larger ambiguities. If we consider it acceptable to verify the result obtained from early-stage estimation activities with the exact result, it is fundamental that teachers regard estimation as a task in itself, with its own validation procedures according to the context's requirements

Finally, we consider it crucial to define a mathematical concept precisely when introduced into an educational system. In addition, official programs and didactical guidelines accompanying textbooks should provide examples from appropriate activities, distinguishing them from those that are not. Otherwise, it is highly likely that the curricular changes the country wants to achieve may not be transferred to the classrooms effectively.

Investigating mathematics teacher identity development: A theoretical consideration

Kirsti Rø

University of Agder, Kristiansand, Norway, kirsti.ro@uia.no

The paper discusses a theoretical framework for investigating the process of becoming a mathematics teacher, based on the need to better understand how mathematics and teaching combine in developing mathematics teacher identities. Identity is understood as a function of participation in and at the boundaries of various communities of practice, during university teacher education and at school. In order to reveal possible relationships between developing teacher identities and the discipline of mathematics, teachers' changing concept images of mathematics are embedded within the definition of identity.

Key words: Identity, identity development, transition, situated concept images.

INTRODUCTION

Becoming a secondary school mathematics teacher can be described as a role change, as one goes from being a university student who is learning and knowing mathematics for oneself, to becoming a mathematics teacher in school and being able to enable others to know it (Rowland, Huckstep, & Thwaites, 2005). It is about carving out a space for one's identity as a mathematics teacher (Alsup, 2006), as one is negotiating shifting conceptions of what mathematics teaching is or should be (Beauchamp & Thomas, 2009). In parallel with undergoing the transition from university teacher education to a professional debut in school, the character of the mathematics content is changing. It goes from being a scientific discipline represented by the discourse taking place between mathematicians and mathematics students at the university, to becoming a school subject as part of general education, preparation for everyday life and as a basis for higher education. Hence, the process of becoming a mathematics teacher is concerned with both; changes in practices and changes in the mathematics content.

The purpose of this paper is to understand better how mathematics and teaching combine in teachers' development of identities (Adler, Ball, Krainer, Lin, & Novotná, 2005). From research on mathematics teacher education, there is known a great deal about some of the specialty of mathematics teachers' knowledge (e.g., Ball, Lubienski, & Mewborn, 2001) and their beliefs (Phillip, 2007). However, there is a need to understand better the dynamics of mathematics teachers' learning, as they move across different practices in university and school and unite their experiences into a role as a professional teacher. According to Lerman (2000), this requires an extension of the unit of analysis from concerning the individual mathematics teacher, her mathematical knowledge and beliefs, to also including the social practices in which the teacher participates. In order to study how learning takes place within and across practices and institutions, I present a theoretical framework for investigating how prospective mathematics teachers make sense of undergoing the transition between university teacher education and school. Learning is here understood as identity development, when a person participates within and at the boundaries of communities of practice (Wenger, 1998). Further, I assume that the discipline of mathematics is a distinguishing characteristic of the learning context, meaning that the nature of practices of mathematics is fundamentally different from other disciplines. Consequently, developing an identity as a mathematics teacher is different from developing a teacher identity in other subjects.

In order to study identity development through the profession of a secondary school mathematics teacher, I offer for critique a situated understanding of teachers' concept images in mathematics as being part of their professional identity and development. The framework is used in a longitudinal interview study of a group of prospective secondary school mathematics teachers' accounts of their ongoing transition into the mathematics teacher profession. It is based on the assumption that the teachers' accounts provide a window into the sort of learning they can experience as they move from one setting into another (Jansen, Herbel-Eisenmann, & Smith III, 2012). Embedded in the learning process are the teachers' situated concept images in mathematics. Hence, the focus of the study is the teachers' meaning making when participating in different communities of practice, rather than identifying possible impact from communities on their concept images.

OUTLINING A FRAMEWORK FOR INVESTIGATING MATHEMATICS TEACHER IDENTITY

Identity in teaching has been explored from a range of theoretical approaches (Beauchamp & Thomas, 2009). It spans from categorising aspects of teacher identity in order to better understand and describe it and possible influences on teachers and their practice, to viewing identity as a function of participation in different communities (Wenger, 1998). The latter is in line with what Lerman (2000) has denoted as the *social turn* in mathematics education research, identified by the rise of theories viewing learning as participation in practices rather than as acquisition of new knowledge structures or beliefs. Following Wenger (1998), identity develops through "negotiated experiences of self" (p. 150), as a person interacts with others and regulate her participation according to the reactions of others to her. In other words, mathematics teacher identities exist both in teachers and in their relations with others (Ponte & Chapman, 2008). Consequently, mathematics teaching can be considered a complex personal and social set of embedded processes and practices that concern the whole person (Olsen, 2008).

Wenger's (1998) theorisation of identity in communities of practice enables me to study individual mathematics teachers through their social settings. Hence, the primary unit of analysis is neither the individual mathematics teacher, nor the learning communities in the transition from university teacher education to school, but instead the teacher-in-the-learning-community-in-the-teacher (Graven & Lerman, 2003; Lerman, 2000). The first part, teacher-in-the-learning-community, acknowledges that the object of study is more than individual cognition and affect, because learning is the development of modes of participating with others in society. The second part, learning-community-in-the-teacher, implies that participation develops identity in such a way that the practice becomes part of the individual. In other words, the focus is neither directed towards categories of mathematics teacher knowledge, nor is it directed towards measures of teachers' mathematical knowledge for teaching. Instead, I study mathematics teachers' developing sense-making of mathematics and mathematics teaching in light of their experience of participating within and at the boundaries of communities of practice in university and school.

In the following, I willpresent a framework that allows me to change the focus on the object of study, by placing respectively the collective and the individual in the foreground (Palmér, 2013b). With the collective in the foreground, I am interested in the mathematics teachers' community memberships in terms of modes of belonging: engagement, imagination and alignment (Wenger, 1998). Further, becoming a mathematics teacher is about reconciling various memberships across communities, and consequently, trying to establish continuity across community boundaries. By placing the individual in the foreground, I assume that when a teacher is stepping into a practice, the teacher is somehow changed. By orienting towards the practice, taking up new practices or marking a distance towards it, the teacher consequently develops new understandings of herself as a learner and doer of mathematics and mathematics teaching.

Wenger (1998) provides a general theorisation of learning and a superior framework for this paper, and I will in the following section elaborate on an understanding of mathematics teacher learning within and between communities of practice. In order to adapt the framework to *mathematics* teacher identities, I will argue for the necessity of combining Wenger's notion of identity with a situated understanding of Tall and Vinner's (1981) definition of concept image. This is built upon a sociocultural understanding of concept images (Bingolbali & Monaghan, 2008), and its compatibility with Wenger's concept of reification.

MATHEMATICS TEACHER LEARNING WITHIN AND BETWEEN COMMUNITIES OF PRACTICE

Based on the assumption that learning is located in the relationship between a person and the world in which the person participates, Wenger (1998, 2010) considers meaning making as a dual process. On the one hand, a person engages in different forms of *participation*, referring to the social experience of living in the world in terms of membership in social communities and active involvement in social enterprises. On the other hand, *reification* accounts for the way in which a person of a community builds her own meaning for her participation. For Wenger (1998), reification and participation are viewed as complementary concepts naming the process whereby individual and community experiences are shared and lead to the production of shared ideas and concepts. A mathematics teacher's identity can therefore be understood as the intersection of individual and social aspects of learning. Individual aspects represent who one is as a mathematics teacher due to one's knowledge and views about mathematics and mathematics teaching and learning. However, these individual aspects are continuously negotiated through the teacher's participation in different communities of practice.

For prospective mathematics teachers, learning can take place when they enter communities of practice during teacher training as peripheral participants and gradually develop as central participants (Lave & Wenger, 1991). A gradual change in participation, from the periphery towards the centre, can be described in terms of engagement, imagination and alignment (Wenger, 1998). Within the community, the prospective mathematics teacher *engages* with ideas about mathematics and mathematics teaching through engagement in communicative practice and develops the ideas through exercising *imagination*. Further, the prospective teacher *aligns* with conditions or characterisations of the practice. The term alignment has later been challenged by Jaworski (2006) in terms of *critical alignment*, a means of not just aligning with practice as established in the community, but of looking critically at that practice while aligning with it. The *boundary* of the community is constitutive of what counts as central participation and what does not. Other learning opportunities will therefore occur *at* the boundaries, as the mathematics teachers are exposed to foreign competences when they enter other communities in school and may try to create bridges across them and former communities (Wenger, 1998). I explore the transition between mathematics teacher education and the professional debut in school in terms of *boundary crossing*, as prospective mathematics teachers become participants in communities of practice in school and do the work of reconciliation of different forms of memberships in various communities. Hence, different forms of knowledge and understanding of mathematics and mathematics teaching may coexist. Developing a mathematics teacher identity during boundary crossing is then about continuously synthesizing what counts as legitimate knowledge within various communities. Simultaneously, the teacher is striving towards continuity across boundaries by maintaining a sense of self through time (Abreu, Bishop, & Presmeg, 2002).

Wenger (1998) discusses how participation and reification have the potential to create continuities across boundaries in terms of brokering and boundary objects. *Brokering*, as participation across communities, is provided by people who can introduce elements of one practice into another. A prospective mathematics teacher may act as a broker when moving between communities in university and school, and bringing ideas of mathematics and mathematics teaching stated in teacher education into communities of mathematics teachers in school. However, acting as a broker is challenging and uncomfortable, since it requires enough legitimacy to influence the development of practice within a community, and enough courage to address conflicting interests. Hence, entering school as a novice mathematics teacher can be described as an experience of confrontations between own expectations about teaching and expectations stated by teacher education, students in the classroom and colleagues. Another dimension of continuities across boundaries is constituted by *boundary objects*, being reified connections between communities (Wenger, 1998). An example is the guidance paper that student teachers are supposed to write and submit to a teacher educator at the university and their tutor in school prior to their lessons during teacher training. The paper may act as a boundary object when it bridges views and knowledge of mathematics teaching in university with experiences of classroom practice in school.

In Akkerman and Bakker's (2011) review of research on literature on boundary crossing, boundaries are defined as "sociocultural differences leading to discontinuities in action and interaction" (p. 133). The definition highlights that boundaries are not about sociocultural differences per se. Instead, boundaries are "real in their consequences" (p. 152). Thus, unlike describing sociocultural differences in university and school, I am interested in how the differences play out in and are being shaped by the process of developing mathematics teacher identities. By overcoming discontinuities, boundary crossing carries a potential to learn about practices and about one's own identity. Akkerman and Bakker (2011) present potential learning mechanisms that may occur when crossing boundaries, two of them concerning processes of making sense of practices in multiple contexts. *Identification* entails a renewed sense making of different practices and related identities, by encountering and reconstructing boundaries but not being able to overcome discontinuities. Learning in terms of *reflection* will result in an expanded set of perspectives and a new construction of identity, which in turn will have an impact on future practice. Here, reflection is the desirable learning outcome, when one is establishing continuity across boundaries by reconciling memberships across communities. For prospective mathematics teachers, crossing boundaries is both a valuable and a risky process. On the one hand, they are in a position to introduce elements of one practice into the other. On the other hand they face the risk of never fully belonging to or being acknowledged as a participant in any one practice.

MATHEMATICS TEACHER IDENTITY AND SITUATED CONCEPT IMAGES

As have been emphasised by other researchers (e.g., Palmér, 2013a), Wenger (1998) does not focus specifically on mathematics education and mathematics teaching, but on learning in its broadest sense. Yet others have discussed the possibility of Wenger's framework to take into account the full spectrum of locations of cognitive development, from in-the-brain to socially dependent (Van Zoest & Bohl, 2008). In order to comply with this request, Van Zoest and Bohl (2008) combine Wenger's (1998) theory of communities of practice with Shulman's (1987) heuristic of teacher knowledge, and an understanding of knowledge and beliefs as cognitive in nature. However, unlike viewing identity as dynamic and in continuous development, they describe it as something the teachers "carry with themselves as they move from context to context" (Van Zoest & Bohl, 2008, p. 338). Consequently, their framework is not consistent with my investigation of how teachers make sense of their ongoing transition, due to their present situation of participating in communities of practice.

Taking a different theoretical approach, Palmér (2013a, 2013b) connects Wenger's notion of identity with Skott's (2010) and Skott, Larsen and Østergaard's (2010; 2011) theory of patterns of participation. This is done in order to describe primary school mathematics teachers' professional identity development, "by including both the individual and the social parts of identity development" (Palmér, 2013a, p. 2851). Further, the theories are argued to be consistent within a situated learning perspective. However, in Palmér's (2013b) study of primary school mathematics teachers' way into their profession, the discipline of mathematics do not appear as a prominent part of the teachers' developing identities. Even so, I claim that prospective secondary school mathematics teachers need to some extent relate to and cope with mathematics both during university studies and in their profession. Hence, there is a need for developing an analytic tool which makes the mathematics within the teacher identity more visible. Inspired by Bingolbali and Monaghan (2008), I consider the notion of concept image (Tall & Vinner, 1981) as being a helpful construct when placing the individual mathematics teacher in the foreground (Palmér, 2013b). Tall and Vinner (1981) describe *concept image* as the total cognitive structure associated with a concept in an individual's mind, which includes mental pictures, associated properties and processes, strings of words and symbols. Unlike a *concept's definition*, the concept image is dynamic and develops differently among persons and through a multitude of experiences. Although concept image and concept definition are terms originating from cognitive theories of learning and a focus on individual student mathematical constructions, Bingolbali and Monaghan (2008) argue that the dynamic nature of concept image is consistent with a sociocultural perspective on learning:

> Indeed, the construct can be viewed in terms of Vygotsky's (1934/1986) *complexes*, a 'phase on the way to concept formation' (ibid, p. 112) and the original view of concept images as developing differentially over students through a multitude of experiences is essentially a contextual viewpoint. (p. 21)

Bingolbali and Monaghan (2008) base their argument on a study of undergraduate students' learning of the derivative, in which the context of learning is regarded as paramount. They found that students' developing concept images are closely related to teaching practices and departmental perspectives, respectively within mechanical engineering and mathematical sciences. I will take a step further by claiming that the dynamic nature of concept image is compatible with a situated perspective on learning. According to Wenger (1998), different types of memberships in various communities entail opportunities and limitations for developing practice, which consequently affects a mathematics teacher's knowing. Hence, I assume that situated concept images in mathematics are embedded in a mathematics teacher identity. It is about knowing mathematics for oneself and for teaching, which is related to one's views and emotions about mathematics and mathematics teaching. Further, concept images are dynamic in the sense that they are negotiated through interaction with other participants within various communities of practice.

A further argument for the compatibility of Wenger's notion of identity and a situated understanding of concept images can be found by the term reification. As part of the negotiation of meaning, reification is a way of giving form to our experience "by producing objects that congeal this experience into 'thingness'" (Wenger, 1998, p. 58). Simultaneously, reification shapes our experience, since forming a certain understanding about a topic brings a new focus for negotiating meaning within a community, leading to new ways of reasoning or acting. Reification of practice can appear as abstractions, symbols, concepts and tools, and becoming a participant in a community is then about growing into the practice in which one engages, including its reifications. Regarding the prospective mathematics teacher, she takes up new practices in mathematics and mathematics teaching by participating in different communities of mathematics students at university, mathematics student teachers during teacher training and teacher colleagues at school. These practices include knowledge of mathematics concepts, skills, and beliefs about mathematics and mathematics teaching, which I further assume provide a basis for developing situated concept images in mathematics.

Nevertheless, reification in terms of situated concept images does not mean that they are simply objects of knowledge and beliefs in mathematics that teachers have or gain, but instead they are both "a process and its product" (Wenger, 1998, p. 60). In other words, a situated understanding of concept image highlights its location in social practices, being continuously negotiated through participation. Further, situated concept images are only "the tip of an iceberg" (Wenger, 1998, p. 61), being indications of larger contexts of meaning realised in human practices. This is in line with Tall and Vinner's (1981) notion of evoked concept images, which is the part of a person's memory evoked in a given context, and which is not necessarily all that a person knows about a certain topic or area. Hence, there is a problem of gaining insight into mathematics teachers' concept images. However, based on a longitudinal interview study, including interview tasks in mathematics, I gain insight into an ongoing process of identity development on given times and over a prolonged period of time. I am therefore able to describe the dynamic nature of mathematics teacher identities and associated concept images, not as objects within teachers, but as objectifications of ongoing processes (Palmér, 2013b).

Taking a situated perspective on concept images, they do not count for comparing a teacher's knowledge and/or beliefs before and after undergoing the transition between university and school. Instead, the underlying question is under which conditions successful participation in university communities facilitates successful participation in school communities (Greeno, 1997). This re-establishment of participation across settings may lead to experiences of discontinuities, e.g., experiences of shifts in practices of mathematics teaching and in the mathematics content. By overcoming them, boundary crossing carries a learning potential of developing one's identity as a mathematics teacher and consequently one's concept images in mathematics.

FINAL REFLECTIONS

I have presented a framework for investigating teacher learning in the transition between university teacher education and the professional debut in school, using Wenger's (1998) theory of community of practice as a starting point. In addition to recognise the learning potential that resides within a community, the framework takes into account learning during boundary crossing, where reflection is the desirable learning outcome (Akkerman & Bakker, 2011). Developing an identity as a mathematics teacher is then about negotiating what counts as legitimate knowledge within various communities in university and school, comprising shifting conceptions of what mathematics teaching is or should be. Based on the assumption that the discipline of mathematics is a distinguishing characteristic of the learning context, I have argued for the necessity of combining Wenger's notion of identity with a situated understanding of mathematics concept images. They are related to the teachers' knowledge and views about mathematics and mathematics teaching, and continuously negotiated through their participation in various communities of practice.

I take the mathematics teacher's perspective and investigate identity development based on how prospective mathematics teachers make sense of their ongoing transition between university and school. This meaning making is situated within a context, based on the teachers' participation in various communities of practice. Hence, the way the teacher looks back and reflects on being a student teacher in mathematics and a novice mathematics teacher in school, and how she discusses mathematics and mathematics problems, may change and develop due to her present situation. In addition, the teachers' accounts provide a means for them to create continuity across time, in terms of maintaining a sense of self. I thus assume that possible changes or development in the mathematics teachers' accounts constitutes evidence for their identity development, in which the teachers' situated concept images of mathematics are embedded.

Using Concept Cartoons to investigate future teachers' knowledge

Libuše Samková and Alena Hošpesová

University of South Bohemia in České Budějovice, Faculty of Education, České Budějovice, Czech Republic, lsamkova@pf.jcu.cz

In the study presented here, we address the issue of how to investigate future primary school teachers' responses to more or less expected children's answers and questions. We observe future primary teachers exposed to contingent situations mediated by an educational tool called Concept Cartoons, and analyse their responses with respect to mathematics subject knowledge. The Concept Cartoons presented in this article deal with addition of natural numbers.

Keywords: Concept Cartoons, teachers' knowledge, mathematics subject knowledge, knowledge quartet, contingency.

INTRODUCTION

The study presented here is a part of a three-year project focusing on opportunities to influence professional competences of future primary teachers through experienced *inquiry based mathematics education*. We realize a set of university mathematics courses for future primary teachers in which they can experience inquiry based education as students, and analyse its impact on their content knowledge. An integral part of the project consists of repeated diagnosis of mathematics subject knowledge of project participants. We generally observed inquiry based education from the perspective of the *knowledge quartet*, and realized that this kind of education is extremely rich in *contingent* (unpredictable) situations. As far as contingent situations are unpredictable, and it is difficult to simulate them systematically, we decided to imitate such situations by an educational tool called *Concept Cartoons*. We use this tool as one of the diagnostic tools in our project.

In this particular study we observe future primary teachers exposed to contingent situations mediated by Concept Cartoons, and analyse their responses. Our research question is: What aspects of future teachers' mathematics subject knowledge can we investigate using Concept Cartoons?

THEORETICAL BACKGROUND OF THE RESEARCH

Teachers and their knowledge

Describing and analysing teacher work is a very attractive field of recent international research in mathematics education. Starting with Shulman's widely accepted concepts of *subject matter content knowledge* (SMK) and *pedagogical content knowledge* (PCK) (Shulman, 1986), researchers try to analyse different kinds of teachers' knowledge, its content, relations, and obstacles in their formation.

An extensive research on mathematics subject knowledge of future primary teachers has been conducted by a group around Rowland. Their research resulted in the identification of aspects of the behaviour that seems to be significant as information about one's SMK or PCK in mathematics. They introduced 20 categories which were subsequently grouped into four broad dimensions: foundation, transformation, connection, and contingency – the so-called *knowledge quartet* (Rowland, Huckstep, & Thwaites, 2005; Rowland, Turner, & Thwaites, 2013, 2014). Knowledge quartet and its subsequent categories can now be used as a tool for conceptualizing the ways in which teachers' knowledge comes into play in the classroom.

As for the particular dimensions, *foundation* refers to teacher's theoretical background and beliefs, *transformation* concerns knowledge-in-action with central focus on representations (analogies, examples, explanations, etc.), *connection* refers to ways the teacher achieves coherence within and between lessons. The last dimension, *contingency*, involves aspects dealing with unpredictable (contingent) events in the classroom. It concerns teachers' responses to events that were not anticipated in the planning. The dimension of contingency consists of five subcategories: *responding to students' ideas* (RSI), *deviation from lesson agenda*, *teacher insight*, *use of opportunities*, and *responding to the (un)availability of tools and resources* (Rowland et al., 2014).

In our study, we shall investigate responses related to the RSI code:

> This code includes the ability to make cogent, reasoned, and well-informed responses to unanticipated ideas or suggestions from students. These teachers' responses are to students' contributions to the (mathematical) development of the lesson. These contributions are typically oral, but could be written. Our analysis of the data available to us identifies three sub-types of triggers in this category: 1) student's response to a question from the teacher; 2) student's spontaneous response to an activity or discussion; 3) student's incorrect answer – to a question or as a contribution to a discussion. ('Knowledge Quartet', 2012)

In addition to knowledge quartet we also observe future teachers' knowledge from procedural and conceptual perspectives. Hiebert and Lefevre (1986) characterized conceptual knowledge as a connected network of facts and propositions, and procedural knowledge as a structured set of mathematical symbols and conventions for their use, rules, algorithms and procedures. This construct was attacked by some researchers for inconsistency, and reconceptualised several times. We find the most suitable the reconceptualization given by Baroody, Feil, and Johnson (2007, p. 123):

> *Procedural knowledge* consists of mental actions or manipulations, including rules, strategies, and algorithms, for completing a task.
>
> *Conceptual knowledge* is knowledge about facts, generalizations, and principles.

Concept Cartoons

In our research we make use of an educational (and in this study diagnostic) tool called *Concept Cartoons* (CCs). CCs were developed in 1991 by Keogh and Naylor as a tool for learning and teaching science (Keogh & Naylor, 1993); lately they have been created also for other school subjects, for example, mathematics (Dabell, Keogh, & Naylor, 2008). Each CC is a cartoon-style picture showing a group of children in a bubble-dialogue based on an everyday situation, the children presenting different viewpoints on the situation (Figure 1). The alternatives displayed in bubbles may be based on real events, on classroom scenarios, on common conceptions and misconceptions, or might be prepared intentionally.

CCs are used mainly in the classroom to support teaching and learning by generating discussion, stimulating investigation, and promoting learners' involvement and motivation, i.e., as a tool oriented mainly on pupils (Naylor & Keogh, 2012). In the study presented here, we aspire to use CCs innovatively for investigating future primary teachers' content knowledge.

In view of the fact that each CC offers a situation not invented by the teacher, and children's various responses on this situation, a suitably chosen CC can provide the teacher an educational model of a contingent situation. In the context of the RSI code, each CC is an artificial reality that partially imitates triggers of the 1st type (it shows children's responses to a question, but the question was not asked directly by the teacher, and sometimes the question is not explicitly expressed in the cartoon), and with an appropriate choice of the content of bubbles it can partially imitate triggers of the 2nd type (children in the picture can response to other children's answers; this case would serve Peter's bubble in Figure 1 changed to "Kevin, you are not right, they scored more."), and entirely imitate triggers of the 3rd type (some answers in bubbles are incorrect).

As the RSI code admits not only oral but also written contributions from children (see the characteristics of RSI above), we place CCs on worksheets, and let the respondents react to them in written form.

DESIGN OF THE STUDY

Participants

Participants of the research are two groups of master students of primary teacher training from our Faculty of Education. This master's degree training lasts 5 years, and covers all the primary curriculum subjects. We involved 29 students of the 2nd year, and 35 students of the 3rd year. The 2nd year students

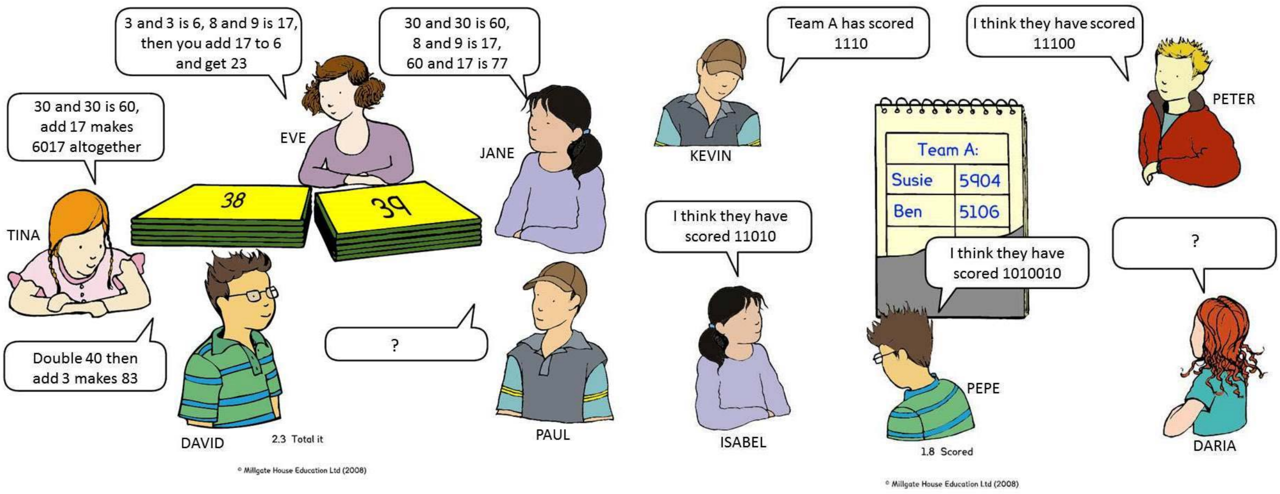

Figure 1: Two examples of Concept Cartoons; taken from (Dabell et al., 2008), slightly modified

have recently completed the "Natural numbers" part of Arithmetic courses, but have not attended any Didactics yet. The 3rd year students have recently completed the "Natural numbers" part of Didactics of mathematics courses.

Course of the study

In the data collection stage of the research we gave each respondent a worksheet consisting of four CCs on addition and subtraction of natural numbers (two of them are in Figure 1), with four common questions:

1) Which child do you strongly agree with?
2) Which child do you strongly disagree with?
3) Decide which ideas are right and which are wrong. Give reasons for your decision.
4) Try to discover the cause of the mistakes, and advise the children how to correct them.

Respondents were asked to fill in the worksheet individually. For all respondents it was the first occasion to work with CCs.

We processed this output qualitatively, using grounded theory methods (Strauss, 1987): we started with open coding, then grouped the codes according to similarities and internal relation into categories, and marked codes with plus or minus sign to denote positive or negative aspects (good or poor knowledge, correct or incorrect recognition, etc.). Then we several times reinspected all the output, looked for new fragments and new contexts, rearranged existing fragments and codes, and debugged the coding process as well as the process of sorting codes into categories.

As relevant for our study appeared the following code categories:

A) respondent's spontaneous response (the very first opinion) on ideas in bubbles

B) respondent's subsequent response on ideas in bubbles

   – recognition of right and wrong answers

   – recognition of procedures used by children, identification of the causes of mistakes

C) the way how the CC was composed, i.e. the nature of the CC

We distinguish between A and B categories, because in relation to contingency we consider as important an immediate response to the content of bubbles. We assume that such immediate response can be triggered by worksheet questions 1 and 2, while subsequent response is rather a matter of questions 3 and 4. More precisely, thought processes caused by questions 1 and 2 are different from those caused by questions 3 and 4 – respondents do not need to go into a deeper analysis while looking for a child with whom they strongly (dis)agree. Therefore, aspects related to A codes are mainly triggered by questions 1 and 2, aspects related to B codes are mainly triggered by questions 3 and 4.

In the next stage of the analysis we examined relationships between codes and between categories, from the perspective of the content of particular bubbles as well as from the perspective of particular respondents.

FINDINGS

The initial finding we made during the coding process was that participants' responses are substantially affected by the nature of the individual CC (i.e., by aspects hidden under the C codes). The effect is clearly seen when comparing the two CCs from Figure 1 – both of them show a situation that need to be transformed to mathematics, mistakes displayed in bubbles are standard, and each bubble contains no more than one type of mistake. But their other features differ, for example:

Figure 1a

- the arithmetic task is not explicitly stated, it needs to be revealed from the picture
- each bubble describes the procedure of calculation, and the result

Figure 1b

- the arithmetic task is outlined, numbers to sum are aligned below each other
- each bubble shows only the result of calculation

Thus, with the first CC respondents can comment results and procedures described in bubbles, and look for errors in procedures leading to incorrect results (and also in procedures leading to correct results). While with the second CC respondents can comment only results; it simplifies decision at a bubble with a correct result, but complicates decision at a bubble with an incorrect result: the procedures hidden behind the incorrect result are not described, and respondents have to make an attempt to discover them.

In the first CC, majority of the 2nd year respondents failed to decode the David's procedure, many of them even mentioned David as the child with whom they strongly disagree:

P28	Where did David take the 40?
P11	I strongly disagree with David. David – I do not understand how he came to the 40.

But the David's procedure is very inventive, with only a small mistake in the final. The bigger compliment goes to these respondents who praised David for his procedure, and advised him the right ending:

P31	David has a good tactic, but he mistook a sign, instead of adding there should be subtracting. David, you do not have those 2 x 40, you have less, so you must subtract.

On the contrary, the 3rd year respondents managed the David's issue without hesitation. Here the PCK acquired in Didactics courses comes into play – these respondents already attended Didactics on natural numbers where they learned how to utilize various counting procedures in the classroom.

Some 2nd year respondents had also difficulties with the Eve's procedure; they were not able to discover why she started with 3 + 3:

P22	Eve counted wrong from the start.
P20	Eve makes a sum of random.
P31	Eve does not watch orders, she is short of tens.
P27	Eve counted tens incorrectly; she took 3 + 3 instead of 30 + 30.
P12	Eve has a problem with counting of tens. Eve, we decompose 38 to 30 and 8, not to 3 and 8.
P33	Eve handled incorrectly the numbers; she did not take them as wholes, but separately. She did not realize that 39 is 30 and 9, and made 3 and 9 of it. Eve, you messed ones and tens, 39 must be expressed as 30 and 9.

To clarify the situation we should mention that counting tens separately during mental addition is not a standard procedure in our schools. On the other hand, the respondents recently attended Arithmetic courses on decimal numeral system, so that the excerpts above point to inflexible thinking of their authors.

In the second CC, respondents often succeeded in finding the procedure hidden behind the results, some of them suggested really credible rationale for why the mistake happened:

P14	Kevin completely eliminated the column with zeros.
P27	Kevin, if you count 0 + 0, you must enter the final 0 to the calculation.
P14	Peter probably thought that 0 is not a number, and added 1 to the next sum.
P37	Peter forgot to add 1 to the tens place, and added it later to the hundreds.

But there appeared also rationales that do not look likely:

P13	Peter swapped 0 and 1.

The tendency not to seek the procedure but only compare the bubble and the correct result, which is noticeable on the last line of the transcript above, appeared even stronger in some 3rd year students' outputs:

A03	Peter wrote the third '1' to the wrong place.
A10	Peter is coming to accuracy, but his result is 90 more. Peter, recount it again, your result is 90 more than the correct result. Pepe has 2 more zeros in his result. Pepe, your result is too high compared to the computed numbers. Recount again the example, and remove some numbers.

Among 2nd year respondents we found two who confused terms 'number' and 'digit' in their explanations. Further analysis of their responses showed that the problem might not be only terminological:

P24	Tina is right. If I add 17 to a digit 60, I get 6017. But if I count up, I would get 77.
P18	Tina and Jane are right, they followed the instructions exactly. David's bubble should be corrected: 2 x 40 = 80, add 3 makes 803.

These statements can be signals of deep misunderstanding of the concept of number. To be sure, we would need further data from these respondents.

During the analysis of completed worksheets it became apparent that in some responses to the first CC it is possible to distinguish between procedural and conceptual knowledge. This fact was especially evident for the following two respondents; both are 2nd year students, with average performance in Arithmetic. The first respondent answered the questions as follows:

P33	ad 2)	I strongly disagree with David.
	ad 3)	David is wrong. He confused it all.
	ad 4)	Instead of subtracting 3 from $40 \cdot 2 = 80$, he added it. He needs to have the whole counting explained again.

In the beginning, David is the only child in reply to a question with whom the respondent strongly disagree. Then we can see that the respondent knows the procedure that David used; she even says where the mistake is and what the correct version of this part of procedure is. Yet in the end she states that David needs to learn the whole procedure again. This respondent probably got her knowledge by rote learning. She does not understand the procedure as a sequence of individual steps, but as one indivisible whole. She knows the procedure very well; she is even able to compare her calculation with David's, and find the mistake. But she is not able to divide the procedure into individual steps, and repair just the wrong one. In her kind of understanding the only way how to repair the procedure is to learn it again as a whole. Summarized, in this task the respondent displayed no conceptual knowledge, and only superficial procedural knowledge.

With this respondent we can also clearly illustrate the difference between SMK and PCK: she knows how to count the example for herself (an indicator of SMK) but is not able to help the child (an indicator of a lack of PCK).

The second respondent wrote:

P37	ad 2)	I strongly disagree with David and Tina.
	ad 3)	Eve is wrong.
	ad 4)	Eve, you can calculate this way, but you have to write the second number under

the first, digits lined up in columns.
David, you must not round the numbers. If you round, you have to sum the numbers, and subtract their difference from the result.

This respondent has her knowledge too closely tied to the context in which it was learned (e.g., counting of numbers that are written below each other), so that the knowledge cannot generalize to other situations. As Hiebert and Lefevre (1986, p. 8) note, also this kind of knowledge used to be obtained by rote learning. Again, this respondent shows no conceptual knowledge, and superficial procedural knowledge. As in the previous case, the respondent displays SMK but no PCK.

CONCLUSIONS

In this study we introduced an educational tool called Concept Cartoons (CCs), and used it innovatively for investigating future primary teachers' mathematics content knowledge. For this purpose we prepared a set of CCs on an essential topic "addition and subtraction of natural numbers". These CCs imitate contingent situations, and we may observe future teachers' responses to more or less expected children's ideas.

As the results show, CCs are a very flexible tool, and we may investigate various aspects of knowledge with them. If the CC contains bubbles showing both procedures and results, then we might be able to distinguish clearly between procedural and conceptual knowledge, and between SMK and PCK (David & P33, Eve & David & P37). This kind of CCs also reveals when respondents have troubles to decode a simple procedure containing a mistake (David's and Eve's cases). The incorrect procedures presented by children might be ambiguous at first glance, and some respondents could display inappropriate spontaneous reactions – disagree strongly with an idea they do not understand (David & P11), or wrongfully blame the child to count randomly (Eve & P20). Moreover, the description of an incorrect procedure in the bubble can influence some respondents to incorporate the mistake into their own responses (David & P18, Tina & P24).

The CC containing bubbles with results only can serve as a useful supplement to the previous type. Respondents can display good transformation knowledge when looking for examples of procedures that could fit to incorrect results in bubbles (Kevin & P27, Peter & P14). On the contrary, some respondents can show a lack of PCK by just comparing the incorrect result in the bubble with the correct result, and giving the child advice without looking for the procedure hidden behind the mistake (Peter & P13, Peter & Pepe & A10).

The analysis of the data obtained during the research led us to the need to investigate deeper the question how different kinds of knowledge can be displayed through the mediation of CCs. This is the direction we will continue our research. We found out that further systematic triangulation from different perspectives (responses to CCs, Arithmetic tests, interviews) is necessary for the creation of a grounded theory.

We appreciate the advantage that CCs offer in comparison to other diagnostic tools such as videos or classroom scenarios: the possibility to prepare the content of the bubbles intentionally, on a chosen purpose. We expect that this feature shall allow us to investigate teachers' knowledge more deeply through presenting bubbles with alternatives that are able to reveal important aspects of teachers' knowledge but sometimes might remain unspoken in a real classroom.

Lessons we have (not) learned from past and current conceptualizations of mathematics teachers' knowledge

Thorsten Scheiner

University of Hamburg, Hamburg, Germany, Thorsten.Scheiner@uni-hamburg.de

This paper attempts to capture some of the breath of frameworks and models on mathematics teachers' knowledge in order to identify central lessons we have (not yet) learned from past and current approaches in theorizing and conceptualizing a knowledge base for teaching mathematics: there are accounts of the complex and multidimensional nature of teachers' knowledge but no accounts as to the reorganization of dimensions of teachers' knowledge in order to be more consistent with a constructivist view on learning and teaching; there are accounts of what teachers' knowledge is about but no accounts as to a structural description of teachers' knowledge. The paper highlights several unsettled issues of this research field and certain profitable directions for advancement.

Keywords: Teacher education/development, teacher knowledge.

MAPPING THE TERRAIN OF RESEARCH ON TEACHERS' KNOWLEDGE

With his influential construct of dimensions of teachers' knowledge in the 1980's, Lee S. Shulman (1986) at Stanford University has guided the research on teachers' knowledge in a new direction and, simultaneously, proposed an approach to educational reform that labelled teaching a *profession* (Shulman, 1987). Shulman (1986) promoted a *paradigm shift* in educational research by assuming the existence of a knowledge base that is special for the purposes of teaching. Since then, several interesting approaches, partly distinct and partly overlapping, have been developed that shape the current theoretical landscape in mathematics education research on teachers' knowledge. In the research literature, it is common to follow Shulman's (1987) conceptualization of a knowledge base for teaching including (1) content knowledge, (2) general pedagogical knowledge, (3) curriculum knowledge, (4) pedagogical content knowledge, (5) knowledge of learners, (6) knowledge of educational contexts, and (7) knowledge of educational ends, purposes, and values, and their philosophical and historical grounds. Several researchers have made attempts to identify features of mathematics teachers' knowledge that (may) matter in the work of teaching – in many ways, making Shulman's (1986, 1987) conceptualization of domains of teachers' knowledge, and, in particular, subject matter knowledge (SMK) and pedagogical content knowledge (PCK) specific to teaching mathematics.

The frameworks and models that shape the theoretical landscape in the conceptualization of and research on mathematics teachers' knowledge are within a broad spectrum of specificity, ranging along general, discipline-specific, domain-specific, and concept-specific frameworks and models. Various general frameworks contributed to the field, for instance, in (a) documenting teachers' resources (including knowledge), orientations (including beliefs), and goals as critically important determinants of what teachers do and why they do it (Schoenfeld, e.g., 2010), (b) highlighting that besides subject matter knowledge per se there is subject matter knowledge specific for teaching (Shulman, 1986, 1987), and (c) providing insights in teacher proficiency including the identification of various dimensions such as knowing students as thinkers and learners, reflecting on one's practice, among many others (Schoenfeld & Kilpatrick, 2008). Schoenfeld and Kilpatrick's (2008) contribution builds the bridge to discipline-specific frameworks since their work has been initially developed for identifying dimensions of mathematics teachers' proficiency but can and has been extended to a general (discipline-unspecific) framework.

A considerable number of research work is located in mathematics education research, providing both discipline-specific and domain-specific frameworks and models (e.g., Ball et al., 2008; Baumert et al., 2010; Blömeke et al., 2014; Fennema & Franke, 1992; Hill et al., 2008; Kilpatrick et al., 2006; Rowland et al., 2005; Tatto et al., 2008, 2012). These contributions, among others, are of interest in this paper since each contribution introduces and examines a particular approach in theorizing and conceptualizing the construct of mathematics teachers' knowledge. They are chosen because of their *complementary* power and their potential to study teachers' knowledge in a more comprehensive manner. Instead of reviewing each contribution in detail, the following section presents some central lessons we have (not yet) learned from these approaches.

Notice that, with few exceptions (e.g., Even, 1990), the mathematics education research community has almost neglected concept-specific frameworks. However, from the author's perspective, investigating teachers' knowledge at the level of specific concepts is an important issue that needs more attention in future research on teachers' knowledge.

THE RECENT DIVERSITY OF CONCEPTUALIZATIONS AS A RESOURCE FOR CURRENT AND FUTURE RESEARCH ATTEMPTS

The mathematics education research literature contains a broad range of approaches in theorizing and conceptualizing a knowledge base for teaching mathematics. The diversity of approaches is, of course, a reflection of the complexity of the research field that cannot be described, understood, or explained by only one theoretical framework. Different frameworks evolve for multiple purposes due to different needs in given contexts with different implications – some on a theoretical, methodological, and/or empirical level. The diversity of frameworks may provide a rich resource for future research attempts – the frameworks and models are important in their own right and may prove to be productive in some contexts.

The broad diversity of approaches starts with the versatile function of frameworks and models of teachers' knowledge: (a) as *tools* or (b) as *objects*. While most of the frameworks and models of teachers' knowledge are used as *tools* for guiding research practices, in particular for analysing data in empirical investigations, only a few function as an *object* of research – they are the aim of research practices. This distinction between 'tools for research' and 'objects of research' has already been made by Assude and colleagues (2008) with reference to theories in mathematics education. While the conceptualization by Ball and her colleagues (2008), for instance, can be understood as the result of an intensive 'job analysis', where 'conceptualizing a knowledge for teaching' was one of the goals, the conceptualizations by Blömeke and her colleagues (2014) and Tatto and her colleagues (2008, 2012) provide tools for empirical investigations in an international comparative, large-scale study. However, the distinction between frameworks as tools or as objects is rather inclusive (than exclusive) since the ways in which teachers' professional knowledge is understood and conceptualized impact on how teachers' knowledge is investigated, and vice versa.

THE KNOWLEDGE BASE FOR TEACHING MATHEMATICS IS COMPLEX AND MULTIDIMENSIONAL

The different approaches converge in an understanding that teachers' knowledge is complex and multidimensional. Although the discipline-specific models and frameworks mentioned above differ in detail, many of them converge in efforts to further *refine* the construct of subject matter knowledge (SMK) and pedagogical content knowledge (PCK). The following is an attempt to shed light on ways how Shulman's dimensions of SMK and PCK have been refined in the above mentioned contributions.

Subject Matter Knowledge (SMK)

The literature suggests that subject matter knowledge (SMK) can be further differentiated in terms of substantive and syntactic structures (Schwab, 1978), in terms of ways of understanding and ways of thinking (Harel, 2008), in terms of school mathematical knowledge and academic content knowledge (Bromme, 1994), among others. Each further distinction has shed light into important issues: Shulman (1986, 1987), for instance, emphasized Schwab's (1978) distinction between substantive and syntactic structures of a discipline. Substantive structures are the key principles, theories, and explanatory frameworks that guide inquiry in the discipline, while syntactic structures provide the procedures and mechanisms for the acquisition of knowledge, and include the canons of evidence and proof. As already noticed by Rowland and Turner (2008), the term 'syntactic' is mainly associated to the formal structure, thus, it seems that Schwab's (1978) choice of the word 'syntactic' is unfortunate since it does not capture the heart of the intended meaning that is, as argued by Rowland and Turner (2008), the heuristics of inquiry. However, Schwab's distinction has been an initial point to think about various dimensions of SMK.

In synthesis, it can be stated that several researchers have refocused on the centrality of SMK in teaching. However, crucial in the literature is the assumption that there is *unique* content knowledge for teaching mathematics and that having such knowledge is key to the enactment of rich mathematics. The notion of 'specialized content knowledge' introduced by Ball and her colleagues, described as pure content knowledge "that is tailored in particular for the specialized uses that come up in the work of teaching" (Hill et al., 2008, p. 436), is a key contribution in efforts to examine dimensions of mathematical knowledge considered as being crucial for the purposes of *teaching*. In contrast to the former refinements of SMK, the notion of 'specialized content knowledge' has the potential to go beyond just differentiating mathematical content knowledge in various (qualitatively different) sub-facets (such as to think about content knowledge in terms of procedural and conceptual knowledge, school mathematical and academic content knowledge, etc.). This 'specialized content knowledge' is not the kind that disciplinary experts would necessary possess. As a consequence, in contrast to Shulman (1986) treating 'subject matter knowledge *for* teaching' as equivalent to PCK, these considerations lead to the claim that there is pure mathematical knowledge specialized *for* teaching mathematics. Furthermore, it is argued that this kind of mathematical knowledge is not merely qualitatively but may be fundamentally different to SMK per se. This argument is rooted in the observation that SMK per se is primarily aimed at creating new knowledge, while SMK for teaching is essentially aimed at promoting students' mathematical thinking and learning. In this work, the former kind of knowledge is called *mathematical content knowledge per se* (MCK per se) and the latter kind of knowledge is called *mathematical content knowledge for teaching* (MCK for teaching).

Notice that 'mathematical content knowledge per se' is not equal to what Ball and her colleagues (e.g., 2008) described as 'common content knowledge' since it is not limited to the knowledge 'held or used by an average mathematically literate citizen' but may also include academic content knowledge, for instance. Mathematical content knowledge per se can be considered as not only including basic factual knowledge of mathematics but also the conceptual knowledge of structuring and organizing principles of mathematics as a discipline as described and operationalized in the TEDS-M framework (Tatto et al., 2008). Moreover, it can be described in terms of Kilpatrick, Blume, and Allen's (2006) *mathematical proficiency with content* including conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, productive disposition, and knowledge of structure and conventions, among others.

Pedagogical Content Knowledge (PCK)

Since Shulman's (1986) introduction of the construct of PCK, many researchers have added and further elaborated attributes and components of PCK. The above mentioned contributions provide various ways to refine the construct PCK, including, but not limited to, knowledge of cognitive requirements for learning, knowledge of students' conceptions, knowledge of epistemological obstacles of particular mathematical concepts, and knowledge of instructional strategies. Although even representing refinements of PCK, these subcategories are quite broad and often remain unspecified. Rowland and his colleagues' (e.g., 2005) work let to the identification of several subcategories that could be grouped into four units. Although their units are broad, the underlying subcategories provide some specificity. Another example is the work by Hill, Ball, and Schilling (2008) in making effort to conceptualize, develop, and test measures of teachers' knowledge of content and students (KCS). The same authors, although providing with KCS a subdivision of pedagogical content knowledge, state that even their subcategory is multidimensional (see Hill, Ball, & Schilling, 2008). Thus, various researchers assume that it is reasonable to further refine the various subcategories.

The subcategories of PCK identified in the above mentioned frameworks and models can be clustered into three dimensions, namely (1) an epistemological dimension, (2) a cognitive dimension, and (3) a didactical dimension. The *epistemological dimension* refers to knowledge about the epistemological foundations of mathematics and mathematics learning (see Bromme, 1994). For instance, Harel (e.g., 2008) calls for teachers' knowledge of epistemological issues involved in the learning of specific mathematical concepts, including knowledge of epistemological obstacles. The *cognitive dimension* refers to knowledge of students' cognitions (Fennema & Franke, 1992), in particular, knowledge of students' common conceptions (see Shulman, 1987), knowledge of students' cognitive difficulties involved in concept construction (Harel, 2008), and the interpretation of students' emerging thinking (Ball et al., 2008). In other words, it includes knowledge of how students think, learn, and acquire specific mathematical knowledge (Fennema & Franke, 1992). The *didactical dimension* refers to what Shulman (1986, p. 9) described as knowledge of "the most useful ways of representing and formulating the subject that make it comprehensible to others", including teachers' illustrations and alternative ways of representing concepts (and the awareness of the relative cognitive demands of different topics) (Rowland et al., 2005) and knowledge of the design of instruction (Ball et al., 2008).

In summary, it can be stated that the frameworks and models about teachers' knowledge mentioned above can be understood as elaborating rather than replacing Shulman's (1986; 1987) contribution within this field. The approaches taken and the conceptualizations of teachers' knowledge proposed are not inconsistent, nor are the identified dimensions of mathematics teachers' knowledge mutually exclusive. In contrast, the identified dimensions are *complementary* and provide, taken together, a more *refined* picture of conceptualizing the teachers' knowledge base.

The considerations proposed above demonstrate the multidimensional nature of mathematics teacher knowledge, in particular, the multidimensionality of SMK and PCK. Although the distinction between SMK and PCK is ambitious, several scholars take the view that the two categories, and, in particular, their corresponding subcategories, are useful tools in describing teachers' knowledge for research purposes and particularly in devising teachers' professional development programs.

MOVING AWAY FROM SHULMAN'S ORIGINAL CONCEPTUALIZATION

The above mentioned contributions present strong cases that progress can and has been made in the conceptualization of teachers' knowledge. As mentioned above, several scholars have particularly reformulated the concept of PCK, by refining sub-dimensions or identifying dimensions of teachers' knowledge and adding them to the construct of PCK. Thus, it can be seen that researchers have assimilated the notion of PCK and redefined it according to their beliefs or to findings from empirical studies. Although the mentioned studies represent reformulations of the concept of PCK, Shulman's conceptualization of PCK was still the theoretical starting point for these studies. In this process of further refinement and extension, however, researchers' understanding and interpretation of PCK have moved away from Shulman's original conceptualization. For instance, the concept of PCK has almost lost its most important characteristic, namely its topic specificity (Hashweh, 2005). PCK, according to Shulman's definition, is not only specifically related to topics within certain disciplines, but also research on PCK typically does not result in a description of 'expert teaching' as if there would be one optimal way to teach certain subject matter (see, Shulman, 1987). From the author's perspective, recent research on mathematics teachers' knowledge tend to ignore the complex nature of PCK as a form of teachers' professional knowledge that is highly topic, person, and situation specific (for overviews see, e.g., Abell, 2007; Van Driel & Berry, 2010).

A NARROW FOCUS ON THE DISCIPLINE

Many in the field of teacher education today take Shulman's conceptualization of the knowledge base for teaching for granted – accepting the view of pedagogical content knowledge (PCK) as an adaption of subject matter knowledge for the teaching enterprise, a process Shulman (1987) called *transformation*. However, with restricting PCK to the capacity to transform the subject matter of the discipline to subject matter of the school subject, Shulman places the subject matter content at the centre of conceptualizing the knowledge base for teaching. As a consequence, past and recent research on mathematics teachers' knowledge limited their focus on teachers' *unpacking of mathematics content* in ways accessible to their students. In doing so, the attention is focused entirely on the discipline. However, in being more consistent with a constructivist view of learning, the emphasis needs to be shifted from knowledge of the discipline to knowledge about how students' knowing and learning actually progresses. Thus, a reconceptualization of the knowledge base for teaching mathematics is needed toward a theory of teaching grounded in research on students' learning.

FROM REFINEMENT TO REORGANIZATION: TURNING THE REFINEMENTS ON THEIR HEADS

We have learned a great deal of the necessity for refining Shulman's initial work toward more specific descriptions of the knowledge base for teaching mathematics. Whereas it was important to initially identify and define various sub-dimensions of SMK and PCK and making progress in obtaining empirical evidence to support each piece of the puzzle, interpreting them in light of a model of cognition and learning certain subject matter may allow for the integration of the various pieces into one framework for mathematics teachers' knowledge. Thus, the time has come to move from further refining to reorganizing sub-dimensions of teachers' knowledge. As indicated above, the various refinements of PCK seem to converge in three domains, namely (1) *knowledge of students' understandings* (KSU), (2) *knowledge of learning mathematics* (KLM), and (3) *knowledge of teaching mathematics* (KTM). KSU refers to a cognitive perspective, KLM to an epistemological perspective, and KTM to a didactical perspective on this issue. In this work, knowledge of students' understanding (KSU), knowledge of learning mathematics (KLM), and knowledge of teaching mathematics (KTM), together with mathematical content knowledge per se (MCK per se) and mathematical content knowledge for teaching (MCK for teaching) *build* the knowledge bases that constitute the particular kind of knowledge that is considered as specialized for the purposes of teaching mathematics. In doing so, past and current approaches in research on mathematics teachers' knowledge are turned on their heads in the sense of taking the identified (and refined) knowledge dimensions as *building blocks* for the construct of 'knowledge for teaching mathematics'.

GOING BEYOND WHAT TEACHERS' KNOWLEDGE IS ABOUT: A WINDOW TO A STRUCTURAL DESCRIPTION OF TEACHERS' KNOWLEDGE

While the subcategories of mathematics teachers' knowledge identified in the above mentioned contributions are crucial pieces of the puzzle, we have not learned how these pieces fit together. In the past, the primarily focus was on what knowledge is held by teachers, and how that knowledge is used in practice. It seems that, with few exceptions, the literature has limited its focus on the content teachers do or should possess. However, a key theoretical concern arising in the realm of theorizing and conceptualizing mathematics teachers' knowledge is the question on how the knowledge is structured and organized. To put it in other words, what is missing in the current landscape of the conceptualization of mathematics teachers' knowledge are attempts to go beyond what the teachers' knowledge is about to include a *structural description* of teachers' professional knowledge. Drawing on the 'knowledge in pieces' framework developed by diSessa (e.g., 1993), Scheiner (2014) proposes to consider teachers' professional knowledge as a complex system of 'knowledge atoms'.

> 'Knowledge for teaching mathematics' is considered as the repertoire of 'knowledge atoms' that have been transformed along (1) knowledge of students' mathematical understandings (KSU), (2) knowledge of learning mathematics (KLM), and (3) knowledge of teaching mathematics (KTM), taking (4) mathematical content knowledge per se (MCK per se) and (5) mathematical content knowledge for teaching (MCK for teaching) as the cornerstones. (Scheiner, 2014, in press)

With this perspective, several angles for theoretical reflection on the *nature* and *form* of teachers' knowledge are presented, including those concerning the degree of integration, size, specificity, and source of teachers' knowledge. The notion of 'transformation', for instance, indicates that the constituent knowledge bases are inextricably combined into a new form of knowledge that is more powerful than the sum of its parts (concerning *degree of integration*), while the notion of 'knowledge atom' indicates that knowledge is of a microstructure, highly context-sensitive, and concept-specific and has to be considered as of a fine-grained size (concerning *size* and *specificity*). Notice that in contrast to Shulman and his proponents' work taking content knowledge and pedagogical knowledge as the constituent knowledge bases for teaching, it is KSU, KLM, and KTM, together with MCK per se and MCK for teaching that build the constituent knowledge bases for teaching mathematics (concerning *source*). A more detailed elaboration of first attempts towards a structural description of teachers' knowledge can be found in Scheiner (in press).

2 Universität des Saarlandes, Saarbrücken, Germany

In recent years, some efforts have been made to consolidate out-of-field-teaching as research field in mathematics education. Taking teachers' professional knowledge as reference frame, out-of-field-teachers seem less qualified regarding CK and PCK in mathematics than teachers that were especially trained to teach their subject. In this paper, we approach the phenomenon of out-of-field-teaching by focusing on both teachers' beliefs and competencies while the latter is operationalized as skills in designing mathematical tasks for written exams. Data was collected throughout a qualification program particularly focusing on out-of-field-teachers' domain-specific professional knowledge. We discuss in detail design aspects of our on-going research and give first insights into the changes of out-of-field-teachers' beliefs reflecting their professional development in the course of the qualification program.

Keywords: Out-of-field-teaching, beliefs, competencies, CPD.

INTRODUCTION

Current developments in mathematics education show an interesting phenomenon: A considerable body of mathematics lessons is taught by teachers who have not been qualified as mathematics teachers through certified courses of studies at university (cf. Törner & Törner, 2010). In the following, we refer to this heterogeneous group of teachers by using the term "out-of-field". Due to a thin research base, there are barely information about the range of this phenomenon which strongly varies across different countries, educational systems and school types. In the U.S. for instance some efforts by Ingersoll (1999) have been made to estimate the amount of out-of-field-teaching in a large-scale study which reveals that up to one third of all high school mathematics teachers do not hold a teaching certificate in mathematics. For Germany, Törner and Törner (2010) state that almost 80% of primary mathematics lessons are taught by teachers who have not taken any mathematics courses during their professional education. Although, in higher education the average percentage of out-of-field-teachers in mathematics education decreases, it still remains on an estimated level of 15% referring to lower secondary grades (cf. Bosse & Törner, 2013). Against this backdrop, the issue of out-of-field-teaching is *undertheorized* and *underresearched* in reference to crucial aspects that characterize out-of-field-teachers' professional knowledge and practices. Within this contribution, we discuss an initial approach to address this lack of research.

Considering out-of-field-teaching in the light of models of teachers' professional competencies (cf. Blömeke, Suhl, & Döhrmann, 2012) we encounter a twofold problematic scenario: Due to missing courses of studies it can be assumed that – put carefully – out-of-field-teachers are faced with considerable knowledge-gaps concerning different facets of their professional competence. These gaps in turn affect their capability to act effectively in the classroom, to provide high quality mathematics lessons, and to support sustainably students' performances (Richter, Kuhl, Haag, & Pant, 2013). In our study, we thus put emphasis on key-aspects of out-of-field teachers' professional knowledge to understand which categories are decisive for describing their specific situation. Reflecting on research about out-of-field-teachers' professional identity we additionally focus on teachers' beliefs about mathematics and the teaching and learning of mathematics, as these are crucial parameters considering teachers' decision-making and lesson practice (cf. Bosse & Törner, 2012; Hobbs, 2012). In our study we address this aspect by focusing on out-of-filed-teachers' skills to design mathematical tasks for written exams. In sum, we will consider the issue of out-of-field-teaching from two perspectives:

(1) First, we outline some key aspects of the *theoretical* foundations, in particular on mathematics-related beliefs and on designing mathematical tasks as one crucial aspect of teachers' competencies.

(2) Second, we discuss in detail our *methodological* approach using mixed methods to capture teachers' beliefs and their competencies, displayed by designing mathematical tasks. As core element of this perspective we describe and validate a category system which has been developed to characterize out-of-field-teachers' decisions while choosing mathematical tasks for class assessment.

In this paper, we give preliminary results of our on-going research while accompanying a group of out-of-field teachers throughout a one-year qualification program.

THE ROLE OF BELIEFS AND COMPETENCIES

Teachers' professional knowledge has been researched in depth and from various perspectives considering both cognitive and affective-motivational aspects (cf., Shulman, 1986). Drawing on key findings of these studies teachers' professional knowledge is conceptualised as interplay of *Content Knowledge (CK), Pedagogical Content Knowledge (PCK), General Pedagogical Knowledge (PK), professional motivation, beliefs* and *self-regulation*. Large-scale empirical studies capture the interplay of these cognitive facets and affective-motivational characteristics and underpin efforts to capture classroom practices with regard to both dimensions (cf. Blömeke et al., 2012). Ball and Bass (2000) further work on a domain-specific conceptualization when focussing on mathematical knowledge needed for teaching. They elaborate on teachers' knowledge of mathematics as the decisive parameter for improving their instructional quality. One promising attempt to conceptualize teachers' professional knowledge from a more situative perspective is provided by Lindmeier and colleagues (2013). In particular, she stresses that a subject-specific model for teacher cognition encompasses three components: *basic knowledge* (CK, PCK), and the two complementary components *reflective competences* and *action-related competences*. In particular, the action-related competencies comprise the abilities needed to perform in the classroom. What is more, Lindmeier and colleagues (2013) stress that for both reflective and action-related components, basic knowledge plays a key role for enactment.

Considering in addition the role of teachers' beliefs, one can conclude that these play a key role for decision-making in the classroom (Törner, Rolka, Roesken, & Sriraman, 2010). Our research refers to the dimensions of beliefs presented by Grigutsch, Raatz, & Törner (1988): *beliefs about the nature of mathematics*, *the teaching and learning of mathematics* and *students' mathematics achievement*. Beliefs are often robust and therefore difficult to change or as Sowder (2007) puts it "many of teachers' core beliefs need to be challenged before change can occur" (p. 160). What this quotation stresses is that any change or development in teachers' beliefs is a long-term process. Accordingly, Toerner, Rolka, Roesken and Schoenfeld (2006) analyse the teaching practice of an experienced teacher after having participated in an in-service training course on using open-ended task in mathematics teaching. Since it was not the focus of the study to examine the effectiveness of the professional development event, it turned out that the teacher's beliefs built a hindrance to successfully implementing new ideas. Nevertheless, other studies report about quick changes in beliefs while teachers participated in a professional development program.

DZLM QUALIFICATION PROGRAM: PROFFUNT

The German Centre of Mathematics Education offers various qualification programs and training courses for multipliers and out-of-field-teachers in order to foster their *Continuous Professional Development* (CPD). The project ProFFunt[1] is a certification course especially designed to support out-of-field teachers in lower secondary school, and is a collaborative project of the Universität des Saarlandes, of the Landesinstitut für Pädagogik und Medien of the Federal State of Saarland and the DZLM. The course has lasted one year, and addressed teaching in grade five and six, and will be extended to grades seven and eight in the next year. ProFFunt draws on the success-

1 ProFFunt = „Professionalisierung fachfremd Unterrichtender"

ful KOSINUS program2 that so far has reached more than half of the respective schools in the Saarland. Support for teachers for probing issues in practice is provided by the chair of mathematics and its didactics.

The ProFFunt project especially focuses on the development of out-of-field teachers' competencies which are considered as being decisive in regards of teachers' professional knowledge (cf. Blömeke et al., 2012). The content was developed throughout analyses based on *Stoffdidaktik* including relevant mathematics topics in grade five and six such as algebra, geometry and basic ideas in stochastics. Throughout the ProFFunt project teachers additionally received a profound overview on PCK issues and were supported in implementing these aspects into their teaching, ranging from task design to planning of teaching sequences. Teachers were required to participate in teams of two (tandem) in order to foster collaboration in their respective school. Furthermore, the course consisted of six modules with a total workload of 200 hours. ProFFunt follows a so-called *sandwich-structure* with alternating theoretical and practical phases in which the participants experience a combination of learning, implementation and reflecting phases, comprising also e-learning and working on a portfolio. The intention of this structural design is to foster long-term changes in teachers' views on mathematics learning and to enable sustainable competence development. In this regard, it appears promising to stress teachers' beliefs and action related-competencies, as these are long-term developing aspects of teachers' professional knowledge.

RESEARCH ON PROFFUNT

A broad research plan has been developed in order to cover various aspects of out-of-field teachers' professional knowledge. The research design acknowledges the researchers are not involved in conducting the course and that out-of-field teachers' development should not be bothered by intensive testing. An overview on the research design is given in Figure 1 and is briefly explained hereafter.

Our approach is twofold and addresses teachers' beliefs and competencies: On the first level we focus on out-of-field-teachers' development of beliefs throughout the qualification program. On the second level we scrutinize teachers' competencies in designing mathematical tasks for written exams. Both constructs are investigated in a pre-post-comparison design referring to the period before and after the ProFFunt course. In addition, we evaluate our results in view of a control group of teachers who studied mathematics as a school subject at university so that we are able to describe and understand crucial differences between *in-field* and out-of-field-teachers. Finally, the connection between out-of-field teachers' beliefs and the way of designing mathematical tasks before and after the qualification program is considered in order to check for correlation between these two categories (Figure 1). In particular we focus on the following research questions:

a) What categories do out-of-field-teachers consider in designing mathematical tasks for written exams? What influence has a one-year qualification program on the development out-of-field of teachers' competencies in designing tasks?

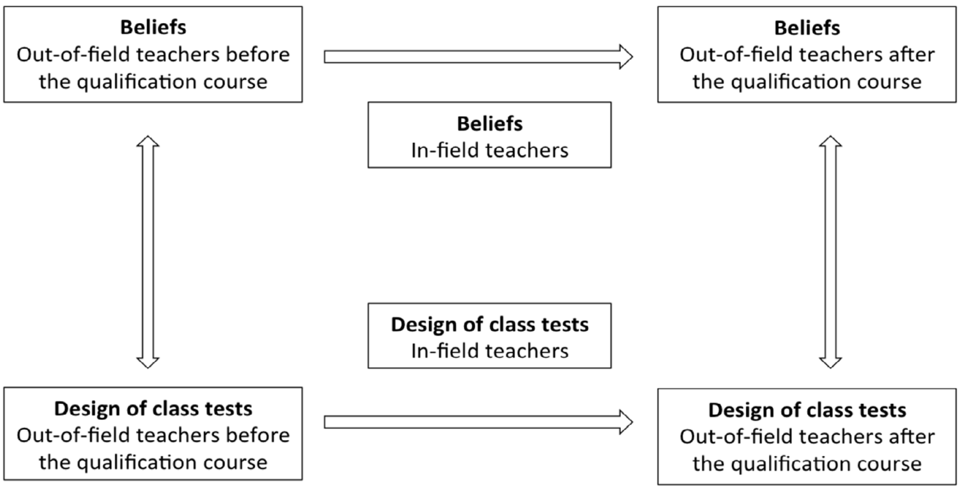

Figure 1: Overview on the research plan

b) What mathematics-related beliefs do out-of-field-teachers possess? What influence has a one-year qualification program on the development of out-of-field teachers' beliefs?

c) What differences between out-of-field-teachers and in-field teachers could be detected with reference to both constructs beliefs and action-related competencies?

In this paper, we do not fully answer our research questions, but outline our research design, carefully describe our instruments and present preliminary results.

METHOD

In the one-year ProFFunt course, 13 out-of-field-teachers participated, representing a highly heterogeneous group of teachers which non-mathematics educational practice varies from less than 5 years to up to 15 years. Working as a teacher within the educational system in Germany requires studies in CK and PCK in at least two different subjects complemented by pedagogical courses. Hence, participants of our study have a considerable body of previous knowledge concerning pedagogical aspects like for example learning theories and implementation strategies, but established in a different context than mathematics. Combined with the fact that the participants' knowledge differs in the specific subjects they have studied, these circumstances increase the heterogeneity of the sample and makes working with the group of out-of-field-teachers in terms of CPD-training and research challenging. As a control group we refer to data raised within the scope of the MT21 research program (Blömeke, Kaiser, & Lehmann, 2008), where prospective and in-service teachers (N=139) who studied mathematics at university participated.

Data was collected through combining qualitative and quantitative methods to capture the complexity of out-of-field-teachers' specific situation. Their mathematics-related beliefs have been revealed by using a questionnaire which has been developed and validated in the scope of the TEDS-M study (cf. Blömeke, Suhl, & Kaiser, 2011). This instrument displays a shortened and slightly modified version of the items originally developed by Grigutsch and colleagues (1988). The questionnaire was distributed to the participants before and after the DZLM qualification program. The questionnaire consists of 33 items that are rated on a six-point Likert-Scale, ranging from strongly disagree to strongly agree. Considering various aspects of teachers' beliefs the instrument encompasses the following five subscales: *nature of mathematics as rules and procedures* (6 items), *nature of mathematics as process of inquiry* (5 items), *learning mathematics through teacher direction* (8 items), *learning mathematics through active learning* (6 items) and *mathematic achievement as fixed ability* (8 items). A short excerpt from this questionnaire is shown in Figure 2. Applying the TEDS-M belief questionnaire ensures a stable instrument with sufficient scale reliability.

Focusing on designing mathematical tasks for written exams as a core aspect of teachers' action-related competencies, we developed a category system which refers to key findings from current research in mathematics education. Throughout the qualification program, participants of our study were asked to allocate and provide the written exams they delivered in grade five. Concerning content, the written exams mainly focussed on arithmetic and geometry in grade 5. As a result of this procedure we are able to gain theory-based insights into crucial aspects of out-of-field-teachers' professional knowledge. In the developmental process of the category system we brought together various findings from research

	Strongly disagree	Disagree	Slightly disagree	Slightly agree	Agree	Strongly agree
Mathematics is a collection of rules and procedures that prescribe how to solve a problem.	☐	☐	☐	☐	☐	☐
In mathematics many things can be discovered and tried out by oneself.	☐	☐	☐	☐	☐	☐

Figure 2: Exemplary items of the belief questionnaire

on mathematics education and pedagogical theory concerning learning and achievement through tasks. The instrument consists of four domains reflecting key-aspects of teachers' professional knowledge:

(OCS): *Orientation toward task-related competencies and educational standards,*

(OPK): *Orientation towards task-related PCK*

(OCP): *Orientation towards task-related cognitive processes*

(ODC): *Orientation towards task-related difficulty and complexity*

For the sake of brevity, we do not discuss every domain in detail, and limit ourselves to shortly describing our methodical procedure for analysing mathematical tasks. In the first domain (OCS) we focus on three categories referring to the learning standards in mathematics education in Germany (cf. Blum, 2006). In particular, we regard the design of a task from the perspective of content-related and process-related competences. An example of categories used in the domain OCS is shown in Figure 3. Categories located in OPK deal with key aspects of pedagogical content knowledge in mathematics. In the context of our research, we choose 4 categories in this domain: First, we take a look on how the structure of the task motivates students' learning processes (cf. Bruder et al., 2008), second we concentrate on which strategies in designing a task are used to foster students' active engagement in a comprehensive learning process (cf. Büchter & Leuders, 2005). While the third category in this domain emphasises the form of representation, the fourth category considers linguistic aspects of the task (cf. Meyer & Prediger, 2012). Reflecting on students' cognitive processes working on a mathematical task in the domain OCP, we include categories dealing with Blooms taxonomy of learning domains (cf. Bloom, 1976) to cover a more pedagogical perspective. The second category in this domain deals with the question what level of mathematics-related cognitive processes like generalising or using formal and abstract expressions are required for solving the task (cf. Cohors-Fresenborg, Sjuts, & Sommer, 2004). In the last domain ODC we include several complementary categories covering key aspects of difficulty and complexity of a mathematical task (cf. Bruder et al., 2008). In particular we focus on students' required time to solve the task, amount of steps to provide a correct solution, the response format, and finally mathematical correctness.

Three experts in mathematics education from our research team independently used the developed category system to analyse 10 exams (60 tasks) in order to check the quality and sensitivity of our instrument. The degree of agreement was calculated by estimating the inter-rater reliability in terms of Cohen's kappa for each category. In regard of the constructed instrument we estimated Cohen's kappa between 0.72 and 0.95 for tasks which shows satisfying agreement (Hallgren, 2012).

PRELIMINARY RESULTS AND DISCUSSION

Reflecting on our broad research plan, we will limit ourselves to preliminary results respecting the development of out-of-field-teachers' beliefs before and after participating in the ProFFunt course, in comparison to a group of "in-field" mathematics teachers. In addition, we would like to stress several aspects of our research questions, to draw some conclusions concerning our methodical approach and to anticipate expectable results of our on-going research process.

First, we concentrate on the results derived by the TEDS-M beliefs questionnaire. An overview showing means and standard deviation of out-of-field teachers' beliefs on the five subcategories before and after

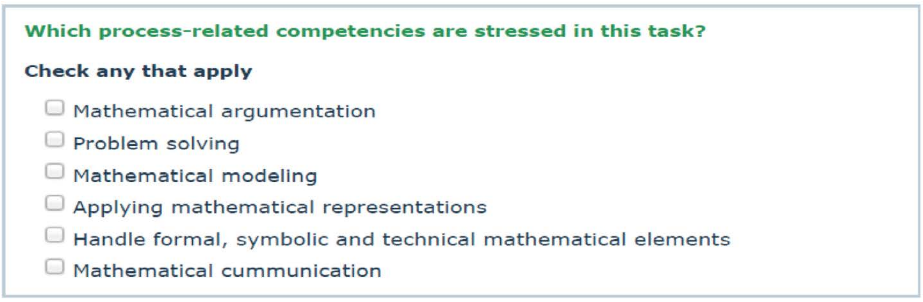

Figure 3: Exemplary item of the domain OCS of the category system

participating in the qualification program is given in Table 1. Considering beliefs about the nature of mathematics it becomes apparent that the participants are strongly oriented towards the *nature of mathematics as process of inquiry* at the beginning and even more at the end of the ProFFunt course, showing a small effect size. On the contrary the *nature of mathematics as rules and procedures* is rated less frequently before the course and decreases afterwards, showing a medium effect size. With reference to the beliefs about learning mathematics we can find that out-of-field-teachers in this study before and after the ProFFunt course lay a strong emphasis on *learning mathematics through active learning* whereas *learning mathematics through teacher direction* is considered minor relevant. In addition, *mathematics achievement as fixed ability* is rated low before and after the qualification program. Our results support the assumed changeability of out-of-field teachers' mathematics-related beliefs after participating in a qualification program.

In comparison to the sample of "in-field" teachers derived from the MT21 study, the group of out-of-field teachers in ProFFunt shows minor differences when it comes to their mathematics-related beliefs (Table 2). Out-of-field teachers consider *mathematics learning through teacher direction* as minor relevant compared to "in-field" teachers.

These findings show an interesting phenomenon: Despite the fact, that being out-of-field in most cases comes along with considerable knowledge gaps in CK and PCK, participants in this study strongly emphasize mathematics' dynamic character and its potential as source of effective and active learning opportunities at the start of the qualification program. These results are remarkable because they contradict the popular assumptions that out-of-field-teachers feel less competent in mathematics and teaching mathematics and therefore preferably refer to structures, rules and procedures. We take these surprising aspects in our findings to contemplate on one essential issue: Who are we talking about when labelling

Dimension of beliefs		pre	post	effect size
Nature of mathematics as rules and procedures	Mean StD	3.8 .81	3.4 .89	-0.29
Nature of mathematics as process of inquiry	Mean StD	5.0 .43	5.3 .61	0.11
Learning mathematics through teacher direction	Mean StD	2.4 .75	2.5 .68	0.05
Learning mathematics through active learning	Mean StD	5.1 .49	5.2 .60	0.01
Mathematic achievement as fixed ability	Mean StD	2.5 .70	2.5 .82	-0.08

Table 1: Out-of-field-teachers beliefs before and after the qualification program

Dimension of beliefs		Sample (n=11)	MT21-Germany (n=139)
Nature of mathematics as rules and procedures	Mean StD	4.0 .67	3.9 .98
Nature of mathematics as process of inquiry	Mean StD	5.1 .48	4.9 .87
Learning mathematics through teacher direction	Mean StD	2.4 .74	3.2 .88
Learning mathematics through active learning	Mean StD	5.2 .41	5.3 .71
Mathematic achievement as fixed ability	Mean StD	2.6 .68	2.2 .82

Table 2: Out-of-field-teachers and in-field-teachers mathematic-related beliefs

teachers as being "out-of-field"? What is missing is a concise definition who out-of-field teachers are and what out-of-field teaching is about. In the light of these thoughts our paper enables an innovative approach to characterize key aspects of out-of-field-teachers' professional knowledge on the basis of cognitive and affective competencies. In our further research we take up these findings and compare our results on out-of-field teachers' beliefs to their action-related competences. The category system described and validated in this paper provides a sustainable basis concerning the approach to characterize the issue of out-of-field-teaching more precise.

Contradictions and shifts in teaching with a new curriculum: The role of mathematics

Konstantinos Stouraitis[1], Despina Potari[1] and Jeppe Skott[2, 3]

1 University of Athens, Athens, Greece, kstouraitis@math.uoa.gr

2 Linnaeus University, Kalmar, Sweden

3 Aarhus University, Aarhus, Denmark

In the framework of Activity Theory (AT), contradictions are sources of change and development. Borrowing concepts from AT, we attempt an interpretation of identified contradictions in a collaborative context where teachers plan and evaluate their teaching in the process of enacting a new curriculum. We examine the connection between contradictions and shifts in teaching activity, with a special focus on the mathematical character of these contradictions. We claim that dialectical oppositions lying in the background of these contradictions promote teachers to broaden their teaching activity by embedding into it new mathematical and pedagogical possibilities.

Keywords: Activity theory, contradictions, curriculum, teacher choices.

INTRODUCTION

A new, reform oriented curriculum was introduced and piloted in a small number of schools in Greece. During the year 2012–13 we collaborated with the teachers of three of these schools supporting them to enact the new curriculum in their classrooms. This collaboration was taking place in group meetings at the school where the teachers worked. During the meetings they planned and evaluated their teaching while the first author, who was also a member of the team that developed the curriculum, supported them by providing explanations about the rationale of the curriculum as well as teaching resources. Our main research goal is to understand the teachers' decisions and choices in relation to the curriculum documents and resources and the factors that framed them. Analysing the data we found that a variety of contradictions appeared to trigger discussions in most cases. Drawing on AT we explored further the possible role of these contradictions for teachers' choices and the development of the teaching activity. In general, the development of mathematics teaching has been studied in the context of planned interventions aiming to teachers' professional development. Few studies though investigate teachers' professional learning and the shift of their teaching activity in contexts where learning is not promoted by an expert. Some of them refer to teachers' learning through reflection on their own teaching (Chapman & Heater, 2010) or to joint reflection in collaborative contexts (Potari, Sakonidis, Chatzigoula, & Manaridis, 2010). In these contexts professional learning is a complex and long process framed by many different factors and conditions. Our study attempts to contribute in understanding of this complexity by using contradictions as a tool for our analysis.

In this paper, we refer to the emerged contradictions "as sources of change and development" (Engeström, 2001, p. 137). Especially, we focus on contradictions that seem to challenge teachers' choices and on possible shifts in their teaching activity.

THEORETICAL FRAMEWORK

Current research in mathematics education recognizes that in the context of reform teachers are not expected to implement a predefined set of methods in their classroom, because there are not such methods. On the contrary, teachers are required to play a substantial role as a link between the curricular and other reform priorities and their classroom (Skott, 2004). This requirement, which Skott calls "forced autonomy", brings the teacher at the center of the curriculum enactment but also creates new challenges and conflicts. Within this perspective, teachers are not considered as mere transmitters of a curriculum formulated by some experts outside their classroom, but as active agents and designers. Teachers' instructional actions are influenced by curricular materials but also shaped by their interactions with the students in the classroom (Remillard, 2005).

Analyzing data through a grounded theory approach we found ourselves trying to understand and interpret the emerged contradictions and we turned to AT for this purpose. AT is trying to capture the complexity of teaching, integrating dialectically the individual and the social – collective and focusing on the activity of the subject. The activity is driven by subject's motivation and directed towards an object (Leont'ev, 1978). The unit of analysis in this context is the activity system (AS) that incorporates social factors that frame the relations between the subject and the object with the mediation of tools. These factors are related to the communities in which the subject acts, the rules of these communities and the division of labor (Engeström, 2001).

In the present study we consider the activity of the participating teachers to be the teaching of mathematics in the context of introducing a new set of curricular materials. As the subject of this activity we see teachers as a group and as individuals. A main object and motive of the teachers' activity is their students' mathematical learning, in combination with other professional obligations such as implementing the mandates of the educational authorities. Their activity is mediated by tools such as curricular documents, school textbooks and other teaching-learning materials, instructional strategies, and lesson plans. They constantly balance school community, students' and parents' communities, mathematics teachers' community and other communities that influence the teaching activity. Teachers' activity is framed by rules such as institutional commitments (e.g., examinations, time constraints, timetables) or traits of mathematics as discipline and as a school subject. The division of labor refers to the teacher's role in the classroom or in the school and to the distribution of classrooms among the mathematics teachers in their school.

One of the fundamental characteristics of every AS is contradictions. They emerge when an AS adopts new elements from the outside, such as a new tool or a new rule, causing a conflict with the old elements. Contradictions are neither everyday solvable problems nor temporary conflicts that may easily be overcome. Moreover, the term "contradiction" in AT has not at all the meaning of a logical contradiction. "Contradictions are historically accumulating structural tensions within and between activity systems" (Engeström, 2001, p. 137). Roth and Radford (2011) refer to a special type of contradictions as "inner contradictions" to describe the often mutually exclusive aspects of the same phenomenon that coexist dialectically and "cannot be removed". Contradictions create learning opportunities for the subject and may broaden its activity to a wider horizon of possibilities (Engeström, 2001; Potari, 2013).

There is an increasing amount of research literature about contradictions in mathematics education. Some of them use the concepts of AT to identify, describe and interpret contradictions in teaching (for example, Barab, Barnett, Yamagata-Lynch, Squire, & Keating, 2002; Jaworski & Potari, 2009) and in teachers' professional development (Potari, 2013). In these studies contradictions refer mainly to pedagogical or professional issues, paying less attention to mathematical and epistemological ones. Another dimension of this research is related to the use of contradictions to stimulate expansive learning in developmental interventions with groups of teachers (Engeström, 1994; Jaworski & Goodchild, 2006). Our initial research goal although developmental, was not based on stimulating contradictions as the ground of expansive learning. So, our view in this paper related to expansive learning is restricted in a snapshot of what is called expansive cycle. However, we adopt Engeström's position that professional learning often is "something that is not stable, not even defined or understood ahead of time" and "there is no competent teacher" who knows what must be learned (Engeström, 2001, p. 137–138).

In this study we understand contradictions in two ways. First, as conflicting elements of the teaching-learning activity. Such is the contradiction between the tools and the rules of the activity (e.g., between the choice of computer based instructional tools and time restrictions). Second, we identify contradictions as conflicting opinions, practices or choices between two teachers or a teacher and some external agent (e.g., the curriculum, the students, etc.). An example of the latter is the contradiction between the use of tasks that require conceptual understanding of divisibility (promoted by the new curriculum) and, the use of tasks that can be solved using keywords such as "less than" or "at least" that indicate LCM or GCF.

Some of the emerging contradictions are characterized by a dialectical opposition. Here, as dialectical opposition we consider some opposing aspects of a mathematical concept or of how it is transformed in teaching. Often, these opposing aspects are complementary, they can't be separated, and both constitute the concept. For example, the distributive property encompasses two opposing but complementary uses: it can be used to transform a product to a sum or a sum to a product. In our analysis such oppositions appeared in some cases underlying a contradiction. Dialectical oppositions of this kind allow us to consider more deeply in our analysis the mathematical dimensions (e.g., content, processes) of teaching.

METHODOLOGY

The research was conducted during the pilot implementation of the new curriculum in three junior high schools (grades 7–9). The new curriculum emphasizes students' mathematical activity that promotes mathematical reasoning and argumentation, connections within and outside mathematics, communication through the use of tools and metacognitive awareness. It also attributes a central responsibility for the teacher in the process of designing teaching. In this study, the mathematics teachers at each participating school (school A, B and C) worked together to enact the new curriculum with the support of the first author. The main tasks undertaken in the groups were planning lessons and reflecting on their experiences with teaching some modules of the designed curriculum in the classroom.

For this paper data consist of transcriptions of audiotaped conversations and written documents (worksheets, lesson plans) from 8 meetings with the 5 mathematics teachers of school A. This school is an experimental and model school where participating teachers have long teaching experience and are familiar with educational innovations. In general, the school culture is characterized by an innovative spirit. In this paper, we refer to two teachers, Marina and Linda, with over 25 years of teaching experience, with extra qualifications (both have masters degree, Marina in mathematics and Linda in mathematics education) and both with experience of innovative teaching approaches in their classrooms. In the past, both had participated in teacher collaborative groups developing classroom materials or writing papers for mathematics teacher journals and conferences. In general, Marina was more informed than Linda about the research activities of the mathematics education community in Greece. Both had a critical stance to innovations in general, adopting some of them and rejecting others and had strong views about their teaching choices. Concerning the new curriculum, in an interview at the beginning of this research study they had said that it came as a legitimizing umbrella over their practice.

The transcribed conversations were analyzed with grounded theory methods (Charmaz, 2006). The written documents were used to exemplify the conversations. The initial open coding resulted in the identification of discussion themes for each meeting, forming thematic units. In each unit teachers' choices, their rationale and emerging contradictions were identified. As indicators of a contradiction were disagreements among the participants or between the participants and an external source. Each identified contradiction, was formulated as a dichotomy (e.g., the choice of tasks aimed at conceptual understanding or at procedural fluency). For every identified contradiction we used descriptive codes related to its content, the agents (e.g., a contradiction between participants and the curriculum) and teachers' awareness (whether or not they recognise the contradiction). Then, contradictions were categorized and traced through data for possible effects on teaching.

RESULTS

The content of the identified contradictions concerned issues such as: teaching planning and strategies, students' activity and difficulties, institutional constraints, teacher collaboration, classroom management and epistemological issues. Data analysis showed that in some cases contradictions led teachers to question their own teaching and start transforming it. Below we elaborate two of these cases as exemplars of shifts in teaching activity. The first exemplar underlies a dialectical opposition in the teaching of a mathematical property, while the second shows an epistemological opposition concerning the validation of school mathematical knowledge.

Contradicting goals and dialectical oppositions in teaching the distributive law

In the second meeting at school A (A2, turn 138) Marina described her teaching plans for algebraic transformations in grade 9 (operations with polynomials, identities and factorization). Starting from her observations on students' mathematical activity she said that in the expression $3 \cdot (a + b + c)$ "children see completely different things than us ... they see addition and multiplication [while] we see ... a product with two factors". Seeking to obtain "a common language" with the children about the structure of algebraic expressions Marina decided to emphasize this issue in her teaching. She designed to teach multiplication of polynomials in parallel to the factorization of a polynomial. In the meeting Marina presented the worksheet she used in the classroom and described that she divided the blackboard in two parts, with the expression $3 \cdot (a + b + c) =$ on the left and the $3a + 3b + 3c =$ on the right. With this approach she hoped to make clearer to the students that the use of distributive property depends on the structure of the expression we have and the structure we want to get.

At the next meeting (A3, turns 105–114) Marina said that she used this approach in the teaching of algebraic identities and she expressed her satisfaction commenting:

> I think ... they have understood better that this way or the other is in fact about polynomials' operations. Until now identities have been presented as something to be learned by heart, and it was a special thing, completely away from the other operations, as well as the factorization was ... say these things were not connected at all. And I think that their connection helped students to understand them and to use them in a flexible way. (A3, 113)

In this episode a contradiction comes to the fore: the teacher has the goal for the students to identify the structure of an algebraic expression as sum or product, while the students recognize only the operations that the expression calls them to do, a well-known problem in learning algebra (Sfard, 1991). In the background of this contradiction lays a dialectical opposition concerning the use of the mathematical object: distributive property may be used to transform a product to a sum or to factorize a sum to a product. Recognition of this contradiction by Marina was based on her past experience and observation of students' mathematical activity. However, it was triggered by the new curriculum, which called to emphasize the structure of algebraic expressions, and by the discussions in the group related to the new curriculum. Marina also recognized the dialectical opposition in the distributive property and based on this her teaching attempts to overcome the contradiction between her goals to emphasize the algebraic structure and her students' tendency to see the tasks operationally.

A "traditional" teaching approach leads to two separated readings of distributive property, attempting to plan teaching based once on the first (operations to get a sum) and then on the other (factorization to get a product). This is the structure of the school textbook, as there was not a new textbook in the philosophy of the new curriculum. This was also the approach of the other teachers in the group, as with different rationale everyone adopted the well known teaching sequence. Especially Linda explained her choice saying that she believed that students needed time to consolidate their knowledge in operations with polynomials. However, she also valued the recognition of the algebraic structure: "I also ask the students: is this a sum or a product?" (A3, 251)

So, Marina's instructional choice on this topic can be regarded as a change to what she was doing before and to what usually her colleagues and most mathematics teachers in Greece used to do. The new perspective that Marina adopted considers the two usages of distributive property as two dialectically opposite ways that need to become explicit to the students and, consequently, to highlight the structure of algebraic expression. This perspective, stemming from the recognition of the initial contradiction, can be considered as an indication of broadening the horizon of Marina's teaching activity, encompassing new possibilities to it. On the other hand, Linda recognized the same contradiction but she did not choose to change her teaching, following the mainstream approach.

Contradicting tools and dialectical oppositions in using geometrical transformations in teaching congruence

Although some elements of reflectional and rotational symmetry existed in the previous curriculum and in the textbook, the geometrical transformations, namely translation, reflection and rotation were introduced as a distinct topic in the new curriculum mainly in the 8th grade. The rationale of this introduction was connected with the development of students' spatial sense and with the value of transformations in tackling congruence and similarity. The topic emphasized the transformation of a figure as a whole supporting more intuitive and dynamic approaches to the geometric shapes and their properties. The focus was on the relationship between the two figures (original and image), highlighting the relation of congruence or similarity and attributing to the transformations the character of a proving tool (for further discussion on this relationship see Battista, 2007). Therefore, geometrical transformations constitute an alternative approach to the Euclidean perspective in school geometry indicating a different epistemology: the use of the moving figure as a proving tool is not compatible with the rigorous deductive rationale of Euclidean geometry.

In the discussion in the fourth meeting (A4), Marina referred to her introductory lesson on the congruence of triangles (grade 9) and she was pleased that in her question "how could we ascertain that these two triangles are congruent?" some students answered "if the triangles match after translation or reflection or rotation". She refers to Freudenthal's claim that Euclidean geometry is abused in school and she says that she is thinking to use tasks with geometrical transformations in teaching the congruence of triangles (A4, 132). However, she was questioning how this could be introduced in her teaching: "but there is a need of investigation and inquiry before doing so" (A4, 126); "I want them [the students] to understand that when we compare angles or segments or generally elements of polygons, we have two tools. One is the transformation and the other the criteria of triangle congruence" (A4, 136).

Linda listened to what Marina said and asked for clarifications. Finally, she commented that Marinas' thoughts were interesting but "every topic has its purpose". She did not criticize Marina's choices, but she claimed that "there is a purpose to learn to write, to observe the shape, to distinguish the given from the required, to make conclusions, and to prove ... [Congruence] has its meaning" (A4, 137).

In the next meeting (A5) Marina described the way that students of grade 9 worked with the congruence of triangles in parallel to geometrical transformations to prove the congruence of segments or angles. She argued that there are tasks that can show to the students when one approach is more appropriate than the other. For example, the task "the two triangles formed by three pairs of diametrically opposing points, are congruent" can be easily tackled by a 180° rotation, while the use of the criteria of triangle congruence is very complex (A5, turns 7, 9). On the basis of these special tasks, epistemological issues were also discussed in the meeting, about the rigor and the intuition of different approaches (A5, turns 11–15). Marina's descriptions show that her students used transformations as an alternative way to triangle congruence. This happened regularly in the classroom she had also taught in the previous year, but with more difficulty in a classroom she has been teaching only this year (A5, turn 7). Linda follows the discussion expressing positive opinions on Marina's strategies (turns 8, 10, 16, 20).

In the sixth meeting (A6) Marina said that in a test she asked her students to prove the congruence of two segments with two ways and many of them referred to rotation. Reflecting on her attempt to use transformations as an alternative to triangle congruence, Marina admitted:

> the introduction of transformations in the 8th grade gives you the opportunity to change the framework [of proving] in the 9th grade ... [for the students] to see that you can cope with the proof of geometrical properties with two strategies ... using transformations and the triangle congruence ... And it was done easily ... it came from the students. ... And I think it is very nice that for the first time it is given the possibility to get away from Euclidean geometry... (A6, turns 324–334)

In the 8th meeting (A8) Marina mentioned that some students used transformations in other topics, such as trigonometry, indicating that they used them as an operational tool to visualize and prove congruence. Reflecting on her favour for transformations, she mentioned a seminar on transformations she had attended three years ago and her experimental teaching in another school. Linda expressed her disagreement to such intertwining of different topics. She said: "I like transformations per se. I don't like overusing them later in congruence ... I don't find the reason to [do so]" (A8, turns 123,125)

In our interpretation, the discussions on transformations and triangle congruence reveal a contradiction between these two concepts as two different tools that a student can use to prove geometrical properties. In the background of this contradiction lies the epistemological difference between rigorous, deductive foundation of knowledge in Euclidean geometry and more intuitive, visual, dynamic aspects of geometrical transformations. We see this epistemological difference as a dialectical opposition, because the opposing aspects can be synthesized in a way that benefits students in grasping the concepts and properties of congruence. This is the intention of the new curriculum. Marina recognizes the contradiction between the two tools and their epistemological differences (as a dialectical opposition) although she does not use this terminology. This allows her to attempt a shift in her teaching by using the two tools in parallel and synthesizing them in the students' mathematical activity. This shift is a change in comparison with Marina's previous teaching and with the other teachers' teaching, for example, Linda's.

Any attempt to interpret Marina's shift, must incorporate social and cultural factors. Here we discuss some of them, trying to operationalize some concepts from AT. First of all is the obligation of implementing the mandated curriculum (rules) to which Marina's perspective was in accordance. The idea of using transformations in parallel to triangle congruence was triggered by students (community) on the basis of the curriculum philosophy (tools) and Marina's content knowledge and professional experiences (tools). The distribution of classrooms among the teachers (division of labor) led Marina to teach students she had taught transformations in the previous year. Marina's conversations in the group of teachers and with other mathematics teachers (community) helped her to clarify and identify her approach. The specific approach was consistent with the norms of classroom and the active role of students (division of labor). The aforementioned factors embed historical evolution, both in the teachers' biography and in the formation of the tools, rules and communities, but the space limits hinder any further reference on this.

Linda seemed to like the introduction of geometrical transformations by the new curriculum, and recognized them as a proving tool. However, she chose not to synthesize the two tools, pursuing the benefits of emphasizing the deductive approach of congruence in Euclidean geometry. Linda and Marina share similar perspectives about the new curriculum and similar experiences on teaching geometrical transformations. Both work in the same school with innovative culture and participate in the same collaborative group for planning and reflecting on teaching. The apparent differences can be possibly explained by the different tools they use (e.g., content knowledge on the topic of transformations) or the different communities they had participated). But what is making the difference in their activity are the different learning and teaching goals the two teachers set for their students concerning geometrical transformations.

DISCUSSION

Activity theory views contradictions as a prerequisite for the transformation of activity through an expansive cycle (Engeström, 2001). Here, we cannot follow the expansive cycle of the teaching activity but we observe some snapshots, some instances of "creative externalization ... in the form of discrete individual violations and innovations" (Cole & Engeström, 1993, p. 40). This is the way we see the shifts in Marina's teaching. In the two presented examples, dialectical oppositions of epistemological character underlie the identified contradictions. In the first example, the contradiction is between the teacher's goals and students' operational understandings while the dialectical opposition is in the use of distributive property. In the second, the two contradictory proving tools are underpinned by opposing epistemologies that can be dialectically synthesized.

Barab and colleagues (2001, p. 104) argue that "when systemic tensions are brought into a healthy balance they can facilitate a meaningful interplay that enriches and adds dynamism to the learning process". These claims highlight the dialectical dimension of tensions and contradictions that have emerged in our study. It appears from our analysis that recognizing the contradiction and deciding to incorporate both opposite aspects dialectically, has an effect on "broadening the horizon of the activity" (Engestrom, 2001; Potari, 2013) as in the case of Marina. The dialectical oppositions attribute mathematical and epistemological characteristics to the contradictions that can form the basis for a shift to the teaching activity. The above claims are in accordance with Chapman's and Heater's position (2010) that key issues on teacher change are: the experience of authentic tensions based on actual, personal classroom experiences, the willing to take ownership of the change and the acceptance of a degree of uncertainty. Although from the AT analysis we see commonalities in the social factors that frame both Linda's and Marina's teaching activity, we identified different teaching and learning goals for their students. In other words, their activity is motivated by different objects as "images of thought" (Leont'ev, 1978, p. 86), that is, they hold different anticipations about students' learning.

We don't know if the identified shifts in Marina's teaching will be sustained and if they can be expanded in the collective activity of mathematics teaching in Greek schools. Such an investigation requires long periods of time and different research methods. What we can claim from this study is that contradictions may be overcome in a dialectical way that challenges dichotomies between "effective" and "non effective" teaching towards a more dynamic view of teaching.

Confluence of research and teaching: Case study of a mathematics teacher

Shikha Takker

TIFR, Homi Bhabha Centre for Science Education, Mumbai, India, shikha@hbcse.tifr.res.in

The complexity of research and teaching itself influences education in myriad ways. The insulation between research and teaching is counterproductive to the growth of mathematics education as a field in general and in developing a grounded understanding of teaching in particular. This study aims to understand teachers' knowledge about students' mathematical thinking in situ. Next, an attempt is made to enhance teachers' knowledge through contextually appropriate intervention using artefacts from teachers' practice. The collaboration between researcher and teacher to unpack students' thinking and make informed teaching decisions guided learning among students, teachers, and the researcher. This paper argues for the value of a situated approach to theories about teaching and also develops opportunities to support teacher learning from practice.

Keywords: Mathematics teacher learning, professional development, situated approach, teacher knowledge and practice, teacher-researcher collaboration.

INTRODUCTION

The gap between research and teaching has been widely acknowledged by researchers in mathematics education (Lerman, 1990). The insulation between the communities of teachers and researchers is unfortunate for there is a major overlap between their interests and focus. Concerns like understanding students' thinking, identifying and testing learning trajectories, trying out different teaching methodologies, focus on content and its connections, etc. are some of the research areas that are directly linked to teachers and teaching. In contrast to these, theorising about teacher knowledge, beliefs and practices has extensively been a domain of researchers or educationists. There has been lesser participation from teachers in unpacking their own knowledge and beliefs for that requires metacognitive awareness about their work. Teachers primarily focus on their *routines* of everyday classroom which leaves little time for them to reflect on what is being taught. Teachers make decisions about the content to be taught and ways in which this it can to be communicated to make it accessible for learners of specific age groups. This distinctive feature of teacher knowledge, choice of representations or mathematical tools along with the knowledge of students is described by Shulman (1986) as *pedagogical content knowledge* (PCK). In teacher education programmes in India, we are yet to think about ways in which PCK can be discussed and enhanced in teachers in ways that they become instrumental in their own learning from practice.

A framework that is particularly useful in identifying the relationship between teacher knowledge and practice for teacher learning is proposed by Cochran-Smith and Lytle (2000). They distinguish between knowledge *for* practice, knowledge *in* practice and knowledge *of* practice. *Knowledge for practice* separates the knowledge producers from knowledge users. Knowledge is generated by experts (researchers and teacher educators) and then selectively shared with teachers (practitioners) for implications in classroom. *Knowledge in practice* is the practical wisdom that teachers or practitioners gain from their practice of teaching over the years. Teacher deliberation and reflection on the experience of teaching is the source of this knowledge. *Knowledge of practice* is the knowledge generated in the field and connected with the existing theoretical knowledge. In a way, knowledge *of* practice combines knowledge *in* and *for* practice to suit the needs of classroom and support teacher reflection and learning.

In the Indian context, research geared towards identifying meaningful connections with the teacher community is scarce (Batra, 2005) and initiatives and interventions in the area of mathematics teaching have not been documented and analysed (Banerjee, 2012). More common approaches of working with in-service teachers are short term workshops and sessions where the knowledge from research is made accessible to teachers (Kumar, Dewan, & Subramaniam, 2012). The reforms in education are communicated to teachers in a top-down manner. Teachers are expected not to engage in matters of policy and theory (Kumar, 2008) but to implement the changes proposed by reforms in education. The agency of the teacher in actively informing curriculum change or policy is missing. Within this socio-political scenario, teachers perceive their role as 'teaching' (translated into telling) students to pass the examinations by completing the stated syllabi and assessments. Learning from the experience of teaching is assumed but not explicated or harnessed. More so, teachers actively taking part in their own professional development is not a part of this imagination. Practical difficulties of convincing authorities, teachers, and their sustained participation adds to the reluctance among researchers to work in collaboration with teachers or schools. The increasing insulation between research and teaching in India is mutual. Teachers criticise research for its apparent disconnectedness with the reality of classroom and the lack of its practical utility. A serious consideration of the gap between research and teaching has been identified by the recent policy documents (NCF, 2005; NCFTE, 2009) and efforts to bridge it in ways conducive to classroom teaching and learning are being explored. There is a need for models of teacher education where the community of teachers and researchers can work together to create opportunities for students as well as their own learning.

This study tries to identify and provide opportunities to teachers to generate *knowledge of practice* by reflecting on their practice using research based knowledge about students' thinking in a particular topic domain. Central to this research has been the collaboration of researchers and teachers to facilitate student learning in classroom. The process of generation of knowledge of practice gave researchers an opportunity to build a relationship with teachers and connection between research and teaching.

THE STUDY

The study was carried out in an English medium school in Mumbai, India. The school is a part of network of schools run by an autonomous body under the Government of India and caters to students and teachers from different locales of the country. Four elementary school mathematics teachers participated in the study which was carried out in 2012–2013.

Objectives and Context

The study aimed to understand the nature of teachers' knowledge of students' thinking gained from the experience of teaching mathematics and explore ways in which this knowledge can be supported and enhanced *in situ*. The observations of teaching practice and literature on students' thinking in the same topic domain, were utilised to design contextually embedded tasks to support teacher reflection and learning. Qualitative changes in teaching practice and ways in which teachers discussed about students and mathematics were noticed.

Knowledge of mathematics and about students' learning mathematics guides teachers in planning lessons as well as in taking in-the-moment decisions while teaching in the classroom. Knowing about students' mathematical thinking supports opportunities for asking questions linked to students' ideas, eliciting multiple strategies, drawing connections across strategies, and so on (Franke, Kazemi, & Battey, 2007). Unfortunately, knowledge of content and students' thinking are dealt separately in the teacher education programmes in India (NCFTE, 2009). The psychology courses deal with the components of students' thinking and learning. The concept-related discussions are confined to the subject related methods courses. It is believed that the experience of teaching would help teachers to integrate the two knowledge pieces together and blend them in their teaching. The nature of knowledge that teachers gain from experience remains hidden, unarticulated and mostly unchallenged. Discussions on concept-specific students' thinking and learning in teacher education needs exploration in the Indian context. Concept-specific students' thinking was chosen as an artefact for discussion with teachers because it is close to the *work of teaching*, provides opportunities for teachers to formulate hypothesis and creates opportunities in classroom to explore teaching possibilities (Takker & Subramaniam, 2012). The dynamic approach enables teachers to be more thoughtful and informed in their decision-making.

Methodology and data

The investigation adopted a case study methodology which included exploration and intervention. Four elementary school mathematics teachers, each with a teaching experience of more than ten years, participated in a two year long study. Two of these teachers teach mathematics and environment studies from Grades 1 to 5, and the other two teach mathematics and physics from Grades 6 to 10. The objectives of the study were explained to the teachers. The school time-table had 8 lessons per day. The participating teachers were assigned 6 (or more) lessons to teach everyday by the school. This made it difficult to maintain a follow up with each teacher immediately before and after a lesson. Data was collected through classroom observations, task based interviews before and after teaching a lesson, two long interviews with individual teachers, and after school meetings with all the teachers. The data is in the form of thick descriptions (Geertz, 1994), audio and/or video records which are in the process of being transcribed for the purpose of analysis.

Preliminary data analysis

The data from diverse sources is triangulated to make meaningful interpretation of the classroom events and then analysed for qualitative patterns. Thick descriptions allowed for a microscopic interpretation of the flow of discourse in classroom. Theoretical propositions that guided the study and description of each case (Yin, 2009) were used to analyse data from classroom observations and teacher interviews. In this paper, I discuss the case of one teacher, teaching division in a Grade 4 classroom.

Teaching division at Grade 4

Pallavi (pseudonym) is a primary school teacher. She has been teaching mathematics and environment studies to students from Grades 1 to 5 for over 15 years. In the years 2012–13, she was teaching mathematics to Grade 1, 4 and 5. Her class size varies between 30–38 students, including girls and boys. She appears confident about the content to be taught in a lesson. She does not plan her lessons because she thinks that with experience a teacher knows the content and its sequence. She is unhappy with the new textbooks introduced after the National Curriculum Framework 2005 (henceforth NCF 2005) because "they appear more like story books and less like mathematics textbooks". She likes the old textbooks as there were "sufficient number of problems for practice", concepts were neatly arranged with no overlaps, and "the teacher knew where to start and where to stop teaching [a topic]". In our initial interactions, Pallavi was reluctant to spend any time outside the classroom to talk about the teaching. Her classroom observations revealed a disciplined classroom where rules were laid down by the teacher. Over a period of time, the relationship between Pallavi and researcher changed. Pallavi became more reflective about her teaching and the researcher became a co-teacher.

Pallavi has been teaching division to fifth graders for almost as long as she started teaching. She has always 'taught' them long division beginning with division of a single digit number with another single digit number, double digit divided by a single digit, three digit by a single digit, two digit by a two digit and so on (see Year 2012 in Figure 2). She believes that children should be taught the algorithms as they are an important part of school mathematics. The revised textbooks (post NCF 2005) however do not provide a single method for division but suggests learners to think of different ways to solve division problems. These ways include repeated subtraction or subtraction using chunking of twos, repeated addition of the divisor, multiplication facts, etc. (NCERT, 2006a, 2006b). Pallavi has a clear opinion on these methods, which is captured in the following vignette from the interview transcript.

Pallavi: Different methods confuse a child. You know they are very young for understanding all this [methods]. Understanding comes later when their brain has grown a bit. In these [primary] classes, children should be clearly told what to do so that they can follow. And there are different methods to solve different problems. Like when I teach division, I don't teach anything else. I just teach long division and give lot of practice, sums [mathematical problems]. The more sums they do the more they learn. You can't expect them to learn so many methods like the new textbook gives. It says you teach this method also that method also. It is very confusing for students and then when you ask a question, which method do you want them to use? They should use long division. It is what we have been doing for ages, I did it

> when in school. And it is the systematic way. (P.I, 2012)

On several occasions, Pallavi was asked to think about why the long division algorithm works. In one of our (researcher and Pallavi) interactions, Pallavi was encouraged to unpack the algorithm by studying it in parts through questions like why take one digit at a time, what is the meaning of multiplying divisor with a number, what is the number being subtracted, etc. Pallavi is convinced about the digit-based approach (taking one digit in each step and dividing it by the divisor). She was taught the same algorithm as a student and once memorised it works for all numbers. Like many teachers, Pallavi 'operates in the field based on her old biases and prejudices formed through her schooling' (Mahapatra, 2004).

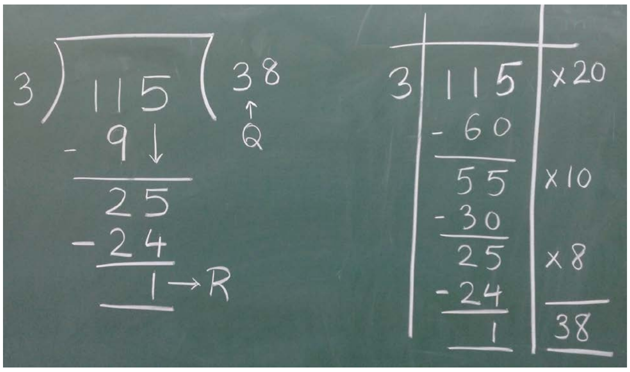

Figure 1: (a) Long division algorithm, (b) Grouping using convenient numbers

Apart from the discussions centred around her teaching, researcher had meetings with Pallavi and three of her fellow teachers teaching mathematics to middle grades. Tasks during teacher meetings involved thinking about students' responses and unpacking students' thinking in their (incorrect and correct) explanations. For instance, one of the tasks was to identify differences in the explanation of two students who both gave a different wrong answer for the same problem. The discussions around the task included talking about the errors, reasons for response, information they convey about student's knowledge or difficulty, and exploring connections between different topic areas of mathematics to identify possible thinking trajectories that students' might take with this kind of thinking. Teachers were engaged in the process of creating problems which would address different kinds of students' thinking.

Pallavi considers the new textbooks 'telling' her a number of methods to be 'taught' in the class. Looking at the methods from the perspective of something to be taught and ensure that it is learnt by all students, Pallavi was not confident on the rationale for using the grouping method. It was hard to convince her to try to use different methods for solving a division problem. She strongly held the belief that the alternative methods would be confusing for students and therefore should not be dealt with in the class.

> Pallavi: Now I have tried this method given in the book but see it is confusing... have always done long division only with children. So I am not sure how to introduce it, how to actually do it in class. I am comfortable in long division and it is shorter you know. It is a step by step process, take one digit at a time so they [students] can easily divide. Why don't you [to researcher] take this [division by grouping] in my class? Tell them what this method is. [After a pause] Yes we can see how they pick it and decide then only which method. I don't know if they will understand. I tried around 8 to 10 numbers, dividing them using that method. The bigger the number, the more confusing it was. I think it can confuse. But you try and let me see how they try to do it. (Pre-Class Interview, P119N10, 2013)

Several considerations seem to be guiding Pallavi's choice of a method for teaching division. These include her competence to use a method as a teacher, systematicity of the method i.e. one step follows from another, comprehensiveness and the cognitive demand it places on students while not being confusing, belief in the legitimacy of the established method, etc. At the same time it was clear that she is looking for support and some evidence of learning using different methods. As a result, she suggested an exchange of roles, where she becomes the observer and researcher becomes the teacher. The role reversal is an important event in this interaction as the teacher gives an opportunity to the researcher to collaborate in teaching which is at the core of the shared interest. As a researcher, there were two kinds of concerns emerging from this decision. Firstly, the teaching goal was to engage students with the grouping method as a way of solving division problems. This goal was partially shared with Pallavi who wanted to assess students' engagement with the method. Secondly, it was important to support Pallavi in teaching different methods as well as engage with students' struggles while they use the alternative routes in their attempt to solve a division problem. An important teaching decision was to think of a relevant context where students would find the need to use grouping in order to solve the problem.

Pallavi started teaching the lesson by revising long division using number problems (two-digit number divided by a one-digit number). Then she called upon the researcher to teach and explain a 'new' method to the students. The researcher started with the context of distributing money among three friends equally to find the share of each friend (Rupees 75 among 3 friends). Students were asked to think about the amount that can be safely given to each friend from the total amount to be shared. Students began by suggesting different combinations on how the money can be distributed "give them 10 each, 20 each or 15". When asked to justify their answers, students explained different combinations of numbers to distribute the money equally. In the second problem, the number of friends was increased to 5 while the amount to be shared remained the same. Even before solving the problem, students figured out that the share of each friend would be lesser and used grouping with convenient numbers to justify their answer. As the lesson was progressing, Pallavi gradually stepped in, helped in eliciting different combinations from students, making them think of efficient combinations and asking students for reasons for their choice. Later on she completely took over to use the method with different numbers (115 divided by 3 in Figure 1). It seemed that along with the learners, Pallavi was also testing whether this method works for different numbers, the appropriate choice of numbers (dividend and divisor), and its linkages with related concepts like multiplication. After the class, Pallavi reflected on the use of method and its affordances by comparing it with the long division algorithm.

> Pallavi: I think the method is good. They can use different ways to get it. Also it is very clear, this vertical arrangement of numbers. And grouping by tens they are aware also. Then slowly they can move to choosing bigger numbers. Actually you know the number of steps increases if you take small numbers [multiples]. But it doesn't matter because they anyway get it. They can use 8 directly or if not 4 and 4 or 5 and 3, it doesn't matter. This method is better and they [students] picked it up faster also. As a teacher, I can see how they are liking it. Taking it as a full number [number as a whole] is clear to them. They find it more easy. Easy only, no? They can make as many groups and how much they want. This also tells us about their multiplication knowledge. But you know one more difference is there. In long division I have to teach them for each increasing digit like dividing by one digit, then 2 [digit number] and 3, all are different. But in this they have to use the same method for big numbers, by themselves and they can do also. (Post-Class Interview, P120N10, 2013)

While reflecting on the lesson, Pallavi was considering the affordance of the grouping method mathematically as well as from the view point of students. Mathematically, she unpacks the idea of grouping using convenient numbers, flexibility in the number of steps, efficient choice of combinations, treating dividend as a whole, and workability of solution for other sets of numbers. She noticed that students came up with the method themselves and were using it flexibly without making a common error, skipping a digit while using long division algorithm without understanding. In the next lesson, Pallavi asked students to choose any method to solve the division problem and identify the similarities in long division and grouping. Further, Pallavi made a decision to include the grouping and other methods in her teaching of division henceforth.

In the course of intervention, Pallavi realised the importance of listening to students not just to evaluate what they do not know but to make it a part of her decision making in teaching. Pallavi engaged with the basic principles of analysing a given method of solving arithmetic problems. The structure that underlies the method and its connection with the algorithm was discovered by Pallavi along with the students. Thus, the choice of method(s) is not guided by the authority of the method given in the textbook but from an engagement with the structure of a method and its ra-

Year 2012	Year 2013 (Planned)	Year 2013 (Taught)
Multiplication tables	Multiplication tables and facts	Making combinations of a number in rows and columns*
Repeated subtraction	Repeated subtraction	Multiplication facts*
Long division (one-digit number by one-digit number)	Long division (one digit and two digit numbers)	Repeated subtraction (with and without chunking)*

		Link different methods and choose a method*

Figure 2: Teaching trajectory for division (*using both number and word problems)

tionale. Another evidence of change noticed in Pallavi is the difference in her teaching trajectory over these two years (refer Figure 2).

The episodes reported in this paper are used to exemplify one of the ways in which knowledge from teachers' classroom was utilised to mediate teacher reflection and learning around the content of mathematics. The role of researcher was to notice opportunities for communicating important mathematical ideas from teachers' teaching and bring these for discussion with the teacher(s). The discussions centred around the rationale of mathematical procedures, conceptual understanding, and identifying important mathematical ideas to be communicated.

DISCUSSION

The paper presents preliminary analysis of a case study where teacher's knowledge of students' thinking was utilised to support her reflection and learning. Although a more rigorous analysis is in process, some interesting patterns are reported in this paper. Evidences of students' thinking from teachers' classrooms as well as from research served as concrete artefacts to talk about mathematics, making intervention more grounded and connected to the classroom reality. Teachers' explorations in their classroom gave them an opportunity to test propositions emerging from meetings with other teachers and researchers. The change in the positioning of teacher and researcher marked an important learning turn in the collaboration. The methodology allowed for the researcher to engage with teaching and students' learning directly. The impact of such collaborations on learning needs further investigation.

Researcher's own experience as a teacher and work with teachers and teacher educators has indicated the need for building teacher communities. Teachers need spaces to articulate their struggles of teaching mathematics, their conjectures about students' learning and its interaction with the content, etc. A model for affording such an interactive space to discuss the work of teaching needs to be created in our country. Research which focuses on students' thinking is a beginning to an attempt towards building communities of teachers for sustained interactions. In this study, an exploration into knowledge required for teaching mathematics with a focus on practice created space for teachers and researchers to work together. More focused efforts are required to connect knowledge *in* and *for* practice to generate knowledge *of* practice through teacher-researcher collaboration. The voice and agency of teachers in programmes aimed at their professional development needs to be respected for making interventions meaningful.

Teaching mathematics through storytelling: Engaging the 'being' of a student in mathematics

Amanjot Toor and Joyce Mgombelo

Brock University, Faculty of Education, St. Catharines, Canada, aman.toor@peelsb.com

The paper draws from a hermeneutic phenomenological research study, which aimed at exploring the meaning of teachable moments from the lived experiences of grades 6–8 mathematics teachers. A primary and important stage of hermeneutic phenomenological study is for researchers to begin their research with a personal story. This paper presents the results of this primary stage, which focused on one of author's experiences of storytelling in a grade 6 to 8 mathematics classes for the purpose of humanizing mathematics as a way of engaging both the 'being' of mathematics students and their cognitive faculties. Data was collected from personal teaching stories of one of the researcher/author. The paper argues that teacher's storytelling humanizes mathematics in ways that engages both the 'being' and cognitive faculties of a student.

Keywords: Humanizing mathematics, teaching, learning, storytelling.

INTRODUCTION

What does it mean to teach mathematics? Researchers in mathematics education address this question in various ways. On one side, mathematics education researchers tackle this question by focusing on the question of how one can be an effective mathematics teacher. With regard to the question of an effective mathematics teacher, research tends to focus on teachers' content knowledge and/or pedagogical knowledge, or an integration of the two. Foote, Smith and Gillert (2011) suggest that teachers seeking to communicate a subject effectively and comprehensively should be equipped with an in-depth understanding of content knowledge, whereby they are able to provide alternative explanations for the same concept or topic in order to fully explain the subject. However, having an in-depth understanding of content knowledge in mathematics does not necessarily equate to or result in teaching mathematics effectively. Researchers argue that in order to be a successful mathematics teacher, "[one] must develop multiple expertise in knowledge of mathematical content, pedagogy for teaching mathematics, and knowledge of students"(Foote et al., 2011, p. 71). Some researchers are concerned with the question of how the two categories of knowledge, mathematics (subject matter) and teaching (or pedagogy) can be integrated. An initial articulation of this integration comes from Shulman's (1986) work on pedagogical content knowledge. Building on Shulman's work, Ball and Bass (2000) elaborated on pedagogical content knowledge using the term 'mathematics knowledge for teaching' to capture the complex relationship between knowledge of mathematics content and knowledge of teaching. Even though researchers seem to agree on the importance of teachers' knowledge, there is little agreement over what teachers actually need to know in order to become effective mathematics teachers.

On the other side, mathematics educators and researchers suggest that to effectively teach mathematics means to humanize mathematics for its learners. While talking about the role of education, Doxiadis (2003) states that, "[it] should be, at its best – a process involving the complete human being" (p. 2). In this sense, humanizing mathematics requires teaching mathematics in a way that focuses on the 'being' of a student as a participant in mathematics, which is beyond delivering content of mathematics or teaching certain skill sets. From a humanistic perspective, Chapman (2008) reveals that, storytelling is "... a way of specifying experience, a mode of thought, a way of making sense of human actions or a way of knowing" (p. 16). Therefore, storytelling humanizes mathematics, where students are able to relate to mathematics at a personal level. Humanistic mathematics involves interdisciplinary connections between mathematics and other worlds of thought and methods of learning

(Tennant, 2014). According to Cernajeva (2012), it is important to humanize a study process, which means to approach educational content and its acquisition process using the principles of humanistic recognitions, while taking into consideration the interests and abilities of its learners. Consequently, humanistic approach to education may allows for one to develop human values, self-confidence, self-values, and gives room for self-reflections while at the same time it may increase awareness of others' need, which may result in sense of belonging in mathematics for students.

Doxiadis (2003) states that mathematics education will not change for its perspective learners unless what counts as mathematics changes. He adds that what counts as mathematics needs to include the stories of doing mathematics, where its participants are able to relate to the subject by talking about mathematics. Without stories, mathematics is striped off of its humanity. Students need to be involved in complex mathematics, where they are given the opportunities to think in depth, rather than to adopt easy to use mathematical procedures. Stories in mathematics provide such opportunities. In his presentation, *Mathematics through an Arts lens*, Gadanidis stated that students in mathematics crave to be surprised, where they can flex their imagination and gain new mathematical insights. Further, Gadanidis indicated that story is a biological necessity, an evolutionary adaptation that prepares and trains one to explore the possibility of mathematics in actuality, effortlessly and playfully, which in turn has the capacity to make all the difference for mathematics students. Stories in mathematics highlight one as a human 'being' and enhance one's experience of learning mathematics (Gadanidis, 2012). Storytelling provides opportunities to solve puzzles in artistic way where the storyteller creates situations for its audience to experience the pleasure of surprise and insight in mathematics (Gadanidis, 2012).

Our work aligns with this research which is premised on the idea that to teach mathematics effectively, means humanizing it for learners. By humanizing we mean making the subject more humane and relatable so that learners appreciate mathematics by developing a personal connection with it. This paper draws from a hermeneutic phenomenological research study, which addresses the question: what does it mean to teach mathematics? The purpose of the research is to explore the meaning of teachable moments from the lived experiences of grades 6 to 8 mathematics teachers. Here, the term teachable moment is defined as an opportunity that arises when connections have been made to advance learning by a learner and/or an educator. More specifically, the term moment is distinctly defined as an expected or unexpected occurrence that allows learners and/or educators to deepen their understanding. The paper presents findings from one of the author's experiences of storytelling in a grade 6 to 8 mathematics classes for the purpose of humanizing mathematics in ways that engage both students' 'being' and cognitive faculties in mathematics

STORYTELLING AS A WAY FOR HUMANIZING MATHEMATICS

From the beginning, storytelling has been used as a fundamental method for transferring knowledge. While discussing about the reason for many cultures to retain their storytelling legacy, Zazkis and Liljedahl (2009) state that storytelling, a traditional way of transferring knowledge, provides a unique way of looking at and understanding the world. On one side where mode of storytelling such as fairy tales, poems, nursery rhymes are entertaining, however, on the other side, they transfer essential information in a memorable way for its listeners (Zazkis & Liljedahl, 2009). Storytelling in mathematics is an approach for creating a safe-learning environment where a learner might openly appreciate, understand and enjoy mathematics (Modi, 2012). Storytelling in mathematics makes learning more accessible, where students are more engaged with their learning. Modi (2012) states that, "the value of story to teaching is precisely its power to engage the students' emotions and also, connecting their imaginations in material of curriculum (p. 31). Modi suggests that storytelling in mathematics classroom creates an environment of imagination, emotion, and thinking, which makes mathematics more enjoyable and more memorable for its participants. Storytelling provides ground for its participants to engage in a mathematical activity, which provides them with the opportunities to think, explore, and understand mathematical concepts and ideas (Modi, 2012). Further, storytelling creates a comfortable and supportive atmosphere in the classroom, and builds a bond between an educator and learners (Modi, 2012).

According to Schiro (2004), type of stories a society narrates, is a mirror of what information is considered important by that society, which contributes to the beliefs and the values it members adhere. Evidentially, type of stories that are narrated in mathematics classroom, might contributes to the beliefs and the values, which the learners may hold onto. For example, storytelling in mathematics classes that highlights the importance of failure as essential step to master a mathematical skill and/or to be successful in mathematics might influence one's perception of mathematics more so as a humanistic subject. According to Modi (2012), stories emerge in various places, where some are real while others are fictional, which may provoke one to think and wonder about the things which they may not have thought before. Though 'story' is defined at times as a 'sequence of events', it is not the events that are of interest here, rather the outcomes, in terms of impact, of storytelling on students in mathematics classroom (Modi, 2012). Modi believes that there are various types of stories that one might experience in mathematics. First type of story provides the background for a mathematical activity. For example, a historical content on mathematics, where the mathematician is given an image of a hero, while highlighting the importance of their initial struggle with a mathematical concept or idea. Second type of story provides explanation. For example, a story which may explain students about Pythagorean's triangle, division by zero, division by a fraction, and the manipulation of negative integers. Third type of story poses a question, for example, 'word problems such as 'does equal mean fair?'

RESEARCH FRAMEWORK

The epistemology of phenomenology centers on didactic meaning as opposed to arguing or developing abstract theory. In their discussion of the theoretical and conceptual framework for a phenomenological study, Savin-Baden and Major (2012) stated that "the essence experience is so central and is to be uncovered before it is categorized, researchers do not tend to use a theoretical or conceptual framework... [because] doing so could impose presuppositions on the meaning of the experiences" (p. 221). Additionally, Patton (2002) informs that phenomenology intends to acquire a deeper understanding of the nature or meaning of one's everyday experiences. Subsequently, the objective of the study here is not to make broad generalizations about experiences of all mathematics teachers, but instead to examine individual teachers' personal experiences associated with a very specific phenomenon, and to compare and contrast their experiences as well as lived realities. In order to understand what it means to teach mathematics, it is necessary to first gain insight into teachers' lived experiences of teaching mathematics.

Van Manen (1990) considers phenomenology as the most appropriate method to research the phenomena of pedagogical significance, which elaborates phenomenology as a response to how one orients to lived experience and questions the way one experiences the world. Van Manen states that " a phenomenological researcher cannot just have a question – he or she must live it" and that " ...lived experiences is the starting point and end point of phenomenological research. The aim of phenomenology is to transform lived experience into a textual expression of its essence – in such a way that the effect of the text is at once a reflexive re-living and a reflective appropriation of something meaningful: a notion by which a reader is powerfully animated in his or her own lived experience" (p. 36). Van Manen informs that "the questions of knowledge always refers us back to our world, our lives, to who we are, and to what makes us write, and read, and talk as educators: it is what stands ironically behind the words, the speaking and the language" (p. 46). A true phenomenological questioning is not possible until the researcher displays his or her interest in the phenomenon as lived. Additionally, Van Manen states that, lived human experiences cannot be captured in "deadening abstract concepts and in logical systems that flatten rather than deepen our understanding of human life" (p. 17).

METHODOLOGY

The question, *what does it means to teach mathematics,* is a highly subjective phenomenon, which calls for a hermeneutic phenomenological research design. A phenomenological research describes a "lived experience" of a phenomenon. Phenomenology becomes hermeneutical when its method is taken as interpretive manner compared to descriptive as in other forms of phenomenology such as transcendental phenomenology. Heidegger (Savin-Baden & Major, 2012) argues that all descriptions are based on interpretation and every form of human awareness is interpretive. Drawing from Heidegger, Van Manen (Savin-Baden & Major, 2012) offers a methodological structure encompassing six themes as a helpful guide to hermeneutic phenomenological research: (a) turning to the nature of lived experience in formulating a research question that concerns a phenomena of deep interest—in this case teachable moments in mathematics; (b) investigating lived experiences by collecting descriptions of lived experience of the phenomena under study; (c) reflecting in a hermeneutic phenomenological sense, by recovering themes constituting the essence of the phenomena (d) writing hermeneutically, describing phenomenological experience of the emerged themes; (e) preserving a strong and oriented relation by maintaining a true interest to the phenomenon; and (f) balancing the research context by considering parts and whole, by creating a structure and a planning work for carrying out the phenomenological research.

These six themes guided our primary data collection and data analysis while mindfully dealing with any ethical concern regarding the study. In "Researching Lived Experiences", Van Manen (1997) notes that to investigate the notion of teachable moments – in particular storytelling one needs to orient themselves to the question of meaning of teachable moments. And this meaning of the teachable moments needs to be found in the experience of teachable moments. "And so we need to search everywhere in the lifeword for lived experience material that, that upon reflective examination, might yield something of it fundamental nature" (p. 53). Van Manen offers a number of approaches to gathering or collecting lived experience materials of different forms such as personal experiences, interviews, observations and fictional texts. In our work in this paper we focused on personal experience of teaching mathematics as a lived experience material for reflection on teachable moments.

Van Manen (1990) recommends that phenomenological researchers to begin their research with a personal story as a starting point for a phenomenological study. Further, Mason (2002) states that, "in order to turn from professional development to research, you have to address the questions of convincing others of what you claim to have found out" (p. 176). Keeping this is in mind, as a focus of this paper, as well as a primary observation to the research question, we decided to explore one of the author's teaching experiences of storytelling in her teaching of grade 6 to 8 mathematics classes. Data in this sense was collected from the personal stories of the teacher/author. For the purpose of this paper we present two stories where the author utilized storytelling in her teaching for the purpose of humanizing mathematics. As in any phenomenological study, the author's personal experiences of teachable moments are immediately accessible to her in a way that others are not. However as Van Manen (1997) argues, the focus for a phenomenologist is not on private or autobiographical facts but rather "in drawing from personal descriptions of lived experiences, the phenomenologist knows that one's own experiences are also the possible experiences of others" (p. 54). The stories presented in this paper were selected by the author based on what she thought to be teachable moments and also in collaboration with the second author as what we thought could be possible experiences for others. In describing these stories we tried to align with the phenomenological tradition by trying to describe them in experiential terms focusing on classroom situation and events and refraining from abstractions.

First story

During my first year of teaching mathematics, I tried to make math more realistic and humanistic through storytelling. It was for the first Halloween as a teacher that I decided to talk about the invention of a concept of circle and the impact of such an invention on the world. Therefore, I dressed up like Cleopatra to bring the historical perspective and started talking about how the circle might have developed. First, I talked about how one day someone might have realized that there is a thing called line, which might have led to the idea of two lines intersecting and developing a corner. Next, I talked about the idea of four lines where two lines at a time, intersect, led to the development of four-sided figure like rectangles and squares. Further, I said, that there might have be one day that someone might have asked 'can a line intersect itself?' and in the process of examining that they might have connected the two ends of the line and might have made a circle, and this invention of a circle might have contributed to the invention of wheels. The moment I made the connection of circles and wheels, a lively class discussion ensued where one student said, "it may also be the reason why Christopher Columbus discovered the world because he might have realized that there are other shapes than four sided figures". Then the other student made a reference to spirituality and said, "It could also be when people realized the karma ...you know what goes around is what comes around". At this point, I was aware that my role was no longer didactic. The students have changed from being passive consumers of mathematics to participants in knowledge creation, a change may see as empowering. As their teacher, I was amazed with this class discussion, but did not know what to do with it other than to say, " That's interesting..." And what did it have to do with teaching mathematics? Even though my intention was to bring a humanistic aspect to mathematics, I knew then that what had just happened was bigger than my intention.

Second story

During one of my lesson on geometry to my grade 6's, I was showing a 3-dimensional objects to my students. The purpose of the lesson was to help student develop understand of the relationship between an object and its net. While using real life examples like chocolates boxes and lunch boxes, I demonstrated for my students (while holding a 3 dimensional object in my hand) that if we open up all the sides of this objects and lay it flat, it would result in a net. And (while demonstrating) that if we put together all the sides of the net together, it will result in a 3 dimensional object. Next, as a class, we discussed about the characteristics of a net, which upon folding can result into a 3 dimensional object. In addition, we talked about what type of net may not make a 3-dimensional object (i.e. missing face in net). After discussion, students were challenged to create various type of net and then to check what type of 3-dimension object their net would turns into.

While students were working, a student asked me, " Ms. Toor, what is a side?" I responded to her by saying, " it is one of the faces of an object." She asked again, " no Ms Toor, what is a definition of side...is a side always straight...because if it is straight, then why do we call a side of a road side when the road is curvy?" At this point I knew that she was thinking beyond what I intended to teach. I was aware that without knowing about different braches of mathematics, she was talking about the difference between Euclidian and non Euclidean geometry. Consequently I knew that had also become a participant in knowledge creation of mathematics. However, I did not know how to guide her thinking so that she would not be overloaded with difference of Euclidian and non Euclidean geometry, causing her to become a knowledge consumer of mathematics.

ANALYSIS, DISCUSSION AND CONCLUSION

The purpose of hermeneutic phenomenological reflection is to try to grasp the meaning of a phenomenon under study. In order to come to terms with the meaning of the phenomenon like teachable moments a phenomenologist has to engage in a reflective activity and think of the phenomenon described in terms of structures of meaning, meaning units or themes (Van Manen, 1997). Phenomenological themes may be understood as structures of experience and can be uncovered from any description of lived experience such the above stories. More importantly the meaning of phenomenon can only be communicated textually. So in order uncover the theme for this paper we reflected on the concrete situations in the above stories by asking questions such as what does this mean for this student, situation or action while focusing on the meaning of teachable moments. We then proceeded in describing the phenomenological experience of the theme.

Teacher's storytelling has its place in mathematics teaching. Storytelling as a method of humanizing mathematics, in ways that touches the 'being' of a student, was the common reoccurring theme in both of the stories mentioned earlier. In both of the stories there are three different personal experiences, from which students draw their humanistic connection to mathematics. These personal experiences are examples of the aspects that make these students human beings participating in mathematics. From close observation of the first story, we see that there are two personal experiences, historical curiosity and spiritual need, from which students make their human connection to mathematics. For example, in the first story, a student makes reference to Christopher Columbus by connecting it to the invention of circle. Here the student makes connection between mathematics with his historical curiosity. This connection allows for this student to be a human being, participating in mathematics, where he is able to talk about mathematics beyond the classroom boundaries. The spiritual need is another personal experience, an aspect of 'being' human, where a student talks about karma: "It could also be when people realized the karma ...you know what goes around is what comes around". Here, once again, the student draws connections between his personal experience and mathematics, which touches and deepens his connection with his 'being'. This connection, humanizes mathematics for this student where the student is able to explore his spiritual world by participating in mathematics.

Just as the first story, second story also highlights similar connections. In the second story, a student is curious about something that is beyond the curriculum expectation. Here the element that makes her 'being' in mathematics is the process where she question mathematical definitions. The student wonders about the definition of a side and relates it to her everyday life. Just like the other two students from the first story, this student also humanizes mathematics by making a connection to an element that makes her human. In all three cases students are engaged both cognitively and as human beings as they participate in mathematics.

From the researcher's storytelling experiences as a teacher, we have found that stories allow for one to teach and to learn about the things, which perhaps in the purposeful lesson plan would be lost. Near the end of the school year, the students from these classes where storytelling was utilized, often through voluntary verbal feedback inform their teacher that they (the students) viewed stories as a valuable learning tool, which enhanced their understanding of mathematics by acting as memory joggers and in some cases enticed them to further explore mathematics. All too often education becomes the consumption by students of defined knowledge presented by the teacher in a transmission model. Education should involve an exchange of knowledge between the learners and educators, where these experiences can enhance both teachers and students' mathematical understanding. Storytelling as a pedagogical practice is a method where both the teacher and students learn from one another, while engaging in mathematics. The stories that we have presented in this article show that students are able to relate to mathematics in ways that they are able to see themselves as mathematical 'beings' who have abilities to explore and to be curious about mathematics.

The findings for this study, as discussed above, have implications for both educators and further research. This study contributes to mathematics education research by focusing on lived experiences of teachers' storytelling to humanize mathematics, a certain element of teaching which most theories, models, and methods of mathematics teaching tend to ignore or to not address. This study brings awareness for mathematics education researchers and practitioners by highlighting the need for humanization of mathematics through utilizing storytelling as a teaching tool. Further, the findings from this study allows one to see mathematics teaching (and learning for students) possibilities in ordinary incidents, and to be able convert these seemingly unimportant incidents into significant mathematics teaching (and learning for students) moments – teachable moments.

As much as these stories had positive impact on the students, the teacher/author often found herself questioning her role as a teacher while utilizing storytelling in her classes. As a teacher, the author questioned her decision, and reason behind acting in a certain way especially when facing and dealing with the outcome of storytelling. She wondered if she was guiding her students in right direction, especially when students were engaged beyond the initial aim of story that the researcher intended. Van Manen (1990) states:

> In all of our interaction with children, we are constantly involved, whether we like it or not, in distinguishing between what is good and what is not good for them (in contrast, educational research is usually more interested in distinguishing between what is effective and what is in- effective). Yet even (or especially) the best educators temper their practice with the knowledge that we all often fall short and do not know what is best. (p. xii)

There is little research that focuses on the particularity and uniqueness of the day-to-day, moment-to-moment nature of teaching mathematics. It is clear from researcher's experiences of storytelling, that there is a need for further research where the focus needs to be on how decisions are made in a mathematics classes while focusing on, what it means to teach mathematics on day-to-day and moment-to-moment bases. This question will be explored in the bigger research study from which this paper was derived. The authors plan on conducting interviews with mathematics teachers in order to collect other experiences of teachable moments so as to deepen the understanding of the question, what does it mean to teach mathematics.

2 University of Huelva, Huelva, Spain

This paper analyses the classroom practice of a university lecturer in Linear Algebra under the model Mathematics Teacher's Specialised Knowledge (MTSK). The knowledge revealed, related to the topic of Matrices and Determinants, is found to pertain chiefly to the sub-domain Knowledge of Topics (KoT). The categories of classification which comprise this sub-domain are of particular utility in the identification of this knowledge. Evidence of knowledge associated with other sub-domains comprising Subject Matter Knowledge and Pedagogical Content Knowledge is also found.

Keywords: Specialised knowledge, linear algebra, university lecturer.

Studies into university lecturers' knowledge remain quite rare in the context of Mathematics Education, and thus it is that our study sets out to explore the specialised knowledge in evidence in the course of a lecturer's classroom practice while teaching Linear Algebra in the first year of a degree course. We use the model denominated *Mathematics Teacher's Specialised Knowledge* (MTSK) (Carrillo, Climent, Contreras, & Muñoz-Catalán, 2013) to analyse the lecturer's teaching sessions, with the aim of achieving a better understanding of the knowledge brought into play by topic *Matrices and Determinants*.

THEORETICAL BACKGROUND

In the field of research into teachers' content knowledge of a particular subject, Shulman's (1986) study has proved particularly influential for its manner of differentiating components. Various models have drawn on Shulman's groundwork to describe the kind of knowledge deployed by mathematics teachers (e.g., Fennema & Franke, 1992; Bromme, 1994; Rowland, Huckstep, & Thwaites, 2005; Ball, Thames, & Phelps, 2008), most notable amongst which has been the model developed by Ball and associates (*Mathematical Knowledge for Teaching* – MKT), which applies the basic distinctions made by Shulman (*Subject Matter Knowledge* – SMK – and *Pedagogical Content Knowledge* – PCK) to the specific demands of teaching this subject. Based on our experiences of using the MKT model, and specifically the difficulties encountered in specifying and demarking certain sub-domains when applying it to teacher research (Flores, Escudero, & Carrillo, 2013), the Research Group for Mathematics Education at the University of Huelva is currently developing an alternative model denominated *Mathematics Teacher's Specialised Knowledge* (MTSK) (Carrillo et al., 2013), the aim of which is to capture the specialised nature of the teacher's knowledge as a whole. This specialisation is intrinsic to the teaching of mathematics, and as such permeates both SMK and PCK.

The MTSK model consists of two principle domains. The first of these is *Mathematical Knowledge* (MK), which covers "the whole universe of mathematics, comprising concepts and procedures, structuring ideas, connections between concepts, the reason for, or origin of, procedures, means of testing and any form of proceeding in mathematics, along with mathematical language and its precision" (Carrillo et al., 2013, p. 2990). MK is divided into the following subdomains: *knowledge of topics* (KoT); *knowledge of the structure of mathematics* (KSM); and *knowledge of practices in mathematics* (KPM). The second, *Pedagogical Content Knowledge* (PCK) concerns the teacher's knowledge of teaching and learning mathematics. PCK includes the subdomains *knowledge of* *mathematics teaching* (KMT); *knowledge of features of learning mathematics* (KFLM); and *knowledge of mathematics learning standards* (KMLS). The MTSK model also contemplates teachers' conceptions about mathematics, its teaching and its learning (in line with Bromme, 1994).

KoT supposes a thoroughgoing, well founded knowledge of mathematical content. In order to facilitate the identification of this knowledge, five categories have been demarked. The first of these, *Procedures*, responds to the questions *How is something done?, Under what conditions can something be done?, Why is something done in this particular way?*, and *What are the key features of the result?* The second, *Phenomenology and applications*, concerns awareness of phenomena and contexts with which a particular topic is associated (Freudenthal, 1983) and relevant applications. As the name suggests, *Definitions*, the third category, refers to knowledge for describing and defining concepts, including appropriate examples and images. Fourthly, *Representations* comprise the knowledge of the different ways that a topic can be represented (Duval, 1995) including the associated notation and mathematical terminology. Finally, *Properties and fundamentals* encompasses knowledge of the properties inherent to a mathematical item or necessary for carrying out a particular procedure. This sub-domain receives a more detailed attention in comparison with the other sub-domains comprising MTSK for the reason that, as seen below, it has greatest relevance to the analysis of the work of the teacher participating in the study.

KSM consists of the connections between different contents. It implies being able to view content from different perspectives, that is, basic mathematics from a more advanced vantage point (*connections of increasing complexity*) and advanced mathematics from a more basic viewpoint (*connections of increasing simplicity*); it also includes connections between distinct concepts (Fernández, Figueiras, Deulofeu, & Martínez, 2010).

KPM corresponds to knowledge of the ways of proceeding in mathematics, such as the role of definitions, how to establish relations, correspondences and equivalences, the means of selecting representations, and forms of argumentation, generalisation and the examination of concepts (Carrillo et al., 2013).

KMT enables the teacher to select material appropriate to teaching a specific concept or procedure, and includes the categories of *theories of teaching*; *material and virtual resources*; *activities, tasks and examples for teaching*.

KFLM concerns the ways by which mathematical knowledge is acquired, with a clear focus on mathematical content as the object of learning. Categories in this sub-domain include *learning styles*, *areas of strengths and weaknesses associated with learning*, *students' forms of interacting with the content*, and *students' motivation with regard to mathematics*.

KMLS largely consists of knowledge of the curriculum and its varying demands, and the objectives and performance measures established by external agencies such as examination boards, professional associations and research groups.

A useful reference in the case of teachers of Linear Algebra is the study by McCrory, Floden, Ferrini-Mundy, Reckase, and Senk (2012), which places secondary teachers expertise on two planes, the first mapping their *Knowledge of Algebra for Teaching*, and the second describing their performance in terms of *Mathematical Uses of Knowledge in Teaching*. Some of the categories comprising the first of these dimensions overlap with corresponding categories within MTSK, for example *Knowledge of School Algebra*, detailing knowledge of the basics of the area, *Knowledge of Advanced Mathematics*, which establishes connections between contents, and *Mathematics for Teaching Knowledge*, in which elements of PCK and other teaching-specific content can be identified.

METHODOLOGY

The study followed a qualitative and interpretative methodology, with a case-study design (Yin, 1989), focussing on the specialised knowledge of a university lecturer teaching Linear Algebra to first year students. The research question was, 'What specialised knowledge does a Linear Algebra lecturer reveal in the course of teaching matrices and determinants?'

The lecturer was invited to participate for his disposition and willingness to collaborate. Also relevant was that he worked at the same university as the lead author of this paper, whose professional interests lie in exploring the knowledge of mathematics teachers working in university contexts, with a view to possible follow-up action.

The topic of *Matrices and Determinants* was chosen as it was the first topic in the programme for Linear Algebra and essential for subsequent topics. The lecturer had originally studied Educational Sciences (specialising in mathematics) at degree level, and could draw on 18 years' experience at secondary level and 10 years at the university. The main data collection instrument was non-participatory teaching observation. In total thirteen classes of around two hours each were video recorded. The observations were conducted in two blocks over two consecutive academic years (October 2011 to January 2012, and October 2012 to January 2013) to coincide with when the lecturer was teaching the topic of matrices and determinants. A semi-structured interview was also conducted to provide a degree of triangulation for the evidence garnered via the observation.

Data analysis followed the methodology of content analysis (Bardin, 1977), in which meant sifting the teacher's actions and utterances for evidence of the MTSK sub-domains. The theoretical basis for the analysis consisted of the categories outlined above in the background section. These categories, which we consider still somewhat in development, derive from the intersection between the theoretical readings and joint reflections of the research group and the practical application of the model to teachers' knowledge in various research projects in progress. Finally, it should be noted that although MTSK also contemplates teachers' *conceptions* about teaching and learning mathematics, this aspect of the model is not considered here.

ANALYSIS OF THE KNOWLEDGE OF A TEACHER OF LINEAR ALGEBRA

In terms of the definitions of the MTSK sub-domains and constituent categories, the analysis of the teaching sessions revealed a predominance of KoT, although evidence of KFLM, KMT and KPM were also found. By contrast, there was no evidence of knowledge which could be attributed to the KSM and KMLS sub-domains. Emphasis is thus given below to the consideration of KoT and its corresponding categories. The units of information which form the basis of the discussion are drawn directly from the analysis of the teacher's performance over various teaching sessions; in the case of KMT, these have been complemented by units of information taken from the interview so as to provide a degree of triangulation.

Knowledge of Topics (KoT)

Of the categories comprising this sub-domain, there is evidence of the teacher's knowledge in all five, albeit somewhat scant with regard to *Phenomenology and applications*. In terms of *Definitions*, those provided by the teacher generally tend towards the conventional. Examples include definitions of unitary matrices, equal matrices and orthogonal matrices. At the same time, he also shows knowledge of *Properties*, such as the fact that the determinant of a triangular matrix equals the product of the diagonal entries. The excerpts below illustrate these points:

> Teacher: The unitary matrix is the identity matrix. The matrices which are the same are those with the same dimension and the elements placed in the same location and with the same value. When the inverse coincides with the transpose, we get the orthogonal matrix.
>
> Teacher: This is a triangular matrix. What is the determinant of this matrix A? Well, we can compute the determinant using the properties; if we have a determinant with all its elements, we can make it triangular with the elementary transactions between rows and then we can calculate the determinant by multiplying the principle diagonal.

With regard to *Representations*, there is evidence of knowledge of the notation of mathematical objects, such as the notation for matrices and determinants.

> Teacher: An important point. The 2x2 matrix is like this [...] When we calculate the determinant we no longer write it this way. I'm going to calculate the determinant of the matrix A, so here instead of brackets we have to put vertical bars [...] The determinant is denoted like this <det (A)> or like this <|A|>.

The teacher uses *algebraic* and *arithmetic* registers (D'Amore, 2004) for representing basic operations between rows and for matrix algebra. In addition, and connected to the algebraic register, he reveals knowledge of the matrix register (Ramírez, Romero, & Oktaç, 2013) for different types of matrices, linear equation systems and determinants; and finally the verbal register for setting exercises where the students apply their understanding. His knowledge allows him to encourage different types of representation, although he is not observed to go into the significance of these. However, he does make his awareness of the conventions of notation explicit, an element of knowledge pertaining to the subdomain *Knowledge of Practices in Mathematics* (see the section on KPM below).

There is little evidence for the teacher's knowledge of *Phenomenology and applications* of matrices. He makes mention, albeit briefly, of applications outside mathematics, such as real situations or situations connected to the degree course he teaches. In terms of examples of his knowledge of applications within mathematics itself, we can mention the determinant for finding the inverse matrix or for solving systems of linear equations using Cramer's rule, basic operations between rows applied in calculating the determinant, obtaining stepped and canonical matrices, inverse matrices by the Gauss Jordan method, and the solution to systems of linear equations by the Gauss and Gauss Jordan methods.

With respect to knowledge of *Procedures*, he shows that he knows the procedures appropriate to the topic, and is able to give a full description of them (*How is something done?*). Likewise, he knows where these procedures have their limits, and what is required to be able use them (*Under what conditions can something be done?*), which can be exemplified with his knowledge of the necessary conditions for multiplying matrices:

> Teacher: We have matrix A. What are the dimensions of this matrix? [...] The dimension of this matrix is 2x3. In order to be able to multiply two matrices we need the number of columns of the first matrix to be the same as the number of rows of the second matrix. If A is like that, B needs to have three rows, it doesn't matter how many columns.

In some instances, he shows that he knows why certain procedures are used (especially in relation to ways of simplifying a procedure) (*Why is something done in this particular way?*). An example of this can be seen in his explanation for calculating the determinant of a matrix:

> Teacher: Likewise, you take the column or the row that you want, but here's an interesting thing. Here, there's a zero; this zero helps us to reduce the degree of difficulty because you are always going to multiply the determinant of the submatrix you've got by the value of the element you're focusing on, so it is always a good idea to take a row or a column which has a zero or lots of ones.

Regarding deeper knowledge relating to the mathematical foundations underpinning the procedures, no evidence came to light. It should be noted that the teacher emphasised the *features of the result* obtained by following certain procedures, as in the example below, summarising the characteristics of the product of matrices:

> Teacher: The product of matrices has the same number of rows as the first matrix and the same number of columns as the second.

In his teaching, a tendency to rely on exercises of a mechanical nature was observed. This was closely connected to the learning of algorithms and syntactic conventions for the representation of the content, before conceptual aspects (in the terms of Hiebert & Lefevre, 1986). That said, the teacher does call the students' attention to connections between properties, different registers for representation, certain features and reasons for the procedures and their results. As can be seen, analysis of actual instances of the teacher's practice reveals knowledge pertaining chiefly to categories pertaining to KoT. Nevertheless, evidence of other sub-domains was found and this shall be discussed in the following sections.

Knowledge of Features of Learning Mathematics (KFLM)

We also found evidence of the teacher's KFLM, in the category of *areas of strengths and weaknesses associated with learning* concerning unforeseen pitfalls associated with the topic. This knowledge prompts the teacher to warn his students about potential problems in putting certain procedures into effect. The unit of information below illustrates this knowledge with a warning about changing rows in a matrix and in a determinant:

> Teacher: So you need to be careful here. When we're working with matrices we can say that the matrices are equivalent if we change one row for another. But if we're working with determinants and we change one row for another, the determinant changes sign [...] Matrices and determinants are not the same thing. [...] I repeat, with determinants it's not the same as with matrices, with determinants a change in rows means a change in its sign.

There is abundant evidence of this category in the teacher's reiterated warnings about aspects of the topic which can easily lead to error.

Knowledge of Mathematics Teaching (KMT)

In this sub-domain, the teacher's *Knowledge of Mathematics Teaching* (KMT) is reflected in the *examples* he selects in his teaching. In this instance, we can take his introduction to row echelon forms of matrices, in which his approach aims to ensure that students receive a broad coverage of the features of this type of matrix (as expressed in interview):

> Teacher: Now, I'd like you to look this way at the blackboard. What do you notice about the first matrix? First, they are not square. [...] What do you notice about the zeros? [...] The zeros increase as you go down the rows. The important thing to note is that in this row there are various zeros before a non-zero element. [...] What do you notice in this second matrix? [...] What about the third matrix? Take good note that it is of no interest to us if there is a zero here, what is important is that in this row there are zeros before a non-zero element. This type of matrix is called the row echelon form. As you go down the rows, the number of zeroes increases until you get to the non-zero element or the whole row is zeroes.
>
> Teacher: My intention was to give them three different matrices, each with a different row echelon form. I gave them those so that the students would realise that there are different kinds of row echelon forms and realise what it is that fundamental to the row echelon form (interview excerpt).

The choice of these three examples constitutes evidence of the teacher's knowledge for teaching regarding the relevance and variability of examples, specifically three matrices of the same order, although with different row echelon forms.

Knowledge of Practices in Mathematics (KPM)

Finally, as mentioned above, we have the example of *Knowledge of Practices in Mathematics* (KPM), regarding mathematical notation, to which the teacher attaches great importance and mentions several times over the course of the observed sessions. Here is just one of the examples:

> Teacher: We need to be careful when we write on the blackboard, and not put signs and strokes in any old place, because there are signs in mathematics which mean something. Write the symbols properly. If you are going to calculate the determinant, don't put it in square brackets, you have to put it between vertical bars. This way, like that, is a matrix. But if you are going to calculate the determinant you need to put vertical bars instead of square brackets.

With respect to the two broad domains comprising MTSK, we have been able to note evidence of knowledge corresponding to both in the teacher's professional practice. In terms of MK, there is KoT and KPM (but not KSM, for which we failed to find evidence); and in terms of PCK, there is KFLM and KMT (but again, no KMLS).

CONCLUSIONS

The purpose of this study has been to get a picture of the specialised knowledge in evidence during the observation of a university lecturer's teaching of Linear Algebra. The purpose was not to make any evaluation of the teaching that took place in terms of what might be considered desirable practice. The final picture that emerged is essentially one predominated by KoT, with indications of KFLM, KMT and KPM. We failed to find evidence of knowledge related to the sub-domains KSM and KMLS, and it should be noted that the teacher's conceptions, whilst forming part of the model, were not made subject of the study. We can say that the teacher's practice is characterised by procedural knowledge, not only in terms of how to proceed, but also with regard to the conditions for proceeding, why to proceed and what characteristics can be expected as a result. In addition to this, he demonstrates knowledge of standard definitions, different representations of content, and applications to other areas within mathematics. His choice of examples, and his warnings to students of unforeseen pitfalls provide examples of his knowledge of the difficulties associated with learning certain content, and questions of exemplification.

The knowledge above was revealed through analysis of classroom observation (in conjunction with complementary data drawn from interview, and commenting on the former). To this extent, we cannot claim that the resultant snapshot corresponds to the teacher's knowledge of the topic, merely what was deployed in the course of his classroom practice. Evidence of knowledge pertaining to other sub-domains and categories of specialised knowledge might well be revealed through the use of other data collection tools. By the same token, the knowledge on display might be closely linked to teaching style and the teacher's beliefs and conceptions with regard to teaching and learning. To this end, the study aims to continue its investigation into better understanding the teacher's practice by bringing his conceptions into the analytical procedure.

Finally, we would highlight the utility of the MTSK model and its corresponding analytical categories, above all those relating to KoT, in enabling us to detail the knowledge in evidence during this teacher's classroom performance.

2 University Bremen, Bremen, Germany

Our study focuses on kindergarten teachers' and primary school teachers' professional competencies related to mathematics and didactics of mathematics, more precisely on the competencies which are absolutely necessary to support children in learning mathematics during their transition from kindergarten to primary school. To measure these competencies in a situated way, a computer based assessment using image vignettes and video vignettes was developed. The results of n = 123 kindergarten teachers and primary school teachers show a crucial aspect: the insufficient mathematics-related competencies of kindergarten teachers and primary school teachers who did not study mathematics but practise out-of-field-teaching in mathematics.

Keywords: Image vignettes, video vignettes, teachers' professional competence, mathematics, out-of-field teaching.

THEORETICAL BACKGROUND

The concept of *teachers' professional competence* was progressively differentiated in the past decades (e.g., Shulman, 1986; Weinert, 2001; Ball et al., 2008). In the following, we refer to a model developed in the context of COACTIV (cf. Figure 1, Baumert & Kunter, 2013). Thus teachers' professional competence comprises several interwoven aspects: professional knowledge (especially content knowledge, pedagogical content knowledge, pedagogical and psychological knowledge), beliefs, values and goals as well as motivational orientations and self-regulation. Regarding knowledge and beliefs, there is empirical evidence for their impact on the quality of teaching and students' achievement (cf. Staub & Stern, 2002; Hill et al., 2004; Richter et al., 2012; Kunter et al., 2013).

Overlooking current research, there can be found *two approaches to acquire teachers' professional compentecies*. On the one hand, questionnaires with multiple-choice-items aim at professional knowledge and beliefs in large populations, the comparison of partial groups of these populations and the correlation of different aspects of professional competence (e.g., Blömeke et al., 2010; Tatto et al., 2012). On the other hand, image vignettes and video vignettes are nowadays seen as the preferred method to reveal teachers' competencies in situations close to everyday professional life (e.g., Lindmeier, 2011). In contrast to a paper-and-pencil-test with multiple choice items the gain is obvious: Image vignettes and video vignettes do not only capture data regarding teachers' knowledge and beliefs but refer to teachers' acting in situations which are quite realistic and thus closer to their everyday practice.

To consider the *math-related professional competence of kindergarten teachers and primary school teachers*, there exist many differences in professional training of the two groups. Using the situation in Germany as an example, kindergarten teachers are mainly educated in vocational schools where mathematics and didactics of mathematics usually play a minor role. In contrast, primary school teachers study at university and therefore have an academic degree. Although primary school teachers study only two or three subjects, they usually teach more subjects. As a result, *out-of-field-teaching in mathematics* has been estimated as a key problem for mathematics education in primary school (for the situation in Germany cf. Richter et al., 2012; Törner & Törner, 2012; for an international report cf. Tatto, 2012).

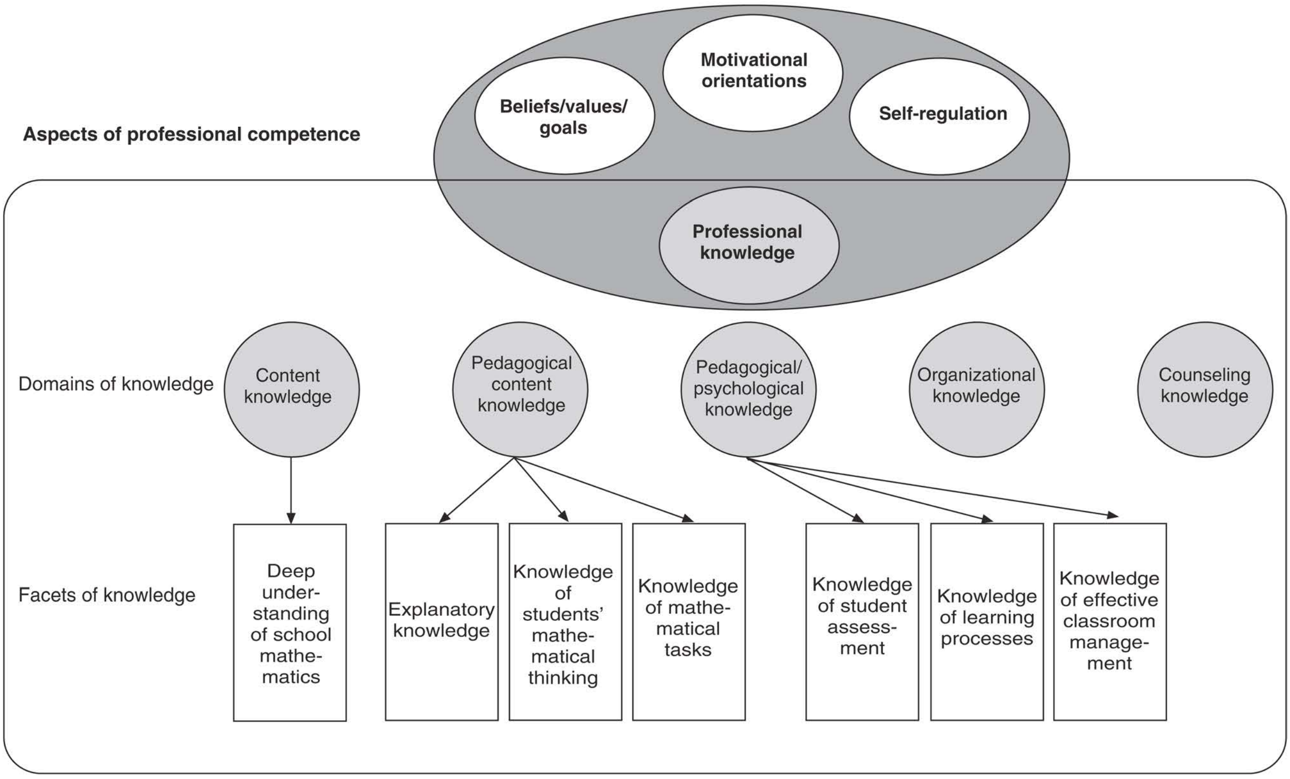

Figure 1: Teachers' professional competence (Baumert & Kunter 2013, p. 29)

Due to this contemporary situation in professional training, *it is an open question whether kindergarten and primary school teachers are able to initiate and foster mathematical learning processes in the transition from kindergarten to school*. We expect differences not only between kindergarten and primary school teachers but also between primary school teachers who studied mathematics and primary school teachers (without studies in mathematics) who practise out-of-field teaching.

RESEARCH QUESTIONS

With regard to the three professional groups aimed above – primary school teachers who studied mathematics, primary school teachers who did not study mathematics but practise out-of-field teaching in mathematics and kindergarten teachers – our *research questions* are the following:

1) To what extent do the three professional groups recognise the mathematical potential of typical situations in the last year of kindergarten or the beginning of the first year of primary school?

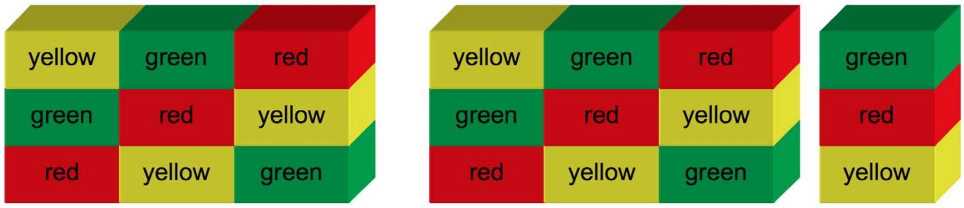
2) To what extent do the three professional groups make use of the range of the five main ideas (for example "number and operations" or "space and shape") in a reasonable way while analysing the mathematical potential of these situations?

3) To what extent are the three professional groups able to foster children's mathematical learning in these situations?

4) To what extent are the three professional groups able to foster process ideas (for example "problem solving" or "reasoning") in these situations?

As we are interested in the competencies of kindergarten teachers as well as primary school teachers, we need to focus on *the last year of kindergarten and the first year of primary school*. Of course, we are aware of the fact that our research objective only hits a small part of teachers' professional competencies, even with regard to mathematics education (e.g., we do not consider primary school teachers' knowledge in written arithmetic).

The reported study is part of a larger research project which aims at professional knowledge and beliefs of kindergarten and primary school teachers (Carle & Wittmann, 2015). Both knowledge and beliefs are seen as an indispensable prerequisite not only for their everyday practice but also for the cooperation of the two professions.



Initial situation — Situation with an additional fourth tower

Figure 2: Situations given in the described video vignette

DESIGN OF OUR STUDY

The *computer based assessment* includes *six image vignettes* and *four video vignettes*. All five main ideas (similar to curricular topics) "number and operations", "space and shape", "quantities and measurement", "pattern and structure", "data analysis, frequency and probability" are covered. Each of the ten situations is followed by two questions concerning one of the research questions. All in all, the assessment consisted of 20 questions for these ten situations.

An example of a video vignette might illustrate the setting. The introduction reads: "Three children (6 years old) got the task to build as many different towers composed of a red, a yellow and a green LEGO DUPLO brick as possible. The video shows a detail of one of the children dealing with this task." The video shows a boy who has already found three different towers (cf. Figure 2, left side) and additionally tries to build a fourth one (cf. Figure 2, right side). After a short moment he removes this tower again and says: "I'm done. I found them all."

Afterwards, the teachers were asked two questions: (1) "How would you react in this situation?" (2) "How can you prompt mathematical problem solving and reasoning in the given situation?" The first question aims at the teachers' reaction to the child's error and the second at an analysis of the situation regarding the learning of mathematics. To meet this situation in an adequate way, a teacher needs knowledge about basic enumerative combinatorics (there are six possible towers, not only three) and didactics of mathematics (e.g., how to give a stimulus) as well as the attitude that it does make sense to use the child's error as a fruitful learning chance.

The teachers typed their answers into the computer; the test took about 1.5 hours. From February to June 2013 in sum N = 161 assessments were led; for n = 123 detailed information about the teachers' professional training was given (especially whether a primary school teacher studied mathematics or not). The sample was drawn in two federal states in Germany (cf. Carle & Wittmann, 2015). It is a stratified sample (relevant criteria were sociodemographic aspects like the number of inhabitants of the community the kindergarten respectively school is located) and hence can be estimated as representative for both professions.

We rated the teachers' answers regarding the adequateness of the situational analysis concerning didactics of mathematics (research question 1). We coded which of the five main ideas the answers refer to (even in an indirect way) and counted how often each of the main ideas was allocated in total (research question 2). Furthermore we rated the quality of the intended action concerning didactics of mathematics (research questions 3) and to what extent they meet the criterion of fostering process competencies (research question 4).

Each answer was rated or coded by two researchers in an independent way; in the case of a divergence they yielded a common result in a consensual way. The interrater reliability was determined by the relative frequency (in percent) of the number of consensuses. It is 0.88 and can be estimated as satisfying.

RESULTS

(1) *To what extent do the three professions recognise the mathematical potential of typical situations?* Primary school teachers who studied mathematics recognise significantly more often the mathematical potential of a given situation than primary school teachers without studies of mathematics and kindergarten teachers (cf. Tables 1 and 2). The post-hoc test of Scheffé discloses two groups (primary school teachers who studied mathematics versus primary school teachers without studies of mathematics and kindergarten teachers; major effect: $\sigma^2 = .13$). With regard to the whole sample the quality of the given answers is quite low ($M = 0.88$;

Profession	M	SD
Kindergarten teachers (n = 82)	0.79	0.45
Primary school teachers without studies of mathematics (n = 20)	0.82	0.55
Primary school teachers who studied mathematics (n = 21)	1.23	0.55
Overall sample (n = 123)	0.88	0.53

Table 1: Recognition of the mathematical potential of typical situations

Source of variance	df	F[a]	Sig	η^2
Profession	2	8.65***	.00	.13
Error within the two groups	120	(0.24)		

[a]One-way analysis of variance, *p < .05; **p < .01; ***p < .001

Table 2: Effect of the profession on the recognition of the mathematical potential of typical situations

Profession	M	SD
Kindergarten teachers (n = 82)	2.26	0.87
Primary school teachers without studies of mathematics (n = 20)	2.95	1.23
Primary school teachers who studied mathematics (n = 21)	3.19	.75
Overall sample (n = 123)	2.53	1.00

Table 3: Number of reasonable allocations of typical situations to the main idea “patterns and structures”

Source of variance	df	F[a]	Sig	η^2
Profession	2	11.10***	.00	.16
Error within the two groups	120	(.85)		

[a]One-way analysis of variance, *p < .05; **p < .01; ***p <. 001

Table 4: Effect of the profession on the number of reasonable allocations to the main idea “patterns and structures”

thereby 0 signifies “no answer or no reasonable answer” and 3 signifies “reasonable answer considering the situation in a multi-perspective way”) with a broad variance (SD = 0.53). Thus, the sampled teachers only rudimentarily recognise the mathematical potential of the situations on average and the quality of answers differs considerably not only between but also within the professional groups.

(2) *To what extent do the three professions make use of the range of the five main ideas in a reasonable way while analysing the mathematical potential of these situations?* The three groups do not differ significantly in the number of reasonable interpretations related to the main ideas “number and operations”, “space and shape” as well as “quantities and measurement”. Yet regarding the main idea “patterns and structure”, primary school teachers (regardless whether they studied mathematics or did not) show significantly higher correct allotments than kindergarten teachers (cf. Tables 3 and 4). The post-hoc test of Scheffé distinguishes two groups (primary school teachers who studied mathematics versus primary school teachers without studies of mathematics and kindergarten teachers; major effect: η^2 = .16). Regarding the main idea “data analysis, frequency and probability”, primary school teachers who studied mathematics allocate the given situations significantly more often in a correct way than primary school teachers without studies of mathematics and kindergarten teachers (cf. Tables 5 and 6). Again the post-hoc test of Scheffé shows two groups which are different though (primary school teachers versus kindergarten teachers; major effect: η^2 = .17).

(3) *To what extent are the three professions able to foster children’s mathematical learning in typical situations?* As above, major effects are found between

Profession	M	SD
Kindergarten teachers (n = 82)	1.68	0.97
Primary school teachers without studies of mathematics (n = 20)	2.10	1.07
Primary school teachers who studied mathematics (n = 21)	2.81	.87
Overall sample (n = 123)	1.94	1.05

Error within the two groups	120	(0.16)		

[a]One-way analysis of variance, *p < .05; **p < .01; ***p < .001

Table 8: Effect of the profession on the teachers' mathematics-related action in typical situations

the professions: The quality of the intended action is significantly higher for primary school teachers who studied mathematics than for primary school teachers without studies of mathematics and kindergarten teachers (cf. Tables 7 and 8). The post-hoc test of Scheffé shows two groups (primary school teachers who studied mathematics versus primary school teachers without studies of mathematics and kindergarten teachers; large major effect: $\eta^2 = .25$). Again, the standard derivation indicates differences within the professional groups as well.

(4) *To what extent are the three professions able to foster process ideas?* Based on four video vignettes, we could prove to some extent whether teachers are able to foster process-oriented ideas: "mathematical communication" and "reasoning" (video vignette 1), "reasoning" (video vignette 2), "reasoning" and "problem solving" (video vignette 3), "using mathematical representations" (video vignette 4). Regarding our previous results, it was not in all cases possible to concatenate each process idea to a specific video vignette as process ideas often are interwoven. Due to this fact and several other impediments (normal distribution of the data was not given, floor effects occurred, the number of situations in total was quite small), the comparison of the three groups could not be done in the same way as above. Instead, nonparametric tests were used: The comparison of the three groups (primary school teachers with studies of mathematics vs. primary school teachers without studies of mathematics vs. kindergarten teachers) is done by the H-test of Kruskal and Wallis whereas the U-Test of Mann and Whitney is used to analyse which of the groups differ significantly from each other.

The results of kindergarten teachers show a floor effect as many answers do not comprise any reference to the designated process ideas. Similarly, the perception and support of process ideas of primary school teachers is quite low. Nevertheless, there can be found differences between the professional groups. Regarding the two video vignettes "using mathematical representations" ($\chi^2 = 12.03$, df = 2; $p < .01$) and "reasoning and problem solving" ($\chi^2 = 9.08$, df = 2; $p < .05$), primary school teachers who studied mathematics act significantly better than primary school teachers without studies of mathematics and kindergarten teachers. The following U-test confirms these two groups ($U = 126.00$, $z = -2.45$, $p < .05$; $U = 636.00$, $z = -2.79$, $p < .01$).

DISCUSSION

The documented results are rather disillusioning. All three professionals groups are *barely able to initiate and foster mathematical learning processes of children* in the laboratory situation of the computer-based assessment. Indeed, we can assume that the acquired math related competencies are even overestimated as the situations presented by the image vignettes and video vignettes are characterised by a reduced complexity in comparison to real teaching practice (e.g., interaction with just one child or a small group of children instead of a whole class). On the other hand, we cannot exclude that the given situations do not really hit the teachers' professional experiences with the consequence that they might act considerably better in real classroom situations.

The differences between primary school teachers who studied mathematics and who did not study mathematics are in line with well-known research results. Whereas TEDS-M shows this differences for future primary school teachers who are still in teacher training (Blömeke et al., 2010), we can approve them for primary school teachers being in service. Hence our study emphasizes that even teachers' professional practice (in many cases for a number of years) cannot solve the reported problems of out-of-field teaching in mathematics. Obviously, the combination of everyday life mathematics, general didactics and pedagogical knowledge (which teachers who practice out-of-field teaching in mathematics for some years can refer to) is not fruitful enough for adequate mathematics instruction und does not lead to mathematics related competencies. The inclusion of kindergarten teachers into our sample furthermore shows that this profession has substantial deficits, too. This fact confirms the problem of out-of-field teaching in a drastic way because primary school teachers show only a gradual better performance than their colleagues from kindergarten.

Subsequently, two *demands regarding educational policy* seem to be reasonable: First, both the education and the in-service training of kindergarten and primary school teachers must be improved: Every kindergarten teacher should be educated and continuously trained in initiating and fostering mathematical learning processes for the age from three to six and the transition from kindergarten to primary school. Every primary school teacher should attend lectures and in-service training in elementary mathematics and didactics of mathematics to decrease the frequency of out-of-field teaching. Notably, we cannot say which elements of mathematics teacher education (for example which lectures of mathematics and didactics of mathematics or rather the practical training at school) and in which combination are really essential to improve the quality of teachers' acting. Second, the support of children while the transition from kindergarten to primary school should not be dedicated to individuals but needs professional teams (language, mathematics, physical development, ...) who are able to foster children in their special field.

Secondary mathematics teachers' content knowledge for teaching in two contexts: Interpreting versus managing didactically students' understandings

Sotirios Zoitsakos[1], Theodossios Zachariades[1] and Charalambos Sakonidis[2]

1 University of Athens, Greece, s-zoitsakos@math.uoa.gr

2 Democritus University of Thrace, Xanthi, Greece

Teachers' content knowledge for teaching mathematics has been the focus of considerable research that aims to identify this knowledge and to explore the ways in which it is related and affects teachers' initial and professional learning. The paper presents a study which examines secondary teachers' mathematical knowledge emerging in their interpretations of and instructional management suggestions for four hypothetical students' misconceptions regarding the decimal representation '0.3999…'. The results show that teachers' mathematically correct conceptions do not guarantee instructional approaches free of erroneous mathematical ideas.

Keywords: Procept, teacher knowledge, decimal number.

INTRODUCTION

Teachers' knowledge for teaching has attracted a lot of research attention in mathematics education, giving rise to finer specifications of the initial categorization suggested by Shulman (1986). For example, Ball, Thames and Phelps (2008) subdivided Subject Matter Knowledge (SMK) into Common Content Knowledge (CCK), Specialized Content Knowledge (SCK) and Horizon Content Knowledge (HCK); and Pedagogical Content Knowledge (PCK) into Knowledge of Content and Students (KCS), Knowledge of Content and Teaching (KCT) and Knowledge of Content and Curriculum (KCC). Some researchers (e.g., Huillet, 2009) question the appropriateness of the distinction between content knowledge and pedagogical content knowledge to help us understand the diversity of the mathematical knowledge for teaching.

Most studies dealing with the question of 'what mathematics knowledge is needed for teaching' focused on primary teachers (e.g., Ball et al., 2008; Rowland, Turner, Thwaites, & Huckstep, 2009; Ma, 1999). However, there are few relevant studies that concentrated on secondary mathematics teachers. For example, Zazkis and Lekin (2010) call for a more articulated relationship between Advanced Mathematical Knowledge (AMK) and mathematical knowledge for teaching. Hossain, Mendick and Adler (2013) adopt a poststructuralist approach to explore what positions of "understanding mathematics in-depth" makes available to prospective secondary mathematics teachers their participation in a training course.

The present study is part of a broader study that examines secondary teachers' knowledge for teaching decimal numbers of infinite digits and especially of period 9. The choice of focus is due to the importance of the idea for both primary and secondary mathematics curriculum and also to the difficulty of its understanding by students of all ages (e.g., Dubinsky, Weller, McDonald, & Brown, 2005; Giannakoulias, Sougioul, & Zachariades, 2007).

In particular, teachers' knowledge related to decimal representation of numbers with infinite digits of period 9, due to its special relationship with infinity, brings to the forth broader cognitive, epistemological and didactical issues. With respect to the former, these representations, their comparison rules, sequences, series and their limit, as well as important properties of the real number set, like density, are all relevant and cognitively challenging ideas for students and teachers alike. Epistemologically speaking, these representations raise questions connected to their nature (process – number), their multiple meaning and to potential and actual infinity. Finally, in terms of teaching, the focus on these representations permit a close examination of fine mathematical ideas widely used, like this of the infinity, for which strict definitions cannot be employed due to pedagogical considerations, unavoidably allowing for a range of interpretations. To this direction, our research aims at identifying teachers' broader mathematical knowledge required for a careful and deep classroom negotiation of these matters. In specific, we examine the involved teachers' conceptions of these numbers studied in a previous work (Zoitsakos, Zachariades, & Sakonidis, 2013) in relation to the mathematical content knowledge emerging through their instructional proposals concerning the effective teaching management of the relevant idea within the classroom.

THEORETICAL FRAMEWORK

Despite the significance attributed to teachers' content knowledge for teaching, its categorization suggested to date has been criticized in many ways. Huillet (2009) advocates that "the distinction between 'purely mathematical' knowledge (SMK or CCK) and mathematical knowledge adapted for teaching (PCK or SCK) is not appropriate" (p. 10). Davis and Simmt (2006) argue against the distinction between formal disciplinary knowledge and instructional knowledge as "mathematics – for – teaching is neither a matter of 'more of' nor 'to a greater depth than' the knowledge expected of students. It is qualitatively different … (it) might properly be regarded as a distinct branch of mathematics" (p. 294). We adopt this latter view in the present study and attempt to gain some insights into this 'distinct branch of mathematics' by concentrating on teachers' mathematical knowledge 'adapted' to the needs and the limitations of the learning and teaching processes.

Research has identified that one of the main difficulties in making sense of representations like '0.999…' is that are seen as referring to a process-sequence which tends simultaneously to a limit and to the value of the limit itself (Gray & Tall, 1994). This dual nature of mathematical notions operating as processes and objects at the same time has been recognized as a source of power but also of difficulties.

Sfard (1989) claims that the ability to conceive notions as processes and objects at the same time, although ostensibly incompatible, it is, in fact, complementary. Much along the same line, Gray and Tall (1994) argue that "[all those who are successful in mathematics] employ the simple device of using the same notation to represent both process and the product of the process" (p. 118). They proposed "the portmanteau word 'procept' to refer to this amalgam of concept and process represented by the same symbol. […] An *elementary procept* is the amalgam of three components: a *process* which produces a mathematical *object* and a *symbol* which is used to represent either process or object" (Gray & Tall, 1994, p. 120).

Gray and colleagues (1999) suggested a model for the performance spectrum of different individuals in different contexts, when using mathematics procedures, processes and procepts. Gray and Tall (2001) expanded this model, providing four possible outcomes of progressively higher level of sophistication: pre-procedure (no solution or partial solution), procedure (step-by-step solution for a routine problem), process (flexible solution with conceptual alternatives) and procept (ability to think about mathematics symbolically).

In Zoitsakos and colleagues (2013), adopting the above theoretical framework, we found that, despite their strong mathematical background, 106 secondary teachers of mathematics, all mathematics graduates, discussing four hypothetical students' answers as to the meaning of the representation '0.3999…' provided a rather disappointing picture as to their own understanding of the representation: almost 3 to 10 appeared to view the representation '0.3999…' only as a process, about 4 to 10 argued for a combination of process and concept (number) with deficiency(ies) somewhere, while nearly 2 to 10 considered the given representation correctly both as a process and as a concept (procept). Embarking from this, we wanted to examine how this outcome, related to these teachers' content knowledge for teaching, might differ when looked at in another context, which comes closer to the teaching practice itself: in teachers' instructional suggestions for dealing with the above hypothetical students' thinking. This, we believe, may provide some access to the qualitatively distinct content knowledge for teaching held by the teachers of the sample.

METHODOLOGY

We developed the following hypothetical classroom/teaching scenario for research purposes. The questions raised in the scenario were answered by 106 practicing secondary school mathematics teachers in writing (36 male and 70 female, with teaching experience ranging from 0 to more than 15 years). The answers were provided in the context of an entry examination paper for a Master's degree in Didactics and Methodology of Mathematics. The scenario had as follows:

> A final year secondary school teacher gave the following question to his students: 'What is the meaning of the representation 0.3999… (infinite number of 9)'?
>
> Four students gave the following answers: (i) *Student A:* The representation 0.3999… means a process that tends to 0.4, (ii) *Student B:* 0.3999… is a number that tends to 0.4, (iii) *Student C:* 0.3999… is the number just before the 0.4 and (iv) *Student D:* The representation 0.3999… is the sum of 0.3+0.09+0.009+… but, as it continuously increases, it cannot be equal to a number. (a) What could be the teacher's goal in asking this question? (b) Comment each student's answer according to the thought process articulated, the positive and the negative points imprinted in his/her view and his possible misconceptions (if there are any) and (c) If you were a teacher in this class, how would you help these students to overcome the misconceptions, you identified?

Teachers' responses to a scenario such as the above can serve as a means a) to study their understandings related to subtle differences of meaning through students' (mis) conceptions and b) to explore their teaching practices of helping students overcome their possible misunderstandings (Biza, Nardi, & Zachariades, 2007).

In a previous study (Zoitsakos et al., 2013) we examined teachers' own conceptions of the representation '0.3999…' through their written reaction to the hypothetical students' relevant misconceptions. The analysis of the data gave rise to five categories of conceptions: a) No response/irrelevant (10 teachers gave no or irrelevant answers); b) Process (30 teachers understood '0.3999…' mainly as a process); c) Process & Concept (number), with at least one of the two false (31 teachers viewed '0.3999…' as a process and the result of a process, but there was somewhere an error); d) Process & Concept (number), wavering between the two (12 teachers held a correct view of the notation '0.3999…' (procept) together with incorrect ones) and e) Procept (23 teachers expressed a correct view of the notation '0.3999…').

In the present study, we attempt to relate teachers' understanding of the representation '0.3999…' with their teaching suggestions for helping students to make sense of it. To this purpose, we analyze these suggestions with regard to two criteria, *mathematical correctness* and *level of formalism* adopted, following a grounded theory technique (repeated cycles of reading, coding, recoding and grouping and re-grouping of the data leading to the identification of categories of answers for each criterion) (Corbin & Strauss, 2008). For each criterion, three types of instructional suggestions were identified, forming a spectrum extending from no to full agreement to the feature indicated by the criterion.

Specifically, with respect to the mathematical correctness, the teaching proposals were distinguished in two types: a) mathematically *correct*, b) *mixed* (a combination of apparently correct and incorrect ideas or ideas that could be seen either as correct or as incorrect because of dubious articulations) and c) *problematic* (clearly mathematically mistaken ideas or thinking). As far as the criterion of formalism is concerned, the teaching propositions were characterized as a) *formal* (when adopting mainly purely formal mathematical methods), b) *combined* (when employing both formal and informal methods, directly or indirectly) and c) *informal* (when resorting to mainly empirical, descriptive and even intuitive approaches).

RESULTS

Table 1 below presents the results of the combined analysis of the teachers' conceptions emerging in their instructional suggestions for helping students understand the representation '0.3999…' with their conceptions of it according to the spectrum suggested by Gray and Tall (2001). There are ten teachers who provided no answer to any of the scenario questions and have been excluded.

		Process 30	Process & concept number, at least one of the two false 31	Process & concept number, wavering between the two 12	Procept 23	Sum 96
Correct 23	Formal			4	12	16
	Combined			1	6	7
	Informal					
Mixed 24	Formal				1	1
	Combined	2	6	4	3	15
	Informal	3	4	1		8
Problematic 28	Formal					
	Combined	1	2			3
	Informal	12	13			25
Incoherent		7	4			11
No-suggestions		5	2	2	1	10

Table 1: Classification of teaching proposals to the correctness and formalism

As it can be seen from Table 1, ten teachers offered no teaching suggestion, whereas eleven teachers' responses were impossible to classify in terms of mathematical correctness and also with respect to the formalism level employed.

The 75 teaching suggestions that were possible to classify are almost equally distributed between the three types of correctness (23 correct, 24 mixed and 28 problematic). However, this is less the case for the criterion of formalism, where informal teaching practices appear to dominate and formal to be the least popular (17 formal, 33 informal and 25 combined).

It noticeable that as the teachers' conceptions of the representation '0.3999…' range from 'process' to 'procept', their instructional suggestions shift from mathematically problematic to correct and from employing informal to drawing on formal mathematical methods. Furthermore, in their attempt to transform their mathematical knowledge to teaching practice, some of the teachers with a complete understanding of the representation '0.3999…' (i.e., among the 23 teachers in the category 'procept') move to mathematically partially correct teaching suggestions (18 correct and 4 mixed). Finally, the majority of the 23 teachers who articulate mathematically correct instructional proposals (16 teachers) employ a formalistic approach, while the remaining incorporate also informal methods of dealing didactically with the particular idea.

In the following, some characteristic excerpts from the data are presented in order to substantiate each category of answers, to clarify its specific features and to highlight the complexity of the teaching practices suggested by the teachers of the sample.

T37 (male, limited teaching experience, PhD student in Mathematics) is one of the 23 teachers who were found to hold a procept conception for the representation '0.3999…'. The passage that follows comes is his actual instructional proposal and constitutes a typical example of a proposition characterized as mathematically correct and formal.

> I would argue (using the knowledge related to the geometric progression studied in the second year of the Lyceum) that, since:
>
> $$0.09 + 0.009 + \ldots + 0.\underbrace{00\ldots0}_{n+1}9 = \frac{9}{10^2} + \frac{9}{10^3} + \ldots + \frac{9}{10^{n+2}} =$$
>
> $$= \frac{9}{10^2}\left(1 + \frac{1}{10} + \ldots + \frac{1}{10^n}\right) = \frac{9}{10^2} \cdot \frac{1-\left(\frac{1}{10}\right)^{n+1}}{1-\frac{1}{10}} = \frac{1}{10} \cdot \left(1-\left(\frac{1}{10}\right)^{n+1}\right)$$
>
> and $\left(\frac{1}{10}\right)^{n+1} = \frac{1}{10^{n+1}} \to 0$ as $n \to +\infty$ then:
>
> $0.3\overline{9} = \lim_{n} (0.3 + 0.09 + 0.009 + \ldots + 0.\underbrace{00\ldots0}_{n+1}9) = 0.3 + 0.1 = 0.4$. That is, that the number 0.4 is the number $0.3\overline{9}$ which is the limit of the sum $0.3 + 0.09 + 0.009 + \ldots + 0.\underbrace{00\ldots0}_{n+1}9$

We concentrate more on the case of teacher T4 (male, about 10 years of teaching experience), whose answer was classified in the 'procept' category and his teaching suggestion as mathematically correct and combining formal and informal methods. The teacher begins to present (a little hesitantly) a (formalistic) proof of the equality 0.3999… = 0.4, being aware though of the limited persuasion power this approach might have for the students. This can be seen as an element of the Knowledge of Content and Students (KCS) suggested by Ball and colleagues (2008). In particular, he writes:

> I would probably present to them the following process initially: $x = 0.3999…$ [then] $10x = 3.999…$, [so] $10x - x = 3.999… - 0,3999…$ [consequently] $9x = 3.6$ [thus] $x = 0.4$ [that is] 0.3999… = 0.4. This would surely seem strange to them. They usually react. They would say that there has been a mistake ….

He then goes on arguing that "I would use the strengths of the students' views in order to help them understand what is happening" and stating specifically:

> Student B says that 0.3999… is a number in contrast with students A and D. The exchange of views between the students will help everybody understand that 0.3999 … is one notation for a number.

At this point T4 highlights the question of the nature of the representation 0.3999… (number-process) given rise by the hypothetical students' views and proposes the development of a discussion among them about this issue guided appropriately by himself. He carries on attempting to respond to the students' misconceptions, restating them on a more theoretical form and using appropriate intuitive arguments. In particular, he argues:

> We must address the following misconceptions: a) A sum of infinite terms may tend to a number. This is done by way of example: cutting a paper in half and the half again in half etc. … ". Of course, this particular suggestion refers to a theoretical possibility rather than to a real application; b) The notion of succession does not exist in real numbers. 0.4 is not next to the number 0.3999… This can be addressed by asking students which number is next to 0.4. They may say that we put 1 *after* infinite zeros. However, there exists the contradiction after infinite ….

In the last part of his answer, after highlighting a key element of the students' misunderstanding, T4 provides a descriptive argument for the equality 0.3999 … = 0.4. He advocates:

> …c) Finally, students ought to understand that 0.3999… *is* the limit of the process they have in mind (and not the process itself). Once we have concluded that there is no successiveness in real numbers and that there is no number between 0.3999 … and 0.4, the numbers are identical, therefore 0.3999 … = 0.4. That is, the limit is equal to 0.4 "(his own emphasis).

The analysis of the responses to the questions of the scenario provided by teacher T6 (male, 12 years of teaching experience) showed that he conceptualizes the representation '0.3999…' as a procept. However, his teaching proposal included mathematically correct and incorrect elements and employed a formalistic approach, showing that formalism and mathematical correctness do not always go together. In particular, he states in his instructional suggestion:

> I would use the reduction ad absurdum. Let 0.3999… ≠ 0.4. Then given the completeness of R, we should be able to find a number between them. If such a number exists, then the number of its [decimal] digits would have been finite. Absurd.

Teacher's T13 (male, more than 15 years of teaching experience) conception was categorized as indicating 'process and concept number, with at least one of the two false'. His teaching practices, as exposed in the following excerpt, were identified as mixed mathematically and as informal methodologically:

> A suggestion would be to introduce students to the paradox of Zenon with Achilles and the tortoise [draws a line with the indicative positions of Achilles and the tortoise]. In this way they could understand the convergence process and accept that an infinite process can lead to a finite result, since experience tells that Achilles will definitely reach the tortoise".

Essentially, teacher T13 cites an empirical-informal argument (Achilles will definitely reach the turtle) to substantiate a correct mathematical idea (a sum of infinite terms leads to a finite result) for which he does not appear to be clear about (hence its classification as above).

Teacher T23 (female, almost no teaching experience) was classified as holding a 'process' conception and her teaching suggestions were seen as problematic as far as mathematical correctness is concerned and as using informal mathematical methods. In her instructional recommendations she states:

> I would explain to the students that this representation has infinite terms (exactly like a sequence has infinitely many terms tending to a limit, and there is always a previous and a subsequent term). Thus, 0.3999 ... is not immediately previous number of 0.4 since these two numbers are separated by thousands digits.

Here, there is a correct idea (0.3999... is not the previous of 0.4) but the justification is incorrect. Then, trying to explain to the students the representation '0.3999...', the teacher uses only intuitive approaches and glides to fundamental errors concerning the nature of numbers.

> This number can be continuously increased, but this is why it never becomes 0.4. In addition, we are not talking about a number, as student B states, approaching another number, but for a representation that gives us new terms 'tending' → [connection to limit] to a number. I would also show to student D that the terms of this representation, if seen as corresponding to images of a function, certainly it would not be a continuous function, so no need to confuse them. A good idea is to show to the students functions as the one with the following graph [has drawn the graph of a function of the type $f(x) = \frac{a}{b}$, which tend, have a limit but do not coincide with a value, they have infinite terms.

DISCUSSION AND CONCLUSIONS

It is clear from the preceding analysis that a significant part of the teachers with an accurate understanding of the representation '0.3999...' (12 teachers: procept, correct, formal) resort to purely formal approaches in articulating a teaching strategy for dealing with pupils' relevant misunderstandings. To this direction, they overdraw their ontological concerns and the mental paradoxes that emerge from the hypothetical students about whether the representation is '0.3999 ...' is a process or a number as well as if the infinite sum of positive numbers can be a number rather than infinity. This phenomenon of teaching mathematics decontextualized from the problems that gave rise to the corresponding ideas has been identified by Chevallard (1991) some years ago.

There is, however, a smaller number of teachers (6 teachers: procept, correct, combined) who, like teacher T4, recognize limited persuasiveness for the students of purely formalistic techniques and accompany them by appropriate intuitive arguments and narrative explanations.

It is also noticeable that of the 23 teachers who have good understanding of the specific representation, only 18 maintain accuracy in their teaching proposals. This means that there is a slippage of mathematical correctness when transforming knowledge for didactical purposes. The subtlety of the idea under consideration (the mathematical meaning of the representation '0.3999...') appears to contribute to this slippage, making clear the special attention needed during its didactical transformation. Furthermore, highlights the qualitatively distinct character of the content knowledge for teaching mathematics (Davis & Simmt, 2006).

On the other hand, the majority of the teachers were unable to both conceptualize and suggest instructional practices to the issue at hand that are mathematically correct. They adrift in informal and vague approaches which fail to respond effectively to the hypothetical students' relevant misconceptions. This is the reverse problem of the one reported in the beginning of this section: we have here a strong effort of embedding mathematical knowledge within an empirical-intuitive context, however, stripped of its mathematical content.

The above findings show clearly the specificity of the mathematical knowledge needed for teaching, especially at the advanced level. Also, highlight the importance of further searching for those features that make it distinct as well as for the reasons that mathematically correct conceptions do not guarantee instructional approaches free of erroneous mathematical ideas.

A proposal for the study of mathematics teacher reflection

Mayra A. S. Báez Melendres and Rosa María Farfán Márquez

Center for Research and Advanced Studies of the National Polytechnic Institute, Mathematics Education Department, Ciudad de Mexico, Mexico, mbaez@cinvestav.mx

The purpose of this poster is to present a proposal for the study of the mathematics teacher reflection. For that, we consider reflection as that which contributes to a change in relation to mathematics knowledge. In this text, we present some theoretical ideas that support the study and an outline of the methodology to be used.

Keywords: Reflection, social development of thought, school mathematical knowledge.

INTRODUCTION

Our problematic centres its attention on mathematics teacher reflection. It is recognized that in the research carried out reflection has been related with the didactic and pedagogic aspects; however, mathematics itself has not been the object of reflection for the discipline (Jaworski, 2014). Given the universality of mathematics, it does not seem to have sense to avoiding reflecting about it, focusing on the issues around it, such as teaching. What is the meaning about reflecting on mathematics? With this question, we do not pretend to question the knowledge of the teacher, but to understand how the thought is developed when the focus of reflection is mathematics itself.

That is how we make the general objective: to typify reflection of mathematics teacher about school mathematics. How to provoke this reflection? We consider a scenario of meanings confrontation is appropriate. Therefore, we highlight two research questions we intend to answer: (a) What reflections features about school mathematical knowledge are configured in a scenario of meanings confrontation? (b) What role does school mathematics play in the generation and depth of reflection?

CONCEPTUAL FRAMEWORK

As the basis of this paper, we have considered taking a social stance of the thought development, and therefore, of reflection. For example, for Radford (2006) thinking is more than a mental activity, where cultural *artefacts* are an integral part of it, so thinking has a close relationship with *objects*. Similarly, awareness is considered fundamental in the reflective process. For Freire (1982), reflection gives way to *awareness*, i.e. to a process of cultural action that seeks the liberation of individuals from the limitations and alienations which they are subjected to, affirming themselves as conscious subjects and co-creators of their historical future: a break of boundaries to be participants of the creation of new knowledge.

Regarding mathematics, we have also considered a stance of social construction, the Socioepistemology (Cantoral, 2013). This theoretical perspective is centered on studying the problematization of mathematical knowledge, taking into account the historical and contextual aspects which give sense and meaning to mathematics itself. Thus, the development of reflective thinking towards mathematics will deal with the relationship with it when meanings are constructed or reconstructed. The analysis of instances of reflections from this perspective will allow to identify elements to understand and explain the relationship between teachers regarding school mathematics and how reflections occurs.

THE STUDY

With qualitative style, we have considered making a case study (Merriam, 1998). Thus, the consideration of context is critical because it particularizes the *how* of the case study. The participant population is high school mathematics teachers in Mexico, with whom there will be working sessions with meanings confrontations: their own ones and those which were shed in the socioepistemology investigation, in the issue of proportionality (Reyes, 2014). We will also apply a semi-structured interview that allows us to know with acuity other aspects that influence in the teacher's thinking. We are interested in studying the moment of confrontation to identify the teacher reflection about the proportionality regarding their conceptions, their uses and the contexts or situations where the teacher is present. For this purpose, we construct categories of the pilot test.

CONCLUDING REMARKS

From our point of view, studying of reflection from the planned perspective will allow the teacher to question the school meanings and concepts in order to create conditions (arguments, instruments, strategies, etc.) that enable them, firstly, to modify their actions on the teaching of proportionality; and secondly, deepen their learning of mathematics.

Teachers' subjective theories on algebra

Julia Meinke

Georg August University Göttingen, Göttingen, Germany, julia.meinke@mathematik.uni-goettingen.de

This project concerns the impact of the belief system of teachers on their algebra teaching practices in secondary education. The first step is to reconstruct this belief system. The methodological framework is provided by the Research Project Subjective Theories (RPST). The research design is described here.

Keywords: Algebra, teachers' beliefs, subjective theories.

INTRODUCTION AND THEORETICAL FRAMEWORK

The main prerequisite for research on subjective theories of teachers are the assumptions of teachers as crucial factors for learning success (Nye et al., 2004) as well as the necessity to consider teachers' beliefs to understand their actions, planning decisions and behaviour in class (Ernest, 1989). Typical questions that correspond to these actions are: Why is a special content chosen, emphasized or denied? What are the reasons why a teacher decides to use a special method? Stein and colleagues (2007) have shown that planning decisions and the realisation of teaching depend highly on teachers' beliefs. The following figure illustrates the model of Stein and colleagues (2007) that describes the different phases of curriculum use (Figure 1).

Ontological beliefs of teachers and their impact on teaching have been studied in detail for the areas of elementary geometry (Girnat, 2011) as well as of statistics and probability (Eichler, 2004). There are already some hints that subjective theories of teachers differ in dependence of specific disciplines in mathematics (Eichler, 2011). This is why the project focuses on the research concerning the impact of subjective theories of teachers on the teaching of algebra.

Algebra is regarded as one of the most difficult and at the same time most important topics in school mathematics. It can be considered as the language of mathematics. Algebra is used in every case of generalization or in case of simplifying a complex situation (Usiskin, 1995). For this process it has to be clear what the initial situation, what the target is and which role the variable is playing in it. In this context it is most important for students to understand the use of variables and their meaning (Arcavi, 1994).

METHODOLOGY

To reconstruct the structure of the intended curriculum the Research Project Subjective Theories (RPST) is used. Subjective Theories are defined as „complex cognition aggregates of the research object, in which their cognitions relating to the self and the world become manifest and which show an at least implicit argumentational structure" (Groeben & Scheele, 2001, p. 2). The outcome of this is the dialogue-hermeneutic method. The researcher has to communicate with his research object to understand the cognitions behind his actions. The study was conducted by interviewing nine teachers by using half-structured interview-guidelines, based on an interview-study that was conducted before. Afterwards teachers were visited twice in their algebra classes unheralded. To remain as impartial as possible in the observation of the classroom situation, the visits took place before the interviews were analysed. The observation records will be used to investigate how the intended and enacted curriculum relate.

Mathematical knowledge for teaching geometric proof: Learning from teachers' practices

Lisnet Mwadzaangati

University of Malawi, Faculty of Education, Zomba, Malawi, lmwadzaangati@cc.ac.mw

The aim of mathematics education courses in both undergraduate and post graduate programmes in Malawi is to improve teacher's mathematical knowledge for teaching. Although the number of colleges and universities offering secondary mathematics education courses is increasing in Malawi, the quality of teaching has not improved to a greater extent (Government of Malawi, 2009). The capacity of the teachers to teach geometric proof in particular is still inadequate. The purpose of the study in progress, is to explore the knowledge that teachers require in order to teach geometric proof well in Malawian context. The initial findings of document analysis and the pilot study results will be presented in the poster.

Keywords: Geometry, geometric proof, teacher knowledge, teacher education.

THEORETICAL FRAMEWORK

Many studies have been conducted in different areas in reaction to Shulman (1986) notion of pedagogical content knowledge (PCK). Such studies aimed at developing content knowledge (CK) for specific subjects. In mathematics education, most of the studies aimed at developing models of mathematical knowledge for teaching (MKT) and developing instruments for measuring its domains (Ball, Thames, & Phelps, 2008). Professional Knowledge for Secondary School Mathematics Teachers (PKSSMT) is one of the recent models that build on Shulman's and Ball's models of teacher knowledge. PKSSMT was developed by Baumert and Kunter (2013) from the COACTIV project. It shares a common theoretical approach with Ball's mathematical knowledge for teaching (MKT) model, to the extent that its focus is on mathematical knowledge needed for understanding of instruction. Unlike MKT, PKSSMT regards CK as including secondary mathematics only. It views CK as a prerequisite for PCK. There are basically three categories of PKSSMT model which are CK, PCK and pedagogical/psychological knowledge (PPK). My research is guided by this model and it only concentrates on CK and PCK because PPK is mainly about individual and class management. In my view, PPK is common knowledge needed by every teacher hence not in the interest of this study. PCK emphasizes on three aspects; knowledge of cognitive activating tasks and their sequence, knowledge of student's cognitions and ways of assessing them, and knowledge of explanations and multiple representations. This shows that PCK mainly emphasise on tasks, student cognitions, representations and explanations (Baumert & Kunter, 2013). CK and PCK imply that research on the teaching of mathematics has to focus on teacher's conceptual understanding, tasks used for explaining and assessing teaching, how the teacher evaluate the tasks, and how the teacher explains and represent concepts to students. Based on this view, I developed these questions for my research; 1. How is secondary geometric proof conceptualised by the teachers? 2. What is the nature of the problems that are selected and used to enhance students' geometric thinking? 3. How do teachers interpret student productions/solutions of geometric proofs? 4. How are geometric proof concepts represented and explained to secondary school students?

METHOD

Data collection is being done in phases. During the first phase which was a baseline survey, I analysed the Malawi National Examinations Board (MANEB) chief examiners mathematics reports of both junior and senior secondary school for the past five years (2008 to 2013). The reports show that students fail mathematics mainly due to poor performance in geometric proof questions. The chief examiners attribute students' poor performance in geometry to teachers' lack of knowledge to teach this particular branch of mathematics. Students do not understand geometric proof because they are not taught properly how to construct and apply a proof. The Government of Malawi (2009) highlights that one of the challenges facing the education sector is limited human capacity and material resource. The challenge of limited human capacity is in both quantity and capability and is worse in mathematics and science. Challenges in terms of capability entail that teacher education is not equipping the pre-service teachers with proper skills that can enable them teach mathematics, in this case geometry proof, very well. That is why there is need to study MKT-geometry proof. The second phase of the study will use qualitative case studies on in-service teachers. Best and worst teachers will be involved in the study to ensure variety in data collection.

During the CERME9 conference, I will present the results of pilot findings which will be done using tests, individual interviews and lesson observations. The poster will be composed of the introduction, problem statement, conceptual framework, methodology, data analysis and results.
