The other essential notion we consider is student personal work. We conducted an extensive review of literature about student personal work, in order to define the aspects we are concerned with in our study, and situate them with respect to other research tackling the same topic. We advocate that, in mathematics, students need to construct practical know-how in addition to the theoretical knowledge they acquire in order to solve mathematical problems. We refer to Castela's work (2011) on mathematical functioning and her contribution to the praxeological model. Our underlying hypothesis is that such practical knowledge is not explicitly taught nor institutionalized. Thus, students are required to engage in "autodidactical" personal work in order to extend and complete what has been initiated in the classroom. In our study, we are looking to define the nature of this autonomous study and the gestures involved in it, that is what students do in addition to solving problems in order to learn something in mathematics. On one hand, we focus on the disciplinary specificities of mathematics in student personal work. On the other hand, we perceive personal work as defined and influence by the institution and not as an isolated individual endeavour.

RESEARCH DESIGN

Our target group includes first year students who come from preparatory classes in three different Parisian schools[4] of both tracks, where three volunteer mathematics teachers have accepted to cooperate for the research and allowed us into their classrooms over two consecutive academic years (2011–2012 and 2012–12013).

The study uses a combination of qualitative and quantitative methods in order to answer the research questions; the following questions are at least partially addressed within the scope of this paper:

— How does students' personal work evolve throughout a preparatory year, in terms of quantity and forms of study?

— What are the forms of study that students exhibit on their own initiative, in addition to those prescribed and supervised by teachers?

— What forms of study are exhibited by "good" students as opposed to those who are "weak"?

— How do social relationships promote student work, in particular the relationships that are established between the students and those built with the teachers?

Several instruments have been used to collect data: informal discussions with students and teachers, email exchanges with few volunteer students, samples of student notes and documents, student questionnaires,

4 Given that it is not possible to disclose the school names, we refer to them by their initials: D and K from the S track, B from the T track.

teacher questionnaires, interviews with few students, and interviews with the three teachers. All data collected through qualitative methods is intended to provide explanatory elements and validation for the hypotheses and conclusions brought to light through the student questionnaire, which is the main tool of our study and the focus of this paper.

Through this questionnaire, we seek to identify ways of working which are common to students in general, as well as those that differentiate the "good" students from the "weak" ones. We determine a student's achievement level (good, average or weak) solely according to his/her end of year mathematics grade. In fact, the grade is the only criterion used in the "concours" to evaluate students' success and rank them for admission to the "Grandes Écoles". We also look to establish comparisons between the schools and/or the tracks, and examine how the ways of studying evolve throughout the first preparatory year, while considering the influence of the particular institutional context of the CPGE and the social relationships on students' work.

This pre/post questionnaire explores the ways students work for the mathematics course at two moments of their educational path, at the end of grade 12 and at the end of the first preparatory year. It was inspired from several previous similar questionnaires used in studies related to our topic (Adangnikou, 2007; Castela, 2004; Najar, 2010) and was designed to match our research goals and conceptual framework. It includes 55 items from five categories: general work habits (including problems encountered by the students), in class (following, taking notes), between two sessions (studying the lesson, solving exercises, making summary sheets, preparing the "colles"[5]), when reviewing before an exam (the resources, the way of working, the exercises), and self-evaluation of performance and results. The two versions of the questionnaire (pre/post) are almost identical in terms of the questions asked, but each focuses on a different moment of the student path. Most of the items are four-level Likert items (the ordered responses are "never", "sometimes", "often" , "always", or equivalent statements for few specific items), in addition to two multiple choice items, five yes/no answer items, and two open-ended questions (the latter are only found in the post version of the questionnaire since they pertain to the "colles"). The questionnaire was filled out by students of the three schools involved in our study, respectively at the beginning and at the end of the first preparatory year, over two consecutive academic years (82 students, then 97 students).

We used SPSS in order to conduct descriptive statistics analysis and hypothesis testing for the data gathered through student responses. For each item and for both moments of the study, the frequencies of responses were first calculated for the whole sample, then for subgroups of students created according to school (B, D or K), track (S or T) and level of students (good, average, weak) respectively. McNemar tests were used to verify the significance of the evolution of frequencies between the beginning and end of year for both academic years. Chi-square tests were used to check dependence relations between each item responses and the different subgroup modalities. Next, the items were crossed two-by-two in order to look for significant dependence relations using Chi-square tests.

FINDINGS

In this section, we present some of the main findings of the questionnaire data analysis which was structured around eight themes: 1. collaboration between the students, 2. student difficulties, 3. taking notes, 4. managing work and revisions, 5.between two sessions, 6. resources, 7. before an exam, 8. colles[6]. We give few examples of items that differentiate between the two tracks on one hand and between the good and weak students on the other hand.

5 A "colle" is an evaluation tool specific to preparatory classes. It classically takes the form of a one-hour oral examination by groups of three students working individually but simultaneously on the classroom board, answering lesson questions and/or solving problems given by the teacher who is present to supervise and grade the work. In mathematics, a student is subjected to a "colle" every two to three weeks. The conditions and functioning of a "colle" may vary from one school to another. The questions related to the "colles" (4 Likert items and 2 open-ended questions) are only found in the end of preparatory year questionnaire given that this tool is not used in grade 12.

6 Given the specificity of the "colles" to the CPGE context, it is difficult to fully understand their characteristics without a detailed description. Hence, we omit the results pertaining to this theme given the space limitations of this paper.

Collaboration between the students

The data analysis shows that collaboration with classmates is highly valued by students of preparatory classes, even though it doesn't always take the form of group-work. Group-work seems to be a relatively common practice, with an average proportion of students who report working in groups often or always around 50%. The other half – students who never or only sometimes work in groups – can be at least partly accounted for by the fact that students in preparatory schools come from different areas outside Paris, hence they do not live close to school and choose to work most often at home rather than in school or at a classmate's. In addition, group-work is more widespread among students of the S track on one hand, and among the good and average rather than the weak students of both tracks on the other hand. Collaboration also takes the form of a solidarity bond between students who seem to rely on each other for moral support and encouragement for non-academic purposes. In fact, more than 80% of the students totally agree with the fact that mutual support between classmates is as determining as one's personal work for success. This disproves common stereotypes which advertise harsh competition in preparatory classes. In fact, teachers encourage student collaboration by allowing it in their classrooms for specific purposes. Irrespective of the form it takes, we believe that collaboration between classmates has a positive impact on students' personal work.

Student difficulties

Many students in preparatory classes have time management and concentration difficulties when studying at home. The proportions of students who say they often or always have difficulties by the end of the preparatory year are higher than those of grade 12, exceeding 60% in several cases. This is not surprising given the demanding requirements of these classes and the long intense school days. Many students also find it hard to stay focused and follow in class, the lesson rhythm being too fast for them. This problem is more frequent among students of the T track, particularly the weak ones, for whom the situation is aggravated compared to grade 12, whereas students of the S track seem to become less distracted by the end of the first preparatory year. One hypothesis which can partly explain these different behaviours is related to how students of each track perceive the importance of mathematics. This derives from the fact that mathematics is the main subject in the S track and plays a crucial role in the "concours" and recruitment process, while it can be counterbalanced by other subjects in the T track. Despite the many problems they face, students seek less help from others (teacher, parents, friends…) than they used to in grade 12. In fact, the number of students who solicit the teacher's help when they don't understand something in class radically drops by the end of the first preparatory year. This practice remains more common among the good students. Likewise, although the number of those who get help from others such as parents or friends varies from one class to another, the average proportion does not exceed 50%, which shows that students tend to handle their difficulties on their own. This can be interpreted as a statement of independence or a lack of confidence in others. Some students, mostly weak ones, seem to completely shut themselves off from any external assistance, including discussions with classmates, which could suggest they have given up on mathematics.

Taking notes

We explored the way students take notes during the lesson and what they add to those notes. More than 90% of the S track students copy everything the teacher writes on the board, while the proportion drops to around 73% for those of the T track. On the other hand, fewer students take notes based on the teacher's oral comments. The proportion of those who do differs from one class to another, but it doesn't exceed 60%. This seems to be related to the students' level in mathematics and their difficulties while following the course pace. As for student contributions to the notes, many claim that they add personal comments and signs, especially good students, but very few indicate the things they did not understand while taking notes. These behaviours are analyzed and interpreted in light of the differences between the teachers' lessons, the content of the sheets they distribute to the students, the ratio of written and oral comments they add, as well as the students' level and difficulties.

Managing work and revisions

We tried to establish patterns in the way students organize and schedule their regular work and exam[7]

7 In CPGE, mathematics exams are not typical university exams, but are rather similar to high school exams in format and content. They take place regularly every four to five weeks on a Saturday, are usually four hours long, and consist of exercises related to the last chapter or two chapters covered in class.

revisions for the mathematics course. Despite the differences between classes, it is possible to observe that, compared to grade 12, more students use a tentative work plan to organize their work. It appears that this practice is more common among good students of the T track. Additionally, the number of students who wait for exam periods to review their lessons and work decreases by the end of the first preparatory year, particularly in the S track, where many students become more systematic in their work. This can be partly attributed to the "colles" which require students to learn their lesson fortnightly. Similarly, very few students start exam revisions at the last minute or the day before the exam, while more students begin their revisions two days prior to or at least one week before the exam. This shows that students in general become more organized, regular and anticipatory than in grade 12, although some differences and exceptions can be noted. We can also find extreme cases of both very studious students and very careless students. No statistically significant conclusion can be drawn about the differences between good and weak students with respect to ordinary study habits or exam revisions.

Between two sessions

We first consider what students do with the lessons covered in class by focusing on the main three actions of mathematics learning: read, understand, and learn. Between two mathematics sessions, around 35% of the students on average read everything that has been done in class, while almost 45% of the students go over the things they didn't understand in class, a practice mostly common among good students. In addition, less than half the students learn the lesson (theorems, definition, formulas, proofs). These numbers lead us to believe that only some students work on a regular basis between sessions, probably in order to be prepared for the "colles", while others tend to keep most of the work for exam revisions. As for the exercises, few students in schools B and D (around 28% on average) solve the exercises assigned by the teacher for the next session, as opposed to more than 60% of the students of school K. Likewise, very few students in schools B and D complete the exercises which the teacher didn't finish in class, while this seems to be more common in school K. These results begin to reveal a particular attitude among the students of school K with respect to exercises, which is confirmed through the analysis of further items.

Resources

Next we consider the resources which the students have at their disposal in order to prepare for exams. First, we examine summary sheets, self-produced resources that students create using lesson notes and/or exercises. Around 40% of students create summary sheets, mostly by selecting and copying important elements from the lesson and to a lesser extent from exercises. As for the resources provided by the teacher, most students (more than 80%) say they are satisfied with the lesson which they find complete and sufficient for them to succeed, except for those of school D in 2011–2012 where the rate is 40%. Furthermore, around 60% of the students of schools B and K study the comments written by their teacher on their previous exams or graded homework, as opposed to only 45% of those of school D. Finally, less than half the students of schools B and K use resources other than their teacher's lesson, such as books or online references, as opposed to more than 70% at school D. In fact teachers discourage such practice. These numbers, in particular those of the class of 2011–2012 at school D[8], strongly suggest that special consideration should be given to the teacher role while interpreting the data.

Before an exam

In this section, we explore the way students review for an exam. To start with, we analyze the way students study the lesson. It comes as no surprise that students give high importance to learning formulas and their application conditions by heart, and to a lesser extent to learning definitions and theorems. In fact, between 65% and 80% of students verify that they know by heart the different lesson components when preparing for an exam. This could compensate for the fact that more than half the students do not learn their lesson between two mathematics sessions as said above. These practices are slightly more common among students of the S track on one hand and among good students on the other hand. Moreover, 60% of students of the T track on average read and try to un-

8 In this school, two different teachers taught mathematics over the two years of our study. A detailed analysis of several items pertaining to the teacher role as well as information gathered from the interviews and discussions with students and teachers indicate that the relationship between the first teacher (class of 2011–2012) and the students was problematic, while things were smoother for the new teacher despite some minor issues. Being aware of this delicate situation allows us to explain some of the numbers we see, such as the lack of appreciation of the first teacher's lesson.

derstand proofs, and 40% try to re-do proofs as part of exam preparations, while the respective average proportions for students of the S track are 50% and 15%. Hence, it seems that proofs play an important role in the T track exams, whereas the S students encounter them mostly in the "colles". Despite these differences, good students in general and in the T track in particular seem to pay more attention than others to studying proofs before exams. Lastly, 75% of students of the S track declare that they try to extract ideas (examples, methods, tricks) to remember when studying before and exam, while only 45% of students of the T track do so. These numbers underline differences between the two tracks which can be partly attributed to the nature and content of exams for each track. In fact, the latter are aligned with the "concours" objectives and requirements which are not the same for both tracks.

Lastly, we consider the way students handle solving exercises before an exam. To the multiple-choice question "the most important thing to do in order to succeed in mathematics when solving exercises", we provided four suggestions: 1. "being able to solve the exercises assigned by the teacher", 2. "practicing by solving other problems than the ones assigned by the teacher", 3. "identifying standard problems and knowing the methods and tricks to solve them", 4. "other (to be specified)". The majority of S students chose the third option, while the most common choice for T students was the first option. This difference between students of the two tracks can be interpreted using Castela's (2004) work styles conceptions: the choice of T students matches the "reproduction conception", which is also that of successful university students, while the style of S students tallies more with the "transfer conception", given that they tend to look for tricks and methods which can be applied to other problems. Another main difference between students of both tracks is relevant to the way they handle exercises that had been previously solved in class. It appears that, on average, twice as many T students as S students say they only read the correction of an exercise and try to understand it, instead of actually trying to redo the exercise either mentally or by writing. Furthermore, weak students of both tracks tend to avoid redoing the exercises by writing, and settle for either solving mentally or reading the correction, but no such general observation can be made regarding good students. We can conjecture that while redoing exercises by writing is necessary in some cases, it is not always obligatory. However, in order to get something out of these previously solved exercises, it is inevitable to redo them at least mentally, since mere reading does not seem to contribute towards success in mathematics. The difference between the two tracks is also underlined by the fact that more S students solve exercises of different types than T students. For example, 80% of S students on average solve exercises similar to the ones that are most likely to be given in exams, while less than 65% of T students report doing so. Similarly, solving exercises which have not been prepared prior to exam revisions is a common practice for 65% of the S students as opposed to less than 40% of the T students. It is important to note that we also find differences within the S track between the students of schools D and K, and between the two classes of each school. Hence, it is hard to formulate comparisons between students of different levels. Yet we can summarize the main commonalities as follows: it seems that good students are more selective with respect to the type of exercises they choose to work on before an exam; they tend to tackle the long and difficult ones rather than the simple ones or those they previously managed to solve.

DISCUSSION AND CONCLUDING REMARKS

Through our approach, we first consider the CPGE institution as a whole, and then we focus on the functioning of each classroom considered as an institution on its own in order to interpret the results. We examine each classroom as an institution whose stability allows the transmission of norms (Monfort, 2000), despite the different students and in some cases different teachers over the years. Moreover, through its dual role of subjugating its members while providing them with the necessary resources, the institution is responsible for transforming and producing particular student aptitudes. Thus, we investigate the causes behind the observed phenomena at the level of the institution rather than the individual.

It is very difficult to sum up our results given the extensive data and the different levels of analysis involved in the study. In fact, what we present in this paper are only some of the main findings which are accessible to the reader who is not exposed to all the details of the work. For example, we have omitted most of the results of items that distinguish between the three different schools and/or the two years of study. In addition, some items do not suggest any consistent behaviour across schools, classes or years, but instead either produce non-results or reflect special cases.

Nevertheless, we can formulate three main conclusions which are repeatedly conveyed by the results of several items. The first one pertains to the class of school B in 2012–2013. Students of this class appear to be much less studious and less diligent than those of the other classes, in particular when compared to their predecessors of the class of school B in 2011–2012. In fact, their responses suggest that they work significantly less than the others in general as well as before exams. The second conclusion pertains to the class of school D in 2011–2012 which seems to be facing a problematic situation with the teacher. Some repercussions of this situation are still visible in 2012–2013 despite the change of teacher, but to a lesser extent. The third conclusion concerns the class of school K in 2012–2013. Students of this class seem to share some common study gestures which differ from those of other classes, in particular those of the S track, especially with regard to exercises. This is partially ascribed to the fact that two-thirds of its students have an average level in mathematics by the end of the year, as opposed to other classes where more than half the students are weak.

Teacher management of learning calculus: The case of sequences in the first year of university mathematics studies

Imène Ghedamsi

Tunis University, IPEIT, Tunis, Tunisia, ighedamsi@yahoo.fr

In this paper, I present my methodological tool for analyzing regular mathematics courses on calculus *and an application of this tool in the transition from secondary school to university. The tool is based upon the Theory of Didactic Situations (TDS), and especially on the constructs of the "didactic contract" and the "milieu". The data are taken from the transcription of a regular lesson on sequence convergence which took place during a first year university course. The aim is to investigate in what ways university calculus teachers attend to students' prior knowledge in their teaching. The results are not surprising but the used tool does suggest a method of analyzing university teaching and its affordances or limitations for bridging the gap between secondary school and university.*

Keywords: Transition, sequence convergence, university teaching and learning, didactic contract, milieu.

AIM OF THE PAPER

It is widely acknowledged that the transition from secondary school to university on calculus requires students to move from a problem-solving orientation to a formal orientation. A previous study (Bloch & Ghedamsi, 2004), focussed on crucial differences between the secondary school mathematics contents and the university one on calculus, led to the categorization and the formalization of many important changes that should occur in the way students are required to work at the first year of their university studies. We deploy the TDS construct of didactical variables (Brousseau, 1996), which are defined as parameters that influence the mathematics students' work, to characterize these changes. Here are three main relevant didactical variables:

— The use of proof setting: At the first year of the university, the mathematics organisation on calculus is based on Bourbaki's rules; as a result students have to deal with proof by using formal definitions, theorems, logical operations such as negation of quantified predicates, reductio ad absurdum, etc. At the end of secondary school, calculus contents focus on graphic or numerical proofs and indeed on algebraic proofs. At most, students use general statements concerning the operations on the limits of convergent or divergent sequences to "calculate" a limit of a sequence given by its general term.

— The use of technical methods: At the first year of the university to solve calculus tasks an amalgam of technical methods is introduced, whereas, at upper secondary school, a few methods are very well identified and many exercises allow a work on each of them. Students then are never surprised by the work they have to achieve. Yet, at the university they have the responsibility of choosing the adequate technical methods. For instance, to check the convergence or the divergence of a sequence at the university, one can identify adjacent sequences, use sub-sequences, use Cauchy theorem, use De l' Hospital's rule, etc.

— The use of conversion between semiotic settings: At the end of secondary school, the tasks emphasize a fruitful conversion between the setting of algebraic semiotic representatives and the graphic one. These tasks become rather common and helpful for students' work. However, students have almost no possibility to take the initiative of using a graph in a heuristic way since these conversions are generally explicitly enunciated. At the first year of the university, there are no more

> graphs. Students have the responsibility to draw a diagram or a graph and exploit by themselves their potentialities as a heuristic support during a phase of a control or an exploration.

The modifications of the values of didactical variables in the transition from secondary school to university suppose changes in the didactic contract, which is "the implicit set of expectations that teacher and students have of each other regarding mathematical knowledge and regarding the distribution of responsibilities during the teaching and learning processes." (González-Martin et al., 2014, p. 119). In the case of the study above, the values given to the didactical variables are mutually exclusive which may lead to an alteration of major rules of the didactic contract.

According to these results, it is important to investigate the reality of the work during regular mathematics courses, especially the role of the teacher to manage such crucial changes into the students' work at the university. The research questions of this paper therefore are: To what extent does university teaching support the students' shift to formal calculus? How does university teaching help students learn through adjusting previous knowledge? Finally – and this is the main question explored here – how can we model teaching and learning processes in order to allow the assessment of both the students' actual work and the teacher's management of these processes?

For this, I demonstrate my methodological tool for analyzing teaching and learning processes in a regular lesson on calculus, with a particular focus on the transition from secondary school to university. Then, I apply the tool to analyze a regular lesson which took place at the first year of the university, on sequence convergence.

METHODOLOGICAL TOOL – ASPECTS OF MAIN TDS CONSTRUCTS

The central object of TDS is the notion of Situation which is "defined as the ideal model of the system of relationships between students, a teacher, and a mathematical milieu." (González-Martin et al., 2014, p. 117). The learning process is highlighted through the interactions taking place within such system.

In the Situation, the students' work is modelled at several levels with a main focus: on the action "knowing appears as means for action through models that can remain implicit" (p. 119); on the formulation "knowing develops through the building of an appropriate language" (p. 119) and on the validation "knowing becomes part of a fully coherent body of knowledge" (p. 119). The students' work grows up within a milieu "namely the set of material objects, knowledge available, and interactions with others" (p. 119) including the interactions with the teacher.

The foundations of TDS constructs focus on the optimization of interactions taking place within the system mentioned above, "in ways that maximize the students' responsibility for producing knowledge". The use of TDS at the university level compels researchers to reconceptualize the "maximal responsibility" (p. 121) given to the students and leads to an adjustment of the role of the teacher, especially in helping students overcome the new requirements at the first year of the university.

In this sense, in the transition between secondary school and university in calculus, teacher's interventions should not be neglected since he/she has the responsibility to manage students' evolution from problem-solving skills to formal calculus. These interventions should enrich the students' work and its evolution within and against a mathematical milieu during the phases of action, formulation and validation. González-Martin and colleagues (2014) illustrate the potency of TDS to design and to experiment Situations at university level, and demonstrate its application in three recent studies related to calculus and proof.

In regular (non-experimental) mathematics courses, the interactions taking place within the system formed by the teacher, the students and the milieu are governed by the actual didactic contract and evolve according to its nature. As a result, the quest for optimizing the interactions taking place within such system, as stressed in the TDS constructs, has to be the essence of methodological tool that will be used to analyze a regular lesson and that will allow the assessment of the students' actual work and of the teacher management. The emphasis on the phases of action, formulation and validation in the students' work materialize this quest. This should be done with taking into account teacher's interventions to manage these interactions.

Taking these considerations, the methodological tool for analyzing a regular lesson introduced in this paper focuses on two categories of students' utterances that deal with the phases of action, formulation and validation in the students' work; and three categories of teacher utterances, one related to managing interactions and two related to managing phases that support learning. The teacher categories are divided into subcategories that cater for the particularities of paradigmatic examples of didactic contracts (Brousseau, 1996). The definition of these subcategories is helped by the use of Robert's studies (2003; 2007))concerning teacher practices in order to achieve better meaning of transition phenomena. In particular, Robert (2003) attaches great importance to the organization of knowledge as a condition of learning and argues for the "comparison of several methods and the simultaneous operations of several properties at once, including old and new." (p. 70). The subcategories referring to students' work are outlined according to the structuring of the milieu. In the following, I set out the methodological tool with more explanations for each subcategory.

Teacher management

1) Management of interactions

   MI1: Initiate discussion by asking questions about specific knowledge in relation with the aimed one.

   MI2: Leave openings that help students to make a choice, to ask questions and to organize knowledge (Robert 2003; 2007).

   MI3: Abbreviate students' work, including questions.

   MI4: Splitting tasks into elementary subtasks, or specify technical methods to use. In this case, it imports to clarify whether the teacher limits the students' work to an application of juxtaposed knowledge (Robert, 2007).

   MI5: Guide students to take distance from what is happening and to work at the meta-cognitive level (Robert, 2007).

2) Management of action and formulation

   MAF1: Treat examples and counterexamples.

   MAF2: Support students' formulations by providing them with opportunities "to make conjectures, to experiment with heuristic solution, and search for adequate means of reasoning." (González-Martin et al., 2014, p. 122).

   MAF3: Foster the changing of knowledge context by developing an operational status of the notions, if any, by emphasizing relationships among notions, by changing the setting of semiotic representations, etc.

3) Management of validation

   MV1: Enunciate statements about knowledge

   MV2: Argue by using formal proof.

   MV3: Argue by using formulations, explanations, and by changing semiotic settings in a relevant way.

   MV4: Exemplify general statements and discuss the implications of these statements on a certain class of notions (functions, sequences, sets of real numbers, etc.).

   MV5: Make assessments of knowledge (local or global syntheses, including those relating to the use of formal rules of calculation).

Among some of these subcategories, the teacher's interventions do not enable students to undertake efficient interactions within the milieu and to progress in the learning process; this is the case of MI3, MI4, MV1 and MV2. The remaining subcategories emphasize the role that the teacher can play to enrich students' work especially in the case of MI2, MI5, MAF3, MV4 and MV5.

Students' work

1) Action and formulation

   WAF1: Formulate questions concerning specific knowledge in relation with the aimed one.

   WAF2: Express spontaneously knowledge by changing semiotic setting, by making examples and counterexamples, by linking several notions, etc.

WAF3: Formulate views on knowledge.

2) Validation

WV1: Indicate technical methods.

WV2: Perform on validation.

WV3: Discuss validation patterns proposed by peers or by the teacher.

When students demonstrated evidence of maladjusted knowledge, it is important to stress this in the analysis of the given lesson.

EXPERIMENTAL SETTING

Data collection

In Tunisia, mathematics courses at university level are organized into lectures and tutorials. The tutorial constitutes a setting to apply definitions and theorems already studied in the lecture. The lesson I focus on in this study functions as a tutorial, and concerns the applications of the main theorems of sequence convergence studied at the first year of the university. The sequence convergence is a concept met by the students from the third year of secondary school (scientific direction), which lasts four years in Tunisia, and which makes it possible to build a very rich and diverse corpus of knowledge.

This paper draws on the tasks planned by the teacher and the transcription of the whole lesson translated verbatim from French. The lesson lasted 2 hours in which approximately 30 students participated.

Mathematical tasks

Three mathematical tasks were planned by the teacher. The first one is related to the convergence of geometric sequences, the second one is related to the study of several sequences given by their general terms and the third one focuses on the use of Cauchy's theorem. In the following, I present succinct, *a priori* analyses of tasks in order to identify the mathematical milieu, namely the targeted knowledge, the students' previous knowledge and the elements that may optimize learning.

Task 1: General statements for geometric sequences

Let $(u_n)_n$ a sequence defined by $u_n = a^n$, $a \in \in \mathbb{R}$

1) *What is the nature* of the sequence if a = 0, 1 and -1?*

2) *We suppose $a \in]-1, 1[$ et $a \neq 0$. Prove that the sequence converges to 0.*

3) *We suppose $a \notin [-1, 1]$. Prove that the sequence diverges.*

* Across the text 'what is the nature of a sequence' is meant as 'Study this sequence in terms of its convergence or divergence"

At the end of secondary school, the theorem on the limit of geometric sequence is stated only for the case of]-1, 1[. The validation is based on the use of both the graphic semiotic setting and the numerical one. This is done by plotting and discussing geometric sequences graphs, or by computing terms of larger orders. Both cases show how the sequence tends to a specific value.

For this task, students have to pick out, among several university technical methods used to prove convergence or divergence, the relevant one in the case of such sequences. Some of the most useful methods to prove divergence at the first year of the university are: use formal definition; use Cauchy's theorem; prove that the sequence is not bounded; find two subsequences which don't behave the same way; etc.

Task 2: Sequences defined by general terms

What's the nature of these sequences?

$$u_n = (-1)^{\frac{n(n+1)}{2}}\left(1 + \frac{1}{n}\right);\ v_n = \frac{\cos(2n^3+1)}{n+1};\ w_n = \sqrt{n^2+1} - n;$$

$$t_n = \sin\left(\frac{n\pi}{2}\right);\ s_n = \frac{C_n^p}{n^p},\ p \text{ a natural number} \neq 0.$$

The study of $(v_n)_n$ and $(w_n)_n$ requires routine methods from the secondary school which correspond to the use of cosines properties and algebraic operations. The sequences $(t_n)_n$ and $(u_n)_n$ diverge, numerical calculation of some terms permit to identify subsequences to prove the non-convergence. The general term of $(s_n)_n$ is not familiar but its algebraic transformation permits to deduce that the sequence converges to $\frac{1}{p!}$.

Task 3: Convergence and Cauchy's theorem

1) *Let $u_n = 1 + \frac{1}{2} + \dots + \frac{1}{n}$, $n \geq 1$.*
Prove that $u_{2n} - u_n \geq \frac{1}{2}$. Deduce the nature of this sequence.

2) *Let* $v_n = 1 - \frac{1}{2} + \ldots + \frac{(-1)^{n-1}}{n}$, $n \geq 1$.
Prove that $v_n - v_m \leq \frac{1}{n+1}$, $0 < n < m$. *Deduce the nature of this sequence.*

This task requires more formal methods referring to logical operations such as negation of quantified predicates – which is nevertheless rather implicit – necessary condition, and sufficient condition. The intermediate subtasks allow students to use Cauchy theorem in order to conclude. Studying such sequences refers in reality to the study of $\sum_n \frac{1}{n}$ and $\sum_n \frac{(-1)^{n-1}}{n}$.

Under these conditions, the task is widely different from what is common at the end of secondary school. As said by González-Martin and colleagues (2014), "The role of the teacher becomes essential in helping students overcome their difficulties and fully grasp the subtleties they are confronted with." (p. 130).

Overview of transcript data according to each task

A global description of transcripts shows few interactions between teacher and students. Teacher utterances are generally isolated from those of the students. The students' utterances are short and the interactions among peers are non-existent. This compelled me to organize the analysis of the teacher and students utterances separately, and to do it in tandem when possible.

The lesson proceeded as follows in Table 1.

DATA ANALYSIS

Teacher management

The details of teacher utterances are as follows in Table 2.

About 26% of teacher utterances concern the argumentation by using classical formal proofs (MV2), but no interactions were observed with the students. Likewise, the utterances relating to the enunciation of statements about knowledge (MV1) aren't correlated to students' work and refer to the definition of convergence, theorems on the convergence, the definition of Cauchy sequence and its negation, etc. For instance, this is the case of the utterances (35 and 53) bellow:

35 Teacher: If $(a_n)_n$ tends to 0 and $(b_n)_n$ is bounded then $(a_n b_n)_n$ tends to 0.

The second utterance is the only one (from MV1) that is preceded by a student utterance formulated as a question:

23 Student: What's the negation of a Cauchy sequence?

53 Teacher: $(u_n)_n$ isn't a Cauchy one $\Leftrightarrow \exists \varepsilon > 0$, $\forall n_0 \in IN$, $\exists n \geq n_0$, $\exists m \geq n_0$; $|u_m - u_n| \geq \varepsilon$.

The teacher intervened only five times to argue by using formulation and explanation (MV3). Among these interventions (20, 26, 31, 34 and 39), one of them carries some students' knowledge:

6 Student: [talking about $\forall n \in IN$, $n \leq \frac{\log|M|}{\log|a|}$] This statement isn't true because IN isn't bounded!

20 Teacher: Yes, it'is absurd... this means that the set of integers is finished!

The rest of these utterances are isolated from students' work as shown below:

26 Teacher: [talking about $u_n = (-1)^{\frac{n(n+1)}{2}}(1 + \frac{1}{n})$] There's no problem for $\frac{1}{n}$ which tends to 0, then $1 + \frac{1}{n}$ tends to 1.

Task	Teacher utterances	Student utterances	Duration (approximately)
Task 1	1 – 24	1 – 7	35 min.
Task 2	25 – 45	8 – 22	50 min.
Task 3	46 – 57	23 – 24	20 min.

Table 1: Overview of transcript data

	MI_1	MI_2	MI_3	MI_4	MI_5	MAF_1	MAF_2	MAF_3	MV_1	MV_2	MV_3	MV_4	MV_1
Occurrence	7	0	4	10	0	3	3	0	10	15	5	0	0

Table 2: Details of teacher utterances

34 Teacher: [talking about $v_n = \frac{cos(2n^3+1)}{n+1}$] Cosine of any number is between -1 and 1.

39 Teacher: [talking about $0 < w_n \leq \frac{1}{n}$ and $\frac{1}{n} \underset{n \to +\infty}{\to} 0$] This statement isn't available for 0... there is no problem as we search limit on $+\infty$.

However, more than 60% of the total interventions concerning interactions (MI) don't contribute to lead students to make links between knowledge and especially their previous ones (MI3 and MI4). More precisely, in the utterances concerning (MI4), the teacher specifies university technical methods to use; this way of doing limits students' work to an application of juxtaposed knowledge, such as the use of sub-sequences, Cauchy theorem and the theorem on bounded sequence. This is the case of utterances (9, 14, 16, 36 and 40) highly linked to students' work:

2 Student: $|u_n| = |a^n| \prec \varepsilon \Leftrightarrow |a|^n \prec \varepsilon$

9 Teacher: We can apply logarithm for the two members of the equality! [to prove that geometric sequence is convergent given $a \in]-1, 1[$ and $a \neq 0$]

In the utterances 14 and 16, teacher seems to limit the choices of the students by imposing over and over again his technical methods:

4 Student: We can use the subsequences! [to prove that geometric sequence is divergent given $|a| > 1$]

14 Teacher: Perhaps, we also can use a reductio ad absurdum.

15 Teacher: What's the main property of a convergent sequence seen in the lecture?

5 Student: A convergent sequence is a Cauchy one.

16 Teacher: Otherwise, it's bounded and then we suppose it and we conclude that it is absurd.

The teacher reacted in the same way for the utterance (36) that follows:

16 Student: $w_n = \sqrt{n^2+1} - n = \frac{1}{\sqrt{n^2+1}+n}$.

36 Teacher: We can put $\frac{1}{\sqrt{n^2+1}+n}$ between two members that converge to zero.

The teacher kept on imposing his technical method for the utterance (40):

20 Student: $t_n = \sin(n\frac{\pi}{2})$, $t_0 = 0$, $t_1 = 1$, $t_2 = 0$, $t_3 = -1$, $t_4 = 0$.

40 Teacher: It's clear that the sequence diverges. You can easily find subsequences which converge to different values.

Among teacher utterances which explicitly abbreviate students' work (MI3), the following one prevents student to use his/her own method to prove that the sequence converges (for the others, 37, 38 and 56 see students' work section):

7 Student: In this case we can use subsequences to prove that the sequence diverges.

22 Teacher: This is not fast. [meaning the method]

Finally, only 10% of the teacher utterances could help students' work in the phases of action and formulation (MAF). These interventions focus on the potentialities of the graphic setting or the numeric one to make conjectures, as well as, permit to investigate some examples and counterexamples related to aimed knowledge. Nevertheless, these interventions are initiated by the teacher and isolated from students' work.

Students' work

The details of students' utterances are anonymized and are as follows in Table 3.

Among the few questions asked by students (WAF1), three of them (17, 19 and 24) were shortened by the teacher (students who intervened in the exchange below aren't the same):

17 Student: Can't we directly calculate its limit? [talking about the sequence $w_n = \frac{1}{\sqrt{n^2+1}+n}$]

37 Teacher: Well! You're used to do this at the secondary school. Now I apply the theorem on sequence bounded.

	WAF_1	WAF_2	WAF_3	WV_1	WV_2	WV_3
Occurrence	4	7	0	3	10	0

Table 3: Details of students' work

18 Student: $0 < w_n \leq \frac{1}{n}$ and $\frac{1}{n} \underset{n \to +\infty}{\to} 0$ then $\lim\limits_{n \to +\infty} w_n = 0$.
19 Student: What's the theorem on sequence bounded?
38 Teacher: You saw it in the lecture.

A little further:

24 Student: Why n is an integer different of zero? It isn't mentioned in the definition of a sequence?
56 Teacher: It depends on the sequence.

However, the few students' interventions which express spontaneous knowledge (WAF2) emerged in response to questions posed by the teacher (MI1). Nevertheless, both the teacher questions and the students' responses are basic and are not significant of real requirements on convergence.

Finally, students' work in the phase of validation (WV) is rather thin. In this phase, students employed technical methods widely used at the secondary school; some of their interventions are expressed in tandem with the teacher ones.

RESULTS

In this paper, I present my methodological tool, based on TDS constructs, for analyzing a regular lesson on calculus. The application of the tool for analyzing a regular lesson on convergence sequence at the first year of the university allows a global illustration of teacher management and its implications for the learning process, as well as a more local description of effective learning about the convergence of sequences, if any. In this situation, the teacher seems not to care much about students' work as he doesn't intervene to enrich this work by emphasizing relationships among notions, by changing the setting of semiotic representations, by allowing openings to organize knowledge, by making assessments of knowledge, etc. The interventions of the teacher failed to enable students to undertake efficient interactions with the mathematical milieu. For instance, he limits the choices of the students by imposing over and over again university technical methods, as well as, by abbreviating efficient students' interventions including questions that may contribute to make links between knowledge. Furthermore, the few teacher interventions that focus on the potentialities of secondary semiotic tools are initiated by him and isolated from students' work. The teacher's use of the formal semiotic tool is done in an "ostensive way" (Brousseau, 1996, p. 45), which is defined as the act of the teacher who "shows" a mathematical object under the illusion that the students see the object that this "showing" aims to achieve. As a result, students' work is not consistent. The students express basic knowledge with little appropriate knowledge on convergence at the university level. During the whole lesson, the students use methods from secondary school and do not succeed to shift to the use of methods expected at university level.

Mathematics in Engineering: The professors' vision

Gisela Hernandes Gomes and Alejandro S. González-Martín

Université de Montréal, Département de Didactique, Montréal, Canada, gisela.hernandes@umontreal.ca

The debate surrounding the teaching of mathematics in Engineering courses has inspired research for more than a century. However, Engineering students still have difficulties in recognizing the mathematics required to solve problems in non-mathematical contexts. In order to study the vision of mathematics adopted by Engineering teachers and understand its role in shaping teaching practices, we interviewed two Engineering teachers with different backgrounds: one with BSc in Mathematics and MSc and PhD in Engineering, and another with BSc, MSc and PhD in Engineering. Our data reveal differences in the way these teachers approach topics such as mathematical rigor and approximation, and identify challenges faced by their students when working with modelling.

Keywords: Engineering, teachers' background, rigor and approximation.

INTRODUCTION

Mathematics is an important domain in science and technology, and is taught in a variety of university programs such as Administration, Economics, Computation, Engineering, and many other scientific fields of study. In Engineering, the interpretation and solution of certain problems require the direct application of mathematical models. To understand and analyse these mathematical models, it is often necessary to use elements of statistics, linear algebra, or differential and integral calculus. This is one reason why the teaching of mathematics in Engineering courses has been addressed in studies as far back as the early twentieth century (Howson et al., 1986, p. 159). Some authors, such as Murakami (1988), have suggested that mathematics should be taught to Engineering students by mathematicians with the help of engineers, with the latter selecting suitable exercises, to create a learning environment more in tune with students' professional realities.

Cardella (2006) sought to better understand how Engineering students use mathematics. She also identified the mathematics Engineering students use, and consequently, the brand of mathematics that should be taught in Engineering programs. Her results show that Engineering students use mathematical thinking in various ways to solve problems while designing a project (they apply informal and intuitive knowledge of a given mathematical field; employ facts, definitions, algorithmic processes, etc.). She noted the importance of these various types of mathematical thinking, indicating that professors must carefully address students' mistakes throughout their learning process to ensure they understand what is being taught. Regarding teachers, Maaß and Gurlitt (2009) noted that teachers' knowledge of and beliefs on a given topic influence the way they plan, select, implement, and assess tasks. Later, and Maaß (2011) agreed with Schoenfeld (1992), who states that if we know teachers' resources, goals, and orientations — including their beliefs — we can better explain their actions. In this same vein, the study of Clark and colleagues (2014) provides a framework that divides into four categories those elements that can influence teachers' beliefs: "(a) teachers' professional background and experiences, (b) teacher knowledge, (c) teaching contexts, and (d) students' experiences" (p. 251). The conjecture that different teachers will give different lectures on the same topic on the basis of their knowledge and beliefs was confirmed at the university level by Pinto (2013). Pinto analysed the way two different university instructors implemented an identical course plan (both were capable teachers with a solid background in mathematics). He showed that the two instructors held different beliefs, attitudes and objectives and demonstrated varying degrees of confidence in different resources. As a result they offered two substantially different lessons.

Regarding the teaching of mathematics through applications and modelling in the context of Engineering education, Cardella (2006) drew on the work of Schoenfeld (1992) and Doeer (2007) in recognizing the need for mathematics instructors in Engineering programs to better understand how mathematics and mathematical thinking are used in Engineering. She admits that instructors should be familiar with the mathematical content necessary for engineering, and should consider the importance of problem solving, resources, attitudes, practices and of the learning environment.

In this vein, we are interested in identifying and discussing the attitudes and beliefs of instructors with different academic backgrounds to pinpoint how these beliefs influence their teaching of mathematical elements in Engineering programs. To do so, we follow Schoenfeld's approach to mathematical thinking.

THEORETICAL FRAMEWORK

To analyse the mathematical elements preferred by Engineering teachers with different backgrounds, we draw on Schoenfeld's (1992) proposal of five aspects of mathematical thinking: 1) knowledge base, 2) problem solving strategies, 3) monitoring and control, 4) beliefs and affects, and 5) practices. Of these five elements, we focus on the fourth, because we are interested in analysing teachers' beliefs and whether their different backgrounds (as mathematicians, physicians, or engineers) can influence their attitudes and their teaching practices. At this stage of our research, we do not draw on Schoenfeld's later work (1998), which provides a "theoretical account of how and why teachers do what they do [...] why they are engaged in the act of teaching" (p. 1); instead, we draw on his early proposal (1992), since we base our research on Cardella (2006), who in turn based her own work on this early proposal, which discusses "what it means to think mathematically" (p. 334), including the dimension of beliefs.

Using Schoenfeld's work as a basis, Cardella (2006) refers to beliefs and affects in the following way: "an individual's beliefs about and feelings towards mathematics influence how and when the problem solver uses mathematics. These beliefs and affects may be cultural beliefs or affects, or they may be particular to the individual problem solver. Additionally, an instructor's beliefs and affects may affect the student's practices." (p. 26). Cardella concluded that one of the most frequent beliefs observed in the execution of Engineering projects was the "Need to be Precise" (p. 119) promoted by teachers. For her, "this belief impacted the way that the team [working on a project] dealt with Uncertainty and also affected their use of Estimation." (p. 119).

According to Schoenfeld (1998), the "definition of thinking mathematically includes having a solid knowledge base, but it also includes knowing a wide range of problem solving strategies, having modelling skills, metacognitive skills, productive beliefs, and more" (p. 79). This vision of *thinking mathematically* is broad and goes beyond mathematical content knowledge and its relationships; other elements are assigned importance as well, and beliefs about mathematics and mathematical activity are also a part of this expanded vision of *thinking mathematically*. For Schoenfeld (1992), teachers' beliefs about mathematics determine the characteristics of their classroom environment. In turn, this environment "shapes students' beliefs about the nature of mathematics" (p. 359). According to Schoenfeld, "whether acknowledged or not, whether conscious or not, beliefs shape mathematical behavior. Beliefs are abstracted from one's experiences and from the culture in which one is embedded. This leads to the consideration of mathematical practice" (p. 360). Certain practices identified by Cardella (2006) in Schoenfeld's work point to elements in the practice of Engineering teachers, such as: "making multiple conjectures, coming to grips with uncertainty, defending claims mathematically, engaging in a science of patterns, extracting tools from the solution of complex problems, having a mathematical point of view, mathematical sense-making, using symbolic representations and manipulating symbols" (pp. 18–19).

Cardella (2006) followed this approach to study the beliefs of Engineering students' that emerge through their work on projects. Her research influences ours, in which we seek to analyse the beliefs of Engineering teachers with different backgrounds and education.

METHODOLOGY

To pinpoint the different beliefs regarding mathematical elements that emerge from distinct teaching practices, we interviewed two teachers (T1 and T2) from the Engineering school in a private university in São Paulo (Brazil). T1 and T2 have different backgrounds: T1 is a female teacher with BSc of Mathematics, MSc of Space Engineering and Technology, and PhD in Mechanical Engineering. T2 is a male teacher with BSc, MSc and PhD in Mechanical Engineering. T1 has taught at the university for seven years, giving courses in Differential and Integral Calculus, Analytic Geometry, and Linear Algebra. T2 has been teaching at the university for six years. His courses include Introduction to Computational Science, Mechanics of Solids, and Resistance of Materials. In addition to the aforementioned courses, both teachers supervise students' capstone projects in the Production Engineering (T1) and the Mechanical Engineering (T2) programs. Because student supervision is common to both teachers, and considering Cardella's work, which focused on capstone design projects and the use of mathematics in a design problem, we centred our research on the teachers' supervision of student projects to identify implicit beliefs concerning the role and use of mathematics in Engineering programs. The interviews addressed the instructors' teaching practices, in particular their approach to the supervision of students completing their capstone projects. The teachers were interviewed together on two occasions to initiate dialogue between them and draw out contrasts between their different visions and beliefs. The first interview centred on the teachers' supervision of capstone projects in general and their approach to this supervision. The second interview focused more on the supervision process for two specific capstone projects that the teachers singled out during the first interview: Artificial Neural Networks Applied to the Prediction of Values in Sao Paulo's Stock Market, the project supervised by T1, and Software of Simulation Applied to Mechanical Engineering, supervised by T2. Students are required to develop their own capstone project over one and a half years (the last three semesters of the Engineering program). During the first six months, students must select a topic and a supervisor, learn the norms of scientific writing, and begin creating a review of literature in a course entitled Scientific Methodology. In the second semester, supervisors begin meeting with students weekly or biweekly to oversee the project's design, data collection, and the students' first analysis. In the third and final semester, students must finish their project and present it to a panel comprised of two teachers and their supervisor.

The interviews were semi-structured and addressed a variety of topics to extract as much information as possible on the supervision process for capstone projects. In this paper, we focus only on those elements that emerged from the interviews pertaining to the teachers' beliefs, in line with the elements related to beliefs identified by Schoenfeld (1992) and Cardella (2006). These elements illuminate the teachers' approach to supervision, which may influence the way their students use mathematics or how they design their projects. The topics originally proposed for the interviews were: 1) the academic and professional background of each teacher; 2) the supervision of the capstone projects and how this supervision was conducted; 3) the use in these projects of content studied in the Engineering program; 4) difficulties the students encountered while working on the projects; and 5) the resources proposed by the teachers and used by students in completing their projects.

DATA ANALYSIS

After transcribing the two interviews, we created codes based on the teachers' responses and discussions, which allowed us to categorise thematically our data. This codification process was not linear, necessitating multiple readings of the interviews to draft the first codes, which were subsequently divided into subcategories (these subcategories were created because some categories allowed for more than one possible response). The codes were then recombined according to their conceptual similarities or differences, to define the final categories and subcategories (Figure 1).

Both teachers started the interview by providing details of their academic education and their experience in teaching courses and supervising projects in their university's Engineering program. T1, who has a background in Mathematics as well as Engineering, raised the importance of addressing the students' needs:

T1: [...] I came from the Polytechnic School, where I did my PhD working with Artificial Intelligence, neural networks, and genetic algorithms. What could I offer to the student in Production

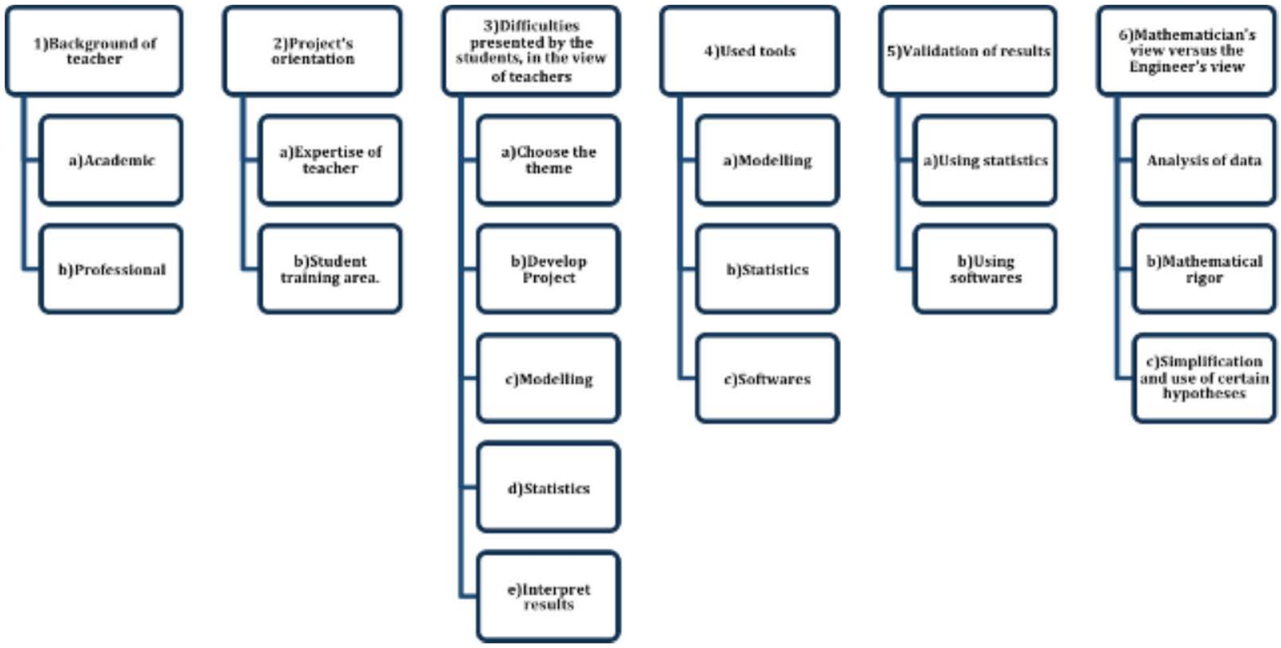

Figure 1: Final categories and subcategories

Engineering? For me to feel reassured, since I was also starting to supervise.

One of the elements mentioned by Schoenfeld (1992), *developing competence with the tools of the trade*, figures prominently in T1's response. In discussing her first experiences supervising students for their capstone projects, she revealed concerns about her ability to adapt her knowledge, which she considered atypical for Production Engineering; we observed that she felt it important to integrate her knowledge in a way that is useful to her students.

Unlike T1, T2's background is in Mechanical Engineering exclusively. However, like T1, his students study topics outside the scope of his education. His courses include Computing and Programming for Materials Engineering, a course in Electric Engineering and another in Mechanical Engineering. On supervision, he noted:

T2: I supervise students in Mechanical Engineering for a simple reason: because I'm a mechanical engineer and within my field of expertise it's more advantageous [...]

We observed a tendency in T2 to supervise students whose capstone projects relate to his field of research, resulting from a belief that it is easier to supervise projects that fall within one's area of expertise, where one masters *the tools of the trade* (Schoenfeld, 1992). Later in the interview, when discussing a particular Mechanical Engineering student's project involving the measurement of a frame, T2 stated:

T2: [...] with some measurement instruments, you measure the deformations of this frame and obviously it's subject to a static charge, which doesn't happen in reality.[...] And then, as you make a static trial, you affect that result with a coefficient, making the effect bigger. And there you judge, as if it were subject to a real condition, what is in fact an approximation. You can also do it with more sophisticated experimental equipment [...] All of that is experimental. You can also make a mathematical simulation, using computer programs, which are professional, commercial, available in the big firms, in the general market.

With statements such as "which doesn't happen in reality" and "what is in fact an approximation", T2 revealed some of his beliefs about mathematics, as an engineer who deals with approximations of real situations solved using computer simulations. This supports Cardella's findings (2006), who pointed out that engineers, when designing a project, work with approximate dimensions and make comparisons with already existing data to verify whether the ideas they propose fall within acceptable limits. According to Cardella (2006), this aspect of an engineer's way of thinking could be classified as a mathematical practice used by engineers. Cardella (2006) refers to Gainsburg (2003), who observed a tendency towards conservatism in structural engineers: "to understand a value or procedure as conservative is to attribute to it a broadly general and widely applicable quality, defined informally as 'safe'." (p. 9). Cardella observed that engineers adopt this attitude to ensure they meet minimum criteria, and that for more precise solutions, they reduce the margin of conservatism when it is justifiable to do so. She also found that despite the lack of precision inherent in "conservatism," engineers still use " = " rather than inequalities such as " > " or " < " (Cardella, 2006, p.20).

T2 also discussed software used to model certain structures. However, he stressed that students encounter difficulties using the software and when modelling problems. Many of his responses indicate that software and modelling are typically used by engineers to solve problems – in agreement with Cardella's (2006) model concerning required knowledge for teachers of mathematics in Engineering – and they revealed T2's awareness that students have difficulty with both.

T1 discussed the case of a Production Engineering student interested in economy and the stock market. T1 provided the student with data sources to allow the student to build an artificial neural network, and after a few simulations, they achieved satisfactory results: "the network had worked, the results were perfect regarding what we had seen in the site". However, for T1, it was still necessary to validate the results:

T1: What else can be done for some work, to give it a better basis, to really being able to say: "Ah, this work doesn't have any problem. Oh, let's do the statistical analysis of this data". And then, [the student] performed all the parts regarding regression.

In this excerpt, we can observe elements arising from a belief that only mathematics can be used to prove the validity of a solution found using other tools (in this case, she used statistical analysis), even when the results are satisfactory as a whole. The use of statistics is also identified as a way to validate knowledge obtained through results analysis. Regarding this last point, T1 added:

T1: [...] the analysis performed by a mathematician regarding that data is different from that performed by an engineer.

At this point, T1 was asked to define the difference, and an interesting exchange between T1 and T2 ensued:

T1: The difference I see: within Engineering, we don't need the exact, exact, exact value, as it is treated with all that...
T2: Rigor.
T1: The rigor with which it's treated in mathematics.
T2: The engineer... let's say he makes some hypotheses to simplify.
T1: Exactly. And she [the student] started from those hypotheses.

To further this discussion, the teachers were asked to elaborate their ideas of what constitutes mathematical rigor. T2 provided an example concerning the resistance of materials, called bending displacement:

T2: Among the different methods to determine the bending displacement, there's [one] called the method of the differential equation of the elastic line of the beam. The elastic line is that configuration the beam acquires when it's deformed because of the load. The equation from which all the textbooks start off, it's a second degree, second order differential equation. A very complex equation. And engineers, based on the fact that in a project – in the majority of projects, to speak carefully – we assume that in the angular displacements the slope is very small, the tangent to the angle, when the angle is very small it's almost the very same angle. And there, a first derivative which makes that differential equation harder for us... and which is to the square, we say it's so small, so small, that it's not considered...

T2 identified elements of mathematical practises that engineers use to solve complex problems, and noted their use of certain hypotheses to simplify mathematical calculations. T2 suggested that these practices are not well regarded by mathematicians:

T2: And there, mathematicians get... crazy. They say no, that's not the exact solution. That "we" [the engineers] are lying. And no. I'm just saying that the dislocation, the angle is so, so, so, so, so small, that I'm not gonna worry, and actually in reality it doesn't make a difference. I just simplify...

We see that T2 uses hypotheses to simplify calculations. Cardella (2006) identified this as a solving strategy used by students, which she termed "problem transformation" (p. 88). This strategy seeks both to simplify problems and transform them into familiar problems. Furthermore, we observe in T2 a way of speaking which seems characteristic of an engineer, using a language different from that of a mathematician (Nicol, 2002). Authors as Godfrey (2013) have labelled this as "An engineering way of thinking".

In addressing the notion of rigor, T1 came back to the work of her student in Production Engineering:

T1: In my specific case, when I speak about this mathematical rigor, when you look at a residual graph and you see the dots disperse or not, that interpretation is very subjective. Then, you take a graph [...] and you go validate with others. And there, I think they look alike, she can think they don't, but what was really important for us was to verify whether the system which had been modelled was giving us a prevision as close to reality as possible, which were the data we originally had. And she got to 98.6% of accuracy. [...] Furthermore, that rigor in Engineering is not considered, especially taking into account that the aim was actually to have a prevision of the data, using a computer tool, which is what was done. We wanted to use an artificial intelligence tool to know whether that tool was capable of doing the prevision. That was done, it was shown and with efficacy.

Again, here we can observe her belief that rigor in mathematics and rigor in Engineering are not the same. This aspect of her mathematical thinking (belief) may have a strong impact on others (monitoring and control, problem solving strategies, practices), and could influence her approach to the teaching of mathematics. Elsewhere in the interview, when discussing her first-year Engineering courses in Differential and Integral Calculus and Linear Algebra, T1 stated:

T1: For me it's extremely important to have that mathematical rigor [...] at the beginning. Mathematics is an extremely important science; [...] even Engineering can't live without those calculations, although in some cases you have: "Ah, it's negligible" or "You don't need a rigor as mathematical as when a mathematician does mathematics". That's one point. Another point is: [the student] needs to know the bond between mathematics, which he has in the first courses, and what he uses in the technical courses. Actually, we try to do that [...], trying to show him that he's gonna use that tool later, the link between all those calculations and the technical courses.

Her response reveals her desire to broaden her students' ability to *think mathematically*, and her beliefs appear to influence her approach to teaching. In the case of T1, we observe a more explicit concern for rigor, and an awareness of the dichotomy between what a mathematician would do and what an engineer would do. According to Schoenfeld (1992, p. 359), these beliefs may determine the way she teaches and, as a consequence, shape her students' beliefs about the nature of mathematics.

FINAL REMARKS

The aspects identified in this study, although taken from interviews with just two teachers, are in keeping with the literature review and the theoretical framework, and they inspire reflection about mathematical practices in Engineering courses.

One issue identified in the teachers' responses concerns mathematical rigor versus approximation. On the one hand, the teachers require students to know (T1) or at least follow (T2) formulas with all the rigor characteristic of mathematics. On the other hand, in applying mathematics to the practice of Engineering and in resolving problems, certain assumptions are made in order to simplify calculations (T2), which corroborates Cardella's research (2006) on the practices of Engineering professors. When results obtained through this process are close to those anticipated, based on the literature, they are deemed satisfactory by engineers. Regarding modelling, both T1 and T2 identified some difficulties related to 'approximation' and data analysis, which is in accordance with Doerr (2007) with respect to the challenges faced in teaching.

Our analyses have identified certain mathematical elements that could be classified according to the elements of mathematical thinking of Schoenfeld (1992) and in keeping with Cardella's (2006) arguments. However, we believe more research is needed in this area. Specifically, more observation of teaching practices is required, particularly of teachers with different backgrounds. Future research could look at the connections between teachers' beliefs, backgrounds, teaching practices and choices, and identify possible consequences for their students' learning. We intend to explore these aspects further in our future research.

Engineering students in Spain and Germany – varying and uniform learning strategies

It is a pattern common to many countries that engineering students have trouble passing mathematics. The manifold reasons so far explored mirror various perspectives on the transition from secondary to tertiary education. Focusing on learning strategies presents a promising supplement to this range, as they have the potential to account for its cognitive complexity and affective considerations. By means of the LIST questionnaire, we explored learning strategies for two samples of 113 Spanish and 159 German engineering students. The findings show that both samples differ regarding their scoring on the scales Organizing, Elaboration, Repeating, and Metacognition. Finally, five clusters were used to group students according to their similarities, supporting the decisive role of metacognitive skills.

Keywords: Engineering, learning strategies, secondary-tertiary transition.

INTRODUCTION

For many engineering students, learning mathematics in tertiary education is a critical issue. They encounter epistemological/cognitive, sociological/cultural and didactical obstacles (cf. Guzman, Hodgson, Robert, & Villani, 1998) as mathematics at university differs significantly from school mathematics. Some authors even label the transition "abstraction shock" since university mathematics adds a formal world to the mathematics encountered at school (Artigue, Batanero, & Kent, 2007; Tall, 2004). Besides these studies that focus on cognitive perspectives, other researchers additionally identified epistemological, conceptual, social-cultural, motivational as well as metacognitive and affective variables having an influence on students' performance. Some authors explicitly elaborate on specific learning strategies students may not have developed throughout school time (Rach & Heinze, 2011). These learning strategies address a combination of both skills and attitudes such as self-organisation, perseverance and frustration tolerance (cf. Pintrich, Smith, Garcia, & McKeachie, 1991; Weinstein & Palmer, 2002; Wild & Schiefele, 1994). In particular, investigating the role of learning strategies allows for revealing the cognitive dispositions as well as affective barriers and pathways, and studying the interrelations between them (Wild, 2005).

Both Spain and Germany face alarmingly high numbers of students giving up studying due to mathematical problems. In engineering courses in Spain, students were usually enrolled for 52.4 credits, but only succeeded passing 31.8 credits, mathematics being one of the subjects with the highest fail rate (MEC, 2013; Rodríguez Muñiz, 2011). The situation is comparable in Germany as 48% of engineering students fail in their first year university studies (Heublein, Richter, Schmelzer, & Sommer, 2012). In this paper, we explore for the two countries which cognitive dispositions and beliefs of students seem advantageous to successfully continue their studies.

THEORETICAL FRAMEWORK

Studies exploring the transition from school to tertiary education mostly concentrate on cognitive aspects when it comes to question challenges in mathematics. These studies elaborate on cognitive difficulties and conceptual obstacles that students experience in how mathematics is communicated to them (Artigue, Batanero, & Kent, 2007), particularly referring to the formal level of university mathematics and the prevalent role of proofs within (Selden & Selden, 2005).

Cognitive processes involve affective stances that moderate the tension between modes of intuitive and analytical thinking (e.g., Fischbein, 1987; Stavy & Tirosh, 2000). In particular, the theory of dual processes in cognitive psychology has been adapted to mathematics education, and the role of affective variables has been pointed out in this context (e.g., Gómez-Chacón, García-Madruga, Vila, Elosúa, & Rodríguez, 2014). Some studies additionally investigate the connection between affective variables and student performances. Findings reveal that students' cognitive reflection, as a metacognitive variable, their beliefs about mathematics, and their self-efficacy, are all correlated positively and significantly with mathematical achievement (Gómez-Chacón, García-Madruga, Rodríguez, Vila, & Elosúa, 2011; Gómez-Chacón et al., 2014). There is also evidence that metacognition impacts positively on learning strategies which in turn influences achievement (Griese, Glasmachers, Härterich, Kallweit, & Rösken, 2011).

An instrument focusing on cognitive, metacognitive and resource-related strategies is presented by the LIST questionnaire comprising 13 dimensions of learning strategies grouped accordingly. The LIST questionnaire (Wild & Schiefele, 1994) for measuring learning strategies in academic studies was first compiled in the 1990s and has since been modified and tested several times. It encompasses general items that can be applied to all kinds of subjects (for examples, see Table 1 below) and uses Likert scales. One root of the LIST questionnaire is the Motivated Strategies for Learning Questionnaire (MSLQ) which measures college undergraduates' motivation and self-regulated learning relating to a special course (Pintrich, Smith, Garcia, & McKeachie, 1993). Apart from *Motivation*, the scales from LIST are derived directly from MSLQ, although the number of items varies. The main difference between the two questionnaires is that MSLQ puts more emphasis on including different aspects of motivation as *Goal Orientation*, or *Control of Learning Beliefs*. Another essential study influencing the LIST questionnaire is the Learning and Study Strategies Inventory (LASSI) by Weinstein and Palmer (2002) which also separates cognitive aspects. LASSI scales partly cover the same contents as LIST though holding different names. As there are no analogous German / Spanish questionnaires on learning strategies, our study opted for the LIST questionnaire, thus hoping for the further asset of a parallel instrument for both countries.

RESEARCH QUESTIONS

In both countries engineering students struggle with mathematics, and in a first attempt to capture differences or commonalities, we used parts of the LIST questionnaire to explore students' learning strategies with respect to *Organizing, Elaborating, Repeating* and *Metacognition.* We therefore translated the German LIST questionnaire into English and then into Spanish (and back into German for additional dependability) and checked for scale reliability. Finally, we investigated if students can be grouped based on their ratings of the different dimensions of the questionnaire. In our comparative study, we particularly pursued the following research questions:

Research question 1a: Does the Spanish translation of the LIST questionnaire yield sufficient scale reliability?

Research question 1b: How do Spanish and German engineering students' differ with respect to their learning strategies?

Research question 2: How are the different learning strategies of students in both countries correlated?

Research questions 3: How can students from both countries be classified with respect to their learning strategies?

METHODOLOGY

Participants and instrument

The two samples from Spain and Germany are comparable in terms of age, gender percentage, and academic year in engineering studies. Moreover, their academic courses are similarly organised.

113 (71.7% male) Spanish undergraduate students attending the first academic year of the *Industrial Engineering Degree* participated in this study. Students enrolling in this course must have obtained high scores in the test of university entrance, even higher than for other engineering degrees. The mathematics module consists of 200 minutes of traditional lectures per week, with optional tutorials and digitalized learning material. The examination is a written test with a focus on calculation and normally without proofs. If students fail, they must retake the course.

Dimension	# Items	Example Item
Organizing	8	I go over my notes and structure the most important points.
Elaborating	8	In my mind I try to connect newly learnt facts to what I already know.
Repeating	7	I learn the subject matter by heart using scripts or other notes.
Metacognition (Planning)	11	Before starting on an area of expertise, I reflect upon how to work most efficiently.

Table 1: LIST dimensions and example items

159 German students (72.3% male) were selected from a larger sample from an ongoing research project to match the Spanish data. The German students had enrolled in different kinds of engineering courses at a university (meaning a slightly more challenging course, compared to a technical college) all starting with near identical mathematics lectures in traditional format, lasting 180 minutes per week, with optional tutorials and digitalized learning materials. As in Spain, there is a written test with focus on calculations. If students fail, they must retake the course, multiple fails result in expulsion. In both groups of students, attendance of lectures is optional and often low.

Originally, the LIST questionnaire comprises 13 dimensions of learning strategies, grouped into cognitive, metacognitive, and resource-related strategies. They each contain between three and eight items. For the study at hand we concentrate on cognitive and metacognitive strategies; an overview on example items is provided in Table 1.

The *Metacognition* scale contains the three subscales *Planning*, *Monitoring* and *Regulating*.

Data analysis

In both cases (Spain and Germany) the data was analyzed by computing the means, standard deviation and internal consistency (Cronbach's α) for each of these scales of the survey (based on Likert scales, from 1 to 5 respectively from 1 to 4); the correlation between scales; the factor pattern matrix; and clusters. Factor analysis was conducted using the extraction method of *Principal Component Analysis* and the rotation method of *Varimax* with Kaiser normalization. For rescaling the data, we calculated $2.5[1/n(x_1+...+x_n)-1]$ for the 5-point Likert scales respectively $100/3[1/n(x_1+...+x_n)-1]$ for 4 points and were thus able to correct the effect of the different numbers of items in different scales. This finally yielded scores from 0 to 100 (scale scores under 25 describing rare use, between 25 and under 50 infrequent use, between 50 and under 75 regular use, 75 or more continual use of the learning strategies).

Regarding clustering the data, the most common partitioning method is the k-means cluster analysis. Conceptually, the k-means algorithm follows the following process: it selects k centroids (k rows chosen at random), assigns each data point to its closest centroid (determined by the Euclidean distance), recalculates the centroids as the average of all data points in a cluster (i.e. the centroids are p-length mean vectors, where p is the number of variables) and assigns data points to their closest centroids. Steps 3 and 4 are repeated until the observations are not reassigned or the maximum number of iterations is reached. The distances are reported in Table 2.

The results obtained show the closest clusters are 1 and 5 or 1 and 3. For the hypothesis contrast, we obtain that the clusters represent data in variables of *Organizing*, *Elaborating*, *Repeating*, *Planning*, *Monitoring* and *Regulating* because of having $p<0.0001$ for values of the p-values. We note that for mathematic academic performance the centroid of this variable is 0 in some clusters and we have significance $p<0.02$ for mathematic academic performance.

Clusters	2	3	4	5
1	56.14	44.00	55.01	39.45
2		61.91	95.47	46.06
3			52.09	44.50
4				54.85

Table 2: Distances between the final centroids

RESULTS

Research question 1a. We calculated scale reliability for the factors *Organizing*, *Elaboration*, *Repeating*, and *Metacognition*. All Cronbach's alpha values are higher than 0.7, except for *Metacognition* in the Spanish study, see Table 3. In sum, the results show sufficient reliability between the different items. The comparative analysis between both countries indicates that there are no significant differences, except for *Elaborating* strategies. For this dimension, Cronbach's α is slightly higher in the Spanish study.

Research question 1b. The results of the factor analysis let to the four main dimensions *Organizing*, *Elaboration*, *Repeating*, and *Metacognition* and the three subscales *Planning*, *Monitoring* and *Elaborating* for the *Metacognition* scale. The variance explained by this factor structure is 54.7 % for the Spanish data and 43.92 % for the German data. In Table 4 we provide an overview on how the students rated in the different dimensions. Students' learning strategies differ significantly across the two countries. In all factors of the LIST questionnaire, except for *Monitoring*, we noted distinctly higher values for the mean in the Spanish than in the German results. For this metacognitive variable there are no significant differences between both means. In terms of standard deviations, Spanish students on the whole produce lower values.

Regarding the maximum and minimum scores, they are the exactly the same for *Organizing* and *Regulating*. For *Elaborating*, *Planning*, *Monitoring*, and *Metacognition* as a whole, the maximum value is higher in Germany, for *Repeating* it is lower in Germany. For the minimum values, we obtain significant differences between all variables but *Organizing*. The results show that the Spanish minimum values for these variables are always higher than the German ones.

Research question 2. In addition to comparing the means for the Spanish and the German data, we explored the correlations among the factors. An overview is provided in Table 5, where the additional variable *Mathematics Academic Performance* is coded as 1 for pass and 0 for failing the exam. It is worth to point out the highly significant strong correlation of the variable *Organizing* (defined as the ability to structure and restructure matter) with the three variables of metacognitive skills: *Planning* (r_S=.45 for Spain, r_G=.48 for Germany), *Monitoring* (r_S=.51 respectively r_G=.48) and *Regulating* (r_S=.46; r_G=.34). In the German data, there are significant and strong positive correlations between *Organizing* and *Repeating* (r_G=.60), *Elaborating* and *Monitoring* (r_G=.52) and *Repeating* and *Monitoring* (r_G=.57). For the mathematic academic performance, results show a negative (though not significant) correlation with *Repeating* for the German data (r_G=-.47) which cannot be found in the Spanish sample.

Research question 3. We realized a k-means cluster analysis with the 272 participants from both countries (113 Spanish (81 male and 32 female) and 159 German

Scale/Country	Spain	Germany
Organizing	.84	.82
Elaboration	.83	.74
Repeating	.73	.73
Metacognition	.65	.73

Table 3: Scale reliabilities for the Spanish and German data

	Mean		Std. Deviation		Maximum		Minimum	
	S	G	S	G	S	G	S	G
Organizing	61.92	47.87	20.67	22.16	100	100	0	0
Elaborating	59.21	48.76	16.58	17.47	90.63	95.83	6.25	0
Repeating	50.60	40.34	15.44	18.73	92.86	85.71	17.86	0
Meta – Planning	57.80	47.78	16.90	21.78	93.75	100	6.25	0
Meta – Monitoring	47.01	46.27	18.53	21.16	87.5	100	6.25	0
Meta – Regulating	72.35	65.15	15.48	20.58	100	100	25	0

Table 4: Descriptive statistics for Spanish and German students

(115 male and 44 female)) according to the variables *Organizing*, *Elaborating*, *Repeating*, *Planning*, *Monitoring* and *Regulating*, using the k-means method. In this case, we present the results using five clusters (Table 6).

The interesting part is how to describe the clusters in reference to the learning strategies employed by the respective students. Table 6 shows the number of participants that belong to each cluster in the last row. *Cluster 1* has high values (>55) in *Planning* and *Regulating* and a comparatively low value in *Monitoring* (<40). *Organizing*, *Elaborating*, and *Repeating* score medium. In this cluster there are 42 students (15.44%), of them 15 (35.72%, 13 male and 2 female) are Spanish and 28 (64.28%, 22 male and 6 female) are German. *Cluster 2* has high values (>55) in *Organizing*, *Elaborating* and *Repeating* strategies and *Metacognition*. In this cluster there are 95 students (34.93%), of them 61 (64.21%, 37 male and 24 female) are Spanish and 34 (35.79%, 20 male and 14 female) are German. *Cluster 3* has relatively high values in *Planning* and *Organizing* and medium values in *Monitoring* and *Regulating* but low values in *Elaborating* and *Repeating*. In this cluster there are 28 students (10.29%), of them 6 (21.43%, 3 male and 3 female) are Spanish, and 22 (78.57%, 15 male and 7 female) are German. *Cluster 4* has low values in all variables except medium values in *Regulating*. In this cluster there are 39 students (14.34%). Very few (2) are Spanish (5.13%, 1 male and 1 female). The rest (37) are German (94.87%, 23 male and 14 female). *Cluster 5* has high values (>55) in *Regulating* and *Elaborating* and medium in *Organizing*, *Repeating*, *Planning* and in *Monitoring*. In this cluster there are 68 students (25%), of them 29 (42.65%, 26 male and 3 female) are Spanish and 39 (57.35%, 27 male and 12 female) are German.

In summary, the data shows that 54.93% of students are concentrated in cluster 2 and cluster 5, whose students show medium and high levels in their learning strategies. However, there are differences between countries. 79.65% of the Spanish students are in these clusters, contrasting with only 45.91% of the Germans.

Table 6: Final centroids of the cluster analysis and number of students

Regarding German students, it is remarkable that there is a group of 23.27% with low levels of learning strategies (cluster 4).

CONCLUSIONS AND DISCUSSION

In our exploration of two samples, we were able to detect commonalities between first-year engineering students of both countries: As much as three quarters of engineering students are male, only one quarter are female. That may seem unbalanced, but it describes a steady growth towards equality over the last decades. Our comparisons cannot be generalized to universal statements about two societies, but provide interesting insights into students' learning behaviour against the background of different economic conditions (where the unemployment rate of 25% in Spain raises higher demands than Germany's 6%).

We found that the questionnaire employed works well in both countries, despite the initial double translation, backed up by the fact that the retranslated items correspond well to the original ones. The differences in learning strategies between the two countries can be condensed in the fact that the German engineering students showed more variation and often scored lower, meaning that the Spanish students tended to state desired behaviour, i.e. diligent learning activities. Both groups score equally low on *Monitoring* skills, which can be interpreted as a teaching perspective.

For both countries, the interrelations between the variables (apart from forming a complex pattern) stress the fact that metacognitive skills are at the core of learning behaviour, and can be viewed as an effective lever by which to influence learning strategies and thus learning success. However, there are no clear indications as for which learning strategies support examination success.

As our sample consisted of 41.5% Spanish and 58.5% German students, we would expect this distribution to reflect on the different clusters as well. That is more or less the case for all clusters but one: Cluster 4 contains almost exclusively German students and can be described as incorporating students who generally score very low, i.e. they do not report to work very ex- or intensively for their studies. This might be traced back to the fact that in Spain, you cannot enter a university course in *Industrial Engineering* without proving your commitment, motivation and capability in an exacting university entrance test. In Germany, there is restriction to university education, too, but it is less strict (meaning they can be sidestepped by time or space). These conditions may have influenced the pattern on cluster 3 as well, where Germans are overrepresented. This cluster contains students with high scores on learning strategies that reflect good intentions (*Planning* and *Organizing*), but low scores on actually realizing these in tedious day-to-day work (*Elaborating* and *Repeating*). Identifying clusters of students with homogeneous learning behaviour implies offering customized courses fostering specific deficiencies.

As a final outcome, our interest in describing, developing and evaluating metacognitive strategies with respect to short- and long-term achievement in mathematics has been kindled. We expect to learn more from future investigations, particularly from a comparative exploration of Rasch analyses of the two surveys. Additionally, we would like to conduct qualitative research which can help to enlighten the quantitative data we already have.

ACKNOWLEDGMENT

The paper' elaboration has been supported by special action grant from Instituto de Matemática Interdisciplinar (Spain) (IMI-2014-Actions Research Committee Grant UCM).

The use of textbooks by pre-university teachers: An example with infinite series of real numbers

Alejandro S. González-Martín

Université de Montréal, Département Didactique, Montréal, Canada, a.gonzalez-martin@umontreal.ca

Textbooks are central to the teaching process at all levels, including the tertiary level. However, the phenomenon of textbook use in higher education has not been extensively studied. In this paper, we analyse textbook use in the teaching of infinite series of real numbers at the pre-university level in Quebec. We interviewed five teachers about their textbook use in order to investigate similarities between their personal relationship with series and the institutional relationship with series transmitted through textbooks. Our results show that the teachers' courses generally follow the textbook's presentation, and that their documentation system is reduced to almost a single textbook, to which they adhere almost exclusively. We also compare our results with those of Mesa and Griffiths (2012) at the tertiary level.

Keywords: Textbook use, pre-university, personal relationship, documentation system.

INTRODUCTION AND BACKGROUND

In this paper, we analyse textbook use by pre-university teachers in Quebec (Canada) in the teaching of infinite series of real numbers (*series* hereinafter). Textbooks play a crucial role in the school environment and "have always played a major role in mathematics education" (Sträßer, 2009, p. 70). However, the vision of mathematics transmitted by textbooks can shape what teachers teach and what students learn. Textbooks can also influence students' attitude toward the discipline of mathematics and affect their self-perception as learners (Raman, 2004). Moreover, textbooks can mould students' beliefs about what they can learn and how they can access and use knowledge (Mesa & Griffiths, 2012). For instance, González-Martín, Giraldo and Souto (2013) recently analysed a sample of secondary textbooks to identify how real and irrational numbers are introduced. They showed that the approaches used in textbooks could have major consequences for students' learning, influencing their vision of mathematics (e.g., 'it is possible to show that a statement is true by giving some examples'), and affecting their subsequent learning of other Calculus topics.

In addition, textbooks seem to play an important role in the teaching of tertiary mathematics (Mesa & Griffiths, 2012, p. 85). Although one might expect such textbooks to meet more rigorous academic standards appropriate for university classrooms, research seems to contradict this. For instance, in her study on continuity in Precalculus, Calculus, and Real Analysis courses, Raman (2004) concluded that textbooks send conflicting messages on the status and purpose of mathematical definitions. These results agree with those of Giraldo, González-Martín and Santos (2009), who also found that the presentation of content related to continuity in undergraduate textbooks sometimes conjures erroneous images that can impede the learning of derivatives and integrals. Lithner (2004) analysed the types of reasoning that Calculus textbook exercises can encourage and instil in students, and demonstrated that exercises in which students merely need to reproduce a given example predominate. Regarding the topic of series, González-Martín, Nardi and Biza (2011) also established a preponderance of algorithmic exercises in pre-university and university textbooks, as well as a lack of conceptually-driven tasks; we come back to this last work later. Because most of these studies on the introduction of Calculus reveal problems with the way post-secondary textbooks address mathematical topics, we decided to examine how post-secondary instructors use textbooks in preparing and teaching their courses.

Research on tertiary textbook analysis is rapidly evolving, but the phenomenon of instructors' textbook use in higher education has not been extensively studied (Mesa & Griffiths, 2012, p. 85). Mesa and Griffiths (2012) addressed this issue and found that tertiary instructors use textbooks for different purposes: generating the syllabus, preparing classes, and designing homework. The various ways textbooks were used included: using the same information contained in the textbook (*offloading*), supplementing it with alternative examples designed by the instructors themselves or culled from other textbooks (*adapting*), or changing the presentation altogether, including using different notation (a form of *improvising*). For all the tertiary instructors in their sample, the textbook appeared to be a crucial artefact in the instruction preparation process. However, the more frequently an instructor gave the same course, the less he or she relied on the textbook due to familiarity with its contents and with what it did and did not offer.

Another important observation was that instructors saw the textbooks they used as written *for* students, and not as a tool from which the instructors themselves could learn (e.g., they did not mine textbooks for new ways of understanding certain topics, nor did they draw inspiration from textbooks to vary their teaching methods). Instructors also did not see textbooks as tools that could help them select problems or decide how to sequence topics in constructing their syllabi. In fact, the textbook features that were perceived to be the most helpful for improving the instructors' teaching were problems and examples.

The research presented in this paper seeks to provide more information on this phenomenon, particularly with regard to the teaching of a very specific topic: series. Series are a key notion in mathematics: already present in early Greek mathematics, they were crucial in the development of Calculus. They have many applications within mathematics (such as the calculation of areas by means of rectangles) as well as outside mathematics (including the modelling of situations such as the distribution of atmospheric pollutants). These factors may partially explain why the study of series is included in introductory Calculus courses in many countries.

This is the case in Canada, where each province develops its own official curricula. In the province of Quebec, compulsory education ends at age 16 and students who wish to attend university must first complete two years of pre-university studies (called *collégial* —other countries, such as Spain, follow similar systems). Students pursuing scientific or technical careers are introduced to Calculus during their *collégial* studies, where series first appear. It is in this context that our research, like Mesa's and Griffiths' (2012), seeks to better understand the phenomenon of textbook use. However, while Mesa and Griffiths looked at general textbook use in universities, our work centres on preparatory courses at the *collégial* level and focuses on a topic that is introduced in university in many countries. Moreover, studying the *collégial* experience may help pinpoint gaps and continuities between textbook use at the *collégial* and university levels that could affect students' transition. This could open the door to further research on similarities and differences in practices with regard to a specific topic of study.

Before beginning our investigation of teachers' use of textbooks in the teaching of series, we first developed an analysis of how series are presented in *collégial* textbooks, following an anthropological approach. We also identified some possible consequences of this presentation for students' learning (González-Martín et al., 2011). Our sample consisted of 17 textbooks used in *collégial* studies in Quebec from 1993 to 2008 and our main conclusions can be summarised in four main results:

R1: Series are usually introduced through organisations that do not lead students to question their application or importance (*raison d'être*).

R2: Organisations tend to introduce series as a tool to later introduce functional series, but the inherent importance of series is not usually discussed.

R3: These organisations tend to ignore some of the main difficulties in learning series identified by research.

R4: The vast majority of tasks concerning series are related to the application of convergence criteria, or to the application of algorithmic procedures.

Having identified how *collégial* textbooks introduce series, the next stage of the research consisted of analysing *collégial* teachers' practices and their use of textbooks (González-Martín, 2010). In this paper, we discuss how *collégial* teachers use and view their textbooks, specifically in relation to the topic of series.

THEORETICAL FRAMEWORK

We are interested in two main issues: determining how *collégial* teachers use their textbooks, and defining the relationship between teachers and textbooks.

To study how teachers interact with a range of resources, and how these interactions are central to their professional activity, we followed the documentational approach (Gueudet, 2014; Gueudet, Buteau, Mesa, & Misfeldt, 2014). In this approach, a resource is anything that can possibly intervene with the activity of a subject, including artefacts or even a discussion with a colleague. In the case of teachers, they may select, combine, and design their own resources. They may use resources in class, modify them (on the spot or afterwards), or share them. All this constitutes the teacher's *documentation work* (Gueudet et al., p. 142) and, as a consequence, the teacher develops a structured *documentation system*. Teachers, through their use of given resources in pursuit of a teaching objective, develop a *document*: "a mixed entity, associating resources and utilization schemes of these resources" (Gueudet, 2014, p. 2336); this process is called a *documentational genesis*.

The knowledge involved in developing schemes is professional knowledge and can concern a given resource ('this exercise is a good one to trigger an interesting discussion to start this chapter') or the mathematical content to be taught ('I have to work on the idea of slope of functions before introducing derivatives'). The *resource system* is the part of the *documentation system* that refers only to the resources used. This approach therefore considers the professional activity of a teacher in its entirety, both in and out of class.

All the processes studied through the documentational approach are developed in an institutional environment, which establishes (and sometimes imposes) a set of conditions and constraints. Chevallard's anthropological theory provides tools that allow a better understanding of choices made by an institution in organising the teaching of mathematical concepts, as well as the possible consequences of these choices on an individual's practices. A fundamental aspect of this theory is the notion of *institution*. An institution I is defined as a social organisation that allows, and imposes on its *subjects* (every person x who occupies any of the possible positions p offered by I), the development of *ways of doing and of thinking proper to* I (Chevallard, 2003, p. 82). For instance, a classroom is an *institution* (with two main positions: teacher and student), as is a school (consisting of several more positions: teachers of various disciplines, students in different grades, the principal, course coordinators, etc.), or an educational system.

To analyse how an *institution* approaches notions, further definitions are required. An *object* is any entity, material or immaterial, that exists for at least one individual; in particular, any intentional product of human activity is an *object*. Every *subject* x has a *personal relationship* with any object o, denoted as $R(x, o)$, as a product of all the interactions that x can have with o (using it, manipulating it, speaking of it, etc.). This *personal relationship* is created, or modified, by coming in contact with o as it is presented in different *institutions* I, where x occupies a given position p. From this *personal relationship*, an individual will be endowed with what could be designated as 'knowledge', 'know-how', 'conceptions', 'competencies', 'mastery', 'mental images', 'representations' and 'attitudes' (Chevallard, 1989, p. 227).

This notion of *relationship* is also applicable to *institutions*: given an object o, an *institution* I, and a position p in I, we define the *institutional relationship* with o in position p, $R_I(p, o)$, as the relationship with the object o, which should ideally be that of the subjects in position p within I (Chevallard, 2003, p. 82); this is, 'what is done with o within I' (Chevallard, 1989, p. 213) for any *subject* in position p. By becoming a *subject* of I in position p, an individual x is subjected to the *institutional relationships* $R_I(p, o)$, which in turn will re-model his or her own *personal relationships*. For our research, we consider as institution the system of mathematics teaching at the *collégial* level (MTCL). The *institutional relationship* of MTCL with series is mainly determined by official programmes and by textbooks that develop the contents required by these programmes.

In the case of teachers, their *personal relationships* will be affected by the *institutional relationships*, which impose constraints on what to teach and how to teach it (for instance, through textbooks). This *personal relationship* can be seen as an element of the schemes developed as a part of a *document*. In this sense, the *document* is constructed by taking into account a number of resources, as well as the *personal relationship* of the teacher with the topic being taught, which has a strong influence on his or her view of what should be taught and how this should be done, and guides the teacher in selecting which resources to use.

We can now state the main objectives of the research presented in this paper. We are interested in: 1) analysing *collégial* teachers' *personal relationship* with series and seeing how it relates to the *institutional relationship* promoted by textbooks; 2) analysing *collégial* teachers' *documentation work* concerning textbook use in preparing for the teaching of series.

METHODOLOGY

The research reported here is a part of a larger project aiming at identifying *collégial* teachers' practices regarding series (González-Martín, 2010), guided mainly by our results on the introduction of series in textbooks (González-Martín et al., 2011). To achieve the objectives of this larger project, and guided by the results of our analysis of textbooks, we constructed a protocol for semi-structured interviews. These included questions about the textbook used by the teachers, their opinion on the adequacy of this textbook for the students and for the teacher, the number and type of different representations used, the number and type of examples and applications used to teach series, their opinions on the most important tasks for students to perform during the learning of series, and their awareness of the main difficulties in learning series, among others. For this paper, we focus on questions concerning the textbook and its use as a resource in preparing lessons about series. The interviews were conducted from June to November 2009, with an average length of 45 minutes. They were videotaped and later transcribed for further analysis. Once transcribed, the data was organised into clusters of different topics, with special attention paid to keywords that could serve as indicators of the teachers' *personal relationship* with series and of their approach to preparing and organising their textbook use.

In order to cover a wider variety of practices for the teaching of series, we selected five teachers from various *collégial* establishments in Montreal, the biggest city in the province of Quebec. We thereby avoided interviewing teachers working in the same establishment, who tend to organise their teaching in similar fashions. These teachers, designated T1, T2, T3, T4, T5, had varying levels of teaching experience at the *collégial* level and varying levels of experience teaching series (Table 1).

It is important to clarify that because we were interested in the use and role of the textbook within the *resource system* of our teachers, we did not collect all the resources of the teachers (see Gueudet, 2014); we had previously analysed these teachers' textbook (which shared the characteristics *R1* to *R4* described in the Introduction) and inquired about their vision and use of it. The study of the *resource system* as a whole will be the focus of future research. In the following section, we present the main results derived from the interviews.

SOME RESULTS

Coincidentally, at the time of the interview our five teachers were using the same textbook for their courses. This textbook was part of our earlier study's sample, and, as mentioned above, had been analysed by us previously. It displays the general characteristics *R1* to *R4* of the textbooks within the sample. The teachers' reasons for choosing it were varied (all quotes have been translated from the original French):

T1: I find that it is better than the others. [...] All textbooks are basically similar, but the order and the way they present content, I think that this one is good.

T2: Because two teachers from here wrote it [...].

	T1	T2	T3	T4	T5
Experience teaching in *collégial*	5 years	20 years (mathematics and informatics)	32 years	6 years	7 years
Experience teaching series	5 years	4 years	More than 20 years	4 years	2 years

Table 1: Teachers' experience at the *collégial* level and experience with teaching series

T3: [...] for many reasons. The simplest reason is that [it] covers the course content so it's a good work tool [for] students [and] the teacher.

T4: [...] I found that it was better where integration techniques are concerned. Especially the way the exercises are grouped together. [...] At the beginning, the drill exercises are grouped together so that one can associate a concept with many examples [...] So, I find that it is an appropriate learning sequence. [...] I believe a lot in drill exercises. I try to create a balance, but there are many textbooks that I do not like [...].

T5: Well, it's the one that was used before I started teaching... [...] it is good, it has theory, [...] it has a lot of exercises... it's [...] good enough for the students because [...] it helps the student a lot, [it also helps] the teacher because... it's what we're asked to teach. Meaning that, the parts... I mean, the proofs... [...] here they're not in the textbooks [...] so in that way we know that we don't have to teach those proofs... and [...] it's a well enough organised book... [...] Yes, we use the textbook, but the teachers' syllabi are also useful in order to know how... [...] which is the best way to introduce a concept.

We see here the different purposes of textbook use identified by Mesa and Griffiths (2012): generating the syllabus, preparing classes, and designing homework (when they speak about the exercises). However, the most prevalent use seems to be *offloading,* with the exception of cases where some portions are removed with no alternative information added (which we do not consider to be *adapting*). T2 and T5 seem to be subject to particular restrictions, indicating that they were not entirely free to select the textbook ('*two teachers from here wrote it*' and '*it's the one that was used before I started teaching*'), although T5 adds information concerning his opinion on content and structure. We can observe a phenomenon that was also detected by Mesa and Griffiths: the textbook seems to be perceived as written *for* the student. Moreover, aside from the syllabus, the *resource system* appears, so far, reduced to the use of a single textbook, which suggests that professional knowledge is underdeveloped with regard to the teaching of series in MTCL. We did not see any of the teachers use more than one textbook in preparing their courses.

We were able to confirm later that the most prevalent way of using the textbook was through *offloading*. When asked whether they follow the order of the textbook when they teach series, T1 and T4 said yes (T4 said '*I think so*'), whereas T2, T3 and T5 (transcribed in his previous response) indicated that they '*almost*' do:

T3: Certain sections are set aside and left out, but on the whole we almost follow the order.

T4: Yes, but the textbook contains much more than the course content. So you have to make a selection. For example, the convergence criteria in the textbook — almost 10 criteria are presented. In fact, we only have time to get the students to master perhaps half of the criteria.

In each case, it seems that the teacher's *personal relationship* with series does not diverge significantly from what is presented in the textbooks; the only concern seems to be that there is more material in the textbooks than necessary, which results in some sections being set aside. It is possible that this similarity between their *personal relationship* with series and the *institutional relationship* transmitted by the textbooks is at the origin of the teacher's decision not to enrich their *documentation system* with different sources. This could lead the teachers to develop schemes for the teaching of series that privilege the presentation of routine tasks. This became more evident when we asked them whether they thought the textbook they use meets the needs of the students and the instructor:

T1: Needs of the instructor, yes... I think that it's complete enough when it comes to sequences and series... [...] Meeting the students' needs, well, that's the eternal question of why do we teach that [...].

T2: Hmm, we are currently re-evaluating what we are doing about sequences and series [...] I would say that for the moment, there are not any textbooks that really correspond to what we would like to do. Especially because we are not certain yet of what we would like to do [...]

As long as we don't know what we want to do, we will not find the appropriate textbook…

T3: The one that we use, yes. It's not the only one […]. But that one, yes.

T4: The one that I use does, yes.

T5: Hmm… yes, I would say for the teacher, yes… hmm… for the student […] well […] we do not have a lot of time to make the student practise. They are the ones who have to practise. So the textbooks… […] there are no parts where they can do activities or experiment. Even the teacher does not have a lot of time to experiment with students on the concept of series and organise activities for them. So, time is short for that… and the students… all they have to do is practise with the exercises […]

These teachers seem to see the textbook as being *for* the student and they suggest that it meets students' needs in their learning of series. T2 was the only teacher who seems to question how series should be taught (or *what* should be taught), but he ultimately bends to the pressure of the *institutional relationship* and uses the textbook exclusively. On the other hand, T1 also raises the fact that the reason for learning series may not be clear to students, but he does not seem to *adapt* the textbook and provide extra information to clarify this issue. It seems that the weight of the *institutional relationship* with series deters him from taking initiative and using other resources to enrich his *documentation system* and address these issues.

The teachers' adherence to the presentation and organisation of the textbook seems absolute, and they generally insist on the importance of performing the exercises, which was identified as the most helpful textbook feature by Mesa and Griffiths (2012). In fact, the tasks that the teachers consider to be most crucial in learning series were all taken from the textbook (González-Martín, 2010). As in Mesa's and Griffiths's research, no teacher identified the textbook as a tool from which they could learn or that could help them decide how to sequence the topics.

FINAL REMARKS

We cannot present more excerpts from the interviews here, which would allow us to gain better insight into the use of the textbook by our teachers and paint a clearer picture of their *personal relationship* with series and their apparent compliance with the *institutional relationship*. This will be the subject of future papers.

However, the data presented here allows us to observe a kind of *yielding* to the institution's approach to introducing series (through textbooks). There appears to be a similarity between the teachers' *personal relationship* and the *institutional relationship*, in spite of the weaknesses on the way series are introduced by textbooks (González-Martín et al., 2011). Perhaps the fact that the teachers' *resource system* seems so restricted can be explained largely by this *yielding*: our teachers may not see any reason to seek out complementary resources in preparing their lessons. Our data indicates that the *resource system* of our teachers is by and large reduced to the use of a single textbook that the teachers do not question, and the choice of this single resource as core of the *resource system* appears to be guided by the *personal relationship* of these teachers with series, which appears to be quite close to the *institutional relationship* transmitted in the textbooks.

In general, our results echo those of Mesa and Griffiths (2012). However, textbook use at this school level seems to be more restricted to *offloading* (which in this case includes using material from the textbook while setting some parts aside). *Offloading* is the primary way textbooks were used by our interview subjects. Also, textbook use is quite prevalent, which is common in *collégial* studies in Quebec although it diminishes at the university level. In spite of their varied experience, the instructors relied on the textbook to an equal degree, and in this way they seemed to differ from the tertiary instructors interviewed by Mesa and Griffiths.

The conclusions of the study conducted by Mesa and Griffiths, as well as our own research, reveal a number of important tendencies related to textbook use that may have a strong impact on students' learning at the post-secondary level, especially in light of research results on post-secondary textbook content. We are aware that our sample is quite small, and that we only focus on a specific mathematical topic; however, the similarities between our and Mesa's and Griffiths's results lead us to identify some possible concerns. The need for more research on textbook content and textbook use at the post-secondary level is therefore crucial.

Media and milieus for complex numbers: An experiment with Maple based text

Niels Grønbæk[1] *and Carl Winsløw*[2]

1 University of Copenhagen, Department of Mathematical Sciences, Copenhagen, Denmark, gronbaek@math.ku.dk

2 University of Copenhagen, Department of Science Education, Copenhagen, Denmark

Based on the notion of institutionally conditioned relationship to an organisation of knowledge and practice, we present our first design and implementation of a self-study module on complex numbers in an introductory mathematics course for non-mathematics majors. The basic idea is to develop an "interactive text" in the computer algebra system "Maple", designed to create a reasonably self-sustaining dialectics of media and milieus for students to learn about and work with complex numbers. We discuss some of the obstacles and constraints met in a first implementation of such a text, as well as hypothesis for future implementations.

Keywords: Media-milieus, Maple, self-study, interactive text.

INTRODUCTION

Mathematics departments and auditoria are among the last strongholds for chalkboards. Sfard (2014) reflects on the reasons why lectures continue to be a common teaching format in undergraduate mathematics education and hypothesizes that "watching a mathematician in action and imitating his moves while also trying to figure out the reasons for the strange things he is doing may be the only way to come to grips with [*mathematical objects*]" (p. 202). She also points out that this "coming to grips" can be initiated but by no means accomplished through watching; it requires solitary "thinking" (or "self-communication", in the terminology of Sfard). However, the importance of individual study in advanced mathematics is indeed upstream our current "world of incessant chatter, where everybody talks to everybody else and where educators preach collaborative learning" (p. 202).

This necessity of individual work could, in turn, be related to and in part explained by the primacy of *written discourse* in post-elementary mathematics, a phenomenon which appears already in the context of school algebra and which breaks with the usual role of written text as merely a formalized version of spoken language:

> It is important to notice that in the algebraic symbol manipulations, this relationship between oral and written work is reversed: writing comes first and orality is just a "secondary" accompaniment of the written algebraic formulations, which are furthermore not always easy to "oralize". Contrary to our mental habits, written algebraic symbolism is not a derivation of oral language: it is the source, the manifestation and the touchstone of algebraic "thinking". (Bosch, 2012, p. 7)

Certainly, the primacy of individual written work is fully compatible with the ostensive functions of chalkboard lectures and also with other common formats of university teaching such as exercise tutorials. It does not imply that other more interactive forms of teaching cannot be very useful. But given the crucial role of individual writing in advanced mathematics, the proliferation of online courses, and the increasing pressure on universities to deliver cost effective teaching, the following question is increasingly urgent for university mathematics education: to what extent can cost-intensive face-to-face teaching be dispensed with? What kinds of "real time" interaction with teachers and fellow students are necessary, if any?

These questions arose in a very practical and rather abrupt form for the first author, as he prepared to teach a first year course on calculus for a mixed public of science students: due to a mismatch of administrative rules and the calendar around Christmas, the course had to do with 8 instead of the usual 9 weeks of teaching. Given the density of topics to be covered in the course, spanning from review of secondary level calculus over linear differential equations to surface and multiple integrals, the decision was made to select one week of the normal teaching programme, in which complex numbers and basic complex functions are introduced – and replace it with "self-study". That did not mean that complex numbers should be any less part of the course as they continued to appear in other topics, in exam questions etc. It also did not mean that no support was to be given for students work with complex numbers; only would normal teaching time not be set aside for it, neither in lectures taught by the first author, or in class sessions taught by instructors.

Our basic idea for dealing with this situation was to create an "interactive" text based on the computer algebra system *Maple 17*. In this paper, we present our first designs and observations, as well as a theoretical framework, which helps to shape our work with the task and to situate it in the wider problem area, which was outlined in the first paragraphs above. We stress that this is on-going work, and we present neither a fully developed design, nor a systematic empirical study of its functioning. Thus, the points of the paper are, mainly, a set of theoretically sharpened design ideas.

THEORETICAL BACKGROUND: MEDIA AND MILIEUS

To render the quandaries outlined in the introduction more precise, we have found it useful to model them within the framework of the anthropological theory of the didactic (see, for instance, Chevallard, 1999; Winsløw, 2011, for more detailed introductions). In the most general formulation, we consider an organization O of mathematical practice and knowledge, a generic student x within an institution I, and we are interested in the conditions and constraints for establishing a given relationship, denoted $R_I(x,O)$, between x and O. Among the most immediate conditions are the *media* and *milieus* (cf. Chevallard, 2009) made available by the institution to establish and develop $R_I(x,O)$. According to the original definitions,

> The word *media* designates any system of representation of a part of the natural or social world in view of a certain public: the lecture of a professor of mathematics, a treatise on chemistry, a televised news programme, a regional or national newspaper, an Internet site, etc., are in this sense media systems. A *milieu* is understood in a sense close to that of *adidactic* in the theory of didactic situations. In fact, we designate as *milieu* any system that can be regarded as *devoid of intention* in terms of the answers it can bring, implicitly or explicitly, to a given question. By contrast (...) media are in general motivated by certain intentions, for instance, the intention to "inform". Naturally, a media can also, with regard to some particular question, be considered a milieu and used as such. (Chevallard, 2009, p. 344).

Medias and milieus in the university context

Adidactical situations in the university context do not always take the form of teacher initiated student work within a classroom setting, as in the primary school settings investigated by Brousseau (1997). The individual work of students referred to in the introduction must be considered an important form of *adidactical situation* if this notion should apply to central learning situations in the university setting. Thus, when students study a textbook and encounter an inference they do not follow, they are supposed to consider the text as a milieu that resources and constrains their efforts to fill in the gap. Similarly, an exercise to be solved is part of a milieu to which the students can apply and adapt their own relevant knowledge, and thus develop their relationship with the mathematical organizations to be acquired.

Consider a generic student x of the mathematics course *MatIntro* at the University of Copenhagen (I) whose relation to the mathematical practices and theories related to complex numbers ($O_\mathbb{C}$) we wish to study, and which of course have to be specified further. Without further assumption about x, we may have reason to stipulate a number of conditions and constraints related to x, in view of developing $R_I(x,O_\mathbb{C})$ according to the aims of I; in particular, we may assume that the students has established certain relations $R_I(x,O_i)$ to other mathematical organizations O_i in some way related to $O_\mathbb{C}$, as a result of being a student in secondary school (I') and university (I). In the example, such assumptions concern the detailed practice and theory previously encountered by students in relation to relevant domain such as arithmetic and basic algebra, including polynomial equations, vectors in the plane and exponential functions. Such assumptions can be based on a study of media and milieus through which many students are likely to have established their relation to O_i – for instance textbooks (media), tasks devolved to students (part of milieu) and computer algebra systems (which can function as kind of a milieu for students).

Chevallard (2009, p. 345) insists that "the existence of a vigorous (and rigorous) dialectics between media and milieus is a crucial condition to avoid that the study process is reduced to an uncritical copying of elements of answers which are scattered in institutions and society". In fact, even in the situation of lectures referred to in the introduction, this dialectics is possible: while the lecturer is of course, basically, acting as a medium, he may use the blackboard to create a milieu and let the students observe how he interacts with it, as when he says: "Let's see what happens if we replace z by $re^{i\theta}$ in these identities", and subsequently calculates in *real time* (with the possibility of committing errors, of volunteering students contributing at least orally, etc.). This way, students may observe "the mathematician in action" against a milieu, and students should try to follow and even anticipate the moves, which bring about the solution to whatever problem is at stake – but in the secure position of individual "thinking", without being exposed to the responsibility of completing all required actions in public, as the lecturer.

Even in the most traditional university teaching of mathematics, one can find rigorous systems of media and milieus. The main problem is that of their being vigorous: to what extent do students develop a critical and autonomous relationship to the "answers" found in the media proposed by the institution? Do students interact with milieus in which these answers are related to meaningful questions?

CONTEXT AND DESIGN

We now return to the somewhat special task of "teaching" first year students the basics of complex numbers without disposing of any regular teaching time. Focusing on this context as a case, the aim of this paper is to discuss design principles for creating a *rigorous and vigorous system of media and milieus for students' self-study*, using a computer algebra system, i.e. a mono-media rather than a multi-media design. And, since *vigour* is also an empirical quality, we end by a few observations of the first experiments with our design. We first specify some conditions and constraints, which the design was based on.

Conditions and constraints from the context

The course *MatIntro* caters to a number of different BSc study programmes in science, including pure and applied mathematics, and its contents are thus the result of adapting to the needs of these. The reasons for sharing this and other first year courses among study programmes are in part financial, but also the flexibility it gives for students to change programme without having to take new basic courses. On the other hand, this arrangement leaves little room for the teachers in charge to change the contents of the course. The "self-study" material developed for complex numbers thus had to be relatively neutral in relation to its specific use in science disciplines.

The design was experimented in a run of a version of the course with about 250 students from biochemistry, chemistry and nano-science. There was no face-to-face teaching assigned to the design, and only very limited human resources available for interacting in other ways with the students, for instance providing feedback to exercise work. The only exception was what the lecturer (the first author) could use his own time during the course period. The design should thus provide students with media, which they could access on their own, and milieus in which they could both acquire and validate adequate relationships to the subject.

Another important condition for the solution to be developed is that *MatIntro* uses the advanced computer algebra system (CAS) Maple substantially, including weekly "labs". Maple functions as a learning resource in the course and as a tool supplementing and enhancing paper and pencil techniques. The focus is on insight rather than on computing results. The course grade is based on weekly hand-ins requiring Maple and two multiple-choice tests, in which no electronic tools are allowed.

As with many other CAS, work in *Maple* takes place in a window where input and output appear in consecutive lines, much as in a word processor window with the crucial exception that the latter has *only* input. The contents of the window can be saved as a file (called a *Maple sheet*), for later use and development. Students less familiar with *Maple* often use *Maple* sheets found on the Internet (including the manufacturer's own support pages) in order to get ideas for how to solve a given problem. In *MatIntro* and similar courses, teachers regularly publish Maple sheets on the course web page, to demonstrate *Maple* techniques and other mathematical points to students. Such sheets are typically short and sketchy, and the idea is that students may use them (or parts of them) in their work with related tasks.

Design

The basic idea of our design was to create an interactive introduction to complex numbers as a set of Maple sheets to be used for self-study by the students. 'Interactive' means that the document serves both as media and milieu and 'self-study' means that Sfard's 'observing a mathematician in action' (e.g., in a lecture) is replaced by 'observing Maple in action' through embedded input-output turns.

The choice of a course theme (complex numbers) for self-study was motivated by two considerations. Firstly, this subject is somewhat isolated in the course syllabus, which makes the experiment less risky for the course as such. Secondly, it seems particularly suited to exhibit *Maple in action*. The course goals focus on a small number of connected techniques within complex arithmetic, algebra of low degree polynomials, and basic properties of the complex exponential function. These are linked only to relatively simple Maple routines; moreover, complex numbers is a new area to most students and as already said, is relatively isolated in the course. So it could be conceivably developed as a kind of "Maple world".

Traditional use of Maple in teaching is as a *milieu* in which certain computations, visualisations and experiments can be performed using an input-output scheme. This milieu becomes operational only as a supplement to media and other elements of milieus that students interact with during lectures, exercise solving etc. The students must navigate in this juxtaposition of different media and milieus to build a set of relationships $R_I(x,O)$ as demanded from I. The common formats of teaching gives various support to the student, and in particular the 'mathematician in action' is not just part of a media system for mathematical content but also demonstrates how to use milieus (which could be Maple experiments) to take on various concrete tasks. If "live" (blackboard or otherwise) manipulations of mathematical objects are to be replaced by a simple Maple sheet, it must reproduce some of the same experience of purposeful, reasoned instruction, complemented with work in explorative milieus. One added potential (difficult to realize!) is that students could take on a more active role as compared with the common situation in lectures.

In our design, we used Maple to create a media-milieu dialectics in three ways: as a generator of *dynamic text* (media with embedded milieu), as a generator of *drills for techniques to solve specific tasks* with *feedback to students' solution proposals* (milieu with embedded media), and to *explore and exhibit phenomena* (media with embedded milieu). In order to explain these options, we name the main components of a Maple sheet:

- *Maple text*: non-executable text, essentially as in a word processor;
- *Maple input* : executable text;
- *Maple output* : results of executions;
- *Maple Components*: programmable interactive components (code is not shown) including sliders, buttons, Math Containers for in- and output, and other items.

The user or author of a sheet may hide or show Maple input, to produce different appearances of the worksheet. With the input hidden, the worksheet may read as a simple textbook (media) with its mixture of text, formulae, calculations and graphics; it is invisible that the latter are in fact Maple output. When the Maple input is revealed one sees the embedded milieu, which can be acted on.

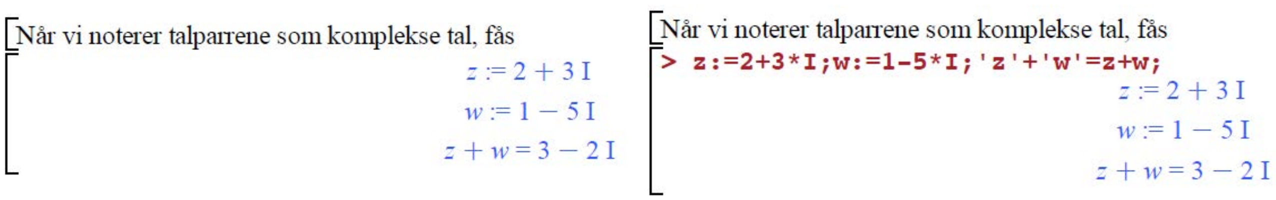

Figure 1: An excerpt of a Maple sheet with text, input (hidden in left version) and output

Here is a simple example (cf. Figure 1 which shows a short excerpt of an introductory Maple sheet for the course): if we have defined two complex numbers by `>z:=2+3*I;w:=1-5*I;` a statement of their sum should be coded `>'z'+'w'=z+w;` rather than `>'z'+'w'=3-2*I;`. In both cases the output as part of the text reads $z+w=3-2\,I$, but the first option will preserve the correctness of the second part, even if changes are effected in the first. Thus, '`=z+w;`' is "Maple in action", while '`=3-2*I;`' is just communicating the sheet author's knowledge.

The example illustrates how media-milieu dialectics is used explicitly in the design. When Maple is the primary source of mathematical content the Maple in- and outputs are a-didactical and the dialectics is rigorous so that the user may act in this milieu (here, mainly re-assign *z* and *w* or change the operation). Conversely, no non-Maple manipulation, such as '`=3-2*I;`' can be negotiated by the user and therefore may lead to imitation rather than construction of knowledge.

Milieus are embedded more explicitly into the sheet by using Maple applets. The most basic way is a *drill*, aimed at education a specific technique. Computation of reciprocals of complex numbers serves as an example. It consists of six components (see Figure 2): a button "new number", an output container exhibiting a complex number, an input container to be filled by the student, an erase button, a true-false button, and an output container displaying either "true" or "false".

When "new number" is clicked, Maple exhibits a complex number randomly chosen from a pre-set range (with more than 400 different numbers). Thus Maple serves two purposes. It generates a variation of tasks of identical type and provides feedback to the student's performance with a technique to solve the task.

Math containers are also used to let the students investigate phenomena from a more theoretical point. The geometry of complex multiplication by a real factor is explored by means of a "new number" button, a slider to choose the real factor and a plot container exhibiting the geometric effect of multiplication. Similar milieus are offered to explore the geometric meaning of multiplication by purely imaginary factors and the general case. The student is asked to insert personal descriptions in terms of modulus and argument in the text (for this, no feedback is available). The full Maple material can be consulted at the web address http://www.math.ku.dk/kurser/2013-14/blok2/matintrokem/selvstudium/, where the reader may explore the examples mentioned above, and more.

The functioning of the sheets produced so far is incomplete in at least two respects. The plainest is that feedback, which can be produced with Maple, is very limited and (as with most software) merciless on syntax and other formal errors, which are naturally common for beginners. Also, institutionalization (in the sense of Brousseau, 1997, p. 215) is independent of what students have actually achieved in a milieu.

To address these problems in part a discussion forum dedicated to the self-study part of the course was set up in the on-line platform of the course. Here students and teachers could post and answer any question or comment. The intention was that teachers monitored the discussion forum in a stipulated weekly time slot, and students were promised answers and rectifications to questions and problems, if possible immediately but else within a deadline.

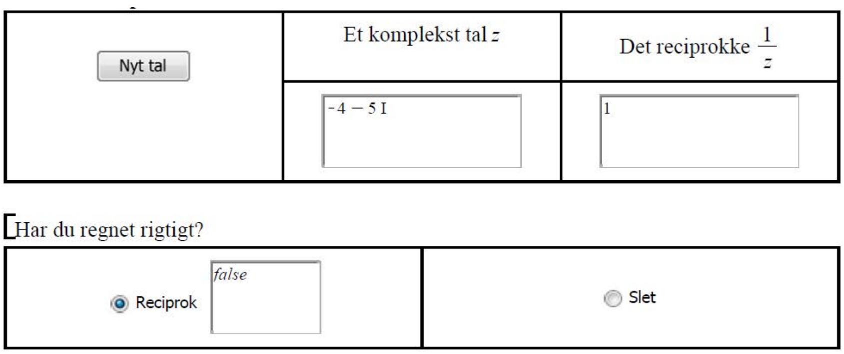

Figure 2: A simple drill applet to work with a technique for taking reciprocals

SOME OBSERVATIONS FROM A FIRST EXPERIMENTATION

Students were free to choose when to work with the material, and to work individually or with others. In their rather tight schedule only Friday afternoons were available to all students. Collaboration was encouraged in this slot. We reserved three afternoons for the monitoring of the discussion forum, corresponding to the three sub-modules into which the Maple sheets for the full self-study, corresponding to one week of teaching, were organized: (i) arithmetic and geometry of the complex plane, (ii) the quadratic equation, the exponential function, (iii) review of main points. Very few used the Friday slots and the discussion forum was practically unused (6 questions altogether). We have no solid evidence of the reason for lack of use of the discussion forum, but from focus group interviews, it appears that students preferred to confer with fellow students and instructor, as well as more informal channels such as *Facebook*.

A focus group test and interview

Following the first module a focus group interview was set up with four volunteer students commencing with four written tasks very similar to the drills of the first module sheets. Having collected the students' individual solutions to these tasks, we asked a number of questions about their experience with the sheets. The students reported to have worked with the sheets, in a combination of individual work and conferences with study groups. None reported difficulties; some even said the exercises were too easy. However, our written tasks suggested severe difficulties; for instance, not one of them had been able to compute $(1+2I)(3-I)$, and in at least two of the cases, this appeared to be related to an inappropriate mastery of the distributive law. From this experience at least two observations can be made.

The first is methodological: what students *say* can be strongly misleading as to what they are actually able to do. The reasons could be reluctance to admit difficulties to fellow students and lecturers as well as self-deception. The latter might in part be due to insufficient feedback from the sheets (in fact, one student noted that the applets may only let you know *that* you are wrong, not why).

The second point is specific to students' insufficient relationship with the distributive law (and other organisations of knowledge in the borderland between arithmetic and algebra). Whether or not it is rooted in CAS-use in secondary school, it becomes an obstacle to using the theoretical definition of operations in the setting of complex numbers. We had not anticipated such obstacles in our design.

Students' results

The most important measure of $R_I(x,O)$, from the viewpoint of students and institution (the university) alike, is that of summative assessments. In *MatIntro* naturally some of the items of the multiple choice tests are on complex numbers. Each test had one such task: in test 1, to calculate $\frac{(2+3I)(1-I)}{1+I}$; in test 2 to find a polynomial with roots $1+7I$ and $1-7I$. Texts and notes, but no computers, were allowed at the test. Students performed roughly 20% less well on these items than on the tests as a whole, but this is insignificant as the relative difficulty of items cannot be assumed to be uniform. However, the 250 students were organized in nine classes (for exercise sessions with instructors), and we observed significant variations among classes as concerns the ratio of *class average score on complex numbers items* and *average score on all items*. We suspected these could be related to class instructors' own initiatives to include complex number tasks in their teaching, even if they were not asked to. So, a survey on this was sent to them after the completion of the course. Indeed, it turned out that one instructor (whose class performed very well on complex numbers) had written and used a hand-out on complex numbers, based on the Maple sheets and providing an overview of most formulae and results on complex numbers to know about; these were also used by the instructors of a few other well performing classes. One could thus suspect that parts of the variations could be ascribed to these initiatives and the differences of focus. We do not have firm evidence to support our hypothesis that test oriented teaching caused the variations observed, but we can confirm that the "self-study of Maple sheets" were, in the end, far from the only source of media and milieus for students to learn about complex numbers.

Students' opinions

Most of our other evidence is gathered indirectly on students' impressions and opinions. These are in particular expressed in the anonymous on-line evaluation of the course, which is usually not very positive with students from the study programmes concerned. In fact, 71 respondents give mostly negative comments about the course as a whole, and also about the self-study (complex number) part. They criticize the lack of feedback, and some say directly that there should be accompanying lectures or videos of lectures. The idea of drills (built into the Maple sheets) seems, however, well accepted by those who mention them. Regular meetings between the lecturer and student representatives confirm these trends.

PERSPECTIVES AND FUTURE EXPERIMENT

The experiment with an "island" of self-study was imposed from the outside as an unexpected addition to the other constraints on this tightly packed introductory course for non-mathematics majors. The reaction of students and teachers alike seem to suggest that a satisfactory form of self-study is very hard to realize in these circumstances. In the absence of familiar teaching formats, they tend to replace a coherent organisation $O_{\mathbb{C}}$ of theory and practice related to complex numbers (as developed in the Maple sheets and foreseen in the course description) with a rather minimal set $o_{\mathbb{C}}$ of disconnected practices which appear in the most rigorously administered parts of the summative assessment (the multiple choice tests). This way, the institution as a whole seems to develop $R_I(x,o_{\mathbb{C}})$ rather than $R_I(x,O_{\mathbb{C}})$, as its way to measure $R_I(x,O_{\mathbb{C}})$ is in fact rather a minimal measure of $R_I(x,o_{\mathbb{C}})$.

One tempting way to proceed (under similar conditions) may thus be to accept that a generic student x in this institutional context I cannot be expected to develop more than $R_I(x,o_{\mathbb{C}})$. The design could be adapted to this situation by replacing most of the text with succinct expositions of task types and techniques, enriched with many more interactive drill items, examples and warnings on typical errors, and so on. This kind of approach seems to be endorsed, at least in deed, by many students and instructors.

This, however, would not be acceptable from the institutional point of view, for the reasons outlined in our exposition of "Conditions and constraints from the context". One could then try to pursue the (quite plausible) claim that the course is much too heavily packed with content, given the course time allotted. This makes the course very vulnerable to incidences as the one we described (one week disappearing), and one may also suspect that whether one accept it or not, outcomes of type $R_I(x,o_{\mathbb{C}})$ rather than $R_I(x,O_{\mathbb{C}})$ will be common unless the size of the total content organisation is reduced and adjusted more exactly to the students' programme. This, however, takes us away from the level of course design to the level of institutional politics.

Indeed, we are certain that the designed Maple sheets reflect the course goals adequately. They have been used with good results in two high school classes, in the spring of 2014 (with much more direct instruction on the use the sheets). This only strengthens our hypothesis that the framework (at the level of pedagogy) for their first implementation in *MatIntro* was inadequate, and that an island of unaccompanied "self-study" in such a course is very likely to result in side effects as those observed.

A third way out, which we shall try to pursue in the next run of the course, is therefore to make use of a new concession of the institution, allowing lectures on some of the Friday afternoons. They will be used to introduce the students to the sheets, and in particular how to make use of them (both as media and milieus). The class instructors will be asked to align with these lectures and use the course material rather than self-made cookbooks on how to pass the tests; in turn these latter will be amended to correspond more fully to both practical and theoretical levels of $O_{\mathbb{C}}$.

University teachers' resources and documentation work

Ghislaine Gueudet

University of Brest, ESPE Bretagne, CREAD, Brest, France, ghislaine.gueudet@espe-bretagne.fr

In this paper, I investigate university teachers' documentation work: their interactions with resources for preparing and delivering their teaching, and the consequences of these interactions. I have interviewed and collected the material resources used by six university teachers working in France. Analysing the data collected, I observe specific features of their documentation systems, concerning crucial resources, professional development, and the place of digital resources.

Keywords: Documentation systems, documentational geneses, professional development, resources.

INTRODUCTION: STUDYING TEACHERS' WORK WITH RESOURCES AT UNIVERSITY

The work presented in this paper belongs to the growing field of research concerning university teachers' practice (e.g., Nardi, Jaworski, & Hegedus, 2005), with a specific feature: I consider the teacher's work in class, but also out-of-class. I investigate indeed university teachers' work with resources, with a documentational approach perspective (Gueudet, Pepin, & Trouche, 2012). Previous steps have been done at CERME8, with a study concerning the detailed case of one teacher, working in a technological institute (Gueudet, 2014). The theoretical aspects of such a study and the specific features from university concerning teachers' documentation work have been deepened in Gueudet, Buteau, Mesa and Misfeldt (2014), within the RME special issue concerning "Institutional, sociocultural and discursive approaches to research in university mathematics education".

I firstly briefly recall the main elements of the theoretical approach. Then I present the methods, organised around the cases of six teachers with different profiles. I present the results obtained by analysing interviews with these teachers and the material resources they use, focusing on the documentation systems structure, on crucial resources, on professional development and on the place of technology.

THEORETICAL FRAME, CONTEXT AND METHODS

I retain in this work the theoretical frame provided by the documentational approach of didactics (Gueudet et al., 2012). According to this approach, teachers interact in their work with a variety of *resources*. The concept of resource is considered here with the meaning introduced by Adler (2000): a resource can be a textbook, but also a symbol, or more generally anything likely to re-source the teacher's professional activity. Teachers look for resources, sometimes they meet resources that they were not looking for (discussing with a colleague around the coffee machine, for example). They associate these resources, modify them, conceive their own resources and use them with students. All this activity is called *the documentation work* of the teacher (Gueudet et al., 2012). During this documentation work, interactions take place between the teacher and the resources; and these interactions contribute to teachers' professional development. Drawing on the instrumental approach (Rabardel, 2002/1995; Guin, Ruthven, & Trouche, 2005), the documentational approach considers that teachers are involved with sets of resources in a goal-oriented activity. Along this activity and for a given goal, they develop a *document*: the association of resources and of a scheme of use (Vergnaud, 1998) of these resources. Schemes of use encompass three ingredients: the objective of the activity; rules of action (a usual way to act for this objective); operational invariants, which are here professional beliefs. This process (development of a document) is called a *documentational genesis*. Multiple documentational geneses occur along the teacher's work for various goals; they contribute to produce the *documentation system* of the teacher, which is the structured set of all the documents he/she develops. With this perspective and concepts, the central research questions that I address in this paper are:

What is the content and structure of university teachers' documentation systems? Which are the evolutions of these systems, and how are these evolutions linked with teachers' professional development?

In Gueudet and colleagues (2014), I have discussed possible specific features of teachers' documentation work, in the context of university. One such feature is the possible central role of the work with resources for teachers' professional development, since in many countries teacher education is limited at university. Such a role has already been identified in the case of textbooks by Mesa & Griffiths (2012), using an instrumental approach: they have identified different schemes of use, shaping the teachers' practice. Moreover, many digital resources are available for university; and the online platforms permit to develop distant work with students. Are these digital resources present in the teachers' documentation systems, where do they intervene? In Gueudet (2014), I have investigated the case of a single teacher, who taught in a technological institute and was not involved in research. He used many technological resources, but he worked in a specific context. The place of technology in the documentation systems of university teachers in more "ordinary" contexts still has to be investigated.

I retain these foci, for the results I present here: the link between documentation systems and professional development, in particular the intervention of research in the development of documents and the place of technology in university teachers' documentation systems.

In this article, I study the cases of six colleagues, all of them working in France in the same middle-size university. These colleagues have been chosen to represent a variety of conditions that can influence their documentation work: experience, research domain, studies in France or abroad, position, gender. Table 1 below summarizes the six cases, according to these factors.

They also teach in a variety of "teaching units", concerning calculus, linear algebra, number theory, probability, numerical analysis in the first or second year of university. A teaching unit lasts 12 weeks and can comprise between four and six hours a week, with generally half of the time for the lectures and half of the time for tutorials. Most of these teaching units concern the "Mathematics, Computer Science, Economy, Electronics" degree (*MIEE*; 270 students in first year, amongst them 60 specialized in mathematics). Some of these teaching units concern all the MIEE students; some concern only one or two options, i.e. "economy and computer science". Most lectures are given in an amphitheatre for a maximum of 150 students. In fact for most teaching units, there is a single amphitheatre, with two exceptions: the first year calculus teaching is organized in small groups, like secondary school classes and in the first year linear algebra teaching, two lecturers work in parallel in different amphitheatres.

I met each of these colleagues for an individual interview (see the interview guidelines in the appendix) and collected all the resources they mentioned. The interviews were recorded and transcribed. I noted in each interview the kind of activities mentioned by the teacher, the resources cited, how many times each of them is cited, and in connection with which activity(ies). I also noted the collective work (with who, for which objective), the beliefs expressed about mathematics or about teaching issues. I then connected teachers' declarations and the content of the resources he/she uses or designs. For space limitation reasons I cannot present here a detailed analysis of each case,

	Experience	*Country of the studies, position*	*Research domain*
Bob (M)	7 years	France, lecturer	Numerical analysis
Doris (F)	17 years	France, lecturer	Symbolic computation
Nadia (F)	24 years	Italy, lecturer	Partial differential equations
Bill (M)	13 years	Germany and UK, lecturer	Geometric theory of groups
Mary (F)	2 years	France, PhD student	Geometric theory of groups
John (M)	1 year	France, PhD student	Spectral theory

Table 1: Profiles of the university teachers interviewed

I only present the main results from the whole group of participants.

RESULTS

General structure of documentation systems for teaching

Documentation systems are individual constructs. A detailed investigation of these systems, for each teacher participated, reveals specific features. Nevertheless here one of my aims is to identify common aspects in the structure and content of these systems. Naturally, a first general description leads to identify two potential systems: one for teaching and one for research. I did not ask the teachers about their resources and documents in the context of their research activity. I focus here only on the documentation system for teaching – but I try at the same time to identify in it documents which can also belong to the documentation system for research.

"Teaching" here refers to a large range of activities, with different aims: preparing a lecture, giving a tutorial, correcting worksheets, answering students' e-mails, etc.

So the documentation system for teaching is itself composed of different subsystems. For the teachers I interviewed and the teaching units concerned, except in special systems which I discuss later, the documentation systems for teaching comprise four subsystems, linked to different activities: (preparing and giving) lectures; tutorials; assessments; and communication.

Starting from this general structure, I first try to identify crucial resources, defined as those that are present in the intersection of several subsystems. These resources intervene in documents for different aims of the activity. As a consequence, their features are linked with schemes and thus beliefs concerning mathematics and their teaching which have an important influence on the teacher's practice.

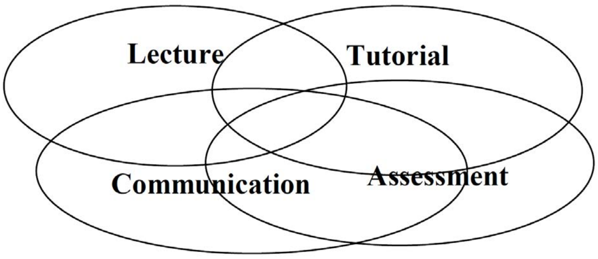

Figure 1: General structure of the documentation systems for teaching

The analysis of the interviews indicates that three kinds of resources appear as crucial: the "polycopie"; the exercises sheets; and the texts of previous exams.

THE CRUCIAL RESOURCES AND CORRESPONDING DOCUMENTS

The "polycopie"

The polycopie is a text, corresponding more of less to the content of the lecture, which is available for the students on the lecturer's webpage as a pdf file, from the beginning of the teaching. Teachers and students at university in France do not use textbooks. This polycopie is used by the lecturer, for the preparation of his/her lecture and by the teachers offering the tutorial, to be informed about the content of the lecture and prepare the tutorial. It also intervenes in the communication between teachers and between teachers and students but not in the preparation of the assessments. The documents developed from the resource polycopie are not the same, when the aim is to prepare a lecture, or to prepare a tutorial. The documents associate indeed resources and schemes. The schemes can incorporate the same beliefs (e.g. "When a usual function is a bijection on a given interval, its reciprocal is also a usual function whose properties must be learned"), with different objectives and rules of action. More importantly, the teachers have different beliefs concerning directly the content and the role of the polycopie. Some of them (Bob, Bill, John) think that students need to have access to the precise text that has been written on the blackboard (the most usual practice in this university, only one colleague amongst the six I interviewed used projects slides). The content of the polycopie should correspond to this content: if a student took incorrect notes, or missed a course, this is not a problem since the polycopie contains the reference text. Others (Doris, Nadia) think that the polycopie must only be a summary of the course, containing the most important results ("for theorems I do not write the proof on the poly", Doris): the students' notes are the reference text for their learning of the course. And one of the teachers I interviewed, Mary, thinks that the polycopie must complement the course by giving additional details, examples, worked exercises ("students must find additional information in the poly"), in particular for high-achieving students. As a result, from one teaching unit to another, the content of the polycopie can be linked to the content of the lecture in different manners.

The exercises list and the previous assessments texts

The exercises lists and previous assessment texts are crucial resources, both for the tutorials and the assessments (and they naturally also intervene in communication). Similarly to the polycopie, the exercises list and the previous assessments texts are given to the students from the beginning of the year, available on the lecturer's webpage. For most teaching units, the exercises list exists for a long time, amongst the teachers I interviewed, only two of them have been involved in the design of such a list. Nevertheless, the teachers develop from this list different documents. For the same objective, these documents encompass different rules of action, linked with different beliefs.

> Nadia: Each year the first thing to do is to investigate who your students are, and adapt the content and expectations to these students *(rule of action).*

Nadia believes that, for the first year students who have a limited mathematical background, it is not necessary to ask for proofs in the tutorials.

> Mary: I always start the tutorial by a summary of the content of the polycopie *(rule of action),* because they do not learn the course before the tutorial, some of them even do not attend the course *(operational invariant).*

Some of these beliefs, present in the documents developed for the tutorial, are linked with the teacher's research activity:

> Nadia: Those who can say – well, I do not know this problem, but I will try to do something with my hands – this is a very important attitude for research.

The preparation of the exam and intermediate assessments texts is always a collective work. It can be shared in the group of teachers for a given teaching unit (in each teaching unit the students take between 2 and 6 exams and intermediate assessments), or proposed by the lecturer(s). This particular documentation work: "writing an assessment text" has been studied by Lebaud (2009). The data confirm the results of the study by Lebaud. The document developed by the six teachers comprises the list of exercises, the previous assessments texts, and beliefs as: "the exercises for the assessment must be similar to those done in the tutorials"; "the assessment must cover all the content of the course". Participating in this collective documentation work contributes to the development by novice teachers of beliefs shared with their colleagues. This issue can be further studied in terms of communities of practice (CoP, Wenger 1998): novice students progressively become member of the CoP of mathematics lecturers, by sharing the same resources and practice.

Professional development and development of the documentation system

The university where the study takes place provides no professional development for the teachers. The progressive integration of novice teachers is managed by giving them gradually increasing responsibilities in the teaching, which I interpret here as: the professional development for teaching of novice university teachers corresponds to a development of the documentation system.

The PhD students I interviewed (similarly to all PhD students in this university) only offer tutorials. This means that they are given the polycopie, the exercises list and previous assessment texts at the beginning of the year. Their responsibility is to choose exercises from the list to work with their students during the tutorial. They could naturally choose other exercises, for the tutorial or for homework, but they do not do it, because the list of exercises is sufficient. Their first opportunity to design themselves exercises is provided by the writing of assessment texts, with other colleagues, as described above. So the professional development corresponds to the development of the documentation system: from a documentation system reduced to the subsystems for tutorials, assessment and communication to a documentation system incorporating also the subsystem for lectures.

In the case of a new lecture, the colleagues declare that they use books. In some cases these books are mathematics books addressed to higher level students: about numerical analysis (Bob), or symbolic computation (Doris), for example. The teacher then makes an important didactical transposition work

Lecture *Polycopie + Books (from higher level, or other countries). Sometimes: lecture notes of a colleague.* *Discussions with students at the end of lectures, evaluation of the teaching unit by students*	**Communication** e-mails sent by students, by colleagues website of the university, of the mathematics department *For a lecturer: Uploading files on his/her webpage to inform the colleagues and the students; discussing the case of specific students with colleagues.*
Tutorials Polycopie+ Exercises sheets + previous assessment texts + e-mails from lecturer + his/her webpage + discussion with the students Students' productions (homework and assessments) + corrections	**Assessment** Exercises sheets + previous control texts + e-mail discussion with colleagues + students productions

Table 2: Evolution of the documentation system: from tutorials to lectures as an enrichment of the documentation system (in italics the lecturer additional part)

(Chevallard, 1985), to produce content accessible for first or second year students.

Digital resources: An increasing, yet limited use

Proposing the polycopie, the exercises sheets, the previous exam texts on his/her professional webpage is done by 3 of the 4 lecturers. The lecturer's webpage is a central resource for the communication from the lecturer to his/her colleagues and his/her students. In general, the use of digital resources for the communication between colleagues, or with the students is a very important evolution, observed by each colleague. Information about the students is available on the university Virtual Learning Environment. Complementary information, such as the official curriculum, students' photos, is provided by the mathematics department website. The discussions within the team of teachers of a given teaching unit, the information on the course progress by the lecturer(s) for the teachers of tutorials are made via e-mail. Some students also write e-mails to teachers, but the in person discussion at the end of the lecture or tutorial remains the main communication mode, between students and teachers.

Nevertheless the use of digital resources remains limited, compared for example with secondary school (Gueudet *et al.*, 2012). The six colleagues declare that they do not search for Internet resources to prepare their courses, considering that they will not find something corresponding to their precise teaching objective. The use of the calculator by students is allowed during tutorials, but forbidden for the assessments. For four out of the six teachers I interviewed, the use of technology seems to be restricted to their documentation system for communication.

I observe a different situation for two colleagues, contributing to two special teaching units: one about symbolic computation (Doris) and the other about numerical analysis (Bob). These teaching units encompass in particular, aside the tutorials, "practical works" in a computer lab. I consider here more precisely the case of Doris. Doris uses Maple for all the aspects of the teaching: lecture, tutorials, practical work – except for the assessment. She has developed different documents involving Maple, and has in particular a strong belief about the link between writing algorithms, programming them, and learning mathematics:

> Doris: They work with algorithms by programming them. This way they can evaluate their efficiency, and see if they are useful.

She uses also Maple in her own research. For this special course, the resources for teaching and the resources for research have a significant intersection: Maple, and associated computer programs. The same situation happens for Bob in numerical analysis, with Scilab. In these cases, the course is designed for mathematics majors, and concerns a topic linked with the teacher's research; there is an associated link between the resource system for teaching and for research.

CONCLUSION AND PERSPECTIVES

The documentation systems of the six university teachers interviewed could be classified in three categories: Lecturer, for a "usual" teaching unit; Lecturer, for a teaching unit involving a specific software; Novice teacher (here PhD student), giving only tutorials in a "usual" teaching unit. The novice teachers' systems encompass only three subsystems: tutorials, assessments, communication; while the lecturers' systems also have a subsystem for lectures, and a more developed communication subsystem (see Table 2). Naturally other kinds of documentation systems exist, for other cases. Nevertheless these six systems have interesting common features and differences.

For all of them, the polycopie, the exercises list, and the previous assessments texts are crucial resources. None of them incorporates resources (exercises, mathematical texts) found on the Internet. This situation is completely different from the documentation work of secondary school teachers in France (Gueudet et al., 2012). Searching for resources on the Internet is a very usual practice in this context, in particular for the choice of "introductory activities" (problem texts, aiming at the introduction of a new concept or method). In fact such introductory activities do not exist, in the teaching at this university. The new concepts and methods are presented in the lecture, and then applied during the tutorials.

Novice teachers progressively develop their documentation systems. They firstly develop documents for the tutorials; then for the assessment, being involved in the collective preparation of assessments' texts. Along this work, they develop schemes which incorporate beliefs shared with their more experienced colleagues. Starting to give lectures is another step, which can lead to the development of more personal beliefs, in particular for a new lecture with no previous polycopie.

In the documentation systems for teaching units involving a specific software, this software is a crucial resource. Otherwise, only technologies for communication intervene, with the lecturer's webpage playing a central role.

Naturally this study remains limited, since I only met six colleagues, all of them working at the same university. Other universities can have different teaching strategies, kinds of resources, different organisations, or local projects that shape the documentation work of teachers. I intend to extend this work, nationally and internationally. Another perspective is also to deepen this work by meeting again the six teachers interviewed, and by observing their courses to confront their actual practice with their declarations.

APPENDIX: INTERVIEW GUIDELINES

This interview concerns resources (mostly material resources), intervening in your teaching for the first or second university year. Our aim is to understand which resources you use, which resources you design for your students etc.

Years of experience in teaching: Research domain:

1) Let us consider a teaching you did this year, for example « linear algebra in year 1 ». Which resources did you use, and design, for this teaching? For the lectures, if you gave lectures; For the tutorials or practical works; For the preparation of the intermediate assessments and exams texts.

2) About digital resources: do you use a professional webpage, a virtual learning environment, specific software? Do you use online resources to prepare your courses, do you project slides during your courses?

3) About collective work: do you work with colleagues to prepare your teaching? Which kind of work do you make for your teaching with colleagues?

4) For experienced teachers: which evolutions do you retain in the last 10 years, concerning the resources you use and design for your courses? For novice teachers: do intend to modify your teaching next year, how and why?

5) Link with research: are there resources that you use both for your research and for your teaching? Or other links, between your teaching and your research?

6) Did I forget to mention important resources, or something else that you consider important concerning your teaching?

Abstract algebra, mathematical structuralism and semiotics

Thomas Hausberger

University of Montpellier, Montpellier, France, thomas.hausberger@univ-montp2.fr

I report in this paper on my attempt to help students reflect on the axiomatic method and structuralist thinking in mathematics through a didactically-engineered activity (the theory of banquets, an invented structure simpler than group theory, but still quite rich semantically), as a lever to tackle the issue of the learning of abstract algebra. It sheds light into the cognitive processes involved in the conceptualization of an abstract algebraic structure, which are discussed within a semiotics framework. Empirical data show an insufficient syntax-semantic dialectic and mental processes based on the recognition of (visual) patterns.

Keywords: Abstract algebra, mathematical structuralism, didactics and epistemology of mathematics, semiotics, syntax and semantics.

INTRODUCTION

This article focuses on the teaching and learning of abstract algebra (the discipline dedicated to the study of algebraic structures, that is, the investigation of logical consequences of specific systems of axioms involving composition laws, and the relationships among them) which is taught at Montpellier University at the third-year university level. The difficulties are acknowledged by several authors (Leron & Dubinsky, 1995; Nardi, 2000; Hausberger, 2013) and reflect a "transition problem" (Gueudet, 2008) which, in the present case, occurs inside the university curriculum.

The epistemological analysis presented in Hausberger (2013) allowed a connection with the following epistemological transitions: "the systematization of the axiomatic method, after Hilbert, and the transition, after Noether, from thinking about operations on elements to thinking in terms of selected subsets and homomorphisms". Indeed, as emphasized by Cory (2007):

> This image of the discipline turned the conceptual hierarchy of classical algebra upside-down. Groups, fields, rings and other related concepts, appeared now at the main focus of interest, based on the implicit realization that all these concepts are, in fact, instances of a more general, underlying idea: the idea of an algebraic structure.

In other words, this epistemological gap leads to the *vanishing of concrete mathematical objects in favor of abstract structures*. This induces the following didactical problems: the teaching of abstract algebra tends to present a *semantic deficiency* regarding mathematical structures, which are defined by abstract axiomatic systems and whose syntactic aspects prevail. How does the learner build an "abstract group concept"? Indeed, what kind of representations can he rely on to do so when the purpose is to discard the particular nature of elements, in other words the mathematical context? Moreover, the investigation of the didactic transposition of the notion of structure shows that it is a *meta-concept* that is never mathematically defined in any course or textbook (and cannot be so):

> As a consequence, students are supposed to learn by themselves and by the examples what is meant by a structure whereas sentences like "a homomorphism is a structure-preserving function" is supposed to help them make sense of a homomorphism (Hausberger, 2013).

As announced in loc. cit., I have engineered an activity for students to reflect on the axiomatic method and structuralist thinking in a simple context (simpler than group theory): the *theory of banquets*, an invented structure. It aims at operating the fundamental *concrete-abstract and syntax-semantic dialectics* (see below) and at clarifying the concept of mathematical structure using the meta lever (Dorier et al., 2000), that is "the use, in teaching, of information or knowledge *about* mathematics. [...]. This information can lead students to reflect, consciously or otherwise, both on their own learning activity in mathematics and the very nature of mathematics".

The purpose of this article is to present a few results that were obtained as I experimented with this activity. It tackles the following questions: what kind of cognitive processes and reasoning do students use to make sense of an axiomatically-presented structure such as the banquet structure? How do they engage in the task of *classifying models* of the axiomatic system (and interpret the task: for instance, what kind of representations do they use, and do they formalize a concept of isomorphism of banquets)? What kind of abstract banquet structure concept do they build through the completion of such a task? Similarly as in the context of classical algebra in secondary education, semiotics will give interesting tools to answer these questions. Still, some adaptation needs to be made to reflect the context of abstract algebra, since structures represent a higher level of organization compared to the classical mathematical objects that they formalize, generalize and unify.

EPISTEMOLOGICAL AND DIDACTICAL FRAMEWORKS

Abstraction

The French verb *abstraire* has three different meanings: 1. to discard ("faire abstraction de") 2. to isolate (from a context) 3. to construct (a concept). Although these are three different actions, they may take place in order to reach a common goal as is the case in abstract algebra: mathematicians disregard the particular nature of elements and isolate relations to build the structure as an abstract concept.

The "principle of abstraction" as a process to create concepts has been used by Frege (1884) to define cardinal numbers. To introduce the reader to this revolutionary idea, Frege gives the enlightening example of the direction of a line which is defined as the class of all lines that are parallel to the given line. The principle was formalized later on by Russell (1903): to say that "things are equal because they have some property in common" and reduce a class to a single element, the relation that traduces this property should be symmetric and transitive (an equivalence relation).

Semiotics

Just as language is compulsory to express any idea, mathematical objects are accessed through mathematical signs. Frege's semiotics will be used in this paper, thus making the distinction between the sense and the denotation of a sign (Frege, 1892). The denotation of the sign is the object it refers to whereas the sense is related to the "mode of presentation" of the object. Mathematical signs are often polysemic but the context is meant to determine the reference uniquely. Conversely, different signs may represent the same object, thus having a different sense but a common denotation. In this way, different representations may bring to light different aspects of an object; they are acknowledged as denoting one and the same object through the realization that a particular processing or conversion of semiotic register of representation (Duval, 1995) allows to transform one representation into the other, and reciprocally. In other words, as stated and illustrated by Winsløw (2004, p. 4), one may "think of objects as *signs modulo object preserving transformations* (OPT)":

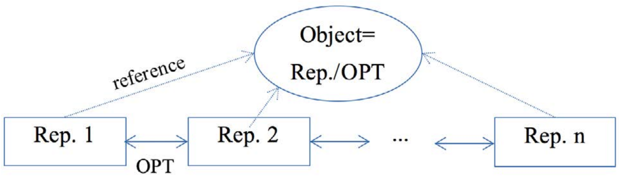

Figure 1

Syntax and semantic

Mathematical signs are organized within sentences and formulae that are built according to strict syntactic rules. From a logical point of view, a definition is an "open sentence" that may be satisfied or not when the variables of the sentence are assigned in a suitable universe of discourse: this is the semantic conception of truth introduced by Tarski (1944); see also Durand-Guerrier (2003) for a more detailed account and didactical applications. In this respect, a piece of data that satisfies the definition of a mathematical structure (which involves a set of axioms that forms its syntactic content) may be called a *model* of the structure (in the given universe of discourse or hosting theory). The

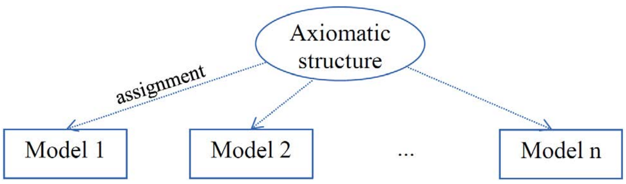

Figure 2

models will be regarded as the semantic content of the axiomatically-defined mathematical structure, its extension as a concept.

Tarski also defined the notion of logical consequence from a semantic point of view. It will be used below in order to show that a given axiom A_1 cannot be deduced from other axioms A_i: it amounts to showing the existence of a model satisfying the A_i's but not A_1. This contrasts with syntactic methods which consist of deduction by application of valid rules of inference.

Structural objects

In a famous dispute with Hilbert, Frege argues against the legitimacy of abstract definitions by systems of axioms. One argument concerns the intrinsic polysemy of such definitions: in semiotic terms, an axiomatic definition as a sign has multiple references, the models of the axiomatic system. In abstract definitions, the context doesn't inform on the denotation simply because it is abstracted (in meaning 1 of the verb).

In order to build an abstract structure (group, ring, banquet, etc.) concept, and therefore give a more adequate (still polysemic) semantic meaning to the set of axioms as a sign, one needs to use structure preserving applications (SPT), the so-called isomorphisms, which are defined as relation-preserving bijections (all models may be viewed as sets endowed with additional data which define relations and satisfy the axioms). This allows us to associate to an axiomatic structure its "structural objects" (our terminology), the isomorphism classes of models or models modulo SPT, in the same manner as mathematical objects were built from representations modulo OPT, by means of the principle of abstraction.

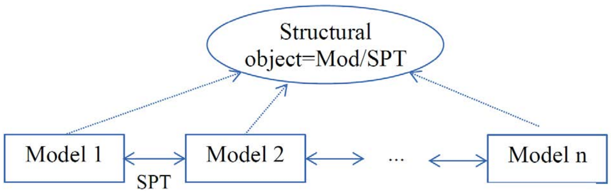

Figure 3

It should be pointed out that, compared to Winsløw's diagram, dotted arrows do not represent the denotation of a sign but only "quotient maps". Since models are accessed through signs, the preceding diagram should in fact be reprinted, to reflect semiotic views, replacing each model by one of its representation and SPT by its semiotic version SOPT (structural object preserving transformations). Dotted arrows may then represent denotation when the context indicates a structural perspective: for instance, Z/2Zx Z/2Z and "the symmetry group of a rectangle" may both refer to the Klein 4-group V_4, as an abstract group concept. One may also write $V_4 = \langle a,b; a^2=b^2=(ab)^2=1\rangle$ for a more syntactical description. Nevertheless, since mathematicians take care in emphasizing the difference between a class and one representative, many authors would prefer to use the sign V_4 to denote the group Z/2Zx Z/2Z and say that it is isomorphic to the symmetry group of a rectangle or to the quotient of the free group on two generators by the relations $a^2=b^2=(ab)^2=1$. The idea behind structural objects is, following Sfard, that some kind of reification must occur for concept building: "Reification is defined as an ontological shift – a sudden ability to see something familiar in a totally new light" (Sfard, 1991). For this to happen, a plurality of models should be needed, borrowed from different mathematical domains and represented in different semiotic registers. Similarly as in Winslow's context, the coordination of these representations (through SOPT) should be crucial to obtain a conceptual schema of the structural object. It should open the possibility to abstract from "templates" a "pattern" (Resnik, 1997). Nevertheless, unlike in Winsløw's context, a representation of a model as a sign may now refer to both the model and the structural object (in a context where both appear), whereas a mathematical distinction must be kept. Solving this issue would require a more direct mediation of the structural object by a new adequate (to be specified) sign.

THE THEORY OF BANQUETS

As a piece of didactical engineering, the theory of banquets was built on the basis of an epistemological analysis previously presented (Hausberger, 2013) in order to cover the three usage contexts of the meta-concept "structure": 1. the structure as defined by a system of axioms 2. the abstract structure (of a given group or banquet) 3. a 'structure-theorem' (which describes the way an object can be reconstructed from simpler objects of the same type). It is filled with meta-discourse, as is already visible in the worksheet title: "The theory of banquets: a mini-theory to reflect on structuralist thinking". The interested reader is requested to email the author for a copy of the complete worksheet.

The activity is divided into three parts: 1. logical investigation of the axiomatic system and classification of models 2. elaboration of an abstract theory of tables (this is the other way round: students are asked to formalize the disposition of guests around a round table) and structure-theorem for banquets (a banquet is the disjoint union of tables) 3. connection with the theory of permutations (a reinterpretation of the banquet theory that permits you to see the structure-theorem as a direct consequence of the well-known theorem of canonical cycle-decomposition of a permutation).

Part 1 and 2 clearly bring-in a concrete-abstract dialectic. A top-bottom approach has been chosen in part 1 for two reasons: as this is the standard strategy in textbooks, it is interesting to inquire how students will make sense of such a definition; moreover, part 1 will suitably enrich the didactical *milieu* for students to be able to model the situation given in part 2. Nevertheless, part 1 is already dialectical in itself: it amounts to making learners move on from the still abstract and syntactical conception of a structure exemplified by Figure 2 to the more concrete and semantic conception of Figure 3 (with several structural objects). The expected result of the abstract-concrete and syntax-semantic dialectics is a formulation of an abstract and syntactic characterization of structural objects (question 2 d of the worksheet, see below).

The definition of a banquet is as follows: it is a set E (the objects) endowed with a binary relation R (encoding the relations between objects) which satisfies the following axioms: A1. No object fulfills xRx A2. If xRy and xRz then $y=z$ A3. If yRx and zRx then $y=z$. A4. For all x, there exists at least one y such that xRy.

In part 1, students were asked the following questions:

1 a. Coherence: is it a valid mathematical theory, that is, are the axioms non-contradictory? In other words, does there exist a model?

1 b. Independence: is one of the axioms a logical consequence of others or are all axioms mutually independent?

2 a. Classify all banquets of order $n \leq 3$

2 b. Classify banquets of order 4

2 c. What can you say about Z/4Z endowed with?

2 d. How to characterize abstractly the preceding banquet (meaning its abstract structure of banquet among all the different classes of banquet, in fact how to characterize its class)?

Solving these questions amount to solving the following tasks and sub-tasks:

T1. Construct a model by suitable assignment of variables

T2. Classify banquets of a given order:

ST2a. Define a notion of isomorphism

ST2b. Give a list that covers representatives of all possible classes

ST2c. Show that two elements of the list are non-isomorphic

T3. Show that 2 models are isomorphic by explicit construction of an isomorphism

T4. Characterize abstractly an isomorphism class

Note that answering question 1 b amounts to solving T1 from the semantic point of view of logical consequence (see above) and negation of an axiom. In doing so, the boundaries of the banquet concept will be marked out. In the sequel, it will be necessary to focus first on T1 and give a list of available domains of interpretation for the axiomatic system and corresponding semiotic registers, since available representations greatly impact the other tasks.

Empirical interpretation: the name banquet may suggest by itself (or by reading the entire worksheet) guests around tables, so one defines xRy if and only if x sits on the right of y. Note that proving that this universe of discourse can serve to interpret the whole banquet theory reduces to proving the structure-theorem. One could also imagine a rectangle table and pick up guest sitting face to face, as a particular model.

Set theory: the set E is described by naming its elements and the binary relation is represented by its graph inside E^2. This straightforward representation is not very interesting since it doesn't “encode” much structure.

Matrix theory: a binary relation may be seen as a function from E^2 to {0,1} (true/false), and therefore be represented by a double-entry table, in other words a matrix. In this interpretation, the axioms say that the diagonal contains only zeros, that there is exactly one '1' in each row and at least one in each column. In finite dimension, one can easily prove that there is exactly one '1' per row and column, hence it is a permutation matrix.

Graph theory: xRy if and only if vertices x and y are connected by an edge directed from x to y. The axioms say that from a vertex there originates exactly one edge and terminates at most one; therefore, unlike in general graph theory, is it easy to see when two drawings define the same graph.

Function theory: According to axioms A2 and A4, defines a function f and the other axioms say that it is injective and has no fixed point. When the set E is finite, then f is a permutation without fixed points and one may use the standard semiotic representations for these (including cycle-decomposition).

It is in fact quite amazing to see the diversity of interpretations and models, which certainly reflects the unity and creativity of mathematics. Models may be represented in a mixed or purely symbolic register. When the graphical register is used, it may be a personal idealization of people around tables or an institutional representation borrowed from graph theory. Of course, one cannot expect students to connect to all these theories: for, instance, we bet that students won't translate the problem fully in the function setting and identify the connection with permutation theory (which would ruin part 3 of the activity). But one can wonder about the importance they may give to representations connected to everyday life (empirical setting). Moreover, models may be more or less "generic": compare (E,f), E=N and $f(x)=x+1$, with a matrix that may serve to represent any binary operation. Students may also think that a model should be given by a mathematical formula (like the example given in question 2 c), and restrict themselves to concrete examples in function theory, whereas a generic representation of R is necessary to complete the other tasks.

To give an idea about processes and conversions from one setting to the other, one should notice that a representation such as points marked on circles (empirical) is easily transformed into a graph by adding arrows clockwise between points; one may then associate to the graph its adjacency matrix, from which the function is soon reconstructed by reading the positions of the ones. When E is finite, the algorithm of cycle-decomposition of the permutation gives the tables (one per cycle) and the length of the cycle gives the number of people around each table, thus coming back to the empirical setting.

The pertinence of the setting (choice of a domain of interpretation) depends on the task: graph theory may easily suggests a model that verifies all the axioms except A2; matrix theory is quite pertinent for ST2b (a complete list of all possible relations), still, graph theory again (or even better, a cyclic representation as obtained in the empirical setting) is best to decide if two banquets are isomorphic, as it gives a visual representation that makes common pattern visible and illustrates the etymology of isomorphism as a form-preserving mapping.

I will now present some students' productions. Tasks 2 to 4 will be discussed in greater detail while analyzing these.

EMPIRICAL DATA

The full banquet activity has been tried out during the academic year 2013–14 with third year university students with a background in group theory before teaching ring and field theory. They worked in small groups of 4–5 students and were asked to keep a research notebook that was collected before each phase of institutionalization (Brousseau, 1997). In parallel, in laboratory sessions, I videotaped two pairs of more advanced students (having a master's degree). The interviewer (myself) intervened only at the end of part 1 in order to discuss with the students their answers and their conceptions regarding the classification task. Due to lack of space, I will only give an account of the laboratory session with one of the pairs. Nevertheless, this will already be enough to give an idea of some interesting phenomena that could be observed by using our theoretical framework and in particular Duval's *semiosis*, the apprehension or production of semiotic representations (Duval, 1995).

The pair of students tried to recognize the banquet structure as a *pattern* in known mathematical objects and theories ("what is it, what's this structure?"). Unlike in the classroom experiment, they didn't bring

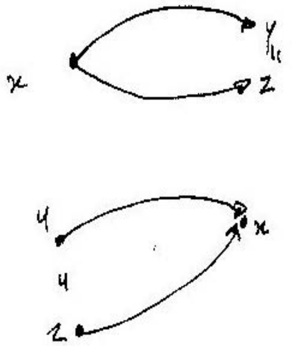

Figure 4a

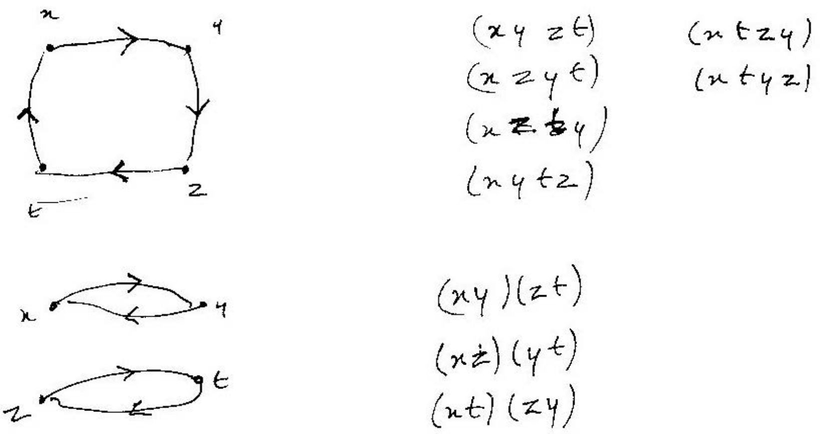

Figure 4b

in wedding banquets; they first thought about the order relation, then analyzed the example B_4=(Z/4Z,*R*) of question 2c as a "kind of a shift" and generalized it (*E*=Z, f(x)=x+1 or x-1). *Semiotic representations* of the *semantic* meaning of axioms A2 and A3 in the *graphical register* (Figure 4a) led them to build *models in graph theory* which they used for tasks T1b and T2. Recognition of *cyclic patterns suggested permutations*, as a common representation: they performed conversions of registers (but didn't connect to the function setting), producing the following classification which comprises 9 banquets of order 4 (Figure 4b).

Student A: Here, we are doing with what we know, but we speak about a structure
Student B: Wait, we can always number the elements [...]
Interviewer: For you, this is an abstract classification because you didn't consider particular relations and you can always rename elements x,y,z,t
A: So there would be 2 classes up to isomorphism?
B: Here Z/4Z and there Z/2Z x Z/2Z
I: You are thinking about the classification of groups [...] So there are 2 types of objects and (x y z t) and (x z y t) would be the same?
B: Not the same, of the same type

The student B couldn't define what he meant by a type, he just made a connection between the word used by the interviewer and the notion of type of a permutation. The word bijection finally appeared but students found it difficult to define what "structure-preserving" meant. They drew the graph for (x z y t) but obtained crossing edges which confused them even more (both are identical as graphs but not as drawings). On the contrary, converting to a graph the example B_4 allowed connection to (x y z t) (obvious congruence of drawings). They didn't realize that abstracting the nature of elements simply meant forgetting letters, a mental process that makes the recognition of isomorphism classes in the representation as cycle products automatic.

CONCLUSIONS AND PERSPECTIVES

This study, through its theoretical framework and the analysis of the presented data, contributes to the recognition of the influence of semiotic representations in cognitive activities dedicated to the learning of abstract algebra. I have discussed the hypothesis that a logical investigation of an axiomatic system and the classification of its models up to isomorphism, in the paradigm of the "theory of banquets" which connects to group-theory, is a cognitive activity that could bring good conditions for learners to develop an appropriate conceptualization of an abstract structure, and in particular access what I called "structural objects". Empirical data show mental processes based on the recognition of (visual) patterns. Conversions of registers were operated on by the two students in order to realize that two objects are isomorphic, a strategy which is successful when the congruence of representations is obvious, but the students couldn't handle the treatments inside a register since they couldn't rely on a formal definition of an isomorphism or make this definition functional, which is evidence of insufficient syntax-semantic dialectic. This also suggests an incomplete understanding of abstraction as a process that leads to structural objects. Finally, the two students tried to work out the analogy with group theory from which they borrowed directly or tried to adapt representations and concepts (see transcript above). As stated by Winsløw (2004), "mathematical concepts are not learned one by one but as coherent patterns or structures", and this also happens at the level of structures themselves, thus gaining access to what I called level-2 unification (Hausberger, 2012).

The analysis of empirical data will be pursued in greater details in an expanded version of this article. It is expected that these investigations and refinements of the semiotic tools will lead to a better understanding of students' difficulties in abstract algebra which are inherent in structuralist thinking, from a cognitive point of view.

The transition from higher education to the world of work: Measuring student teachers' beliefs and practices for purposeful sample selection

Eivind Kaspersen[1], Birgit Pepin[2] and Svein Arne Sikko[1]

1 Sør-Trøndelag University College, Trondheim, Norway, eivind.kaspersen@hist.no

2 Technische Universiteit Eindhoven, Eindhoven, The Netherlands

This paper reports on methodological results from an on-going project investigating student transition from teacher education to the world of work. We argue that research benefits from purposeful sampling, and we present two Rasch-calibrated instruments that aim at finding participants with particular characteristics. With items from existing instruments, one practice instrument is calibrated on Norwegian student teachers. Furthermore, these items are rephrased to fit a second instrument measuring beliefs about teaching mathematics. Finally, 'virtual equating' is used to align items so that measures can be compared across instruments.

Keywords: Student-centredness, measurement, Rasch modeling, sample selection.

INTRODUCTION

A considerable amount of research exists that sheds light on student teachers' transition from higher education to the world of work. Most studies on novice teachers' experiences show that the transition from teacher education to work (as a teacher) is problematic. For instance, many studies describe a gap between higher education and work (e.g., weak relationships between courses and field experiences) (Feiman-Nemser, 2001), and that what students learn in school is not adequately linked to their future practices as teachers (e.g., Liston, Whitcomb, & Borko, 2006). Other studies describe new teachers' first period in work as a time where the workplace communities expect new employees to be able to teach like experienced teachers (Worthy, 2005), a period with high emotional intensity (Flores & Day, 2006) and a period where there is a gap between new teachers' actual identities and the 'designated identities' shaped by the workplace communities (Haggarty, Postlethwaite, Diment, & Ellins, 2011). In most studies, however, the sample selections do not seem to be based on pre-determined criteria (or these are not made explicit).

To build further on existing research, in this paper, we argue that Rasch-calibrated instruments can facilitate the selection of persons with certain characteristics. For instance, some studies would benefit from selecting persons who identify with reform-minded practices, traditional practices, or persons who follow certain trajectories in the transition from education to work (e.g. resisting change; complying with traditional practices; coming to identify with reform-minded practices) etc. Thus, our research question in this paper is: *how can Rasch-calibrated instruments inform the sample selection in studies on student teachers' transition from higher education to the world of work/school?*

In the paper, we report on results from an on-going study where the overall aim is to understand how identities are negotiated in the transition from higher education to the world of work, including those of mathematics teachers in schools. The study follows on from previous studies of the TransMaths project (www.transmaths.org) (e.g., Pampaka et al., 2012; Pepin, Lysø, & Sikko, 2012), and we will present two Rasch-calibrated instruments that measure persons' practices and beliefs about ideal practice. Finally, we discuss how these instruments can inform sample selection.

THEORETICAL BACKGROUND

The literature suggests different ways of characterising teachers. As a frame for our instrument, we build on the notion of student-centredness, defined by Stephan (2014) as

> (...) an approach to mathematics instruction that places heavy emphasis on the students taking responsibility for problem solving and inquiry. The teacher is viewed as a facilitator by posing problems and guiding students as they work with partners toward creating a solution (p. 338).

The notion of student-centred teaching, both in practice and research, has grown in many different directions, and it is impossible to describe one single approach. Nevertheless, Stephan (2014) listed five characteristics of student-centred teaching: problem-solving; collaboration; mathematical discourse; tools/manipulations; and classroom environment (pp. 340–342). Regarding classroom environment, Stephan (2014) emphasized four social norms, documented by Yackel and Cobb (1996), which are supporting student-centred teaching. That is, students are expected to: explain/justify solutions; attempt to make sense of others' explanations; indicate agreement/disagreement; and, ask clarifying questions (p. 340).

The rationale for choosing student/teacher-centredness as a frame is that it is uni-dimensional, and thus meets one basic requirement for Rasch analysis. The construct was used by Pampaka and colleagues (2012) earlier in the TransMaths project, when they used Rasch analysis to construct an instrument to capture teachers' self-reported pedagogies. Their instrument was based upon Swan's (2006) practice-questionnaire, which in turn was based on three teacher orientations: *transmission*, *discovery*, and *connectionist* (Askew, Rhodes, Brown, Johnson, & Wiliam, 1997).

In order to measure the relationship between practice and belief about ideal practice, we have extended the practice instrument (Pampaka et al., 2012) with a 'belief-dimension'. We argue that there are three reasons for including a belief-dimension to the original instrument. First, several studies suggest that teachers' practices are influenced by workplace norms (e.g., Haggarty et al., 2011). Gresalfi and Cobb (2011) distinguish between three ways in which teachers can relate to these workplace norms: *consent and identify*; *consent and comply*; or, *resist*. As such, knowledge about teachers' practices alone does not distinguish between those who identify with their own practice and those who merely comply with a workplace norm (or are constrained by other contextual influences). Second, knowledge about teachers' beliefs alone does not inform the researcher about how central those beliefs are. That is, two persons that express the same beliefs about teaching mathematics can hold those beliefs with different strengths. Green (1971) identified 'the degree of conviction' as one of the three dimensions in belief-systems. That is, beliefs can be central or peripheral, where central beliefs are more strongly held than peripheral beliefs. If the researcher wants to locate persons who hold certain beliefs strongly, we argue that persons who can relate those espoused beliefs to actual practice are more likely to meet this criteria than persons with different espoused beliefs and practices. Third, in longitudinal studies, knowledge about both practice and belief can provide information about participants' trajectories in terms of the three categories presented by Gresalfi and Cobb (2011).

In sum, we claim that knowledge about persons' beliefs and practices can help researchers in making well-targeted sample selections, and that this is pertinent to studies conducted in the context of higher education.

DATA COLLECTION AND ANALYSIS

In our study items in the instruments were influenced by the original items in the 'practice instrument' (Swan, 2006). For the belief instrument, these practice items were translated into belief items. For instance, the practice item: "Students work with tasks with a clear answer" was translated into a belief item: "Students should work with tasks with a clear answer." The items and the response categories were then discussed at a Ph.D. seminar in mathematics education. From this discussion, 27 practice items and 27 belief items were piloted on 42 Norwegian student teachers in their second and third year of education, in addition to 9 teacher educators at the same institution. The items were discussed briefly with all participants. The items were then revised and piloted again on 36 student teachers in their second year of education. After a final revision, 32 items were assigned to a convenience sample of 83 student teachers in their fourth (and for many, final) year of education. As the original practice-instrument identified some problems with the use of five response categories, four response categories were chosen in our study ('in none/almost none of the lessons'; 'in some of the lessons'; 'in most of the lessons'; and 'in all/almost all of the lessons').

In the analysis, the Rasch-Andrich Rating-Scale Model and the WINSTEPS software were used to construct *one practice scale* and *one belief scale*. The Rasch model turns categorical data into interval measurements. Moreover, the model assumes an underlying trait (e.g., teacher-centredness) and is based upon the idea that persons with high measures (e.g., highly teacher-centred) are more likely to agree with the items that define the trait than persons with low measures (e.g. highly student-centred). Similarly, each person is more likely to agree on items with low measures than on items with high measures. A key feature of the Rasch model is that persons and items are not discriminated, which means that they can be measured on the same scale (Wright & Stone, 1979).

Since the purpose of the instruments was to detect persons with particular characteristics (e.g., persons that identify with their practice, or persons with a more teacher-centred practice than belief), we pursued equally scaled instruments. That is, if a person identified with her practice, then her practice-measure should, ideally, be equal to her belief-measure. Moreover, if her practice was more teacher-centred than her belief, then her practice-measure should be larger than her belief-measure. Thus, we conducted four steps for “virtual equating” (Luppescu, 2005): 1) identified pairs of items with, possibly, similar ‘difficulties’; 2) cross-plotted the pairs of items; 3) removed pairs of items that were not close (within a .95 confidence bound); and, 4) rescaled the measures on the beliefs test to compensate for different item spacing. In rescaling the belief-instrument, we used two raw scores at each end of the practice-scale (20 and 45), and their corresponding measures, and computed new UIMEAN (mean of the item difficulty) and USCALE (the user-scale value for 1 logit) for the belief-instrument, so that the measures of the raw scores 20 and 45 were equal in both instruments. This is in principle similar to rescaling a Fahrenheit-instrument to a Celsius-instrument by defining two values (e.g. points of freezing and boiling).

To ensure further validity, we used guidelines presented by Wolfe and Smith Jr (2006) which extends Messick’s (1995) validation framework with two aspects of evidence put forth in The Medical Outcomes Trust (MOT). To summarize, validity is viewed as a unified concept. That is, there are not different kinds of validity, rather, different kinds of evidence that support validity. Accordingly, Messick (1995) presents six different aspects of validity where evidence can be found: the *content, substantive, structural, generalizability, external,* and *consequential* aspects. Furthermore, the MOT presents two aspects not mentioned by Messick: *Responsiveness* and *interpretability*.

RESULTS

We now present the final instruments and corresponding validity arguments. Both instruments consisted of 12 items, whereas item 3 (marked with an [x]) was reversely coded due to negative point measure correlation earlier in the analysis. To find evidence for the *content* aspect of validity, the technical quality of items has been evaluated. Mean squared fit statistics are chi-squared statistics divided by their degrees of freedom (and hence, have an expected value of 1). OUTFIT is outlier sensitive fit, and INFIT is information-weighted fit. Linacre (2002) suggests values between .5 and 1.5 as productive for measurement, and all items in both tests were within this interval, with belief item 3 having the largest misfit (Figure 2). Furthermore, person reliability values, analogous to Cronbach’s alpha, were .87 (practice) and .78 (belief),

Figure 2: Final belief items

and item reliability was .98 on both tests, an indicator that the sample was big enough to provide information for item calibration.

When practice items were cross-plotted against belief items (Figure 3), most items were within a .95 confidence bound. An exception was one border-line item (item 4), but the effect on person measures, when this item was removed, was negligible. Thus we have decided to keep the item in the analysis.

Ideally, we would want each pair of items to have equal measures. The DTF-analysis, however, showed that measures were close but for most items not equal (Figure 3). The next step, then, was to see if the measures were 'close enough'. And indeed, when person measures were compared with the ideal situation (anchoring practice items to be equal to the belief items), only small differences in person measures could be found (.26 logits at the most with r^2=1.00).

Moreover, rating scale analysis has been conducted for both instruments, to find evidence for *substantive* validity. None of the four guidelines suggested by Wolfe and Smith Jr (2006, p. 210) were violated: 1) each rating scale category contained more than 10 observations (65 observations in the first category in the practice instrument, being the least); 2) the shape of each rating scale distribution was smooth and unimodal; 3) the average respondent measure associated with each category increased with the values of the categories; and, 4) the unweighted mean-squared fit statistics were all less than 2.0 (1.25 at the most).

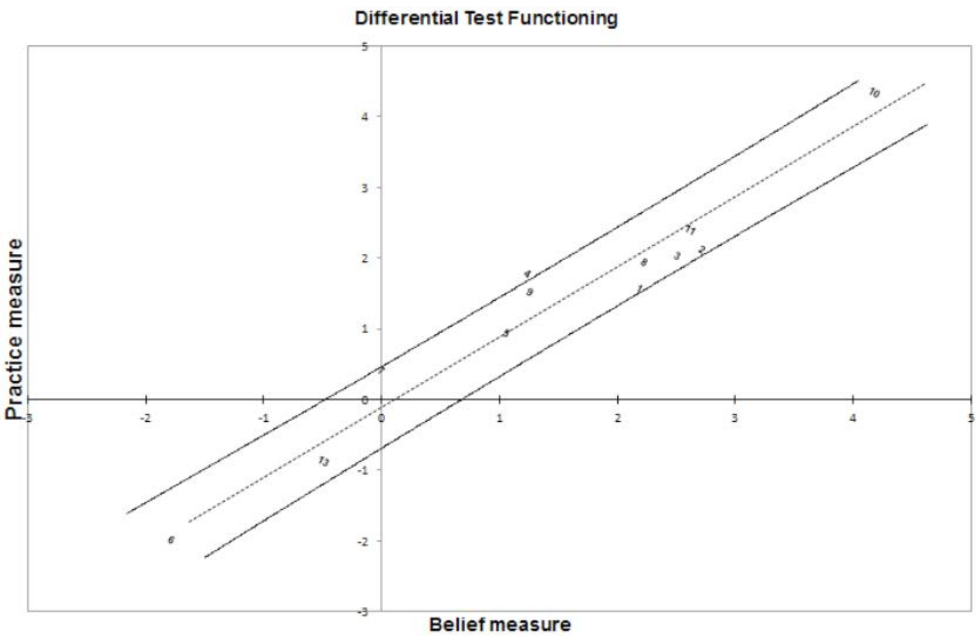

Figure 3: Differential Test Functioning (DTF)

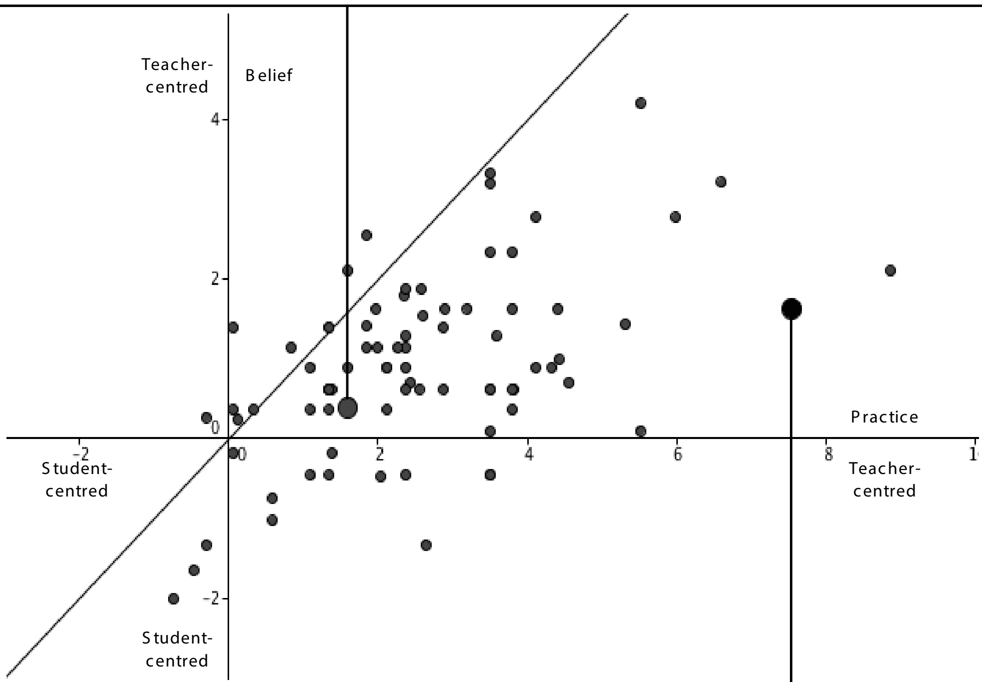
[…] So, we used envelopes and paperclips. Eh, and that X was the envelope, and the number of paperclips in the envelope was the value of X. So, by taking away and adding on both sides of a line, they could solve equations. Eh, and it worked very well.

[…] A good task. Hmm… […] that there is, kind of, a possibility for individual interpretation and exploration. Eh, that it is, it is open. That it is possible to do it in your own way. That it is not constrained by, by the method you are supposed to use, for instance.



[…] it was jus a recap of, they were having a test. And, from one chapter in the book. And then, I read in the book and made my own summary. Formula booklet summary. And then I went to the classroom. And then I went through all I had written down in advance.

[…] that I want, I don't want it to be loose and floating, and, now you are going outside to think about this, and now you are going to play with these bricks. I want some structure, and I want it to be like, ok, now we are going to do this, why do we do it? And I want some rules and stuff. […] But, I think it is also important that you should explore and work with things you know. Perhaps go outside, in mathematics in particular, I think it is important that mathematics is not only abstract, but that you have to work with concretes, real life situations.

Figure 4: The relationship between Norwegian teacher students' practice and espoused beliefs about ideal practice

Uni-dimensionality is a basic assumption in Rasch analysis (Bond & Fox, 2003, p. 32). Thus, we have evaluated dimensionality (*structural* validity) using principal component analysis of the standardized residuals after the Rasch dimension was extracted. Among the practice items, a second dimension could explain 1.9 (in Eigenvalue units) (6.5 %) of the unexplained variance, and among the belief items, a second dimension could explain 1.9 (6.8 %) of the unexplained variance. By default, WINSTEPS stratifies items in three clusters for each contrast. The dis-attenuated correlations between person measures in these clusters were close to 1 on the belief instrument, and .85 in the practice instrument. Thus, we treated the second dimensions as strands (like addition and subtraction on a mathematics test), and not as dimensions that needed separate instruments.

To find evidence for the *generalizability* aspect of validity, we have used Differential Item Functioning (DIF): *the loss of invariance of item estimates across testing occasions* (Bond & Fox, 2003, p. 309). Item calibrations have been compared between genders, classes, and high/low-measured persons. The DIF (Rasch-Welch) t-value was less than 2.0 in all cases, where the belief item 5 had the most misfit between males and females (DIF-contrast = .78 with p = .07).

To look for *external* validity, we have compared the results from our study with the literature on the relationship between beliefs and practices. The results in Figure 4 show that there was only a moderate correlation ($r^2 = .28$) between students' practice and espoused beliefs, consistent with the existing literature (Liljedahl, 2009). However, the responses lie heavily on one side of the identity line; inconsistency was more evident for those who held student-centred beliefs. Although it has not been expressed explicitly, we assert that traces of this relationship can also be found in the literature. Even if different notions are being used, inconsistency is mostly described in situations where participants express reform-minded beliefs (e.g., Kesler, 1985; Vacc & Bright, 1999).

Evidence for *responsiveness* validity can be found in the Person-Item Map (Figure 5). Marks on the right represent item measures, and marks on the left represent person measures. From this, we can see that when person measures exceeded -2 to 4 logits, we can expect that measures were being less accurate. However, since we have used the Rasch-Andrich Rating Scale Model, each item covered more of the trait than a dichotomous item. Thus, the 'lowest' and the 'highest' item measures were not to be considered the 'floor' and the 'ceiling'.

The *interpretability* aspect of validity is the degree to which qualitative meaning can be assigned to quantitative measures (Wolfe & Smith Jr, 2006, p. 227). Thus, excerpts from two interviewed cases are presented in Figure 4. In addition, nine teacher educators, at the same institution, were asked to respond to the belief-test. Other than providing construct validity (as teacher educators were expressing significantly more student-centred beliefs than the students), the instrument was rescaled, so that the mean of the teacher educators' measures was set to zero. This was then used for qualitative interpretation: values close to zero could be thought of as in accordance with the values of the educational institution.

CONCLUSION

In this paper, we have argued that research can benefit from purposeful sample selection, and we have presented two instruments for this purpose. From these instruments, certain 'kinds of persons' can be selected: persons who seem to practise and identify with institutional values (measures close to the origin); persons who seem to practise and identify with traditional values (high measures on both instruments); persons who seem to consent and com-

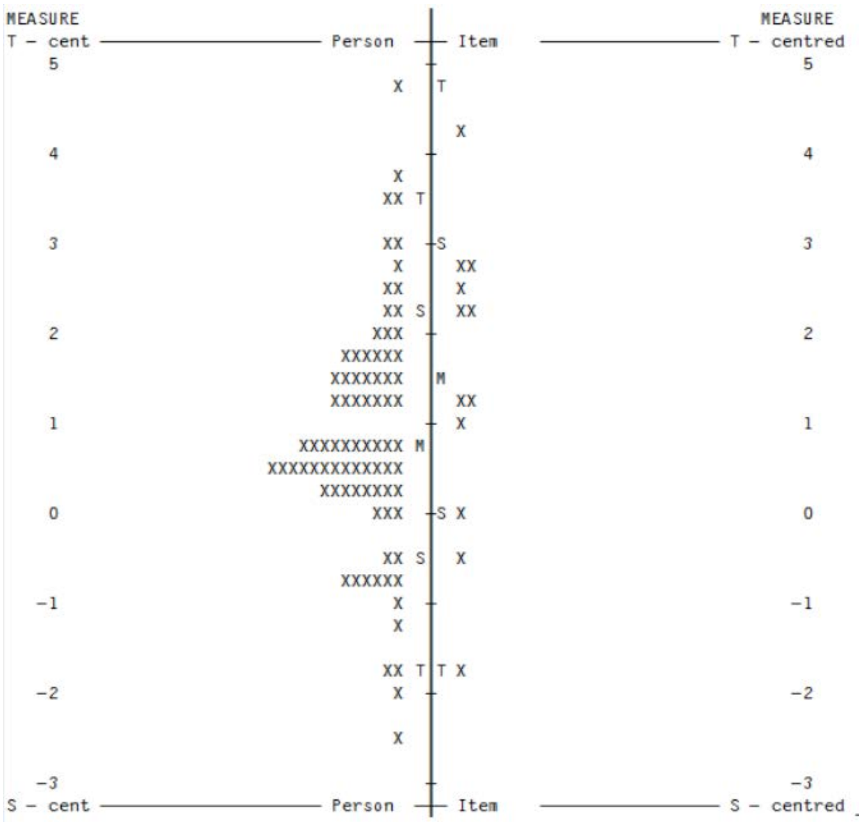


Figure 5: Person-Item Map (belief instrument). M=mean, S=one standard deviation from person or item mean, T=two standard deviations from person or item mean

ply to a workplace norm (having trajectories moving away from the identity line), etc. Our intention is to use these instruments for studying student teachers' transition from higher education to the world of work. However, these instruments can also be used in other kinds of research, we argue. For instance, research on teaching and learning of mathematics in higher education can benefit from selecting particular kinds of participants (e.g. lecturers with a certain practice).

Although we assert that our and similar instruments can be helpful tools for sample selection, we acknowledge their limitations. In our case, we have reduced the practice (and belief) of teaching mathematics to one dimension. This was done due to the statistical benefits, but we emphasize that teaching is clearly multidimensional. Thus, persons with similar measures might, and are likely to have, different practices/ beliefs, even when they are measured with reliable instruments. All we can say is that they probably have some characteristics in common. Nevertheless, we conclude that sample selection is, in many cases, better when it is well-targeted rather than opportunistic.

On advanced mathematical methods and more elementary ideas met (or not) before

Margo Kondratieva

Memorial University, Faculty of Education and Department of Mathematics and Statistics, St. John's, Canada, mkondra@mun.ca

Some mathematical problems, which could be solved by a general approach, also have different and often original solutions that appeal to less advanced mathematics. For example, drawing a tangent line to a parabola can be done by methods of differential calculus, and by exclusively using methods of Euclidean geometry. A project that I conducted with students who recently completed a Bachelor degree focusing in mathematics revealed that they were familiar with advanced methods but lacked more elementary views. I argue that unfamiliarity with alternative elementary solutions hinders for students the opportunities both to build mathematical connections and to appreciate the groundwork of related advanced methods.

Keywords: Problems with multiple solutions, connectivity of mathematics, parabola, Euclidean geometry, calculus.

INTRODUCTION

Some problems employed in teaching to illuminate the essence of a mathematical method appear to be universally useful in a variety of courses. In these cases students can compare how different ideas and techniques are applied to address the same mathematical question. The practice of identification of problems useful for systematic use in various university level courses is discussed in the literature. For example, Mingus (2002) referred to "calculation of n^{th} roots of unity" as a problem that "encourages students to see connections between geometry, vectors, group theory, algebra and long division" (p. 32). Further discussion revealed, "proving identities involving the Fibonacci numbers provide a solid connection between linear algebra, discrete mathematics, number theory and abstract algebra" (ibid, p. 32). Winsløw (2013) referred to several ways to approach constructions of a^x for $a > 0$ and x real, which are based on either "direct" extension of the domain from natural to real numbers, or the inverse function to $\log_e(x) = \int_1^z dt/t$, or the initial value problem $dy/dx = y$, $y(0) = 1$, or the functional equation $f(x + y) = f(x) \cdot f(y)$, or the Maclaurin power series (p. 2481). Sun and Chan (2009) discussed nine proofs of the "Mid-Point theorem of triangles". The fact that "the sum of the interior angles in a plane triangle is 180°" can be shown in eight different ways (Tall et al., 2012, p. 35). In my view, these are examples of *interconnecting* problems, which have the following characteristics: they allow various solutions at more elementary and more advanced levels; they can be solved by various mathematical tools from different mathematical branches, which leads to finding multiple solutions; and they are used in different courses and can be understood in various contexts (Kondratieva, 2011a, 2011b).

When students familiar with a problem from their prior experiences use their intuition to support more elaborate techniques applicable to a problem, they also have a chance to perceive mathematics as a consistent subject (Kondratieva, 2011a). By means of investigation of such problems in different courses "students were able to review concepts from previous courses and improve their understanding of the old and new concepts" (Mingus, 2002, p. 32). Knowledge of multiple ways to treat a mathematical object can strengthen the relation of a learner to the object "in the sense of providing extensions or alternatives to standard presentations" (Winsløw, 2013, p. 2483). Leikin and her collaborators extensively studied "tasks that contain an explicit requirement for solving the problem in multiple ways" (Leikin & Levav-Waynberg, 2008, p. 234), particularly in the context of the development of mathematics teachers' knowledge, and for an examination of mathematical creativity (Leikin & Lev, 2007). When used in mathematics teachers' education, interconnecting problems foster teachers' ability to link elementary ideas with advanced techniques (Kondratieva, 2013), which might contribute to the construction of their horizon content knowledge (Ball, Thames, & Phelps, 2008), that is, an awareness of how mathematical topics are related in the span of the entire curriculum. While being familiar with some individual examples of the use of interconnecting problems in teaching mathematics, I do not know to what extent students in general are exposed to teaching practices that encourage them explicitly to make connections between advanced and more elementary mathematics. According to Winsløw (2013), "there remains a practical need for systematic didactical research on how standard undergraduate mathematics is, or could be, developed in view of facilitating its use by students in inquiries related directly to high school mathematics." (p. 2477)

My research question is to what extent students who have completed a Bachelor degree with a focus in mathematics are familiar with both advanced mathematical methods and more elementary ideas related to them. In order to address this question I developed a research instrument in the form of a handout and questionnaire, which is described in this paper. The handout includes an interconnecting problem, which is typical and familiar for students studying undergraduate mathematics. This problem can be solved by a standard method taught at the university level and also has a more elementary treatment, which reveals some insightful ideas. This research instrument, along with the theoretical framework and results of testing in a small group of students, are discussed in the following sections.

THEORETICAL CONSIDERATIONS

Modern curriculum at all levels is moving from a formal approach to a more inquiry-based study of mathematics, focusing on genuine understanding and connecting various concepts and methods. House and Coxford (1995) argued that presenting mathematics as a "woven fabric rather than a patchwork of discrete topics" is one of the most important outcomes of mathematics education. The goal of mathematical instruction consists of helping a dedicated learner go beyond instrumental understanding secured by knowing mathematical procedures, and achieve relational understanding between different mathematical topics (Skemp, 1987), which assumes connections of various mathematical ideas. "An ability to establish and use a wide range of connections offers students alternative paths to the solution" (Hodgson, 1995, p. 19). While making connections and multiple representations of ideas are recognized among the primary processes in learning mathematics (NCTM, 2000), there is also a need for teaching strategies "for engaging students in exploring the connectedness of mathematics" (House & Coxford, 1995, p. vii).

One possible way to address this need is to use problems which allow multiple solutions, or specifically, interconnecting problems. In the latter approach (Kondratieva, 2011a), students encounter an interconnecting problem several times as they progress throughout their education, each time learning a new aspect of the same problem and building their understanding on "supportive met-befores" (Tall, 2013, p.15). Rephrasing Watson and Mason's (2005) description of reference examples, an interconnecting problem is "the one that becomes extremely familiar and is used to test out conjectures, to illustrate the meaning of theorems" (p. 7). Indeed, problems that have a range of solutions not only can help learners to move from elementary to advanced understanding, but they also may be used to exemplify advanced methods in elementary terms or to come up with an alternative and more elementary explanation of results found in a different way (Kondratieva, 2013).

In order to collect and analyze results presented in this paper, I employ Tall's notion of crystalline concept. Formation of a crystalline concept in a learner's mind refers to a phenomenon where an object of mathematical study "which originally was a single gestalt with many simultaneous properties, and was then defined using a single specific definition – now matures into a fully unified concept, with many properties linked together by a network of relationships based on deductions" (Tall et al., 2012, p. 20). The crystalline concept of an object combines all prior experiences of a learner in relation to this object, which include perceiving, acting upon, describing in natural or symbolic language, further formalizing, theorizing, and organizing knowledge about the object in a compressed way. Perceiving the object in various contexts, recognizing its multiple representations, and establishing equivalence relations between its various properties are important steps in the cognitive development of a learner towards building a corresponding crystalline concept. Eventually, "equivalent concepts may be grasped as a single crystalline concept that has all the requisite properties blended together within a single entity. Powerful mathematical thinking at the highest level involves the external relationship between, and the internal relationship within, crystalline concepts" (Tall, 2013, p. 403).

The notion of crystallization comprises various frameworks and theories of knowledge compression including the Structure of Observed Learning Outcomes (SOLO) Taxonomy (Biggs & Collis, 1982). The SOLO Taxonomy describes the progression of a learner's development using the following stages: (0) pre-structural, when the learner demonstrates a very limited understanding of a problem; (1) uni-structural, when the learner uses only one aspect of a concept and follows a single procedure to solve a problem; (2) multi-structural, when the learner refers to several aspects and is able to carry out several procedures to solve a problem; (3) relational, when the learner relates several aspects together or sees the equivalence of different procedures; (4) extended abstract, when the learner grasps the concept so well that they can apply it outside of the problem's domain. Thus, crystallization requires both the familiarity with multiple aspects of a concept and relational unification of them.

Further analysis of the development of mathematical thoughts at both the historical and individual level suggests that while mathematical arguments become more sophisticated and formal, "true mathematical thinking should become not only more powerful but more simple" (Tall, 2013, p. 19). According to Atiyah, "not only mathematics but science as a whole, only progresses if you can understand things... Its aim is to produce ideas and explain things in simple terms" (see Tall, 2013, p. 400). Similarly, Polya (1945/2004) suggested to always look back at your solution and ask yourself "Can you derive your result differently? Can you see it at a glance?" However, the simplicity and transparency of mathematical arguments produced by students often depends upon their prior exposure to basic but enlightening ideas related to more advanced methods (Kondratieva, 2014), as well as on whether they possess proper crystalline concepts. The aim of this paper is to delve on this issue using an example from undergraduate mathematics.

RESEARCH INSTRUMENT AND ITS PRELIMINARY TESTING

A group of 16 students who had completed their undergraduate degree participated in the project. These students were enrolled in my methods course for pre-service teachers whose teachable areas included mathematics and another subject (most commonly science). Each of these students had taken at least eight mathematical courses including at least three courses at the 3rd or 4th undergraduate level (with average mark above 70%). While the project was conducted during a regular class time, the participation was optional and no mark was assigned to this work. The students could have chosen to perform an alternative practice assignment; however, everyone in class agreed to participate in the project. The students worked in pairs. They were asked to develop a theoretical solution and implement it using technology. They were presented with the problem and questionnaire.

Problem: Use dynamic geometry software to draw a parabola and its tangent line at a point using tools of your preference.

Through other assignments in my course the students were familiar with dynamic geometry software such as GeoGebra capable of drawing points, segments, parallel and perpendicular lines, circles etc., as well as graphs of functions given by their equations in the form $y = f(x)$, and manipulating these objects. The tool of drawing a tangent line to a given curve was not amongst the available options.

Questionnaire:

(1) Have you seen this or similar problems before?

(2) If yes, identify the course title or corresponding mathematical context appropriate to treat this problem (e.g. linear algebra, geometry, combinatorics, pre-calculus, differential or integral calculus).

(3) List all methods you know to approach the problem. Do you see any connections between them?

(4) If you have never seen this problem before, state another problem of which this problem reminds you, and which you can solve.

When students had completed the first four questions (normally within 20 minutes or less) the last question was given to them.

(5) Read the following sample solutions and choose the most appropriate description: (a) I have found the same solution; (b) This approach is familiar but I

forgot the details; (c) I have never seen this method before but I can understand and explain the ideas used in this approach; (d) I have never seen anything like that and I do not understand it.

The students who chose answer (b) or (c) were asked to explain the corresponding solution in writing. Then, we had a whole class discussion where students could reflect on the solutions and connections between them.

Sample solution 1: Use the standard equation of the parabola in the Cartesian coordinates and Differential Calculus.

Let the parabola be given by the equation $y = ax^2$. The derivative of the function $f(x) = ax^2$ is $f'(x) = 2ax$. The tangent line at a point (x_0, ax_0^2) has the form $(y - ax_0^2) = 2ax_0(x - x_0)$ or after a simplification $y = (2ax_0)x - ax_0^2$. Now we can draw the parabola and the line in the coordinate plane using the tool "graphing functions given by their equations $y = f(x)$" for some values of $a \neq 0$ and x_0.

Sample solution 2: Produce this construction by means of Euclidean geometry given the focus F and directrix l of the parabola.

Geometrically, a parabola is the locus of points equidistant from the given point F and the given line l not passing through F. This definition enables the following construction (see Figure 1, left): (1) Drop the perpendicular from F onto l with foot at A; the midpoint V of the segment FA is the vertex of the parabola; (2) Pick any point B on l; join F and B and draw the perpendicular bisector l' to FB; draw l'' perpendicular to l at B; let l' and l'' meet at C. As point B moves along line l, point C traces a parabola (Figure 1, right). Then the line l' is tangent to the parabola with C being the point of tangency.

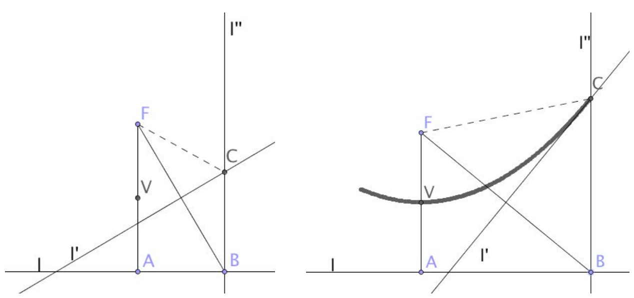

Figure 1: Construction of a parabola given its focus *F* and directrix *l*

RESULTS AND DISCUSSION

The problem that was given to the students is a typical problem studied in Calculus courses, where students are taught that the derivative $f'(x_0)$ represents the slope of the line tangent to the curve $y = f(x)$ at a given point $x = x_0$. They are also supposed to know that the equation of a straight line passing through a given point (a, b) with a given slope k is given by $(y - b) = k(x - a)$. Therefore, Sample solution 1 is a universal approach to this type of problem and all of the 16 participants recognized it as a familiar method to apply. However, none of them mentioned the second method as a possibility to solve this problem and only one participant recognized familiar ideas in the method. The majority of participants (15) answered "I have never seen this method before but I can understand and explain the ideas used in this approach". The problem was that the majority of students did not know the definition of a parabola in terms of its directrix and focus.

Nevertheless, once students read the geometric definition of the parabola all of them were able to understand and explain the construction presented in Figure 1: since C lies on the perpendicular bisector l' of FB, the triangle FCB is isosceles and hence C is equidistant from F and l. In terms of the SOLO Taxonomy described above this signifies passage to the second stage, namely to the multi-structural understanding of the problem by the students.

I refer to the second solution as being more elementary because it uses mathematical ideas less advanced compared to those needed to develop calculus. However, students may have a different point of view. They may perceive the algorithmic approach studied in Calculus as being easier than using Euclidean geometry, which they experienced to a lesser degree.

Knowing two approaches to solve the problem is obviously progress. However, in order to develop the crystalline concept it is also necessary for students to see a relation between the two approaches. Indeed, the students were able to establish a connection to the formulas given in the Sample solution 1 by introducing Cartesian coordinates so that l has equation $y = -p$, and the coordinates of points are $F(0, p)$, $V(0, 0)$ and $C(x, y)$. Without loss of generality we assume that $p > 0$. Then, by the Pythagorean theorem, $\overline{FC}^2 = x^2 + (y - p)^2$. But, $\overline{FC} = \overline{CB} = y + p$, and after simplifications one gets the equation $y = \frac{x^2}{4p}$. At the same time the slope

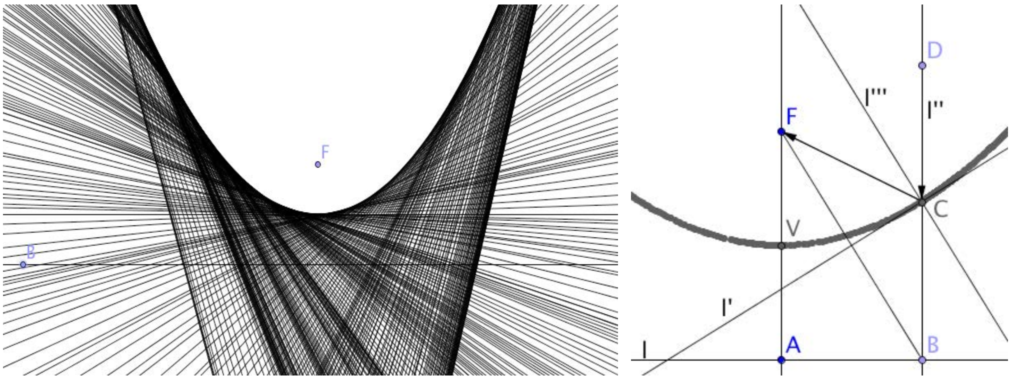

Figure 2: A family of tangent lines to the parabola (left) and reflection property (right)

of FB is $\frac{-p}{x}$, so the slope of l' is $\frac{x}{2p}$. This result agrees with the Calculus approach, by which the derivative is $\frac{d}{dx}(\frac{x^2}{4p}) = \frac{x}{2p}$. Finally, the equation of the tangent line at point $(x_0, \frac{x_0^2}{4p})$ is $y = f(x) = \frac{x_0}{2p}x - \frac{x_0^2}{4p}$. One can also see that $f(x_0) = \frac{x_0^2}{4p}$ and for any $x_1 \neq x_0$ we have $f(x_1) = \frac{2x_0x_1 - x_0^2}{4p} < \frac{x_1^2}{4p}$ since $x_0^2 - 2x_0x_1 + x_1^2 = (x_0 - x_1)^2 > 0$ and $p > 0$. The inequality demonstrates that the points of the parabola $y = \frac{x^2}{4p}$, $p > 0$, lie above any tangent line so that the family of tangent lines form the envelope of the curve (Figure 2, left).

The above derivation, along with reflection upon its results, is an example of constructing the crystalline concept of the parabola. In this project, I was able to observe that my students had adequate knowledge in order to move from the first to the third stage of SOLO Taxonomy in understanding and conceptualization of the parabola within only one lesson period. I did not conduct any activities aiming at identification of the fourth, extended abstract, stage. Nevertheless, I will comment on some opportunities emerging from this lesson. Clearly, a learner familiar with the geometric definition of parabola may find it satisfactory to obtain the same result by the more universal method learned in Calculus. By using dynamic geometry software and moving the point B along the line l, one can see that the point C traces a curve to which the line l' is tangent (Figure 1, right). A learner equipped with such experiences will develop a more comprehensive understanding of the object called parabola and might be able to use alternative representations and properties of a parabola and its tangent line depending on the problems they need to solve. By developing representational flexibility of an object (e.g., the parabola) students become better prepared for solving non-routine problems (see also Bergsten, 2015).

The geometrical view allows students to make closer connections of mathematics with physical phenomena, such as reflection of light from a parabolic mirror. Indeed, since $\angle FCB$ and $\angle FCD$ are supplementary angles, their angular bisectors l' and l''' are orthogonal to each other (Figure 2, right). The parabolic mirror near point C can be 'replaced' by the tangent line l'. This implies that the ray DC parallel to the axis FA of the parabola will be reflected at the point C towards the focus F. Such observations and insights are especially important for future teachers of mathematics and science because it will allow them to enrich discussions in their classrooms.

Students' unfamiliarity with the geometric definition of the parabola prior to my lesson can be explained by recent changes in the mathematical curriculum. Bergsten (2015) observed that in Sweden, while in the 1960s the study of the parabola was embedded in a local mathematical organization of analytic and Euclidean geometry, since the 1980s it became embedded in a local mathematical organization of functions. Similarly, in Canada the geometrical definition of conics no longer has a place in the secondary school mathematics. At the university level, this definition is supposed to appear in the Calculus stream, for example, when equations of conics in polar coordinates are introduced. But at that point there is no time to study the geometry of the parabola in any detail because the focus of the course is on different methods. Thus, university graduates with a mathematical degree may actually never have seen a discussion of a parabola as a geometrical object even though they may know properties of geometrical objects (isosceles triangle, perpendicular bisector, etc.) necessary for understanding how and why the Sample solution 2 works, as was the case in my project.

CONCLUSION

The fact that completion of a bachelor degree in Mathematics does not automatically ensure *deep* knowledge of elementary mathematics is not new (see discussion in Winsløw & Grønbæk, 2014) and references there). Indeed, even if students can apply an advanced approach or formula familiar to them, they are not always able to elaborate or explain why that formula works through connecting more advanced ideas with elementary facts. I conjecture that in some cases the students are simply not aware of relevant elementary ideas, definitions, and interpretations.

To verify my conjecture I developed an instrument that can identify the degree to which students are familiar with various solutions of a standard problem in Calculus. A preliminary study revealed that while the students felt comfortable applying the standard method, most of them were not familiar with the ideas which are more elementary compared to the considered standard method. I am planning to conduct a larger study in order to validate these findings.

Meantime, I suggest that while it is important for students to be exposed to standard and advanced approaches through university courses, their education should also include experiences highlighting other approaches and more elementary mathematical ideas related to these advanced methods (especially if the students already have necessary background to understand and elaborate on these ideas). Otherwise, they will tend to stick to procedural and formal methods and will not be able to fully appreciate the results of advanced approaches because the connection to more basic but enlightening mathematics will be lost.

The Rechenbrücke – A project in the introductory phase of studies

Ronja Kürten and Gilbert Greefrath

University of Münster, Münster, Germany, ronja.kuerten@uni-muenster.de

In the transition from secondary to tertiary mathematics education, major difficulties occur for many students. To respond to this situation, the University of Applied Sciences Münster started the Rechenbrücke project with the object to alleviate the transition from school to university for engineering students through various support measures in the area of mathematics. In this article, we present the preliminary course which is part of the support measures of the Rechenbrücke and aims at refreshing basic calculating skills. The initial results of the pilot study presented indicate the potentially positive effect of these measures.

Keywords: Secondary-tertiary transition, preliminary courses, bridging courses.

INTRODUCTION

The transition from school to university brings along many changes which take part over a vast period of time starting at secondary school and ending at some point during the course of studies. Differences between school and university can be found in thought structures and knowledge organisation, argumentation, and mathematical communication, as well as teaching methods and the expectations of the institution (Gueudet, 2008). Bridging or preliminary courses cover one part of that period and as they are currently common measures to alleviate transition from school to university they present an important factor in the transition issue.

In Germany there are at least two types of tertiary education institutes. Although the differences were reduced in the last years, there are still some important distinctions between universities and universities of applied sciences. While the first ones are "normally strongly research-oriented and typically offer a wide range of subjects" (Hochschulrektorenkonferenz, n.d.) the latter emphasise practical work and application and "usually offer a narrower range of subjects [with focus] on fields of engineering, business, and social sciences" (ibid). Furthermore students at universities of applied sciences are even more heterogeneous with often considerably lower mathematical skills than those at universities as you can start your studies without an A-level school leaving certificate (Abitur) but with an advanced technical certificate (Fachhochschulreife) or even with a finished apprenticeship and some work experience. Therefore many students spend some years between school and university working or in an apprenticeship.

The secondary-tertiary transition is experienced as difficult by many new students who take mathematics courses at tertiary level (De Guzman, Hodgson, Robert, & Villani, 1998). High drop-out rates and low satisfaction with the chosen study course are the results. In universities of applied sciences the drop-out rate of engineering students has been at 31% in the last years (Heublein, 2014, p. 501). While it is difficult to interpret the concrete percentage due to varying definitions of drop-out, the drop out quote of engineers is the second highest (after *Mathematics and Natural Sciences* with 34%) and is notably higher than the average drop-out of 23% (ibid). The difficulties described above also occur for engineering students at University of Applied Sciences Münster, for which reason the Rechenbrücke project has been started in order to alleviate the transition from school to university. The Rechenbrücke is a cooperation project between five of the engineering faculties of University of Applied Sciences Münster and the Institute for Education in Mathematics and Computer Science of the University of Münster [1]. In this project, various mathematics support measures for prospective and first-year engineering students at University of Applied Sciences Münster are developed and evaluated.

THEORETICAL FRAMEWORK

In many countries students entering higher education lack proficiency in basic mathematical concepts and therefore are not able to develop a sound understanding of those key mathematical ideas needed at universities (e.g., ACME, 2011, Biehler et al., 2014). The situation is even worse at universities of applied sciences as there students with many different learning backgrounds enter studies. The Standing Conference of the Ministers of Education and Cultural Affairs of the Länder in the Federal Republic of Germany (Kultusministerkonferenz) adopted educational standards in mathematics in 2003/04. These standards describe subject-based competencies to be acquired by students by certain stages of their school career. The competence K5 "Mit symbolischen, formalen und technischen Elementen der Mathematik umgehen" (KMK, 2012, pp. 8f.) which includes e.g., working with variables, terms, equations, functions etc. is needed by the other competencies as a tool (ibid). Therefore lacking mastery of K5 often results in lacking mastery of the other competencies.

Preliminary courses and other support measures have been created in many countries to alleviate the secondary-tertiary transition. As such courses are often designed by single universities, there are many different approaches. Decisions to be made in designing preliminary courses are discussed in Kürten, Greefrath, Harth, & Pott-Langemeyer (2014): Framework conditions, objectives and contents, and competencies to be taught have to be clarified. Framework conditions vary from e-learning to blended-learning to classroom courses, from some weeks to two semesters, with voluntary or mandatory participation. Course objectives range from compensation of mathematical deficits to repetition of school mathematics to development of skills used at tertiary education. The contents taught vary from specific mathematical contents (from lower secondary to tertiary level) to mathematical ways of thinking to metacognitive competencies (Biehler et al., 2014). Despite this richness in course conceptions, research on these measures is still at its beginnings. Questions like "How can we measure the effects of preliminary courses?" or "What are the effects of preliminary courses?" have yet to be answered (Biehler et al., 2014).

Many support measures share the aim to enhance success rates by reducing student drop-out, but drop-out quotes can only be directly measured after the students of a cohort have left university. Therefore the effects of support measures have to be measured by other variables which can be measured shortly after realization of the support measure and are predictors for the drop-out quote. Heublein (2014, p. 504) characterises the drop-out as result of a complex inter-relationship between individual and institutional factors. Performance in studies is just one factor in that process but on the other hand it is a factor which can lead to drop-out enforced by university. Therefore, and as it can be measured by exam grades, in this paper, we will focus on effects the preliminary course has on the students' performance in studies. A similar approach is used at the University of Applied Sciences Aachen were first results show, that students that attended the preliminary course get significant better results in their mathematics exams than students that did not attend (Greefrath, Hoever, Kürten, & Neugebauer, 2015).

INITIAL SITUATION

In individual interviews with the responsible mathematics lecturers of University of Applied Sciences Münster an estimation of the difficulties, students faced at the beginning of their studies, was ascertained. All the academic staff asked stated a lack of proficiency from school mathematics, especially from lower secondary level. Namely they claim that students fail in written exams in mathematics due to missing skills in term conversion (a common mistake is the linearization of all kinds of terms as in $(a + b)^2 = a^2 + b^2$) and fraction arithmetic (e.g. a common mistake is the addition of numerator and denominator: $\frac{a}{b} + \frac{b}{d} = \frac{a+b}{c+d}$). These basic skills from lower secondary level are required for studying engineering at University of Applied Sciences Münster and therefore are not treated explicitly in the lectures. Nevertheless they are needed for solving of various problems in calculus and linear algebra. In her study regarding the British education system, Kitchen (1999) also determined deficits in the prior knowledge required of new students by universities. The answers from the mathematics lecturers point out numerous parallels to the results of De Guzman and colleagues (1998). They describe a lack of interest in mathematics itself, of necessary prior knowledge, of an appropriate thought structure, independence, learning methods and organisational skills. Therefore the situation at German universities of applied sciences is not unique in Europe. Thus answers to the question whether basic calculation skill training can alleviate transitions problems (especially for students with low mathematical skills) should be of broad interest.

CONCEPTUALISATION OF SUPPORT MEASURES

Within the scope of the project, various measures have been designed which should alleviate the transition to university in the area of mathematics. As the target group contains many students with assumed low mathematical skills, focus was laid on competence K5 to create a basis on which further mathematical understanding could be built as described above. In an initial step, a collective minimum requirements catalogue for mathematics was created. Based on this, a modular preliminary course was developed that encompasses an upstream diagnostic pre-test. Different scientific evaluation measures (e.g., a post-test and evaluation sheet subsequent to the preliminary course) are used to examine the effectiveness and feasibility of these offers.

The minimum requirements catalogue

The minimum requirements catalogue of mathematical prerequisites for students in engineering courses of study is based on the mathematics minimum requirements catalogue which the cooperation team school – university (cosh) in Baden-Württemberg developed as a consensus of schools and universities. As a result, it can provide an expedient basis for the selection of mathematical contents in a preliminary course or a mathematics test at the beginning of studies (Dürrschnabel et al., 2013). In the project this catalogue was adapted and defined in coordination with the mathematics lecturers at University of Applied Sciences Münster. To improve the transparency of the requirements, the catalogue has been published for all interested parties on the homepage of the University of Applied Sciences [2].

The mathematics preliminary course at University of Applied Sciences Münster

The concept for the mathematics preliminary course was chosen to account for three aims: As much facets as possible mentioned above should be considered, it should be possible to recapitulate most of the topics posed in the minimum requirements catalogue by visiting the preliminary course and the expectations of the teaching staff in mathematics should be satisfied as far as possible. The result was a modularly structured preliminary course concept created in the first half of 2013. In the course, contents of school mathematics from the lower and upper secondary levels are addressed in ten modules developed as a consensus of the participating staff of which the following arose from the initial interviews: *Basic calculation methods and fractions*; *terms*; *equations with one unknown* and *functions (part I)*. The minimum requirements catalogue was taken as a basis for the modules that complement the preliminary course: *Percentage calculation, power and square root calculation*; *inequations with one variable*; *functions (part II)*; *differential calculus*; *integral calculus* and *simultaneous equations, vectors and matrices*. Besides post-processing of school mathematics, preparation for the requirements of the study course is also featured. Two modules address interdisciplinary mathematical and course-relevant aspects such as notation of statements and equations, argumentation, systematic approaches, lecture post-processing, examination preparation, etc. Here preparation refers to metaknowledge, interdisciplinary methodology, and organisational information (Hoffkamp, Schnieder, & Paravicini, 2013). The preliminary course takes place as a classroom course composed of lectures and tutorials, which is supported by E-learning contents. Amongst other things, this includes parts of scripts, exercises and short videos regarding individual subjects. Due to the large number of new students, the course is conducted in two parallel courses divided according to faculty.

Based on an entry test, students can decide which modules of the preliminary course they wish to process. Subsequent to conducting the test, students receive feedback as to which tasks they have solved correctly or wrongly. For every wrongly answered task, they receive the additional urgent recommendation to visit the corresponding module of the preliminary course. In this way, the target group should be sensitised to the support offer. Given that the clientele of University of Applied Sciences Münster comprises of full-time, parallel-to-profession and dual system students, the online materials should simultaneously enable preparation for the study course. Furthermore, students can decide which module they wish to process in the classroom course or online. Modularisation and flexibility should furthermore enable preparation for new students for their study course, adapted to their personal proficiencies.

RESEARCH QUESTIONS AND METHODS

Given the initial situation described above and the project aim to alleviate secondary-tertiary transition for engineering students with heterogeneous and partly low mathematical skills, three research questions were designed.

1) What are the difficulties experienced by new engineering students when trying to use school mathematics?

2) Can a preliminary course reduce these difficulties and if yes, to which extend?

3) To which extend do these difficulties influence the outcomes of written exams in mathematics?

Within the scope of the project, data from mathematics tests and exam results are collected. In addition to these quantitative tests, semi-structured interviews are conducted with students and the students' evaluations regarding the conducted measures are gathered with the aid of a questionnaire in order to ascertain the effects of the measures in a differentiated manner. In the following, we address the stated quantitative research methods and initial results.

In the project a pre- and post-test are used in connection with the preliminary course. The pre-test should not merely act as a self-diagnostic instrument providing the students with feedback regarding their existing deficits, but moreover, in combination with the post-test, should serve as an evaluation of the preliminary course. Based on these objectives, the test has become mandatory for all who wish to take part in the preliminary course, and is set up voluntarily for all others. Two dates were selected for implementation – prior to and shortly after the preliminary course. The test procedure is computer-based and, for the objectivity of test procedure, takes place centrally in PC pools at the university. The tests have been integrated into the learning platform, ILIAS, used throughout the university. The evaluation requires automatically correctable task formats such as single choice and multiple choice tasks and tasks with short answers. Given that fundamental proficiencies are queried in these tasks, the test procedure was designed as assistance tool-free. The test comprises of 13 items which are associated with the contents of the preliminary course modules (see Table 1). The following items are two of those used in the pre-test 2013 (translation into English).

Task 2: Calculate and write as an irreducible fraction $\frac{a}{b}$.

a) $\frac{\frac{1}{3}+\frac{3}{5}}{\frac{7}{5}}=\frac{a}{b}$ $a =$ ____ $b =$ ____

Task 10: We are seeking an equation of the line with the following characteristics: intersects the x-axis in and has the slope . The equation should be stated in the form $y = m \cdot x + b$.
$m =$ ____ $b =$ ____

In addition, „Type of school qualification", „Time since the end of school", „Average mark in school leaving qualification", „Final mark in the subject mathematics", and „Use of calculators in upper secondary level" were ascertained. After the preliminary course, the students take part in a parallel-designed post-test. This takes place at the beginning of the lecture period. The first implementation of this test took place as a pilot study in winter semester 2013/14. For organisational reasons, the pre-test was carried out by students on home PCs and the post-test as a paper test during Mathematics I lecture at the beginning of the semester. In addition to the information ascertained in the two tests, the students' results in the written mathematics exams are ascertained after the first (Mathematics I) and second (Mathematics II) semester. An example for items used in the exams is shown in Figure 1.

The written exam marks of the students are anonymously assigned to the corresponding data gathered in the tests. A possible correlation between a preliminary course attendance and the results in written exams should be investigated using this data.

RESULTS

689 test persons took part in the pre-test, and of these, 603 completed the test and provided evaluable results. Of initial interest for the Rechenbrücke project was

1. b) Calculate the real and imaginary part of $z = \left(\frac{i+1}{\sqrt{2}}\right)^{14} \cdot i^3((i+1)^2 + i)$.

Figure 1: Item of the Mathematics I exam in mechanical engineering (translation into English)

the question of whether the contents of the preliminary course were expediently selected, i.e. whether room for improvement actually exists for these topics. The solution rates and topics of the individual tasks are depicted in Table 1. Even the task regarding basic calculation methods, with the highest solution rate, could only be solved by less than three quarters of the test people. Task 4 (power and square root calculation) had the lowest solution rate with only 21% correct answers. The solution rates of the items indicate that addressing these contents in the preliminary course is sensible.

Due to the non-objective test procedure in the pilot study, a comparison of the solution rates between pre- and post-test is only conditionally possible. For a small portion of the random sample (N = 209), the results from the pre- and post-test could be correlated. In the course of this, significant changes with a small effect size (|Cohens d| > 0.2) were indeed determined for several tasks (improvement with tasks 1, 4 and 6 and deterioration for task 7), however these results serve as an indicator at the most and will be checked in the upcoming run in the actual investigation. The

Task and Topic		Solution rate
1	Basic arithmetical operations involving brackets in Z	73%
2	Basic arithmetical operations on fractions, cancelling	61%
3	Percentage calculation: markup problem	67%
4	Solving of a fractional equation where numerator and denominator involve powers and square roots	21%
5	Term conversion using binomial formulas	52%
6	Calculation of inverse proportionality using the rule of three	69%
7	Solving of a fractional equation	70%
8	Solving of a quadratic equation	36%
9	Solving of a linear inequality	63%
10	Setting up the equation of a linear function	53%
11	Offsetting of a parabola	31%
12	Solving of a simple logarithm equation	33%
13	Trigonometry: definition of sine, cosine	53%

Table 1: Solution rate for the individual tasks in the pre-test (N = 603)

reliability of the tests was determined by means of Cronbach's Alpha. For the pre-test, a value of 0.72 (N = 603) resulted. For the post-test, the value lies at 0.73 (N = 805). Therefore the internal reliability of the test is acceptable.

Based on the data of the tests and written exams, the correlations between written exam results in Mathematics I (the first lecture on mathematics in engineering studies at University of Applied Sciences Münster) and potential influencing factors have been investigated. The variables investigated were „Average mark of school leaving qualification", „Final mark in mathematics", „Number of points in the pre-test" and „Number of points in the post-test". Statistically significant correlations ($p < 0.01$) were determined for all variables which lie between 0.37 and 0.45. The differences between the correlation coefficients were tested with Fisher's z-transformation and are not significant.

Furthermore, it was investigated whether the results in the written mathematics exams of students who have or have not visited the preliminary course differ. Looking at the overall random sample (N = 280), no significant deviation could be initially determined. However, if the results are divided according to the preliminary course groups, then for group B (Faculties of Chemical Engineering, Mechanical Engineering and Physical Technology, N = 176) a significant deviation ($p = 0.037$) is obtained with the Mann-Whitney U-test. In these faculties, the written exam results of the students who have taken part in the preliminary course are significantly better than those of the students who have not taken part in the preliminary course. In the other preliminary course group A (Faculties of Electrical Engineering and Computer Science and Energy – Buildings – Environment, N = 104) no significant deviation of distribution could be determined. A comparison of the average mark of school leaving qualifications showed no significant difference between the students either in group A or group B who took part in the preliminary course or not.

DISCUSSION

In winter semester 2013/14, the first measures of the Rechenbrücke project started. In the course of the investigation conducted, initial data was ascertained in pre- and post-tests and evaluated.

The difficulties experienced by new engineering students determined in the pre-test already confirm that the repetition of elementary calculation skills from mathematics lessons is expedient. Corresponding results are also indicated in the tests conducted by University of Applied Sciences Aachen. For each initial test, the students there attained an average solution rate of 40–50%, depending on the prerequisites (Greefrath et al., 2015). The solution rate of the entrance test which has been conducted for more than ten years at the Universities of Applied Sciences in North Rhine-Westphalia lies even below this (Knospe, 2011). A possible reason for this lack in basic skills might be the task of solving arithmetic problems without using a calculator which is unusual for students in North Rhine-Westphalia.

At this point of the project a definite answer to the second research question cannot be given as the results of the pre- and post-tests are not comparable due to the non-standardised procedure. The determined tendencies of a slight improvement for some tasks could however be an indicator for the success of the preliminary course. The cause of the deterioration for the result of task 7 must be further investigated. The introduction of prerequisites which must be observed prior to solving a fraction equation possibly had a negative influence on the previous, direct calculation of the solution. The positive correlation determined between preliminary course participation and performance in the Mathematics I written exam in some faculties can have diverse reasons, such as a higher level of motivation and willingness to learn among students who take part in a preliminary course. The quantitative numbers presented here are underpinned by the answers given in the questionnaire: Students state, that they feel better prepared for mathematics lectures after visiting the preliminary course. The evidence presented above gives reason to state the hypothesis that the preliminary course can reduce the difficulties in school mathematics of new students. Further investigations will test the hypothesis to answer the second research question.

During the search for causes for different effects in both of the preliminary course groups, differences in prior knowledge were sought and measured on the basis of the school leaving qualification marks. However, the research has not yet revealed any significant differences between the different groups. Both preliminary course groups were conducted by the same lecturer in the same way; however, the subsequent mathematics activities in the various faculties are different in their content and in the way they are conducted. For this reason, the match between the preliminary course concept and the lectures is possibly not given to the same extent in all faculties. In the following execution of the preliminary course, audio recordings or written minutes could improve the monitoring of the course implementation.

Concerning the outcomes of written exams in mathematics in this investigation correlations between all variables and the Mathematics I exam have been found. Correlations between pre-test respective post-test and the Mathematics I exam can be explained by the basic skills which are needed to solve the items (e.g., that in Figure 1) used in the exams. An interesting result is that the final mark in mathematics seems to be no better predictor for exam results than the average mark from school leaving qualification or the points achieved in the post-test.

The modular preliminary course concept with the possibility of an individual compilation of preliminary course topics by the students provides great flexibility. To what extent this flexibility is utilised by the students and which effects this has on performance in the written exams will be investigated in the main study. Furthermore, the Rechenbrücke supports the first semester students for the transition from school to university through further, in part freely selectable measures. The results from the pilot study presented in this article indicate promising findings from the performance of the main study in the coming years.

Use of mathematics in engineering contexts: An empirical study on problem solving competencies

Malte Lehmann, Bettina Roesken-Winter and Sven Schueler

Humboldt-Universität zu Berlin, Berlin, Germany, malte.lehmann@hu-berlin.de

The research field of problem solving in mathematics is highly relevant in mathematics education. There are manifold approaches to understand the process of problem solving like Polya's phase model or Bruder and Collet's heuristic methods. In two studies, we investigate how engineering students' performances in higher mathematics and technical mechanics are connected (study 1, n=37) and what role their problem solving competencies play (study 2, n=8). In the first study, we ascertained that mathematical competencies and beliefs about physics are substantial for success in technical mechanics. In the second study, students had to complete sequences of tasks and their usage of heuristics was investigated. The results show that successful students' heuristic tools and strategies are more elaborated.

Keywords: Problem solving, engineering education, technical mechanics, qualitative content analysis.

INTRODUCTION

Mathematics is an important subject in engineering education. The first courses of study are characterized by a high usage of mathematics, be it in mathematics, in physics or further engineering lectures. Besides continuously improving their declarative and procedural knowledge in the respective fields, it is important for students to develop their problem solving competencies as this is one of eight competencies that engineering students need to learn according to the SEFI[1] (2013) framework: *thinking mathematically, reasoning mathematically, posing and solving mathematical problems, modelling mathematically, representing mathematical entities, handling mathematical symbols and formalism, communicating in, with and about mathematics* and *making use of aids and tools*. In accordance with findings in mathematics education (cf. Törner, Schoenfeld, & Reiss, 2007), in SEFI (2013) problem solving as competency for engineering students is characterized as follows:

> This competency [mathematical problem solving] includes on the one hand the ability to identify and specify mathematical problems [...] and on the other hand the ability to solve mathematical problems (including knowledge of the adequate algorithms). What really constitutes a problem is not well defined and it depends on personal capabilities whether or not a question is considered as a problem. (p. 13)

The formation of these competencies is, however, often hampered by an asynchronicity of mathematical and engineering education. The overarching aim of the project KoM@ING[2] is to measure mathematical competencies of engineering students and the relations between the different lectures by combining a quantitative and a qualitative perspective. In the quantitative approach (project partners from IPN[3] Kiel and University Stuttgart), IRT-based measures for higher mathematics and technical mechanics are developed to capture students' development in their first year of study (Nickolaus, Behrendt, Dammann, Ştefănică, & Heinze, 2013). Thus, individual competencies are measured reliably and validly, but no insight is provided into the students' actual problem solving processes. This paper reports on the work of the qualitative project that scrutinizes these processes.

THEORETICAL FRAMEWORK

Mathematical problem solving is an important field in mathematics even at school and at university (cf. Halmos, 1980). There are many different approaches for research on this topic (cf. Schoenfeld, 1985; Chinnappan & Lawson, 1996; Rott, 2013). One perspective focuses on the *inner structure* of problem solving processes considering heuristics and beliefs, another perspective elaborates on the *outer structure* in terms of timing and organizing of processes. In our study, we focus on both aspects by investigating phases of the problem solving process (cf. Polya, 1945) and the use of heuristics (cf. Bruder & Collet, 2011). In his seminal work, Polya (1945) differentiates *understanding the problem, devising a plan, carrying out the plan,* and *looking back* as essential phases of any problem solving cycle. Schoenfeld (1985) extends the model of Polya by adding an *exploration* phase which interacts closely with the *planning* phase, but also allows a throwback to the first phase. Likewise, Chinnappan and Lawson (1996) stress the importance of the first two phases: "[...] the planning process forced the solver to make optimum use of information that was identified and information that was generated" (p. 13). In addition, Chinnappan and Lawson (1996) could show that not only the single use of heuristics is important, but also a training in management strategies that allows for effectively coordinating different phases. However, Rott (2013) could show that completely linear models are not always suitable to describe problem-solving processes and provides empirical evidence for applying a more flexible model. Bruder and Collet's (2011) work on heuristics places the methods in the center and explains the process of problem solving by heuristic tools (e.g., *informative figure*), heuristic strategies (e.g., *using analogies*) and heuristic principles (e.g., *symmetry principle*). In addition, the problem solving process is influenced by the interplay of mathematics and physics as described in the framework by Tuminaro and Redish (2007) that elaborates on so-called *epistemic games*. These *epistemic games* like, for instance, *mapping mathematics to meaning,* allow the description of how students make the transition from novices to experts, and contribute lenses to elaborate on either *individual-related* or *task-related* characteristics. In order to solve problems with physical contexts, students need adequate beliefs about the physical concepts involved. From beliefs research we know that pre-service teachers "who approach learning physics with a more favourable belief structure are more likely to achieve higher learning gains" (Mistades, 2007, p. 185). An instrument to reveal students' beliefs about the force concept is provided by Hestenes, Wells, and Swackhamer (1992) which proved to be useful in several studies. Based on these theoretical foundations, we investigate how students' performances in higher mathematics and technical mechanics are connected and what role their problem solving skills play:

Research question 1: Do students' performances at school, their mathematical skills, and their beliefs about physics concepts (related to the force concept) predict their achievement in technical mechanics?

Research question 2: Can task difficulties in higher mathematics and technical mechanics be described through analysing occurrences of Polya's phases and students' use of different heuristics?

Research question 3: Does working on task variations in technical mechanics that imply increasing difficulty requires using more and different heuristics?

The first and second research question will be answered using the results from study 1. Research question 3 is answered by referring to the results of study 2.

METHODOLOGY

The research comprises two different, but related surveys. The first one is taken from our larger study to investigating the development of students' problem solving competencies in their first year at university. That is, students work on the IRT-scaled test for higher mathematics (HM) and technical mechanics (TM) from the quantitative project. The other survey is task-related and investigates four sequences of tasks about statics and the different usage of problem solving competencies. Here, students are observed while working on and discussing tasks of increasing difficulty.

Our project partners developed *TM/HM pre-tests* delivered at the beginning of students' studies. The pre-tests consist of 28 (TM) and 36 (HM) items with a combination of closed (multiple choice, multiple true-false) and (semi-) open questions. The TM pre-test covers items on statics, kinematics, kinetics, energy and momentum, oscillations and basic concepts, all on a higher school level. For example, one task is:

Time	Content
09/2013	TM/HM pre-test, IQ-test, FCI; Video: easy/difficult tasks (pre-test)
04/2014	Video: easy/difficult tasks (pre-test)
09/2014	TM/HM post-test, FCI; Video: easy/average/difficult tasks (post-test)

Table 1: Overview study 1

Draw a possible amplitude curve of a damped oscillation in the diagram.

The HM pre-test, based on work by Hauck (2012), asks questions on mathematical basics, calculus and geometry. One example is:

Given is a plane E: $6x_1+6x_2-3x_3= -12$ and the point A (3/6/4)

a) Determine the distance d of the point from the plane.

b) Calculate the coordinates of A' (A mirrored at the plane).

These tests are IRT-scaled (pilot study with N=1069 students) and thus enable us to categorize our participants in terms of their mathematical, physical and technical competencies at the beginning of their university course. Additionally, the scaling affords us selecting the five easiest and most difficult tasks.

The Force Concept Inventory (FCI; Hestenes, Wells, & Swackhamer, 1992) investigates students' beliefs about the concept of force which is an important part of competences in mechanics. It consists of 30 items, each of them describing a physical situation. One must choose among five possible answers, one relating to the correct Newtonian concept and four relating to alternative concepts. Opportunities to analyse the scores vary. Either the raw score of correct answers can be used or special attention can be paid to how the wrong answers relate to misconceptions. We decided to use the raw score to investigate students' changes during their first year (cf. Hestenes & Halloun, 1995), because we have been interested in analysing the changes in students' beliefs during the first year.

Design of study 1: Development of problem solving competencies

In the first study data was collected at three points (Table 1). In September 2013, the students (n=37; male=27, female=10) worked on four tests: the TM pre-test, the HM pre-test, an intelligence test (CFT-3, Culture Fair Intelligence Test) and the FCI. In this paper, we only focus on this first measurement point, but provide an overview on the whole study in Table 1. The longitudinal design was chosen to capture students' development of their mathematical and physical skills, and problem solving competencies. These results will be presented elsewhere.

In addition, the students worked in groups of two or three on the five easiest and five most difficult tasks of the two pre-tests (Table 2).

The group work was recorded on video for later analysis. The *thinking aloud*-method (Ericsson & Simon, 1984) rendered thoughts and ideas observable. In order to analyse the video data and the students' work, we developed a category system based on the theoretical framework described above (Table 3).

The category system was carefully tested and optimized in a pilot study. As a result we arrived at 38 categories as an assessable selection with reasonable frequencies.

HM-Topic	Difficulty	TM-Topic	Difficulty
Equation	-3.71	Kinetic energy	-1.98
Number line	-3.39	Deflection curve	-1.89
Reflection at a plane (see above)	2.80	Trajectory	1.80
Exponential function – Extremum	3.22	Load	3.17

Table 2: Overview on topics of the chosen tasks (in excerpts: 2 easy/2 difficult tasks)

Structure	Category	Sub-categories
Inner Structure	Heuristic tools	Informative figure, Table, Equation
Outer Structure	Polya's phases	Understanding the problem, devising a plan, Carrying out the plan, Looking back

Table 3: Category system (in excerpts)

Design of study 2: Task-related problem solving competencies

The second study investigates characteristics of tasks by special sets of TM tasks at two measurement points (cf. Table 4). The set consists of two to four tasks with increasing difficulty for the four topics of gravity, reaction forces, displacement and deformation, free body diagrams and force systems (cf. Figure 1). Four students handled every sequence. These tasks are taken from the piloting phase of the TM post-tests where they showed inadequate model fit and therefore were rejected in the IRT-model. In our study we investigate how slightly changing task features influence students' problem solving behaviour.

Time	Content
05/2014	Video: easy tasks
06/2014	Video: more difficult tasks; FCI

Table 4: Overview study 2

To control for students' competences we considered their first term grades (calculus, linear algebra and mechanics) as indicators. The participants (n=8, male=6, female=2) worked alone on the tasks and received in advance a detailed introduction into the *thinking aloud*-method (Ericsson & Simon, 1984), including a preceding practice task. After that, students chose a topic, were given two to four tasks accordingly (cf. Figure 1), and processed the tasks in ascending difficulty. Finally, all students were interviewed and asked to reflect their courses of action. The video data was analysed by using the category system (see study 1). While students' work was analysed as in study 1, the interview data was also checked for task characteristics and the conscious use of problem solving strategies.

RESULTS

Study 1

As mentioned earlier, only the findings from the first measurement point can be reported at the moment, as the data from the second and third survey have not yet been completely analysed. Our participants are comparable with the students from the larger pilot study conducted by the quantitative project. In detail, they received the following mean personal ability estimates and results: M_{HM}=-0.11 (*SD*=1.38), M_{TM}=-0.86 (1.01), FCI=11.35 (5.78) out of 30 points. To clarify which factors affect students' performance in the processing of tasks due to physical contexts, several multiple linear regressions and the corresponding correlation matrices were calculated. For the correlations of pre-test results and prior knowledge, represented

R^2=0.602			

Table 6: Multiple linear regression

	Easy tasks	Difficult tasks
Heuristic Tools (HM/TM pre-test)	31%	69%
Heuristic Strategies (HM pre-test)	37%	63%
Heuristic Principles (HM/TM pre-test)	0%	100%

Table 7: Distribution of heuristics

by the final grade in school certificate, the results are provided in Table 5.

Collinearity analysis detected that the factor *Grade School Certificate* contains the same information as the factor *result HM pre-test*, it is therefore not important for further calculations (cf. Table 6).

The model explains 60% of the variance in the TM pre-test results. In particular, beliefs about physics have a great influence on these results. In contrast, only 20% of all observed uses of heuristic strategies occurred when students worked on physics problems. Thus, the mathematical problem solving approaches, such as problem solving strategies and Polya's phase model, are only partly suitable for describing processes in solving physics problems. Here analyses by guide of the epistemic games framework, which are reviewed in a forthcoming analysing step, will probably deliver further explanations. However, when just looking at the use of heuristic tools and heuristic principles, we can conclude that these are used in a similar way when solving both mathematical problems and physics tasks. Table 7 shows the distribution of heuristics for the processing of easy and difficult tasks.

The results show that the students are increasingly using both tools and principles for difficult tasks. The situation is similar for mathematical tasks when using heuristic strategies. Overall, the students used heuristics rather rarely. Only in slightly more than half of the task processing of the difficult tasks, the use of heuristics could be observed (tools: 54%, strategies: 55%, principles: 27% of all difficult tasks). When solving the easy tasks, heuristics were less observed (tools: 30%, strategies: 45%, principles: 0% of all easy tasks).

Applying Polya's phase model to analyse the mathematics tasks, it becomes clear that for difficult tasks, students worked much more in cycles (for example, between *carrying out a plan* and *devising a plan*) in their solution process than for easy tasks, where they tend to go through the problem solving process linearly.

Study 2

For the sake of brevity we limit ourselves to presenting only the results of the sequence of tasks to reaction forces (see Figure 1). All students successfully solved the first task, using one specific algorithm. At the end of their solving process, only two students recognized

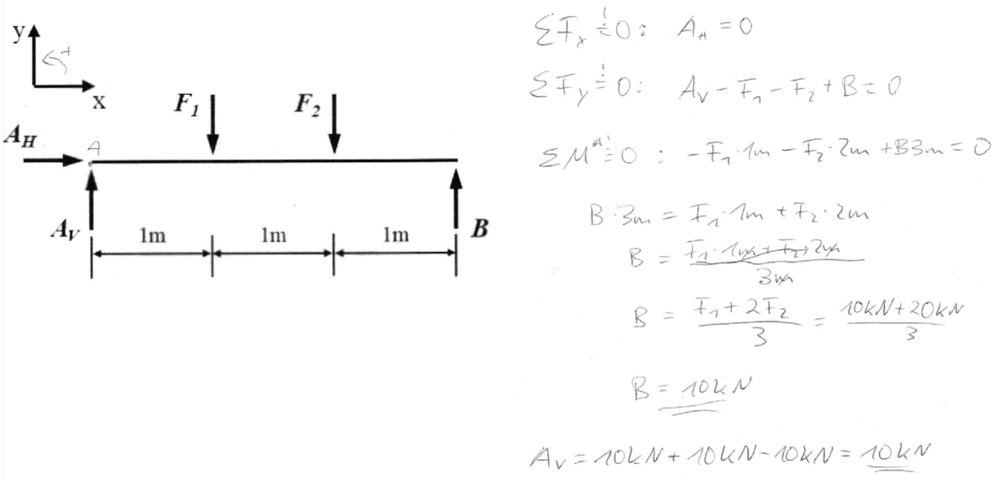

Figure 2: Student D's work on task 1

the symmetry aspect of the task. Students' work differed only slightly concerning the amount of the heuristic tools and strategies used. It is remarkable that the students who had mastered the more difficult tasks of the sequence, switched more frequently between the heuristic tools used when solving the simple task (here *informative figure* and *equations*). Table 8 summarizes the results that the four students received. As it is shown in Figure 1 and Figure 2, students were asked to compute the three forces A_H, A_V and B in each task; yielding the correct result was coded 1, otherwise 0 (see Table 8).

The following transcript of Denise's work shows the alternating use of the two heuristic tools mentioned above. She was able to determine the first two equations for calculating the x- and y- directions, and thus A_H, and started to calculate the third equation for the momentum.

From her think aloud protocol we gain the following explanations:

> So, for example, the sum of all momentums, what will be best? So you have to have any equation with only one unknown that you are looking for, yes. Then you could take, for example, the point (showing on the point, A_V and A_H point to), because the two go through that, then they do not have to be calculated. [The] Sum of all momentums in point A which is here (draws a point to the place to which A_V and A_H point and labels it with A) must be 0. So the positive direction of rotation is this (draws a curved arrow). F_1 (redraws arrow F_1) rotates negatively with the lever arm 1m, meaning minus F_1 times 1m, F_2 negative with 2m, and B (indicates B) is positive with 3m equals 0. F_1 and F_2 on the other side mean B times 3m is equal to F_1 times 1m minus F, plus F_2 times 2m. Then, you need to convey the 3m here (indicates the side of the equation with F_1 and F_2), by dividing, and then we have B alone in the end.

This procedure of combining heuristics is also seen in the processing of the two other tasks. The two other students (Alice, Bob) do not connect the *informative figure* and the *equations* in a similar way. They fail to solve the third task, since they apparently cannot transfer all the information from the figure correctly into their equations.

DISCUSSION

We were able to provide evidence for the expected influence of mathematical skills and beliefs about physics on the achievements in technical mechanics even in our small sample. In view of the above-mentioned asynchronicity of engineering education, this

	Alice[1]	Bob	Chris	Denise
Task 1 (A_H/A_V/B)	1/1/1	1/1/1	1/1/1	1/1/1
Task 2 (A_H/A_V/B)	1/0/0	1/1/1	1/1/1	1/0/0
Task 3 (A_H/A_V/B)	1/0/0	1/0/0	1/1/1	1/0/1

Table 8: Results of the task sequence "reaction force"

means that students first need to master the mathematical basics to be able to successfully work on physics problems and not, as is often the case, learn them at the same time or after encountering the physics contents. The results about problem solving in our first study suggest two conclusions. On average, more difficult tasks require a greater use of heuristic tools, strategies and principles. In addition, we noticed that in some tasks which are assigned a high difficulty estimate by the IRT scaling, the students' use of heuristics is comparable to their processing of the easy tasks. Overall, the students rarely use heuristics in solving the tasks, both in the easy and in the difficult tasks. We note that only in just over half of the difficult tasks the students use tools and strategies when working on them. The cause may lie in a low consideration of problem-solving tasks in mathematics education at school.

The results of the second study clearly show that it is not enough to simply master heuristics, although the use of individual heuristics helps solving tasks, as can be seen in the first item of the task sequence "reaction forces". Only when these heuristics are meaningfully connected, in a way that they support and enhance each other, students are able to solve challenging tasks successfully. An exemplary situation is the following one: first, a student used the diagram to understand the situation. The situation requires a certain algorithm which the student formulated in a general form. Then the components were adjusted using the diagram in the given situation. After that the result was checked for plausibility referring to the diagram. Therefore learning heuristics should attend to two competencies: Students must be able to use some heuristics deliberately, and they need to be able to effectively combine tools, strategies and principles.

Perceived autonomy in the first semester of mathematics studies

Michael Liebendörfer and Reinhard Hochmuth

Leibniz Universität Hannover, Hannover, Germany
Leuphana Universität Lüneburg, Lüneburg, Germany, liebendoerfer@khdm.de

We focus on the perceived autonomy of mathematics students in their first semester at university. According to self-determination theory by Deci and Ryan (1985), students have to satisfy their need for autonomy in order to develop intrinsic motivation. Using two facets of autonomy, we analyse interview data to explore which situations foster or hinder the students' perceived autonomy. The main factors affecting students' autonomy are briefly discussed.

Keywords: Self-determination theory, autonomy, first study year.

INTRODUCTION

Students' interest is an important factor in learning mathematics, especially for deep understanding (Köller, Baumert, & Schnabel, 2001) end of Grade 10, and middle of Grade 12--in order to investigate the relationships between academic interest and achievement in mathematics. In addition, sex differences in achievement, interest, and course selection were analyzed. At the end of Grade 10, students opted for either a basic or an advanced mathematics course. Data analyses revealed sex differences in favor of boys in mathematics achievement, interest, and opting for an advanced mathematics course. Further analyses by means of structural equation modeling show that interest had no significant effect on learning from Grade 7 to Grade 10, but did affect course selection--that is, highly interested students were more likely to choose an advanced course. Furthermore, interest at the end of Grade 10 had a direct and an indirect effect (via course selection. However, in their first semester at university, mathematics students often experience motivational problems (e.g., Daskalogianni & Simpson, 2002), which form – at least in Germany – one major reason for drop-out (Heublein, Hutzsch, Schreiber, Sommer, & Besuch, 2009). Self-determination theory (SDT) by Deci and Ryan (1985; Ryan & Deci, 2002) postulates three basic psychological needs which are central to the support of interest: the needs for perceived competence, autonomy and social relatedness. In this paper, we focus on autonomy, investigating how German first-semester mathematics students experience the satisfaction of their need for autonomy at university. We have chosen autonomy because in our data, many students have a problematic autonomy experience despite possible positive influences at university (they study a topic of their own choice in an institution that gives many freedoms, e.g. minimal attendance requirements). After an explanation of the concept of the need for autonomy we state the research goals and describe the methods we have used. We then present empirical findings and finally discuss factors influencing students' autonomy.

This research is part of a PhD-project focussing on students' interest development.

THEORETICAL BACKGROUND AND RESEARCH GOALS

In SDT, the role of the basic psychological needs for the development of motivation compares to the role of basic physiological needs (food, water) for the development of our body: need satisfaction is necessary to thrive. A major difference is, however, that the satisfaction of psychological needs is a personal perception. Thus, even in the same situation, different persons may experience need satisfaction very differently. The term autonomy as it is used in SDT should not be confused with different usages like independence or influence on one's learning. The need for autonomy is described as referring "to being the perceived origin or source of one's own behaviour" and "concerns acting from interest and integrated values" (Ryan & Deci, 2002). Following Lewalter (2005), we distinguish two different facets of autonomy of Ryan and Deci's description. The first one is the *perceived locus of causality* (PLOC) people feel when they initiate and control their actions (but not necessarily the outcomes, however). The second one refers to their *personal goals and values* (PGV). For example, one might compose music and feel a PLOC concerning the emerging ideas. In contrast, one might play music in an orchestra and give the initiative to the conductor but might still feel autonomous in the PGV sense if one's goal is to play music in an orchestra and one sees being conducted a valuable way to do so. Since studying mathematics includes external causations (e.g. choice of content, exams) one might or might not agree with, we expect the usage of the two concepts to give more detailed results. Based on SDT, Reeve (2002) stresses the importance of autonomy in educational settings and gives descriptions of autonomy-supporting behaviour like being responsive, supportive and flexible (e.g., giving students time to work in their own way). In contrary, using directives, evaluating students and motivating them through pressure hinders their perception of autonomy. Since motivational problems are known in the first semester, it would be interesting to see if and how the basic needs are satisfied. However, we could not find descriptions of students' autonomy experience in university mathematics courses.

Our first goal is to identify typical ways to have autonomy-related experience in the first semester. Our second goal is to find out in how far autonomy in studying mathematics may be perceived very differently across students. Since for the first two aspects, we distinguish two facets of autonomy (PLOC and PGV), our third goal is to analyse the relation between both facets.

DATA COLLECTION AND ANALYSIS

Our data is formed by 17 semi-structured interviews with first-semester students. Some were enrolled in a secondary teacher programme, others studied for a mathematics degree, but they all attended the same lecture on real analysis. The professor held the course in a rather abstract way and included only few numerical examples. The setting was typical for German mathematics or higher secondary teacher programmes: About 100 students attended the lectures where they had to hand-in a task sheet every week. The sheet was marked and then returned in a weekly tutorial where the solutions were presented and discussed. Only students who got at least 50 % of the maximum score were allowed to take the exam. Attendance was neither required in the lectures, nor in the tutorials. The lecture was based on definition and proof and also many tasks included proofs. Many students also attended a course on linear algebra in their first semester, which was more calculation-based in comparison to the analysis course. All students were asked to come for an interview in the lecture. They agreed in the scientific use of their data and were given the possibility to discontinue the interview or delete passages from the tape at any time.

The students were interviewed in the third or fourth week of their first semester and were asked to broadly describe their experience and learning behaviour at university. Subsequently, they were more specifically asked for their satisfaction of the basic needs including autonomy (e.g., referring to their narrative, the interviewer could ask for situations which were similar or very different from those which affected students' PLOC and for issues they did or did not agree with). The students were asked to include the linear algebra course in case they attended it, but happened to mostly speak about their analysis course. The interviews lasted 30 to 60 minutes and were taped and transcribed. To illustrate the very personal nature of need satisfaction, we picked out two pre-service teachers, whom we call Betty and Chris. We included one more interview with each of them which was conducted at the end of the semester in the same manner. They were chosen to maximise the contrast of autonomy experience: Betty experienced very little autonomy and Chris quite a lot.

Since need satisfaction is usually connected to emotions and may thus be remembered quite well, we assume that the students recalled large parts of their important experiences. We thus expect to cover a very broad range of need satisfaction. Students' statements in the transcripts were coded for PLOC and PGV concerning university mathematics anywhere in the interview, not only when the students had been asked for autonomy. As the interviews included both positive and negative experiences relating to need satisfaction, we distinguished positive from negative in our coding depending on students' reported emotions or evaluations. PLOC was coded when students either referred to themselves as source of their actions or described situations where they were far from being the origin of their behaviour (having no idea what to do, feeling desperate). PGV was coded when students reported that issues were in accordance or in conflict with their goals and values. Coding one passage for both categories was also possible. We want to give some examples of our coding:

Positive PLOC

> For example today, I could calculate some things because I knew how to rearrange them. And that felt great, I was really proud since I knew, it was right. And it was my thought.

Negative PLOC

> I found the worst thing which frustrated me very much and still does: You shall prove or justify something but no one tells you how.

Positive PGV

> I find it a great thing, that you simply have a task sheet every week. For this reason I am confident that if I engage with the sheet, then my studies will work.

Negative PGV

> For me, it isn't right, that the lecture is so fast and you really can't follow and I find this really bad.

The codings of each category were then grouped into typical situations by the first author in a rather exploratory way. We believe the method to be sufficient to identify ways to experience or hinder autonomy, although there is no methodological control.

RESULTS

In order to answer the first question of how autonomy typically arises or is hindered, we present the main clusters according to the two theoretical facets.

For the PLOC-facet, 156 out of 204 codings were negative, which corresponds to most students' general experience of some frustrating first weeks.

- Each student felt pressure to hand-in the task sheets in time and get a sufficient grading, which was a rather permanent experience.
- On a situational level, they lost PLOC when they couldn't (immediately) understand the lectures and the pace was too fast for them, so they could only take lecture notes.
- The students also lost their PLOC when they did not know if they were mathematically right or wrong (e.g. if a proof was correct or complete, which argumentation was allowed) or missed explanations of mathematical objects.
- The most serious restrictions were experienced when the students worked on the task sheets. There is a frustrating feeling of being stuck which occurred in three different types of situations:
  - when students did not understand the task itself,
  - when they had no idea how to tackle the problem
  - and when they had an idea, but did not know how to write it down.
- Another autonomy restriction concerns the evaluation of the students' work. The marking on the task sheets, sometimes just the score, and the tutorials did often not provide the students sufficient information to understand in which parts and why they had been right or wrong. Sometimes, students even got different grades for the same solution, so they felt treated arbitrarily.
- When students positively experienced a PLOC, they mostly referred to situations contrary to the above mentioned ones (e.g. having ideas for the tasks). This especially related to calculation tasks.
- In addition, managing their resources like books, the internet or peers gave them feelings of initiative on an organizational level and thus autonomy.

For PGV, negative codings amounted to 65 out of 113 codings.

- Students did not agree with the way mathematics was presented (too few explanations and examples, the high pace in the lectures)
- and in general with a system that is so demanding that many students struggle.
- For the future teachers, another conflict was that the subject matter was perceived to be not appropriate for their future work.
- Positive PGV-experiences were reported with regard to the general aim of deeper understanding
- and in particular concerning the weekly task sheets, which made students work harder than they would have done otherwise and thus learn more.

In order to illustrate personal differences in need satisfaction, we now focus on the two students Betty and Chris who were enrolled in the teacher programme.

The case of Betty

After school, Betty did not immediately go to university but completed a vocational training as an educator and then decided to become a teacher. Her autonomy experience at university was mainly negative. On her first task sheets, she received far less than 50 % and thus reported enormous pressure and lack of time. Her experience covered examples for every negative PLOC category mentioned above. Especially, she did not understand why it had to be so hard. She could work on proof tasks only when the tasks were about proving that something satisfies a given definition. Once, she handed-in a solution copied from a book which proved an implication, where the task had asked for a proof of equivalence. She felt treated unfair since even the book's solution got a bad grading (affecting both PLOC and PGV). Asked for autonomy concerning her studies she confirmed that she knew she had autonomy, "but the feeling didn't show up". Despite her previous aims to fully understand the subject matter, she soon focussed on the minimal requirements and therefore merely worked on the task sheets without having time to review the lecture notes. Betty experienced autonomy using her resources like peers, books and the internet where she tried to get hints or solutions from. In the second interview she said that she had started copying homework although she did not like it. She was torn in her view on university mathematics. On the one hand, she characterised mathematics as "explaining simple things in complicated ways" and saw no use in it, especially in proofs since they would not have any application. On the other hand, she did not want to call university mathematics useless and gave it some importance since teachers should know what is behind the results. Her only autonomy experiences related to connections to school mathematics (PGV), managing resources (PLOC) and few numerical calculation tasks or examples (PLOC and PGV).

The case of Chris

Chris directly entered university after school, where he had reached the highest grades in mathematics. He felt pressure after his first task sheet was graded less than 50 %. He sometimes did not know how to tackle a task or write it down, but also solved some tasks so that positive and negative experiences balanced. Due to his partial success, he believed he could reach the necessary score so that fear and insecurity soon started fading out. He felt his autonomy restricted by having no guidance for proof tasks, getting no informing feedback on the marked sheets and having to do a lot for the tasks so he had less time for self-directed learning. All three aspects refer to both his PLOC and PGV. However, in principal he appreciated the task sheets since they make people work hard. Chris also readjusted his aims from getting good grades to simply passing and started using books and internet resources.

In the second interview, Chris still described some tasks as frustrating but he received sufficient scores and had developed confidence in eventually meeting this criterion. So although he still tried to solve every task, he did not feel pressure to do so. Chris also mentioned that he usually had several ideas and strategies for the sheets, including reviewing suitable parts of the lecture notes. He also highlighted his own evaluation of his solutions and his understanding in addition to the grading. Chris found having his own ideas was much more motivating than collecting information from different sources. Nevertheless, he sometimes searched for hint on the internet. When he found other interesting things there, he followed them for his own interest (PLOC).

Personal differences in autonomy experiences

It is clear, that different situations may lead to different autonomy experiences. Betty perceived very little autonomy when she copied solutions for the tasks, whereas Chris could experience autonomy since he solved the tasks on his own. It is also clear that in similar situations, students may have similar experiences. Betty and Chris both feel pressure from the tasks sheets (PLOC) which they generally agree with (PGV), because they see the sheets as a good measure for their learning. They both appreciate that university mathematics aims at deeper understanding and they both like calculation tasks because they usually know how to tackle them. However, Betty and Chris also had very different autonomy experiences in similar situations:

They both believed that they would not need the university mathematics in their future work at school, but related this to their goals and values very differently. Betty said "Why? I do not want to become a mathematician but a teacher". Chris' reaction was rather opposite: "What else should we do then? They can't tell us again what we already learned in school!" In addition, they both had been looking for solutions in internet forums, but all they had found were hints. Betty disliked such posts and expected others to present the solution. Chris appreciated such posts as protecting him from copying something he would not understand (PGV). Differences also appeared for the PLOC-facet. When working on the tasks, Betty had mostly no idea what to do next whereas Chris often had several ideas and could then choose. In addition, Betty's only reason to work on the tasks was the score, since "I need the crap 50%". Chris, in contrast, saw things differently: "if I did it just for the external pressure, then I would tackle it very differently".

The relation between PLOC and PGV

Although the two facets of PLOC and PGV are connected, they turn out to contradict sometimes. While there was no situation where students had a PLOC but did not experience PGV, it happened that students' experienced no PLOC but felt their PGV were respected. Like Betty and Chris, all students (partially) lost their PLOC due to the pressure from the task sheets. However, this was mostly according to their PGV. A similar situation (no PLOC, but accordance with PGV) occurred when Chris could not find a solution for a task on the internet, but only hints. Concerning the content matter, Betty had very few PLOC experiences and was torn, struggling to connect the content to her goals and values, whereas Chris experienced both facets positively.

DISCUSSION

In our study, we analysed interview data concerning experiences of autonomy using the two different facets of PLOC and PGV. We could reach our first goal by describing typical situations of need satisfaction or dissatisfaction. We could see that studying mathematics at university provides rich opportunities to experience need satisfaction but also dissatisfaction which may cause serious problems for students' intrinsic motivation. Many typical situations could possibly also appear in other study subjects. However, especially those which refer to the task sheets (not understanding the task, having no idea how to tackle it or how to write down a solution) and proof (when is a proof correct and complete?) seem to be typical for university mathematics. Concerning the PLOC concept, autonomy seems to not only have heteronomy as a counterpart, but also feelings of being stuck and having no idea what to do next.

For our second goal, we compared the two cases of Betty and Chris, which illustrated that autonomy experiences strongly depend on both the person and the environment. Similar situations may foster the autonomy experience of some students and hinder the autonomy experience of others.

Concerning the third goal, we could see different, sometimes contradicting experiences for PLOC and PGV, although both facets origin in the same framework. Distinguishing the two facets helped analyse students' autonomy by revealing hidden tensions, where students feel no PLOC and yet experience need satisfaction in terms of PGV. In such a situation, the students may sustain their intrinsic motivation.

General issues affecting perceived autonomy

The *duty to get good grades* on the weekly task sheets clearly affects students' perceived autonomy, as it puts much pressure on them, violating Reeve's (2002) criteria for autonomy support mentioned above. However, to some extend most of the students appreciated the pressure which would eventually make them learn more. In addition, the case of Chris shows that students do not necessarily experience this duty as pressure if they are confident in meeting the criteria. However, like Betty, many students focussed mainly on the tasks and put their learning goals on hold.

Although the students did not express it, this might not meet their PGV.

Another major background is the *personal competence*. We could see that competence affects autonomy on different levels: First, content knowledge affects students' opportunities to tackle the tasks (PLOC) and also to evaluate their own mistakes (PLOC). As Chris' case shows, this ability can also be important to assess the personal work independent of external judgements like grades. Second, mathematical language is needed to even understand the task itself and to write down solutions (PLOC). Language can also affect the satisfaction of PGV, like in the situation where Betty misunderstood the task. A third level of mathematical competence refers to insecurities like how detailed proof needs to be or which arguments will be accepted. They may be described in terms of sociomathematical norms (see, e.g., Yackel, Rasmussen, & King, 2000) as normative understandings which are negotiated in the social context. It is clear to see that calculation tasks, which all students liked, do not address these problems apart from including difficult content. In turn, students may experience a PLOC based on their competence, e.g. seeing different ways to tackle a task or having their own ideas for solving problems.

Proof as a new concept fitted many students' PGV of heading for deeper mathematical understanding. However, students may have trouble to connect proof to their PGV because they do not see an application. In cases of proving obvious statements, they might see no use at all. Here, one decisive aspect is whether students see building a mathematical theory as part of their goals or restrict them to calculations and applications. In addition, *proving* as an activity may involve all competence-based problems mentioned above.

A very interesting point is the *questioning of the need of university mathematics for teaching at school*. The question itself is part of an open debate (e.g., Davis & Simmt, 2006) so there is no clear and simple answer. The students usually do not have teaching practice and see teaching often as "explaining". Taking this as basis, they need to trust in the university doing what is necessary for them. In our study, this did not always happen. We could see that students felt a conflict with their PGV only if they also had a PLOC-conflict. However, it is also possible that some students do actually not agree with the content but do not start to question it unless they start struggling. What we could observe is that the conflict reduced when connections to school were made explicit. Recent projects successfully provided such connections (Leufer & Prediger, 2007). In addition, the compulsory task sheets show that students may value things although they negatively affect their PLOC.

Unlike in school, university requires learning activities which are not explicitly assessed such as reviewing the lecture notes, monitoring the personal progress, searching for alternative explanations and examples or generating them. Students may not be aware of the new rules and experience these changes as "bad and too few explanations" affecting both PLOC and PGV. Such a mismatch of expectations can be described in terms of the *didactical contract* (Brousseau, 1984) which was highlighted by Hourigan & O'Donoghue (2007)the consequences of the 'Mathematics problem' are a source of concern for the education sector and governments alike. Growing consensus exists that the inability of students to successfully make the transition to tertiary level mathematics education lies in the substantial mismatch between the nature of entrants' pre-tertiary mathematical experiences and subsequent tertiary level mathematics-intensive courses. This paper reports on an Irish study that focuses on the pre-tertiary mathematics experience of entering students and examined its influence on students' ability to make a successful transition to tertiary level mathematics. Brousseau's 'didactical contract' is used as an intellectual tool to uncover and describe the contract that exists in two case mathematics classrooms in Irish upper secondary schools (Senior Cycle for the secondary-tertiary transition.

Some findings parallel the work of Sierpinska, Bobos, & Knipping (2008), who investigated "students' frustration" (which can be seen as contrary to autonomy) in prerequisite mathematics courses from an institutional point of view. Especially since both of us found critical elements like techniques of problem solving and learning strategies, rules and norms as well as the didactic contract, we hypothesise that these elements are generally important for autonomy in the learning of mathematics at university level and thus for students' motivation.

Implications

It seems that in general some conflicts with students' autonomy are inevitable. However, at some points help seems accessible, especially concerning aspects which are typical for university mathematics. For instance, students expected to be guided more in their learning process. Making explicit new demands in strategies for learning and problem solving, sociomathematical norms and the mathematical language could possibly help students to experience more autonomy. Since many students seek for suitable resources, books addressing study skills (e.g., Alcock, 2013) and mathematical language (e.g., Beutelspacher, 2004) could be a good start. In addition, making connections to school mathematics more visible would help pre-service teachers to connect their courses to their PGV.

The German community should also question the task sheet system. For instance, students could have to hand-in documents of their learning process (e.g. a learning diary) rather than worked-out solutions only. They could then also be admitted to the exam for learning activities of their choice like engagement with the lecture notes.

Characterising university mathematics teaching

Angeliki Mali

Loughborough University, Mathematics Education Centre, Loughborough, UK, a.mali@lboro.ac.uk

This paper reports early findings from university mathematics teaching in the tutorial setting. The study distils characteristics of two tutors' mathematics teaching and through interviews, their underlying considerations. Analysis of a teaching episode from each tutor illuminates their different teaching approaches and suggests ways in which approaches are linked to students' meaning making.

Keywords: University mathematics teaching, small group tutorials, meaning making.

INTRODUCTION

University mathematics teaching is of major significance in mathematics education. Some of the numerous benefits from research in this area of study are the production of professional development resources for novice and experienced university teachers as well as support to those teachers to create rich learning opportunities (Speer, Smith, & Horvath, 2010). However, the benefits from research go beyond university mathematics teaching and learning. Speer and Wagner (2009, p. 537) stressed that by studying the practice of teachers with strong mathematical knowledge, teacher educators "are better able to detect directions for growth in other areas of knowledge" such as "knowledge of typical ways students think (correctly and incorrectly) about the task or content in question" (p. 558), which teachers at all levels may need.

This report is based on the analyses from my ongoing doctoral project that examines university mathematics teaching through an exploration of tutors' teaching practice with first year undergraduate mathematics small-group tutorials. The analysis suggests that teaching practice can be construed in terms of three elements *tools*, *strategies* and *characteristics* of teaching (Mali, 2014). I focus here only on *characteristics* of teaching, which are patterns in the ways that tutors teach in the tutorials. From observations of tutors' teaching and interviews with tutors about their teaching, the aim of the doctoral project is to identify aspects of teaching practice and knowledge and connect them with students' meaning making in mathematics. Tutorials are studied since they provide opportunities for teacher-student dialogue and interaction through which meaning making can be discerned.

The focus of this report is on two tutors' teaching approaches. It is significant to juxtapose *characteristics* which look similar but are used in different ways by the different tutors to promote student meanings. So, the three research questions are: What are the *characteristics* of the two tutors' teaching? In what ways do two different tutors implement similar *characteristics* of teaching? What are the tutors' actions that encourage students to make meaning (promoting meaning making.) and what do tutors do to find out what meanings have been made (discerning meaning making)?

THEORETICAL BACKGROUND AND LITERATURE REVIEW

University mathematics teaching is an area of interest where research is still rather limited. Speer, Smith and Horvath (2010), after conducting a systematic literature review in university mathematics teaching, reported that there is no systematic data collection and analysis focusing on teachers and teaching. As to the small group tutorial setting, the number of studies is far fewer. Certain studies (including this one) focus on the nature of tutor's teaching and the knowledge that frames it. For example, Jaworski and Didis (2014) introduced the *questioning approach* to teaching and suggested tutor's awareness about her teaching as the basis of *knowledge in practice* which informs future action. Mali, Biza and Jaworski (2014) focused on *characteristics* of university mathematics teaching, such as the use of generic examples, and suggest that the research practices of the tutor (mathematician) influence her teaching practices; an influence which accords with findings in the format of lectures (Petropoulou, Potari, & Zachariades, 2011). Jaworski (2002) distinguished tutors' exposition patterns (*tutor explanation, tutor as expert* and forms of *tutor questioning*) as the main teaching aspect in the context of tutorials. She also stressed that teaching/learning was idiosyncratic to the tutor and to some extent to the particular students. These studies give insight into elements of tutors' teaching practices and their reflective thinking. Gaining access to students' meaning in relation to teaching provides significant information about how tutors encourage students to make meaning; for example, Jaworski and Didis (2014) relate students' meaning making to the *why questions* of the tutor. In our study reported here, we investigate, through a sociocultural perspective, teaching practices of selected tutors that encourage students to make meaning.

The socio-cultural paradigm, rooted in Vygotskian psychology, considers the overall social and cultural context, which frames mathematics teaching and learning in its complexity. Concepts and meanings are experienced and understood in the social and cultural small group tutorial practices (e.g., engagement, participation and interaction). Meaning, thinking and reasoning are products of social activity and take place first on the social plane. Tutors' teaching mediates students' mathematical meaning making by using material (e.g., textbooks, problem sheets) or intellectual tools (e.g., exposition).

In this paper, I embed tutors' *characteristics* of teaching in the socio-cultural tutorial practices of tutor-student interaction and participation relating them to students' meaning making. For the purposes of the analysis, I draw on the literature which considers meaning making in terms of making connections within mathematics through different representations, such as symbols, diagrams, pictures (Haylock, 1982); and between mathematics and "other aspects of the world" (Ormell, 1974, p. 13), such as real world situations. I interpret this collective mathematical meaning making through observing and analysing tutors' and students' actions in the classroom. The tutor's actions relate to the nature of teaching and the approach, and accord with what the tutor says (I can read in transcripts); does (gestures, body language) and intentions (I can ask in interviews or hear in the classroom). The students' actions are what they say and do during the tutorials.

THE CONTEXT OF THE STUDY

The study is being conducted at an English University, where students are in their first year of a straight or a joint programme in Mathematics. They are expected to attend lectures (in analysis modules and linear algebra) and a small group tutorial of 5 to 8 students. Tutorials are 50 minutes weekly sessions and work is on the material of the lectures (lecture notes, problem sheets, coursework and exams). Students are expected to work on the material of the lectures beforehand and bring their questions to the tutorial. The tutors are lecturers in modules offered by the mathematics department and conduct research in mathematics or mathematics education. Phanes and Alex are experienced lecturers as well as researchers. Phanes holds a doctorate in mathematics and Alex holds a doctorate in mathematics education.

THE METHOD OF THE STUDY

This study is part of a doctoral project, which has analysed data from one tutorial from each of 26 tutors, as a basis for conceptualisation of teaching. This has been followed by a systematic study of the teaching of three of the 26 tutors for more than one semester. Phanes and Alex are two of the three tutors. Data consists of observation notes and transcriptions of their audio-recorded tutorials and follow up interviews. The interviews are discussions with them about their thinking behind the teaching actions in these tutorials. A grounded analytical approach is taken to the data in which aspects of tutors' actions that seemed to be informed by their teaching knowledge are coded. Analysis is based on the identification and grounded study of teaching episodes; there are several cycles of interpretation: from initial ones using open coding to more advanced ones creating categories. *Characteristics* of teaching have been identified repeatedly throughout the analysis of each tutor's teaching, emerging from this as a category in the nature of teaching. Examples are provided in the accounts below.

RESULTS

Both Phanes and Alex work on a number of questions/mathematical issues in their tutorials, which is a fre-

	Grounded characteristics of teaching	Phanes	Alex

quent general practice at tutorials. As preparation for the tutorial they look at the lecture materials, including problem sheets, a few minutes before the tutorial. In the following Table, I present *characteristics* of teaching, identified so far, from both tutors. These characteristics emerged in the process of data analysis after the tutorial observations.

In order to scrutinise the different ways tutors implement common *characteristics* and the different issues that are raised, I offer a teaching episode from each tutor. These episodes are paradigmatic cases of the tutors' teaching in terms of manifesting a number of *characteristics* of their teaching.

Phanes' approach

This episode is situated in the second tutorial of the year and concerns work on an exercise from the first problem sheet in analysis:

"Rewrite $||x|-1|$ without modulus signs, using several cases where necessary."

Reading the exercise, Phanes suggests: "we can just sketch the graph of the function". He uses *exposition about know-how to* get rid of the modulus sign (*characteristic* 2/Table 1): "You see, to get rid of the modulus sign of $|x|$, you need to know that x is positive or negative. You have to consider cases. But there is another outer modulus. It's external. Again, to get rid of it, you need to either consider the case whether the expression inside it is positive or not." He offers *a less complicated example to reveal the work on modulus signs* (*characteristic* 3/Table 1); he constructs on the board the graph of $|x^3|$ reflecting the negative part of the graph of x^3 about the x-axis. Then he requests students to work on their scripts for $||x|-1|$ (*characteristics* 7/Table 1), after which the following episode occurs:

Phanes: So, how do I solve this problem? I'll show you. I saw correct pictures; all of you had correct pictures. So, what am I going to do? I will do it step-by-step. First, I will construct $|x|$, right? $|x|$ is this. [Phanes sketches the graph of Figure 1.] Ok? Then, we do $|x|-1$. $|x|-1$ means that you take $|x|$ and you shift it down by 1. This means -1, right? So, it gives you this [g in Figure 1]. These points are 1 and -1. And this point is -1. This is the expression under the modulus sign. And then, you take the modulus of this function and it means that you reflect this negative bit about the x axis, right? And you get this function. Ok? This is the graph of the function. Now, we have to write down the equations for this. You can see that it's given by different functions on different intervals. For instance, this expression is what [f in Figure 1]? This was $y=x$ [e in Figure 1], and then, you shift it by 1, so this is $x-1$ [f in Figure 1]. Is this clear? Please stop me if something is unclear. So, this is $x-1$ [f in Figure 1]. So, what is this [c in Figure 1]? What is this – this bit [c in Figure 1]? It has the same slope as $x-1$ but it's shifted it up.

St2: It's $x+1$.

Phanes: It's $x+1$. So, this bit is $x+1$ [c in Figure 1]. Now, what is this [a in Figure 1]? This graph is $y=-x$ [b in Figure 1], and we shift it down, so it's $-x-1$. So, this thing is $-x-1$. And what is this [d in Figure 1]?

St4: $-x+1$.

Phanes: $-x+1$. $-x+1$. So, what can we now say about this function $||x|-1|$? It equals. Now, it depends on where x is, right? So, we know for this function that on this [Phanes points to interval $[1,+\infty)$], it's $x-1$ if x is greater than or equal to 1. Agree? It is $-x+1$, $-x+1$, if x belongs to $(0, 1)$. It is $x+1$, $x+1$, if x belongs to $(-1, 0)$. And finally, it's $-x-1$ if x belongs to $(-\infty, -1)$.

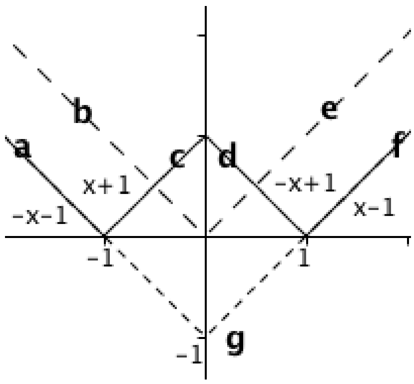

Figure 1: Graph on board, episode 1

In the above episode, Phanes uses the *graph of* $||x|-1|$ *to provide a visual intuition for rewriting the algebraic expression* $||x|-1|$ *without modulus signs* (*characteristic* 1/ Table 1). He first constructs the graph "step-by-step" and then the equations; in this way, he *divides the mathematical task into steps* (*characteristic* 3/ Table 1) and *uses geometric and algebraic representations* (*characteristic* 5/ Table 1). For the construction of the graph, he offers *know-how exposition for the work on modulus signs* (*characteristic* 2/Table 1). Furthermore, for the construction of the equations, he shows how to find $x-1$ and $-x-1$ asking students for $x+1$ and $-x+1$ respectively (*characteristics* 4/ Table 1).

The above *characteristics* (1–5/ Table 1) are within Phanes' thinking on the mathematics. Phanes uses the graph of $||x|-1|$ as a tool to think on the mathematics; he adjusts basic graphs (i.e. $|x|$, x, $-x$) to construct $||x|-1|$ and from that, he extracts the essential information (i.e. equations and intervals) for the solution of the specific exercise. He uses the graphical representation $||x|-1|$ and visual intuition of the equations as a problem solving technique (*characteristic* 3/Table 1), thereby negotiating different contexts (geometric and algebraic) of the concept of modulus sign. Connecting the two contexts/representations, he promotes students' meaning making of the modulus sign. To this end, he also uses know-how exposition, problem-solving techniques, multiple examples of expressing equations and provision of time to students for individual work (*characteristics* 2–4, 7/Table 1).

In the beginning of the episode, Phanes comments that "I saw correct pictures; all of you had correct pictures." This suggests that while circulating and supporting students (*characteristic* 7/Table 1), he also made some judgements about their meaning making of the modulus sign. These judgements arise from his assessment of the students' scripts and indicate that he used *characteristic* 7 to discern their meaning making; not only to promote it. Phanes can also use the multiple examples of equations (*characteristic* 4/Table 1) to discern students' meaning making of the graph by assessing their correct answers for $x+1$ and $-x+1$.

The use of visual intuition of the equations on the graph does not provide enough insight into the intervals. After the episode, Phanes stresses to students that the function is continuous, so "it doesn't matter" if the endpoint is included in the interval; he says to them "strictly speaking, you should include it". In our discussion and in response why he chose a geometric solution when some mathematicians avoid choosing them, Phanes connected his choice with mathematicians' research practices.

> It depends on your research area. If you are a geometer [Phanes is a geometer], you are happy with geometric solutions; it depends on your background I think. [...] You see to me it is easier to see the graph. [...] For instance if you are a programmer writing computer programs, then it is more convenient to you to give an algorithm.

Phanes approaches mathematics teaching putting emphasis on the mathematics and geometric thinking, whereby he relates geometric solutions to his research area. From this thinking on mathematics, he draws out his teaching practice which I recognise through his actions (*characteristics* 1–5, 7/Table 1) to promote and/or discern students' meaning making. In this episode, Phanes presents the ways he is working through the graphs and symbols dissecting the mathematical task to make its aspects more visible to students. He thus works within his thinking about the graphs in *characteristics* 1–5. *Characteristic 7* is different in nature from the others since it can be used in the teaching of other subjects as well as mathematics.

Alex's approach

In his third tutorial of the year, Alex used Venn diagrams to explain the definition of injectivity (*characteristic* 1/Table 1) as well as examples and non-examples of the concept (*characteristic* 4/Table 1). In discussion after the third tutorial, he reflected:

> By the reaction I got when I asked for the definition [of injectivity] the student couldn't even say what the symbols were there. So, I had to repeat it for him. There was not so much meaning making there. So, that's why I decided to use examples, use the Venn diagrams for the sets and what exactly it means to be injective and surjective. [...] If the students get it, I am not sure about that, because after that they still have the face of 'what are you talking about?' So, at that point you say 'Mmm if I carry on with more examples, eventually they will get it', because I don't have any other didactical instrument to make it even clearer for them. Ah in fact when I was preparing my module for another lecture, I thought of a very *good example of the function*. When you go to the supermarket and I am going to say to them next time [...] to explain what an injective and a surjective function is. [...] And I think that's more near the experience of the students, so that they can say "ah yes, I get it now".

Alex implemented the "good example of the function" in the fourth tutorial. He said to the students: "A function is a relationship between a set of inputs, in this case the products in the supermarket, a loaf of bread, and the set of permissible outputs, in this case the prices. So it relates each product to the one, the only one price, it cannot be related to two." In the following episode, we see Alex's implementation of the example for the concept of injectivity. Before the start of the episode, Alex asked the students to express injectivity in the context of his example. As a response to their inability to do so, he asked them to find the definition of injectivity [$\forall x,y \in Dom(f), f(x)=f(y) \Rightarrow x=y$] in their lecture notes (*characteristic* 12/ Table 1). He then wrote the definition of injectivity on the board.

Alex:	How would you read that [the definition of injectivity] in the supermarket example? Which are the x's? What's the domain of the function? St3, what would the x's be in this example in Tesco [i.e. supermarket]?
St3:	Products. Products..
Alex:	The products, exactly. So for all the products in Tesco
St3:	They should be x and y.
Alex:	So why would it be x and y?
St3:	Because it's product and price; x is product, y is price.
Alex:	x could be read, y could be milk, mm? So what would this mean, this then? [Alex points to $f(x)=f(y)$.]
St2:	The same price. [St2's voice is almost inaudible.]
Alex:	What would that [Alex points to $f(x)=f(y)$] mean in the example? I want you to contextualise a very abstract formal definition so we do an everyday job that you can understand; that you give some meaning to those things. Try to think on the example of the supermarket, what would $f(x)$ equal, what would $f(y)$ equal, what would x be, what would y be?
St5:	$f(x)$ would be prices.
Alex:	Yes, the prices, OK. So it says if the prices are equal, let's say 99p, what has to happen to x and y? [Alex sketches Figure 2 on the board.] Let's say x is bread and y is milk, OK? And I notice that the price of the bread and the price of the milk are the same, they are both 99p. Yes? If this function was injective, then the bread would have to be milk, well that's impossible isn't it? [Alex deletes milk on Figure 2.] In other words, I cannot have the price of 99p that belongs to two products, two different products, mm, in the abstract definition, there is no way that 99p comes from bread and milk. Does that make sense or not? Say no if ... well your faces say no.

St1: No, I'd say no.
Alex: OK. Can you think of another example? [...] Do you play a sport?

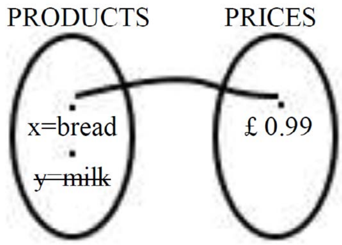

Figure 2: Diagram on board, episode 2

St1 mentioned hockey and Alex devised another example regarding a function that relates hockey players with their scores (*characteristic* 4/Table 1). Despite the real world context of the example of function in the supermarket (a product cannot be related simultaneously to two final prices), a function that relates products/players with their prices/scores is not injective in real life since, there, two different products/players can have the same price/score.

In the above episode, Alex devises a real word example regarding a supermarket (*characteristic* 4/Table 1) to promote students' meaning making of the concept of injectivity: "I want you to contextualise a very abstract formal definition so we do an everyday job that you can understand; that you give some meaning to those things." He uses funnelling (*characteristic* 10, Table 1) by asking what the x, y, $f(x)$ and $f(y)$ are and invites st3 to answer (*characteristic* 11/Table 1); then, he uses the Venn diagram of Figure 2 to provide a visual intuition for the definition of injectivity in the context of the supermarket example (*characteristics* 1, 5/Table 1). In the interview excerpt, Alex stresses that in order to promote meaning making he uses multiple examples (*characteristic* 4/Table 1) and Venn diagrams (*characteristic* 1/Table 1). In discussion with Alex about the use of real world examples, he connects it with research in mathematics education.

> By making it [the example] nearer to the students' experience; that comes from mathematics education. [...] Because you need to make connections in order to make meaning. To understand something you need to make the appropriate connections from your own experiences.

Alex discerns students' meaning making from their faces: "Does that make sense or not? Say no if... well your faces say no" (episode excerpt) and "If the students get it, I am not sure about that, because after that they still have the face of 'what are you talking about?'" (interview excerpt1). In the episode, when st1 answers he doesn't make sense of the example, Alex asks him to devise an example close to his interests (*characteristics* 8, 4/Table 1). After the fifth tutorial, Alex reflects:

> I thought it went a bit better last time when I asked st1: "What do you do in your life?" I play hockey he said. And it went well I thought; at least they said: "Oh yeah I understand now what you mean." That's the design at least to connect with what they do outside.

He also discerns meaning making by the reaction he gets from students.

Alex approaches mathematics teaching bringing in awareness from research in mathematics education; he connects mathematics with students' everyday experiences for meaning making (e.g., Ormell, 1974). A number of his actions (*characteristics* 8, 10, 11, 12/Table 1) to promote and/or discern students' meaning making relates to students' participation, and can be used in the teaching of other subjects as well as mathematics. In this episode, Alex steps out of mathematics, goes into the context of the students and chooses examples there that he can use to parallel injectivity (*characteristic* 4/Table 1). So, Alex roots the abstract mathematics in examples of an everyday nature; starts in the abstract mode through symbols; discerns that students do not make meaning of them; and then brings in a diagram as an alternative way of representing injectivity. He uses this diagram as a tool to explain the mathematics to students; it constitutes another representation of the formal definition which he enriches with explanatory exposition.

CONCLUSIONS

In this paper, I presented two different approaches to teaching, where both tutors put a considerable effort so that students make meaning of the mathematics of the lectures. I related this effort to their actions to promote and/or discern students' meaning making coded in *characteristics* of teaching. I thus looked at the tutor's perspective for students' meaning making, acknowledging that there is no right or better approach. Zooming in each tutor's approach to teaching, they deploy different ways to implement common characteristics; for instance the *characteristic use of graphical representations to provide visual intuition for formal representations*. Phanes uses the graph to make fundamentally mathematical ways of thinking transparent to students, whereas Alex uses it as an alternative to explain the mathematics. In order to promote students' meaning making of how a process works for the modulus function, Phanes uses exposition, problem-solving techniques, explanation, examples and representations all within his thinking of the mathematics. By his exemplification of the process, students can potentially gain mathematical expertise (i.e., use of graphs and visual intuition) to apply in other problems thereby being enculturated into mathematical practices. Alex's real world example is localised around the concept of function and its properties (e.g., injectivity), which is fundamental in mathematics. In order to promote students' meaning making of the concept of injectivity, he uses examples, representations, funneling and invitations as well as requests to students. Evaluation of students' scripts, responses and facial expressions are ways tutors discern students' meaning making. However, promoting and discerning meaning making are two processes that cannot be separated in some cases; for instance, while the tutor *provides time to students to work on their scripts*, he both supports and evaluates them. In future studies, I will analyse data from the other tutors and juxtapose their characteristics of teaching in order to identify aspects of teaching practice and knowledge and ultimately connect these aspects with students' mathematical meaning making.

Faculty knowledge of teaching in inquiry-based learning mathematics

Vilma Mesa and Anne Cawley

University of Michigan, Ann Arbor, USA, vmesa@umich.edu

In the context of using Inquiry-Based Learning (IBL) for teaching, 74 instructors teaching a wide range of university mathematics courses and with different levels of familiarity with IBL filled out bi-weekly logs about the challenges they faced and the solutions they found. The analysis of pairs of concerns and solutions expressed over the three-year study reveals that faculty may be drawing from different domains of teacher knowledge for teaching to solve concerns teaching with IBL. Level of familiarity with IBL did not seem to play a role in the types of solutions proposed, except when faculty reported not having a solution. We conjecture that the method may induce faculty's pedagogical awareness, independently of how experienced they are with teaching university mathematics.

Keywords: Inquiry-based learning, teacher knowledge, university mathematics.

Originally proposed as a way to understand how faculty learn to teach mathematics courses using Inquiry-Based Learning (IBL) approaches, the *Learning to Teach Mathematics with IBL Project* followed a group of instructors new to using IBL over a period of three years and documented their experience using IBL. Prior work interviewing a handful of instructors who were new to the method at our university suggested that at the beginning of the semester, their concerns centred on spatial and logistical aspects of managing the class: where do I stand in the room? How much time is it OK to wait before answering a question? As the instructors gained more experience with IBL their concerns shifted towards an interest in understanding students' thinking (Mesa & Cheng, 2008). Such dramatic change over the course of one semester countered some literature available on instructors' knowledge, more notably work done by Nyquist and Sprague (1998), whom having worked with teaching assistants (TAs), identified three distinct stages of concerns: a self-centred stage in which beginner TAs worried about themselves and students' perceptions of them (am I knowledgeable? do they like me?); a management-centred stage, in which more advanced TAs worried about managing the logistics and the different aspects of the classrooms (making sure students are not engaging in disrespectful behaviours); and a student-learning stage, in which the expert TAs worried mainly about whether students were understanding the material. These are described as stages in the development of TAs' expertise in teaching. Because our own experience did not suggest these stages with the faculty on our campus (Mesa & Cheng, 2008), we proposed this study. The design of this study includes faculty who stated their familiarity with IBL as beginners, novices, advanced, or experts; its longitudinal nature allows faculty to participate two to six consecutive semesters, with some participating only once. New faculty were added each year. We focused on the concerns faculty described and the solutions they proposed to those concerns when they engaged in four areas of teaching: sending students to the board, designing and managing group work, designing assessments, and using assessments. Specifically we investigate the following two research questions: What are the solutions that faculty propose to address concerns in each area of teaching? Does the level of familiarity with the method determine differences in the solutions used? The next section briefly reviews the literature that informs and situates this study; we follow with a brief description of methods. We then present the main findings and their discussion.

LITERATURE REVIEW

We conceive of *teaching* as the interactions between teachers, students, and the mathematical content and embedded within a particular environment (Cohen, Raudenbush, & Ball, 2003). Strategies are defined here as those activities that teachers organize to facilitate some of the interactions of teaching (e.g., discussion with other students, technology or manipulative use, group work, etc.). Laursen, Hassi, Kogan, and Weston (2014) refer to IBL as a student-centred approach that "invites students to work out ill-structured but meaningful problems… [and] construct, analyse, and critique arguments… present and discuss solutions alone at the board or via structured small-group work, while instructors guide and monitor this process" (p. 407). Initial research has documented the positive trends on self-reported student gains in the cognitive and social domains (see, e.g., Laursen et al., 2014). Laursen and colleagues (2014) indicate that students in IBL courses report higher cognitive gains than students in non-IBL courses, in terms of mathematical thinking, understanding of concepts, and application of mathematical knowledge. Students in IBL courses, and in particular future teachers, reported higher cognitive gains. In addition, students in IBL courses reported higher gains in terms of confidence, positive attitude, persistence, independence, and collaboration, than students in non-IBL courses. Finally, women in IBL courses reported higher gains than women in non-IBL courses. Thus, if teaching with IBL methods is related to these gains, assisting faculty as they learn to use these methods is crucial. As important as students' gains are, an important aspect of the process is the teacher and his or her teaching.

The literature on teacher knowledge as it pertains to teaching is extensive at the K-12 level but is sparser in the post-secondary level. Nardi, Jaworski, and Hegedus (2005) interviewed tutors at the University of Oxford over an 8-week period that prompted them to reflect on aspects of their teaching. The researchers identified four types of pedagogical awareness—naïve and dismissive, intuitive and questioning, reflective and analytic, and confident and articulate (p. 293)—which, they propose, reveal a spectrum of awareness about students' difficulties, strategies to overcome those difficulties, and self-reflection about teaching practices. These researchers claim that instructor awareness can feed into other teaching formats (p. 293), which may suggest a similar categorization for instructors engaged in using an instructional method such as IBL. Other accounts of teaching with inquiry-oriented curriculum (e.g., Speer & Hald, 2008; Stephan & Rasmussen, 2002) point at specific dilemmas that instructors face, in particular navigating the need to stay away from lecturing and moving into more discussion based classes. This literature is informative and allows us to think that there might be common concerns that faculty have when they teach with IBL methods, revealing key dilemmas that mathematics teachers face in teaching (e.g., Chazan & Ball, 1999). Simultaneously, we think that instructors bring with them knowledge that helps them deal with many of these dilemmas, and that they can actually be very resourceful in solving some of those challenges on their own, depending on the type of work they are called to do, even if their main source of information is their own experience with lecturing (the predominant pedagogical strategy in university mathematics classrooms, Blair, Kirkman, & Maxwell, 2013). This study, which started with an investigation of faculty concerns, allowed us to also investigate a possible association with the familiarity using this method and the solutions proposed to deal with concerns in teaching.

THEORETICAL FRAMEWORK

We conceive of the work reported here as being under the umbrella of practice-based theorizations of teacher knowledge, as proposed by Ball and colleagues (Ball, Thames, & Phelps, 2008). Their theory starts from observation of practice to derive the types of tasks that teachers frequently engage in when teaching and it seeks to understand the interaction between those tasks of teaching and the specific subject matter one is teaching. It is a further elaboration of Shulman's (1986) idea that there was a kind of specialized knowledge that was needed for teaching. Ball and colleagues' theory includes six areas: Common Content Knowledge, Specialized Content Knowledge, Horizon Knowledge, Knowledge of Content and Students, Knowledge of Content and Teaching, and Knowledge of Content and Curriculum [1]. The last three areas are a further categorization of what Shulman called Pedagogical Content Knowledge. Knowledge of Content and Students, "(KCS), is knowledge that combines knowing about students and knowing about mathematics. Teachers must anticipate what students are likely to think and what they will find confusing" (p. 402). Knowledge of Content and Teaching, (KCT) is knowledge that "combines knowing about teaching and knowing about mathematics" (p. 402), exhibited when teachers decide which tasks or representations to use. Knowledge of Content and Curriculum (KCC) refers to knowledge of the place in the larger curriculum of the various elements of content to teach. Our focus in this paper is on this further elaboration of pedagogical content knowledge as revealed through teachers' practice with a novel method, IBL, and gleaned through two pieces of information, what instructors find difficult to handle—which signals an area of knowledge needed—and what they propose as a solution for that need, which signals the use of one or various domains of knowledge. Within this theory, we also contend that experience with teaching in general and with IBL in particular informs these domains and that differences in how faculty report concerns and solutions signal the use of those domains.

METHODS

Faculty were recruited from the networks associated with the Academies of Inquiry Based Learning and the R. L. Moore conferences and workshops in the United States [2]. Over three years, 74 instructors from 30 different states took part of the study. We collected two types of data, bi-weekly logs and interviews. The bi-weekly logs asked faculty to log into a secure system and document concerns that they experienced over the prior two weeks on 10 different areas (preparing class, designing assessments, using homework, using quizzes/tests/exams, pacing, lecturing, having students do presentations, group work, large group discussion, and mathematics) and the solutions they had found or ideas of what could help them if no solutions were available. In all we collected information on 171 different courses [3] through 943 log entries. In addition to the logs, we selected a purposeful sample of faculty for conducting in-depth interviews. The interviews covered two main areas, instructors' understanding of IBL and the implementation of IBL in the most recent course they had used to fill the bi-weekly logs [4]. We conducted a total of 30 interviews.

In this paper, we discuss faculty concerns and solutions about two IBL practices, group work and student presentations, and two assessment activities, design and use of quizzes, tests, and exams as revealed through the bi-weekly logs. Table 1 shows the number of instructors recruited who logged a concern in each of the areas included in this analysis, separated by their level of familiarity with IBL [5]. Group work and student presentations are two strategies that depart significantly from lecturing and constitute key features of an IBL course. We focus on assessment because our analysis of interviews suggests that this is a major concern for faculty, as they struggle to fit what they understand the role of assessment is with the goals they want to promote by using IBL (Whittemore & Mesa, 2014). In addition, assessment is a practice that teachers, independently of the method, need to manage. We conjectured that the faculty would therefore draw from their prior knowledge more readily when dealing with concerns emanating from these areas than from the other two, therefore providing an important contrast.

We went through several iterations to build a coding system, using constant comparative methods (Corbin & Strauss, 2008), focusing at times on concerns and at times on solutions. Our intention was to create an all-encompassing, parsimonious system for coding concerns and solutions across all areas of teaching. We identified 14 solutions that describe what faculty proposed to solve the challenges they faced over the course of the term when teaching with IBL. The analytical strategy to answer our first question is qualitative in nature, describing the kinds of actions teachers propose, which will be used to connect to the types of knowledge they draw from. To answer our second research question, we model the likelihood that a solution will be chosen to answer concerns in each of these areas (each is coded as 1 or 0 depending on whether there is a concern in that area), controlling for instruc-

	Number of Instructors (L/M/H)[a]	Number of Logs (L/M/H)
IBL Practices		
Group Work	33 (20/12/4)[b]	80 (45/25/10)
Student Presentations	60 (31/24/7)	172 (75/80/17)
Assessment Activities		
Design	38 (21/13/5)	78 (38/28/12)
Use	38 (21/15/5)	79 (45/28/5)

Notes: a. Level of familiarity with IBL, L: low, M: medium, H: High. b. Numbers do not add up because some teachers who participated more than one semester could change their level of familiarity after each semester.

Table 1: Number of instructors reporting solutions to selected areas of concerns and number of logs teachers used for reporting concerns by level of familiarity with IBL

tors' familiarity with IBL and type of course. More specifically, we estimated generalized linear logistic regression models with a binary outcome (proposing any given solution or not) for all the areas of concern.

FINDINGS

In this paper, we describe the four solutions most frequently coded: Provide Direction, Adjust/Clarify Expectations, Prepare, and No Solution. We first describe the qualitative nature of these solutions and then present the analysis by level of familiarity.

Provide Direction referred to solutions in which the instructor guided students along a desired path while refraining from assuming the role of lecturer. The instructor may provide hints, ask students to break procedures down into smaller steps, or pose questions in general with the intent to incite comprehension/reflection or metacognition:

> I try to get the class to realize the problems. Sometimes I jump in, if it involves writing. Sometimes I give the class hints until they get it. I think this is the most challenging part of the experience, and it takes a lot of energy! (Log2.1_I57_M_LD) [6]

Adjust/Clarify Expectations referred to solutions in which the instructor reminded students of course expectations, resources available to them, and the motivation and purpose for success within the course. The solution may involve relaxing or tightening classroom procedures, minimizing or adding to assignments/coursework, and adjusting the intensity of adherence to classroom procedures:

> For the weak students, I have asked students to come and see me prior to class and work with group members outside of the class. I have asked students to go to the numerous daily tutorial sessions. (Log6.5_I58_L_LD)

Prepare referred to solutions in which instructors reread course notes and lecture topics, and put together materials for classes in general. This solution describes instructors desiring to remain vigilant and flexible to the evolving nature of the unfolding work in the classes and ideas of actions they intend to take in the next class. It also included tasks that the instructor had found or created, plans to use those in class, or reports that the students had used those tasks:

> I have been leaning towards teaching IBL style for the last few semesters, so I am adapting a lot of what I've previously used. I've also found some resources by looking on the Internet and emailing people if I saw something interesting. Since this class is really more of a hybrid IBL and not "pure" IBL and we don't do a lot of theory-related things, some [of] the things I have found (JIBLM) don't quite work. (Log6.3_I45_L_UD)

The No Solution code was assigned when the comments indicated that the instructors were unsure about solutions to their concerns, that they had an idea for a solution but that the solution was not working, or that they were "at a loss" about what would help:

> I know I should have the students presenting more proofs in class, but somehow I am not successful this semester at getting proofs presented by the students in class. Most are not even trying the proofs outside of class. Even the examples are not being tried by most of the students. I'm at a loss even to the type of resources I might need. (Log7.4_I62_L_UD)

The frequencies with which these solutions were assigned to the logs by each area of concern are given in Table 2.

	IBL Practices		Assessment	
	Group Work (n = 80)	Student Presentations (n = 172)	Design (n = 78)	Use (n = 79)
Provide Direction	21%	24%	8%	13%
Adj./Clarify Exp.	30%	33%	18%	31%
Prepare	15%	20%	35%	17%
No Solution	24%	7%	13%	17%

Table 2: Frequency of Solutions Proposed by Faculty to concerns on IBL Practices and Assessments (N=409 logs)

We run three separate logistic regression models that included all the areas of concern (not only the ones that are the focus of this paper), the course type, and the level of familiarity with IBL as independent variables and the solution as the dependent variable (using it or not, one model per solution: Provide Direction, Adj./Clarify Expectations, and Prepare). The regression coefficient for level of familiarity with IBL was not significant in any of these models; that is, when controlling for the area of concerns and the type of course (upper division, lower division, or future teachers), the probability of using a particular solution was not significantly different for different levels of familiarity. For simplicity in presentation Table 3 shows only the odds ratios estimate, standard errors, and significance of the corresponding coefficient for the three models for the four focal areas of concern.

We highlight four points from Table 3. First, relative to teachers who report that they have concerns with group work, teachers who do not have concerns are 2.5 (1/0.393) times less likely to use prepare as a solution. This suggests, perhaps unsurprisingly, that when solving problems related to organizing group work in the classroom, faculty are likely to expect to spend time in advance, anticipating ways to handle those problems. Second and third, relative to teachers who report that they have concerns with designing assessments, teachers who do not have concerns in this area are 3.2 times less likely to use provide direction as a solution (1/0.309) and 3 times less likely to adjust or clarify expectations as a solution (1/0.332). This suggests, that in solving problems related to designing assessments for IBL work, faculty will resort to modify the assessment or provide better explanations for the requirements or for the work, in a way suggesting that they need to be flexible in order to account for the special nature of assessments in this environment. Naturally, this is a plausible interpretation that would need to be corroborated with a different design in which instructors describe problems preparing assessments in non-IBL courses. Finally, relative to teachers who report that they have concerns with using assessments, teachers who do not have concerns in this area are 2.3 times less likely to use prepare as a solution. Thus, similar to concerns faculty face with group work, faculty with concerns with the use of assessments for students will spend time thinking through those assessments based on the feedback they gather from how things work during class. When assessments are used they do provide direct information about students' learning, which may trigger realizations for teachers of the need to learn to anticipate issues better.

We obtained an intriguing result when modelling No Solution. The odds ratio coefficient was significant for faculty identified as having low level of familiarity with the method (Odds Ratio, Low Level of Familiarity = 0.296, $SE = 0.603$, $p < .05$) relative to faculty having high level of familiarity. This means that relative to faculty who had the highest level of familiarity, faculty with low level of familiarity were 3.4 times less likely to report that they had no solution for their concerns.

DISCUSSION

Our analysis of the solutions that faculty proposed to the concerns they had with teaching with IBL methods reveals the ways in which faculty use the knowledge they have to manage the situations. Of the three solutions most frequently assigned, Provide Direction, Adjust/Clarify Expectations and Prepare, it seems that the first two need to be deployed by calling upon teachers' appraisal of the instructional situation, namely the way in which students and the material are interacting in the moment and the possible ways in which teachers can provide feedback. In Provide Direction, the teacher refrains from giving a full explanation to the students to answer a particular question. This requires an in-the-moment assessment

Area of Concern	Provide Direction	Adj./Clarify Exp.	Prepare
Group Work[a]	1.137 (0.525)	0.781 (0.458)	0.393 (0.584)†
Student Presentation	1.140 (0.480)	0.835 (0.416)	0.586 (0.598)
Design Assessments	0.309 (0.617)†	0.332 (0.484)*	1.233 (0.617)
Use Assessments	0.595 (0.558)	0.789 (0.454)	0.424 (0.595) †

Notes: a. The reference category for each coefficient is presence of the concern. The odds ratio is the exponential of the coefficient modelled for the cases in which there is no concern reported. The reciprocal of the value gives the relative ratio for the reference category. †: $p < .10$; * $p < .05$.

Table 3: Odds ratios and Standard Errors by Solution and Area of Concern

of students' thinking paths vis a vis the mathematics at stake and a decision-making process regarding the mathematical idea or question that may nudge the student in a different direction. We see this as evidence of teachers drawing from their Knowledge of Content and Students. In contrast, when using Adjust/Clarify Expectations, teachers are taking a larger view of the constraints imposed by using the method; the actions taken refer to larger organizational aspects of the course that impinge on the quality of students' work: more resources, tighter or more relaxed requirements. In order to make such decisions, instructors account for the contextual situation in which students are working and how that affects the pacing or other goals of the course; they need to keep in mind that they might need to adjust further the class organization so that the course maintains its coherence. We see this as evidence of drawing on their Knowledge of Content and Teaching. When using Prepare, on the other hand, instructors bring to bear knowledge in both domains. They need to take into account what the students have done in any given class, and decide on a path that will satisfy the goals of course and the demands students have for understanding the content. It also involves the generation of documents informed by such thinking processes.

The level of familiarity did not play a role in the types of solutions proposed, except in the case in which faculty reported having no solution. We take this result as an indication that the method itself makes similar demands on teachers' knowledge independently of the experience they have with the method. This result does not mean that the method does not get easier with time. Recall that we are talking about solutions, that is, about the types of knowledge that could be drawn from to solve problems of practice. Theoretically, there is no reason to believe that instructors of different levels of familiarity with the method will draw from different knowledge sources. This way of teaching, by making students visible, forces faculty to navigate through the spectrum of awareness described by Nardi and colleagues (2005) and puts all the teachers at the same stage in Nyquist and Sprague's (1998) model of teacher development, in which they have to deal with student thinking in every lesson.

This work implies that teachers use their knowledge of teaching when teaching with a new method. While we did see a large amount of no solutions to individual concerns, we see that faculty draw on their experience and knowledge to deal with the concerns that they face in IBL practice. Because teaching is in the moment, instructors must find a solution to concerns as they emerge in order to manage instruction in the classroom, and working on augmenting their mathematical knowledge for teaching could be a fruitful strategy for sustaining this way of teaching. While there are many outside resources to help teachers using IBL, it seems that for the instructors in this study, given their knowledge, the instructors themselves are their most valuable resource.

ACKNOWLEDGMENT

We thank Inah Ko, Kyle LaFollette, and Tim Whittemore for assistance in earlier analyses of the data. This work has been supported by the Educational Advancement Foundation and the Undergraduate Research Opportunity Program at the University of Michigan.

ENDNOTES

1. Due to space considerations we only describe the domains that are relevant to our study. We refer the reader to Ball and colleagues (2008) for full definitions of the other domains.

2. See http://legacyrlmoore.org and http://www.inquirybasedlearning.org for details.

3. Lower division courses were intended for students in their first two years of college (e.g., 100–200 level courses: Calculus I, II, Discrete mathematics, Cryptology); Upper division courses were intended for students in their last two years of college (e.g., 300–400 level courses: intro to proof, modern or abstract algebra, topology, real analysis, etc.); Future teacher courses were those intended for future teachers and could be of any level (e.g., geometry for teachers, math for elementary teachers, etc.)

4. The protocols for the logs and the interviews are available from the authors.

5. Familiarity with IBL was divided into three levels, Low, Medium, and High, depending on instructors' described experience teaching with the method (e.g., # of IBL courses), the use of own generated notes, and the amount of mentoring they provide, among other dimensions.

6. The identifier Log2.1_I55_L_LD indicates the semester when the data was collected (second), the number of the log (first in the term), the instructor (#I55), the level of familiarity (Low, Medium, High), and the level of course for which the log was being recorded, (Lower Division, Upper Division, or Future Teachers).

Students' understanding of marginal change in the context of cost, revenue, and profit

Thembinkosi P. Mkhatshwa and Helen M. Doerr

Syracuse University, Syracuse, USA, tpmkhats@syr.edu

This paper describes how eight undergraduate students majoring in economics and business studies reasoned about marginal change (marginal cost, marginal revenue, and marginal profit) in the process of deciding how they would advise the management team of an airline about an economic decision involving the addition of another jet plane. To elicit students' understanding of marginal change in an economic context, pairs of students were engaged in a task-based interview. Nearly all of the students were able to reason correctly about marginal change within the immediate context of the task, while four of the students also did so beyond the context presented in the task. Only one student considered the marginal change information in the task as a rate of change.

Keywords: Marginal change, rates of change, business calculus, undergraduate mathematics education, economic decision making.

INTRODUCTION

The role of context in the way students reason about rate of change (average rate of change and instantaneous rate of change) has received considerable attention from researchers interested in the learning and teaching of this concept and students' interpretations of rates of change in various contexts. In particular, there is a large body of research literature on students' understanding of rate of change in a motion context (Beichner, 1994; Bery & Nyman, 2003; Monk, 1992; Nemirovsky, Tierney, & Wright, 1998). Research exists on students' understanding of rate of change in non-motion contexts such as fluid flow, heat flow, temperature, discharging capacitors, and light intensity (Bingolbali & Monaghan, 2008; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Doerr, Ärlebäck, & O'Neil, 2013; Johnson, 2012; Marrongelle, 2004). However, there is little research on the context of economic change, which is the motivation for this study.

THEORETICAL FRAMEWORK

This study draws on a multiple representations theoretical framework (Davis, 2007) to examine how students reason about the context of cost, revenue, and profit within a real-world context representation and across other representations. Davis' multiple representation framework contains five representations: (1) tables, (2) algebraic, (3) graphs, (4) spoken language, and (5) real-world contexts. At the center of Davis's framework are real-world contexts. As Davis puts it, "students' investigations are dominated by real-world contexts and students are frequently translating between tables, graphs, and equations, and vice versa" (p. 391). The framework is an adaptation of Lesh's (1979) multiple representation framework. The current study is part of a larger study that used three tasks that situated the context of cost, revenue, and profit in multiple representations, namely graph, table, and text. The current study reports on what students' reasoning about the context of economic decision making, presented as text, revealed about students' understanding of marginal change. Marginal cost refers to the cost per additional unit produced, marginal revenue refers to the revenue generated per additional unit sold, and marginal profit refers to the profit per additional unit produced and sold. Mathematically, marginal change can be calculated using instantaneous rate of change which can be approximated using average rate of change.

LITERATURE REVIEW

A review of the research literature on students' understanding of rate of change in context reveals several things. First, even high achieving students in calculus have difficulties understanding and interpreting rate information (points of inflection and concavity) in mathematical tasks that are situated in a non-motion context (Carlson et al., 2002). Second, the use of physical models such as the sliding ladder used by Monk (1992) and technology in the form of motion detectors and graphing calculators can enhance students' understanding of rate of change in a motion context (Monk, 1992; Nemirovsky, Tierney, & Wright, 1998). Finally, the research literature reveals that a good understanding of a motion context in physics could enhance students' ability to reason about rate of change when solving calculus problems that have been stripped of context (Marongelle, 2004).

However, research on students' understanding of rate of change in a business and/or economics context is lacking. To the knowledge of the authors, only one study by Wilhelm and Confrey (2003) investigated students' reasoning about rates of change in an economic context. These researchers studied algebra I students' ability to project their understanding of average "rate of change in the context of motion onto the context of money" (p. 887). Wilhelm and Confrey found that some of their participants were able to project their understanding of average rate of change from a motion context to a banking context. However, their study did not examine what students' reasoning about the motion and banking context revealed about students' understanding of instantaneous rate of change and marginal change. The current study seeks to address the gap about what it is that students' reasoning about the context of cost, revenue, and profit reveals about their understanding of marginal change.

Conflating function output values with the average rate of change values for the function considered over subintervals of the function's domain is a well documented difficulty that students have when reasoning about rate of change (Carlson et al., 2002; Monk, 1992; Prince, Vigeant, & Nottis, 2012). It is also known that students have difficulty distinguishing between the amount by which a function changes and the rate at which the function is changing over unit subintervals (Confrey & Smith, 1994; Cooney, Beckmann, & Lloyd, 2010). Research also indicates that students' "understandings of rate in one representation or context are not necessarily transferred to another" (Herbert & Pierce, 2012, p. 455). This study is part of a larger study that investigated students' reasoning about marginal change in three representations, namely graph, table, and text. This paper reports on students' reasoning about marginal change in the latter representation.

METHODOLOGY

This qualitative case study used task-based interviews (Goldin, 2000) with eight undergraduate students currently enrolled in business calculus. Four pairs of students were engaged in the following non-routine task that was designed to elicit their reasoning about the marginal change information rooted in the task, adapted from Hughes-Hallet and colleagues (2006):

> JetBlue is a major airline that currently operates 195 jet planes. The airline serves 84 destinations in 24 states and 12 countries in the Caribbean, South America, and Latin America. The airline is trying to decide whether to add an additional jet plane. The choice that the airline has is between adding this jet plane and leaving things the way they are. The airline's decision is to be made purely on financial grounds.
>
> How should the airline decide on whether or not to add the 196^{th} jet plane?

Setting and respondents

The study was conducted on the campus of a medium sized research university located in the north-eastern part of the United States. The respondents were eight undergraduate students, six females and two males, from the department of economics and the business school who had recently completed a business calculus course as a prerequisite for other required courses in their programs of study. Four of these students were sophomores, one student was a freshman, two students were seniors, and the other student was a junior. Students taking this course are familiar with average rate of change, instantaneous rate of change, and the context of cost, revenue, and profit, hence the reason for recruiting them to participate in the study. Data were collected during a regular semester and the summer following that semester. Three of the four interviews were both audio and video-recorded; one interview was only audio-recorded. Each interview lasted for about 75 minutes. The interview data was transcribed for analysis. Work written by students during the interview was also collected as part of the data.

Data analysis

Transcripts were coded for students' understanding of the marginal change information rooted in the task. In particular, the transcripts were analyzed for students' abilities: (1) to identify and interpret the marginal change information embedded in the task, and (2) to give reasonable advice on how the airline should decide on whether or not to add another jet. Reasonable advice was considered to be one which takes into consideration a comparison of the company's marginal cost, marginal revenue, and marginal profit associated with the jet in question in the process of deciding for or against the addition of another jet plane.

RESULTS

Seven of the eight students who attempted this task were able to reason about marginal change in the context of making an economic decision, that is, advising the management of an airline on whether or not to add another jet plane. Only one student considered the marginal change information rooted in the task as a rate of change. Two of the four pairs of students reasoned beyond the immediate context presented in the task. Following is a discussion of students' reasoning about the marginal change information rooted in the task, first within the immediate context of the problem, and then beyond the immediate context of the problem.

Reasoning about marginal change within the context presented in the task

Two of the four pairs of students reasoned about the marginal cost, marginal revenue, and marginal profit ideas within the context of the problem. The following excerpt illustrates Isabel and Sally's initial response to the question: How should the airline decide on whether or not to add the 196th jet plane?

Isabel: If the rate of change increases with the more jets that they have they should add another jet but if the rate of change is decreasing they should not add another jet.

Researcher: What do you mean by the rate of change?

Isabel: Like say if they had a graph, if the graph shows their financial cost would look like that [drawing the graph on the left in Figure 1] which means that they should add…and then if they have another graph [drawing the graph on the right in Figure 1] where it is going more like this, then they should not add.

Researcher: What is the curve [asking about the graphs she drew]? What does it represent?

Isabel: Their financial, like how much they are making.

In stating that the airline should add another jet if "the rate of change increases", it appears that Isabel is referring to the increasing profit that the addition of this jet would bring to the airline. It also appears that she is working on the assumption that whenever the airline added a jet in the past their profit always increased (graph on the left in Figure 1). In the graph on the right in Figure 1 which illustrates when the airline should decide against adding another jet plane, Isabel appears to be referring to the decreasing profit that would continue if the jet is added. One may argue that Isabel's focus on the graph shifted her attention away from the context. Isabel, however, did not make any reference to marginal cost, marginal revenue, and marginal profit while talking about her advice to the management. Isabel was the only student to spontaneously talk about rate of change.

In talking about her decision, Sally's reasoning was based on comparing the marginal cost and marginal revenue associated with the additional jet as the following excerpt illustrates.

Figure 1: Isabel's graphical illustration of how the management of JetBlue Airline should decide on whether or not to add the 196th jet plane

Researcher: Sally, what's your own view? How should the airline decide on whether or not to add the 196th jet plane?

Sally: I think the profit [referring to Isabel's graphs] works but it would be easier if you do a graph like it was before [referring to a graph from an earlier task that had two curves: a non-linear cost function and a linear revenue function] with the marginal revenue and like the marginal cost. So if this [referring to the graph on the left in Figure 2] I would say 195 just to make it easy, then you would not add with that because for that it would make the revenue smaller than the cost.

Researcher: What is the line?

Sally: It's the marginal revenue.

Researcher: So in that case they should not add?

Sally: Right, but then in that case [referring to the graph on the right in Figure 2] they should add.

Sally appeared to be comparing the marginal cost and marginal revenue associated with the addition of the 196th jet plane. Her left graph in Figure 2 shows a realistic situation for when the jet should not be added: the marginal cost is greater than the marginal revenue generated for any jet plane added beyond the 195th plane. Sally's decision for adding the 196th jet plane in the case of the situation depicted by the graph on the right in Figure 2 is also quite reasonable in that it shows that adding a jet beyond the 195th increases the airline's marginal revenue while adding a jet beyond the 195th decreases the airline's marginal costs and hence it would be in the best interest of the airline to add the 196th jet. The following excerpt illustrates Isabel's reasoning about Sally's graphs (Figure 2) and their final thoughts on the advice they would give to the management of the airline.

Isabel: I see them showing the same thing, the only thing is that you would never know this [pointing at the MR line and MC curve extended beyond 195 in Sally's left graph in Figure 1] because we don't have more than 195 planes, so this is, I don't know but that [pointing at the MR line and MC curve extended beyond 195 in Sally's left and right graphs in Figure 1] wouldn't exist on the graph anyway.

Researcher: Putting your ideas together, you want to give an advice to the management of this airline on what they should do. How can you present your advice?

Sally: If the marginal revenue is higher than the marginal cost for the 196th plane you should purchase it but if it's the other way round you should not.

Researcher: Isabel, how could you present your advice?

Isabel: I agree with her.

Researcher: Would you use exactly the same words she used or?

Isabel: Basically yeah. If it's increasing the profit then purchase it, if it is lessening the gap between the cost and the revenue, then purchase it as well but if it's increasing the gap and the profit is less then don't purchase it.

Sally's advice to the management is based on comparing the marginal cost and marginal revenue. This suggests that Sally is indirectly looking at the marginal profit that adding of the 196th jet would bring to the airline. Isabel, on the other hand, made her decision based on the increasing profit associated with the addition of the 196th jet. When talking about "the gap between the cost and the revenue," Isabel appears to be drawing on Sally's reasoning about marginal change.

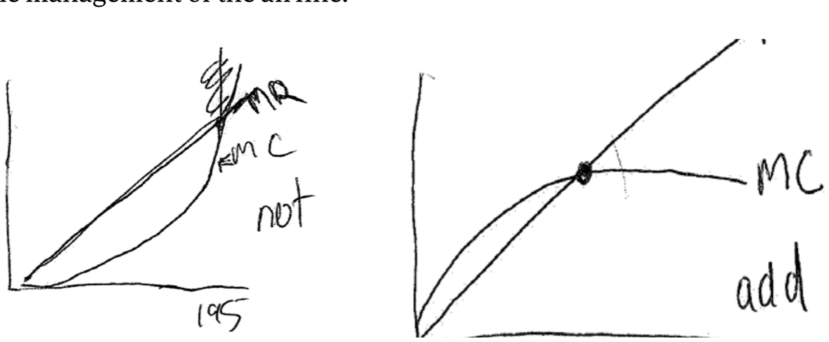

Figure 2: Sally's graphical illustration of how the management of JetBlue Airline should decide on whether or not to add the 196th jet plane

A second pair of students, Paige and Yolanda, reasoned similarly to Sally. Paige said that "they need to see what the potential revenue is from that one plane and then compare with the cost of that plane and see if that would give them more money". Paige's advice is based on the marginal cost, marginal revenue, and marginal profit (which she referred to as "more money") associated with adding the 196th jet. Yolanda said that "they need to see how the profit is at 195 and see how much more one plane makes," thus reasoning about the marginal profit associated with the addition of the 196th jet.

Reasoning about marginal change beyond the context presented in the task

The other two pairs of students who attempted this task reasoned about the marginal cost, marginal revenue, and marginal profit ideas beyond the context of the problem. In particular, the students' thinking showed a consideration of the broader economic issues that needs to be considered in trying to decide whether or not another jet should be added. In the case of Beth and Mary, Beth said that the airline's decision should be "based on how much more profit they will make versus how much they will pay to make the plane". Beth reasoned about marginal change and in particular she reasoned about the marginal cost and marginal profit associated with the jet in question.

Mary, on the other hand, said that "if the quantity of people that are flying increases then it would be acceptable to get another jet plane but if it's decreasing there is no need for another one." After Mary's response, Beth added that "you should always add the plane because that way you could even add more destinations." In giving her advice, Beth initially took marginal profit and marginal cost (cost of making the 196th jet plane) into consideration but then she also thought about the expansion of the airline in terms of adding more destinations. Mary's reasoning was based on the increase or decrease in demand, that is, number of people flying with this airline. Mary's thinking, however, does not show any evidence of considering the marginal change information rooted in the problem.

Noel and Paul's advice to the management of the airline on whether or not to add another jet is another example of reasoning beyond the immediate context. Noel said that "if it adds incrementally to the profit of the airline, then truly based on financial grounds you would add that 196th jet." He went on to add that "they need to know whether there would be capacity on that plane, actual demand, and cost of other things like fuel and union contracts." Noel's decision not only takes into consideration the marginal profit associated with adding another jet, but also several other important economic factors.

Paul, Noel's partner, said that "they should look at the cost of the plane and the marginal revenue they would get." He went on to add that "they should look at the cost per average passenger and average revenue per passenger." Later in the interview, Paul said that "if the marginal profit equals their marginal revenue minus marginal cost equals zero, it makes sense they are still in a capacity to add this jet, if this [the difference between marginal revenue and marginal cost] is negative then it doesn't make sense to add another jet." In this situation, Paul showed an understanding of marginal profit as it relates to the marginal cost and marginal revue associated with adding another jet, thus using his understanding of the mathematical content knowledge (marginal change) to understand the context of the problem.

Summary of students' reasoning about marginal change in context

In summary, the results from this study revealed that: (1) students can correctly reason about marginal change when presented with a problem that is situated in a context [air travel] that is familiar and meaningful to the students, and (2) students are able to reason beyond the immediate information given in a task when it is presented in a familiar situation. A key finding of this study is that students understood marginal change as an amount of change (the difference) and not as a rate of change (the difference quotient). This was supported by the fact that in another task during the interview (not reported in this paper) all but one of the students indicated that the units of marginal change would be dollars instead of dollars per unit.

DISCUSSION AND CONCLUSION

This study investigated what students' reasoning about a real-world problem in the context of cost, revenue, and profit reveals about their understanding of marginal change. Nearly all the students were able to correctly talk about the marginal change information rooted in the task. However, only one student (Isabel) used the language of rate of change to give her advice to the management.

A major finding of this study is that students reasoned about marginal change as an amount of change and not as a rate of change. This finding would appear to be consistent with results from other studies (Confrey & Smith, 1994; Cooney, Beckmann, & Lloyd, 2012). Distinguishing between the amount of change (a difference) and marginal change (a rate of change over a subinterval of unit length) would appear to be especially difficult for students.

Even at the end of a business calculus course students do not speak of marginal change as a rate of change as it is presented in their calculus course and their textbook (Haeussler, Paul, & Wood, 2010). This is problematic because one major goal of a business calculus course is to help students move from understanding marginal change as an amount of change to understanding it as a rate of change. It might be important for future research to consider using modelling tasks (Doerr & English, 2003; Lesh et al., 2003) to support the development of students' understanding of marginal change as a rate of change.

Challenging the mathematician's 'ultimate substantiator' role in a low lecture innovation

Elena Nardi[1] *and Bill Barton*[2]

1 University of East Anglia, Norwich, UK, e.nardi@uea.ac.uk

2 University of Auckland, Auckland, New Zealand

In this paper, we draw on our experiences as member of the International Advisory Board and principal investigator of a research project on undergraduate mathematics teaching and learning to comment on the study of university mathematics as a process of enculturation into new mathematical practices and new ways of constructing and conveying mathematical meaning. We see this enculturation as the adaptation of different ways to act and communicate mathematically. We take a discursive perspective and we treat the changes to the mathematical and pedagogical perspectives of those who act – students and lecturers – as discursive shifts (Sfard, 2008). Our particular focus is on the shifts concerning the 'ultimate substantiator' role typically attributed to the lecturer.

Keywords: Low lecture, 'ultimate substantiator', commognition, enculturation.

UNIVERSITY MATHEMATICS: AN ENCULTURATION PERSPECTIVE

Mathematics undergraduates, and their lecturers, often describe university mathematics as a process of enculturation into new mathematical practices and new ways of constructing and conveying mathematical meaning (Nardi, 1996). As often described in the literature (e.g., Artigue, Kent & Batanero, 2007), what characterises the breadth and intensity of this enculturation varies according to factors that include: student background and preparedness for university level studies of mathematics; the aims and scope of each of the courses that the students take at university; how distant the pedagogical approaches taken in these courses are from those taken in the secondary schools that the students come from; the students' affective dispositions towards the subject and their expectations for what role mathematics is expected to play in their professional life. On their part, lecturers' views on their pedagogical role (e.g., Nardi, 2008) may also vary according to factors such as: length of teaching experience; type of courses (pure, applied, optional, compulsory, etc.) they teach; perceptions of the goals of university mathematics teaching (such as to facilitate access to the widest possible population of participants or select those likely to push the frontiers of the discipline); and, crucially, institutional access to innovative practices (Skovsmose, Valero, & Christensen, 2009).

Here we draw on our experiences, respectively, as member of the International Advisory Board (Nardi, 2014) and principal investigator of the LUMOS project (*Learning in Undergraduate Mathematics: Output Spectrum*; Barton & Paterson[1], 2013) to comment on aforementioned student enculturation, particularly with regard to how students and lecturers experience the innovations introduced in the project. We first outline the project.

LUMOS AND THE LOW LECTURE INNOVATION

LUMOS is a two-year project funded by Ako Aotearoa, the New Zealand government body that distributes national research grants for tertiary education research, as well as the New Zealand Teaching & Learning Research Initiative (TLRI). Its main aim is to understand how course delivery at class level can achieve a range of desired learning outcomes for undergraduate mathematics that includes content and skill related outcomes as well as outcomes related to the processes of mathematics, affect, and broader graduate issues. It is expected that the project will generate evidence that different types of courses contribute to student learning in different ways. Therefore developing a variety of pedagogical practices is part of the project. Three innovations are currently under trial: *team-based learning*, *intensive technology* and *low lecture*. The third of these, *low lecture*, is the focus of this paper.

There are three key assumptions behind the *low lecture* innovation. First, lectures are not necessarily the best means of imparting information or developing skills. They are however useful for material overviews, demonstrating model ways of communicating mathematical ideas and enthusing newcomers with the skill and fluency that can often be found in the communicational practices of old-timers – thus one per week is sufficient. Second, responsibility for learning content and acquiring skills is handed back to students using specific guides of what they are expected to learn and where to find print and online resources, and with regular self- and lecturer-monitoring of progress. Third, learning about, and induction into, the processes of being mathematical are absent from most undergraduate courses, hence the time saved from lecturing is spent in small group sessions of semi-authentic mathematical experiences free from content-learning requirements.

The *Low lecture* innovation was trialled for the first time in 2013, with 14 MATHS108 students. MATHS108 is a Year 1 course for non-mathematical majors that covers: linear functions, linear equations and matrices; functions, equations and inequalities; limits and continuity; differential calculus (one/two variables); and, integral calculus (one variable). Faculty members, as members of the LUMOS team, run the trial on an extra-to-load basis. The trial consists of one lecture per week for the duration of the semester and three 2-hour *engagement sessions* which students need to prepare for in advance, as well as write up a report for afterwards. These reports substitute assignments. The remaining parts of MATHS108 (tutorials, tests and final written examination) stay the same.

The discussion we present here was initiated by the first author's account (Nardi, 2014) of her experience of observing an *engagement session* and the discussions that followed this observation. Our account adopts the *commognitive* perspective (Sfard, 2008). *Commognitive* terms in it are in *italics* and used as defined in the abridged presentation of the framework in (Nardi, 2014, p. 5–6) and (Nardi, Ryve, Stadler, & Viirman, 2014, p. 183–5). We conclude the paper with a consideration of the shifts in the lecturer's role as experienced by the observed lecturer (second author).

As outlined in (Nardi, 2014) the observed *engagement session* was part of the *low lecture* MATHS108 course. Five students (thereafter Students B, N, J, D and A) participated in the session which was their first *engagement session* and took place in the early weeks of the first semester. The session was run by the second author, leading member of the LUMOS team (thereafter Lecturer L). In the account that follows we outline what unfolded in the session and then present the discussions between the observer (first author) and L (the lecturer and second author) that followed.

In presenting this account we are driven by the following questions:

— What were these 'newcomers' to the practices of university mathematics to make of the open task set to them (see below)?

— What were their expectations of the 'old-timer' who led the session?

— In return, what were the 'old-timer''s expectations of the students?

— And, finally, what kind of bearing, if any, did the slightly unexpected nature of the task have on the session and its aftermath?

OBSERVING AN ENGAGEMENT SESSION OF A LOW LECTURE COURSE

The five MATHS108 students arrived in the small, cosy meeting room where their first experience of an *engagement session* was about to kick off. Their preparation for the session consisted of engaging with an open task, sent to them a week prior to the session: exploring functions from $\mathbb{R}$ to $\mathbb{R}\times\mathbb{R}$ – see an outline of the task in Figure 1. The students expected to be invited to share their explorations with the lecturer and the group. We note the deliberately unexpected nature of the task: these students were so far accustomed to working with functions from $\mathbb{R}$ to $\mathbb{R}$ and may have had a general awareness of functions from $\mathbb{R}\times\mathbb{R}$ to $\mathbb{R}$. L comments on the spirit of the task as follows:

> "Engagement Session situations are intended to be open-ended mathematically, both conceptually and procedurally. That is, they are intended to ask students questions about mathematical concepts that they have not encountered before,

although they may be related to the work in the course. Additionally, there are not only many "take-off" points (places where students can start working), but also several, different ways of developing their work.

Furthermore, there is no presumed "correct" process or result. [...] What is important is what they then do, mathematically. [...] Students are not given marks for "correctness". They are marked on "mathematical thinking" in whatever form it is exhibited."

We return to the two omitted ([...]) parts from the above L quotation later in the paper when we examine a little more closely some of the student productions in preparation, during and after the session.

The students and the lecturer were seated around a rotund table, arranged in the middle of a small meeting room. The students arrived with their preparatory

Engagement Situation #1: Functions from $\mathbb{R}$ to $\mathbb{R}\times\mathbb{R}$

Most functions we have been using map a Real Number onto a Real Number.

We write $f : \mathbb{R} \rightarrow \mathbb{R}$ and we say "f maps $\mathbb{R}$ onto $\mathbb{R}$".

But functions can be about any numbers, not necessarily the Real Numbers. That is why we have to specify the domain when we define a function. In fact, a function can map anything onto anything, vectors or matrices, for example.

Not only that, we can define functions that map TWO numbers onto one number. You will learn more about such functions later. An example of such a function is

$$f(x,y) = 3x - y^2$$

We write $f : \mathbb{R}\times\mathbb{R} \rightarrow \mathbb{R}$ and we say "f maps $\mathbb{R}$ cross $\mathbb{R}$ onto $\mathbb{R}$".

What about a function that works the other way? It starts with a Real Number but produces TWO Real Numbers. That is $f : \mathbb{R} \rightarrow \mathbb{R}\times\mathbb{R}$.

Our first problem is to find a suitable notation. Let's take an example. We start with a function f and a variable x. Let the first number created by the function be x^2, and the second number be $(1/x)$. Thus $f(2)$ is 4 and ½.

1) Devise a suitable notation for this.

2) Devise a new function $h : \mathbb{R} \rightarrow \mathbb{R}\times\mathbb{R}$. Make up your own rules for h. Explore some values of h. Check: is h a function? That is, will each separate input x give a unique output pair?

3) Can you find a way of graphing h ? This will need to be a new kind of graph.

4) What can you say about the values of h for different inputs? E.g. what happens to $h(x)$ when x is close to zero, when x gets very large, when x is negative? Find some other things to investigate about $h(x)$.

5) Can you find another function, $j(x)$, which behaves differently? Will your graphing and notation scheme work for $j(x)$?

Figure 1: An outline of the *Engagement Situation* task pre-distributed to the students

work in hand. One – N, the only female in the group – also had her laptop with online access, which she used often during the session. The ambience was convivial and highly respectful of all. The students granted permission to the observer (first author) to join the session and seemed comfortable with her presence. The account that follows – described in (Nardi, 2014) as a sequence of episodes that evidence a substantial shakeup of the *learning-teaching agreement* – is based on notes jotted down during and right after the session. The account is written from a *commognitive perspective* and aims broadly at addressing the questions listed at the end of the previous section.

Shakeup of the learning-teaching agreement in a low lecture session: evidence

At the very start of the session L reminds the students that its overall aim is set out in the preparation sheet (Figure 1). L had set two tasks for this exploration: first, propose a notation for this type of function; second, devise a relationship of this type and explore how we would secure that it is a function, what its range of values would be, what its graph would look like and what its behaviour would be for very small or very large values of *x*. The preparation sheet ends with a request to devise a second function of this type and repeat the exploration with a view to comparing with the first. The students are also reminded that they will be expected to communicate the outcomes of their exploration and that some aids to doing so will be available in the room for them to this purpose. As the session starts, L reminds them that they are ultimately expected to produce a four-page report consisting of: an account of their pre-session efforts (on the first page), their take on the exchanges during the session (on the second and third pages) and their further explorations soon after (on the fourth and final page).

The final words on the preparation sheet were 'happy mathematising and they encapsulate explicitly the *discursive object* of the activity that the students are invited to participate in. L's overall demeanour and utterances throughout the session also convey exactly that: this session is about engaging with the *routines* of a mathematician (he lists several of these in at least two occasions, including hypothesising, justifying, proving, visualising, extrapolating etc.). The students' responses to these meta-discursive utterances by L – particularly when L asks them to cease activity for a moment to heed what they are doing, and how – is rather mute: they seem keen and confident to act but perhaps less so to take up this invitation for reflective distancing from the action. In fact it takes no more than a few seconds for them to return to the vicarious discussion of their exploratory work.

On the grounds of this discussion – which we sample selectively in what follows – there was little doubt that the students' take on the purpose of the session was essentially congruent to that of L. Sfard (2008, pp. 223 onwards) speaks of mathematical *routines* in terms of *deeds*, *rituals* and *explorations* and it would be hard to perceive what was happening in the session as anything other than evidence of *exploration*. L's recollection of the students' work substantiates this claim further:

> [...] in this situation, while students may graph their functions as lines in 3-space, other alternatives are acceptable. For example, students have used the first element created to define a new (curved) axis, on which the second element is plotted; others have used the first element to define a line in 2-space as in a conventional graph, and the second element to determine the width of the line, hence creating a ribbon. [...] For example, the ribbon is not a function, as it is not 1 to 1. However an attempt to redefine "1 to 1" for this context would be an entirely acceptable process.

Let us now consider two aspects of the students' activity that relate to the questions we listed earlier: first, some *features of the students' exploratory work*, particularly in relation to the slightly unexpected nature of the task (from '$\mathbb{R}\times\mathbb{R}$ to $\mathbb{R}$' to '$\mathbb{R}$ to $\mathbb{R}\times\mathbb{R}$' functions); then, some evidence of the students' – and L's – *perceptions of the learning-teaching agreement* that sessions such as this may bring to question.

With regard to the first (students' *exploratory* work), the session was marked by the high likelihood on several occasions of *commognitive conflict*, emerging from the students' *word use* and form of *visual mediation*. Throughout the session the students' standard approach to *substantiation* was to *endorse or reject a narrative* about the objects at stake through indications in favour of – or against – a claim as evident on a screen, or on roughly produced drawings on paper. Combined with their generally non-standard use of *symbolic realizations* (notation, graphs and related terms), the ingredients seemed to be there for *com-*

mognitive conflict. According to the task set by L in the preparation sheet (Figure 1), the students were expected to consider how a graph of a function from ℝ to ℝ×ℝ would look. However, on various occasions, their utterances, and scribbles produced during the session, seemed to concern functions that looked more like $f + g$, fg, $f \circ g$, rather than $f : \mathbb{R} \to \mathbb{R}\times\mathbb{R}$. In this sense the question 'what does a function from ℝ to ℝ×ℝ look like?' – central in the preparation sheet – was not pursued as directly as L might have expected.

L's recollects some of the student productions (not only the five observed in this session) as follows:

> In their preparatory work most students defined two functions, e.g. $g(x) = x^2$; $h(x) = \sin(x)$, and then, to draw the graph, composed them in some way to graph the equivalent of $g+h$, gh, or $h\circ g$.
>
> When it was pointed out that they had essentially created a function ℝ to ℝ, this led to other suggestions such as using the first element to define the axis for the second element, or the first element to create a conventional graph that then got altered by the second element to create some kind of ribbon (2D) or envelope (3D).

Throughout L's contribution was to point out anomalies in such a way that further mathematical invention or adjustments could be attempted, to ask for more exact formulations of what was intended, or formulations using known conventional terms. We remind the reader that the aim was to trigger mathematical actions from the students, not "correct" objects.

In the *commognitive* perspective, one way to evaluate whether the focus and object of the exchanges amongst interlocutors (here L and the five students) are well-coordinated is to examine the forms of *word use* evident in these exchanges. Sfard (2008, pp. 181–2) distinguishes between *passive*, *routine-driven*, *phrase-driven* and *object-driven word use* – and systematic scrutiny of the exchanges can reveal the type of *word use.* In sessions such as the one we are discussing here there is plenty of deictic language, aimed at screen or paper, and this renders such scrutiny more difficult. Audio or video recording of the sessions (not done for the session we discuss here) is then crucial and this is a methodological decision that the LUMOS team might consider (taking account of the intended non-intrusiveness of the innovations).

A similar observation to the one made above considering how the students' engagement met L's expectations applies to the students' loose, non-standard deployments of notation. During the session L seems also alarmed by this and on several occasions he draws on his *ultimate substantiator* (Sfard, 2008, p. 234) status to alert the students to the precariousness of such loose use of notation (see later in the paper one such occasion concerning the use of the expression 'cos(10x) on x^2'). There was one occasion, initiated by Student A, who proposed the introduction of the notation $t \to (\mathrm{f}(t) \cdot g(t))$, which came closest to a standard notational *realization* of the type of function that the preparation sheet invited the students to consider. We elaborate some repercussions of not pursuing this in the session towards the end of the paper.

Further, while the confidence with which the students deployed online software to generate complex and attractive *visual realizations* of their suggestions – often gazed at from all angles and bringing home the potentiality of speedy, intuition-friendly resources – was impressive, it was also notable that these visual awe-inspiring moments were hardly interpreted or explicitly connected to the task set by L in the preparation sheet.

With regard to the second aspect we wish to examine in this account (the students' and L's perceptions of the *learning-teaching agreement*), our account is far less hesitant: simply put, these 'newcomers'' expectations of the 'old-timer', L, who led the session, were very open. It is in fact this openness which brought about the use of 'shakeup' in the title of (Nardi, 2014), the first account of these observations.

Certainly the ethics requirement of the *learning-teaching agreement* for 'tolerance and solidarity' (Sfard, 2008, p. 287) was amply met. One incident illustrates what we see as a substantial power-shifting observed in the session: the exchanges taking place in such a session will, in Sfard's terms, eventually result in conceding to one of the present discourses being ultimately accepted by the interlocutors as privileged and paradigmatic. In a more conventional setting this would most likely be L's discourse. In the observed session this conceding did occur – but on the discursive path proposed by one of the students, not L. This was Student D, who proposed an innovative elaboration of the graph of a function from ℝ to ℝ×ℝ: The student defined two functions, the first was drawn in the conventional manner, and then the second was drawn

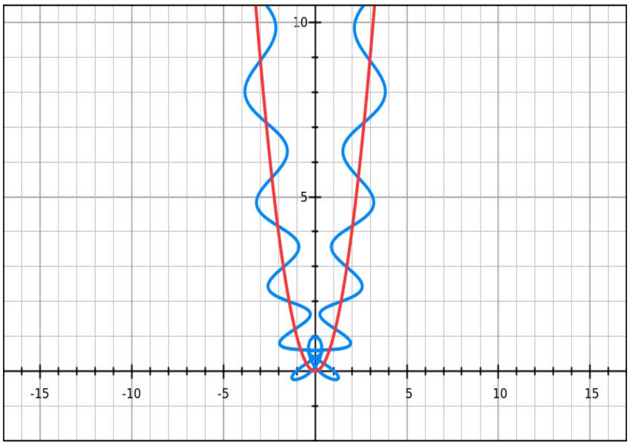

Figure 2: Student D's "$f(x) = \cos(10x)$ on x^2" production. He defines $f: \mathbb{R} \to \mathbb{R}\times\mathbb{R}$, $f(t) = (x,y)$, where $x=t-\cos(10t)\sin(\operatorname{atan}(10t))$ and $y= t^2+\cos(10t)\cos(\operatorname{atan}(10t))$

using the graph of the first as the independent axis with scales along this graph, and perpendicular to it, being the same as the originals. A short time after the session Student D had worked out how to use a computer graphing package to handle drawing such a function and offered the following (Figure 2):

In all this, L coordinated the intense exchanges with explicit and deliberate distancing, in fact with minimal use of his ultimate substantiator status.

It is in this ease with conceding this status that, in our view, the grandest element of the aforementioned 'shakeup' lies: L seemed uniformly open to the *narratives* proposed by the students; he seemed to actively hold back from encouraging their endorsement or rejection by the group. He seemed to sustain a mental list of proposed *narratives* that there had been no time to pursue, such as Student A's (see earlier in this section). In the pragmatic context of limited time – and Student D's more vocal presence attracting perhaps more attention than Student A's – this is not unlikely to happen during teaching. The observations of the session suggest that Student N appeared to experience the most obvious discovery moments. Student J's gestural language and body positioning also suggested so, particularly when 3D images started appearing on the screen of Student N's laptop. Only Student B appeared minimally participant, and quietly perplexed.

The session had buzz and warmth – but also left a slightly anxious sense of unfinished business about not having worked on Student A's proposed *narrative*. We note however that the events that followed on the same evening of the session to some extent appeased that anxiety: Student A wrote to L with an imaginative account of Student D's idea (omitted here due to limitations of space). He had nobly conceded to the temporary dominance of another student's proposed *narrative* in the session but made the most of it ...afterwards. There is at least one implication of this turn of events (and we do say this in full awareness of the modesty of a claim based on evidence from a single observation of a LUMOS innovation session):

> for at least the two hours of this *engagement session* these 'newcomers' slipped comfortably into the shoes of the 'old-timers', with all the fallibility and excitement that walking in these shoes entails. For that alone, surely this is an innovative path worth treading. (Nardi, 2014, p. 10)

A COMMOGNITIVE TRACING OF DESIRED LEARNING OUTCOMES?

Several questions emerge from our account of the 'shakeup' of the *learning-teaching agreement* in the observed session: Is this 'shakeup' liberating, perplexing to the students, both? How does it sit alongside the rest of these students' experiences at this university? They seem comfortable with it but will they stay so throughout? When, if at all, will they demand a reinstatement of L's *ultimate substantiator* status in the form of a demand for (say) specific assessment of their proposed *narratives* (on functions from $\mathbb{R}$ to $\mathbb{R}\times\mathbb{R}$, and beyond)? We conclude with tentative responses to these questions, based on the written reflections of L (second author).

L notes that the 'conceding of much of [his] status' we evidence here does not refer to his 'administrative status, nor [his] professional status' but his 'status as 'old-timer''. He prefers, however, the phrasing 'controller of content of discussion':

> 'I still controlled the direction quite a lot, although I used their prompts, choosing between them for (hidden) pedagogical and mathematical reasons. I believe that I can remember making both pedagogical and mathematical decisions at such moments.'

While on that point he stresses the pressures of 'running one of these sessions':

> '[it] is exhausting for the lecturer because of the constant attending to the direction of the conversation and evaluating it for potential mathemati-

cal (content and process) and pedagogical value. It is why, when a mathematician first watched me run a session [...], then tried it himself, he said that it was much, much harder than it looked.'

As to whether the experience is liberating or perplexing to students, he estimates that 'about half' 'find it liberating' and recalls students talking about 're-finding the creativity in mathematics' and 'expressing their pleasure at the sessions'. For 'about a quarter' though 'it is perplexing – they just do not seem to get what it is about' and for 'another quarter it is a mix between the two – interesting but they feel a bit out of their depth'. These estimates are his 'subjective judgement' and he highlights that 'these groups are not at all related to the students' mathematical ability'.

In relation to how the *low lecture* experience sits alongside the rest of the students' experiences L notes that his institution is 'reasonably liberal' and that it would not be unusual to find lecturers who are willing to 'cede some of their status'. Also many of these students 'will have had a similar sort of experience at times in their final year of school' where they are likely to have been 'treated quite respectfully as mature learners'. While 'probably unusual at first year' this respectful treatment in the *low lecture* innovation would then be 'not so strange'. Other factors, such as the presence of mature students in the group, may also reduce the 'strangeness' of the experience and make the students' commitment to this approach more resilient too:

> 'I've not seen any students in any session get MORE perplexed or uncomfortable, I've seen some get less and some stay the same. For those who were comfortable with it, a few grow into it significantly quite quickly.' [L's emphasis]

As an example, L returns to Student A's 'radical' follow up (see earlier) of the discussion in the observed session: 'He was checking with me that [his ideas] were ok, but he had really taken on the idea that the mathematics was there to be played with'. And while the students 'do check things out' with him (L), 'they have never seen this as "assessment" in the formal way (is it right or wrong)' but rather:

> '[they] seem to have caught on to the fact that this is exploration, and anything goes in some respects – it is what you do with it that counts, not what it is you are working with. I take this as a huge endorsement of the idea of the *engagement sessions* – that they are not about content but about process. I did not expect that most of the students would "get" this so quickly, although I did reiterate it often both in writing and verbally.'

Here we sampled towards deploying the analytical potential of the *commognitive* approach. Analyses from the implementation of the LUMOS innovations are ongoing.

ENDNOTES

We dedicate this paper to our beloved LUMOS colleague Judy Paterson who passed away in January 2015. She will be sorely missed by all in this project and beyond.

A model of mathematicians' approach to the defining processes

Cécile Ouvrier-Buffet

Université de Reims Champagne-Ardenne, CEREP EA 4692, Reims, France, cecile.ouvrier-buffet@univ-reims.fr

This paper presents a modeling of the defining process used by mathematicians. This modeling has a strong epistemological background and has didactical outcomes. The aim here is to propose tools in view of studying the ways to implement a mathematical activity (close to the mathematicians' one) at the university level.

Keywords: Mathematicians, epistemology, conceptions, definitions, processes.

INTRODUCTION – ON THE IMPORTANCE OF STUDYING THE DEFINING PROCESSES OF THE MATHEMATICIANS

The study of defining activities is a discreet but constant didactical topic of research in mathematics education since the 90s. Mariotti & Fischbein (1997) have underscored the importance of such research: "(…) learning to define is a basic problem of mathematical education." (Mariotti & Fischbein, 1997, p. 219). Characterizing the defining processes and the defining activities is a new way, in mathematics education, to explore the mathematical concepts, their learning and their teaching. To place the definitions in the core of the mathematical activity (i.e. an activity that builds new knowledge, brings new proofs and theories), actually reveals an epistemological interest and a didactical interest: besides, the construction of definitions is a component of the research process of the mathematicians. Some researchers in mathematics education have characterized heuristics and behaviors of mathematicians (e.g., Schoenfeld, 1985, Burton, 2004; Carlson & Bloom, 2005; Gardes, 2013), but little research propose a modeling of the defining processes used by the mathematicians. Moreover, the modeling of defining processes in mathematics and the characterization of problems that allow a defining activity should be fruitful from a didactical point of view. Indeed, it brings a new way to analyze the processes of constructing new concepts, new proofs and new theories; then, the analysis and the guidance of the mathematical activity of students becomes feasible.

My research, i.e. the modeling of the defining processes in mathematics, fits into a wider field in sciences education that is the inquiry-based learning. The study of the implementation of mathematical and scientific processes in the classrooms (for mathematics, it means every process at stake in a mathematical inquiry of a mathematical problem) is a crucial point for the research in mathematics education. Besides, the question of the closeness between the results of the on-going mathematical research and the contents of university mathematics has to be studied both by mathematics educators and mathematicians.

In this paper, I propose first to synthesize the research in mathematics education that deal with the activity of mathematicians, with a short focus on the defining processes and the defining activities. I have developed in my research (Ouvrier-Buffet, 2013) a complete modeling of the mathematical defining processes. This model is based upon an epistemological background with a didactical efficiency. In this paper, I have chosen to present the results of interviews with professional mathematicians regarding their defining processes: these interviews bring concrete features of the professional defining activity. They also confirm and enrich the epistemological choices I have made for the design of my model (see Ouvrier-Buffet, 2006, 2011 and 2013 for the whole epistemological component). The last part of this paper opens new perspectives for university mathematics education.

STUDYING THE PRACTICE OF MATHEMATICIANS: AN OVERVIEW

In mathematics education, a recent kind of research deals with the practice of mathematicians. The focus is often made on proof and proving processes, which is legitimated by the fact that proofs are the holder of the mathematical knowledge (Rav, 1999) among other reasons. Hanna & Barbeau (2008) extend this point of view and underscore that the proofs can have other functions such as introducing new methods, tools and strategies to deal with new problems. It fits with Weber's conclusions: Weber (2011) shows that one of the reasons that mathematicians read the proofs of colleagues is to transpose ideas and techniques which may be useful in their own research. Wilkerson-Jerde & Wilensky (2011) analyze the reasoning of mathematicians and students dealing with an unfamiliar proof. They show several processes such as: the use of previous knowledge, the construction of examples, the deconstruction of a concept or an idea into subcomponents in order to explore the different components of a concept, the tests and the explorations of definitions, the attempts to connect definitions. As for Shriki (2010), he considers the creativity in the construction of knowledge. He shows that teachers reckon that mathematics can be taught as a reconstruction: the same kind of defining activities (reconstruction of geometrical concepts) as in the research of Larsen & Zandieh (2008) and Zandieh & Rasmussen (2010) is at stake. The place of the study of the construction and the use of examples in mathematics is also important. The focus on the examples that can be produced by students when they try to understand new concepts and when they want to illustrate mathematical ideas and properties, a focus which has been made by Watson, Mason and other colleagues, leads now to the analysis of the construction and the use of examples in proof processes (Watson & Mason, 2002; Sandefur et al., 2013). Recently, Gardes (2013) models the concept of "gesture" and defines it in a new way based upon the contemporary epistemology in order to analyze the practices of mathematicians. This concept appears relevant (for further research) to analyze the processes of mathematicians and of students during a research, and to consider the question of the transposition of the work of mathematicians to the classroom. In fact, in mathematics education, the defining activities are usually evoked during the study of proofs and of problem solving processes, but are not much studied for themselves. Indeed, it is commonly accepted that a proof can imply the necessity of the reconstruction of a definition: in this case, it concerns the exploration of the meanings of a definition (it can lead to the need of a better definition) and/or the study of the consequences of an assumption (Hanna, 2000). Besides, the way the students learn new concepts can be described with the enrichment of their concept images (Tall, 1991; Vinner, 1991). In fact, in these examples of the emergence of a defining activity, the emphasis is made on a part of the mathematical activity only, and not on the whole process that deals with definitions in the research activity of mathematicians. From an epistemological point of view, the work of Lakatos (1961, 1976) gives a unique example in the literature where the defining process and the proving process interact.

My research (see Ouvrier-Buffet, 2013 for the outcomes) proposes a reference epistemological modeling of the mathematical defining activity, taking into account the dialectic between defining and proving. Theoretical frameworks from the didactic of mathematics (the model of conceptions (Balacheff, 2013) and mathematics (complexity theory, Garey & Johnson, 1979) are called upon. This modeling is also based upon several experiments (at secondary and university levels) and upon interviews with mathematicians. The first level of my research was to identify emblematic epistemological conceptions which can characterize the mathematical defining processes: I have taken on the Lakatosian, Aristotelician, and Popperian conceptions (see Ouvrier-Buffet, 2006, 2011). Yet, these conceptions were not enough to describe the defining processes because some cognitive aspects, for instance, were not taken into account (the didactical experiments have shown this aspect). Besides, the characterization of problems which can lead to a defining activity had not been carried out. Moreover, it was difficult to understand how the epistemological conceptions coexist and interact. Then, I have enriched the epistemological component and I have conducted interviews with mathematicians to propose a complete overview of the defining processes. I have then design four main components to define my modeling of defining activities and processes: the characterization of three main epistemological conceptions regarding defining processes (the Lakatosian, Aristotelician, and Popperian conceptions; Ouvrier-Buffet, 2013, p. 67); the definition of problems that can lead to a defining activity (Ouvrier-Buffet, 2013, p. 72); the emphasis of four moments of work involving definitions (this part highlights the role and the place of the epistemological conceptions and the cognitive aspects; Ouvrier-Buffet, 2013, p. 69); and a didactical methodology to build, to analyze and to guide defining processes in classroom situations (Ouvrier-Buffet, 2013, p. 76).

DEFINING PROCESSES OF MATHEMATICIANS

Research questions and methodology

The aim of the interviews with mathematicians was twofold: firstly, I wanted to enrich my model of the defining activity based upon three epistemological conceptions, and intrinsically to validate it. Secondly, I was searching for a way to complete the aforementioned conceptions and to grasp the whole defining activity of mathematicians. Therefore, my underlying research questions were: how do the conceptions interact? Can one identify different moments when the mathematicians work on definitions, and are the epistemological conceptions operational? What are the types of definitions which the mathematicians use?

Regarding my previous epistemological research, I have defined *six lines* to analyze the data. They deal with the different kinds of definitions which the mathematicians talked about; the features of their defining processes (a focus is made on the interplay between defining and proving); the reasons of the evolution of a definition during a research; the ways the mathematicians valid a definition; the view they have on the defining activity in university mathematics classes; the identification of the moments when the mathematicians work on definitions, and then of their moments of work dealing with defining processes. These features and the elements of the epistemological conceptions gave me a grid with several components to analyze the interviews. I have also focused on the actions described by the mathematicians in order *to connect them to the epistemological conceptions*. In this article, the aim is to provide concrete examples to give an overview of a professional defining activity (following the six lines above-mentioned) and to highlight the characterization of four moments of the work on definitions in particular.

Data for this research

Eight professional mathematicians participated in this study. They come from different French universities and different fields of mathematics. Semi-structured interviews (1 hour or less long) were audiotaped and then transcribed. The questions were oriented towards four elements: their professional profiles, their practices of mathematics, their practices of the definitions and of the interplay between definitions and proofs, their representations of teaching at university level (do they think that implementing defining activities at university level can be useful and relevant?). The description of these interviews is available in Ouvrier-Buffet (2013).

Several kinds of definitions

The interviewed researchers actually identify several kinds of definitions:

— the discrimination between the definitions one knows beforehand and the definitions one can deduce from other results;

— the distinction between the definitions which remain and will belong to the public domain and the local definitions which are used to shorten a talk.

— the working definitions: one starts from the intuition that one gets from objects and problems. With this kind of definitions, one can work with the mathematical objects, and the statement of these definitions can be put off.

These kinds of definitions are linked to different aspects of mathematics and then several moments of the mathematical activity already appear: the moment when the intuition of objects and problems catalyses a research; the moment when working definitions (which can be local ones) give legitimacy to a new object which becomes worthy of interest; and the moment when the theoretical, formal and logical definitions are at stake (here the axiomatic theory is concerned).

The defining process and its interplay with proof

It is clear that the formalized definitions come "after" during a constructing process. The processes involved in the construction of a theory are not really dealt with by the mathematicians. By "defining process", they circumscribe a heuristic domain, from an intuitive exploration of mathematical objects and problem to the validation of a result. The insight of the results is often present. The defining processes specific to the construction of a new theory with axiomatic, logical and linguistic constraints are not much developed. For the mathematicians, to define is motivated by different needs: to have a better understanding of a concept or a problem, to simplify, to generalize, to explore different linked frames or connected fields than the first one, to communicate. The mathematicians consider that the proof is the master and that the proof can imply an evolution of the definitions. When they define or re-define objects during a proof, it is first to continue the research process, then to determine the domain of applicability of an idea or a proof, and finally to study more general cases or more particular cases. The definition of a really new concept (i.e. without an insight of it during a first exploration of a problem and/or a proof) can emerge during a proof. The proof process can have a local or a global impact: the significance of the new built concept will be proved later. Therefore it implies a long-term study of this new concept.

The reasons of the evolution of a definition

The "communication" dimension is important for the mathematicians: they explain that a definition will evolve when they will communicate their results. It can be in different institutions (seminary, talk, publications, university textbook) and the context will lead to one definition in particular or another. The mathematicians underscore the difficult use of the examples and the counter-examples in research. Some mathematical fields, where the concrete and discrete dimensions are involved (such as discrete mathematics), seem to be more suitable for building and using examples and counter-examples. Some defining problems (i.e. problems that can lead to a defining process) are pointed out by the mathematicians and are shortly described through research questions such as: to search if the problem can become a more general one, to search analogies with linked mathematical fields or with other concepts including a similar structure, to define the dual concept (it also implies the construction of new problems).

The validation of a definition

It occurs in different levels and places. The validation (i.e. when one considers that a definition is "correct") can be an individual and personal process (it is a self-validation). The colleagues play the part of the validation too, as well as the mathematical community. The fact that the proof works is also an element for the validation of a definition. In the same way, when a conjecture is "almost proved", or when there are no more counter-examples, or when the validity of a statement is controlled by the use of examples, the mathematicians consider that a definition can be valid. And a definition can also be agreed upon when it has a good strength during mathematical natural transformations or the implementation in different mathematical frames or structures. This being said, a mathematician indicates that for some cases, one cannot bring a validation, in particular when one does not know if the research process is ending (this is consistent with the Lakatosian view). These elements go in the same directions as Weber's results (2008) regarding the validation of a proof by the mathematicians.

A MODEL OF HOW CONTEMPORARY MATHEMATICIANS DEFINE

A basis: Three epistemological conceptions

I have previously presented an epistemological framework taking into account several conceptions: the Aristotelian one, the Popperian one, and the Lakatosian one (Ouvrier-Buffet, 2006, 2011). I have shown the ability of students to build definitions and to make a working definition evolve with the lack of counterexamples and with the reinvestment in a proof. I have also shown that the three aforesaid conceptions are useful to describe the students' defining processes, but not enough to grasp the whole processes, in particular the intuition and the in-action processes. I have then reintegrated the in-action dimension (this cognitive feature was missing in the model) with the in-action definitions and extended the modeling (Ouvrier-Buffet, 2013).

Mathematicians dealing with defining processes: Four moments of work

Four moments of work have been characterized during the interviews with the mathematicians. These moments do not describe a linear activity, but they are connected: they give a dynamic overall view of the defining activity in the mathematical research which also integrates the epistemological conceptions and underscores the different kinds of definitions. The names that I have chosen for these four moments of work are directly connected to the different kinds of definitions which exist in the speeches of the interviewed mathematicians.

The "in-action" moment of work

This moment of work deals with the intuition of mathematical objects, ideas, and results. The mathematical activity is here mainly an exploration and an impregnation of one or several problems and of objects in order to know them better (the use of examples, non-examples, counter-examples is here at stake). Analogies with other close mathematical fields can be used and new weak problems are stated. The Lakatosian conception is operational, with several operators: the statements of problems, the construction of examples and counter-examples, and the change of mathematical framework. In this "in-action" moment of work appear "in-action definitions" (Ouvrier-Buffet, 2011) and concept images (Vinner, 1991). An "in-action definition" is a statement used as a tool (not an object) that enables students to be operational without an explicit definition.

A transitional moment of work between "in-action" and "zero" – A potential link with the "axiomatic" moment of work

Two processes characterize this moment of work: to construct a first classification of mathematical objects and to re-use existing classifications; and to try to use analogies with existing concepts and theories. Here, the classifying, the categorizing activities and the denomination process of objects constitute the defining process. The Aristotelician and Lakatosian conceptions can be mobilized. If a link is made with the "axiomatic" moment of work, the Popperian conception can be used.

The "zero" moment of work

This is the place of the "zero-definitions" (Lakatos, 1961; Ouvrier-Buffet, 2011, 2013), but also of definitions that have a local impact. A "zero-definition" marks the beginning of the research process. A zero-definition can be modified in order to protect a primitive conjecture from a "monster" or because the concept is altered by the presentation of a proof. The Lakatosian operators (to use and to build examples and counter-examples, to use the method of monster-barring for instance) and other processes can be mobilized such as: to do false things, to reach an idea of the proof (the proof constraints the concepts and their definitions, quoting the mathematicians). Then, the zero-definitions and other local definitions have different functions: to denominate, to bring up several ways to grasp a concept, to work on a proof, to delimit the range of use of an idea or of a conjecture or of a proof, to communicate. The Lakatosian operator "to use another mathematical framework" can also be used and a link with the "axiomatic" moment of work made (in particular when a local or global theory pre-exists).

The "formalized" moment of work

I would like to underscore the "communicational" aspect, which appears during both a heuristic research, and a need of formalization, then I use the term "formalized" for this moment of work of mathematicians. Mathematicians can have to communicate (local) results during seminary, prepublications, talks etc. or to write a more formalized paper. In these both cases, there is a gap – an abstraction jump – compare to the "zero" moment of work. During the "formalized" moment of work, the mathematical activity concerns the use of some Lakatosian controls such as: the end of counter-examples implies that definitions, conjectures and/or proofs are solid. Here, "proof-generated definitions" can emerge. The proof and the proof-generated definition work together. A proof-generated definition originates from a proof while stemming from the development of the potential of a zero-definition. The catalysis of a proof-generated definition is impossible without the proof idea. Other operators take part in this moment of work, such as Popperian ones dealing with the construction of local (or even global) axiomatic theories. The writing of formalized and successfully completed definitions can be partially described with the Aristotelician conception. This moment interact with the concept definition (Vinner, 1991). Besides, the statement of new problems (a Lakatosian operator) allows the continuation of the mathematical research. The understanding of the new built concepts, and the generalization and the use of definitions, problems and results can lead new questionings. The exploration of neighboring concepts leads to a new "in-action" moment of work.

The "axiomatic" moment of work

The construction of a new theory (which can be momentarily local) and the construction of new concepts inscribed in this theory are at stake in this moment of work. I choose to call the definitions which are built during this moment "theoretical definitions" in order to underscore that there are inscribed in a theory. The Popperian conception is here clearly useful to characterize the research process of the "axiomatic" moment of work. In particular, the construction of the involved mathematical theory implies the search of the minimal number of rules (axioms) in order to generate results with a wide range. The axiomatic process can also unify concepts (see, for instance, the case of linear algebra, Dorier et al., 2000). The transposition of concepts to other mathematical fields brings opening questions for the research too.

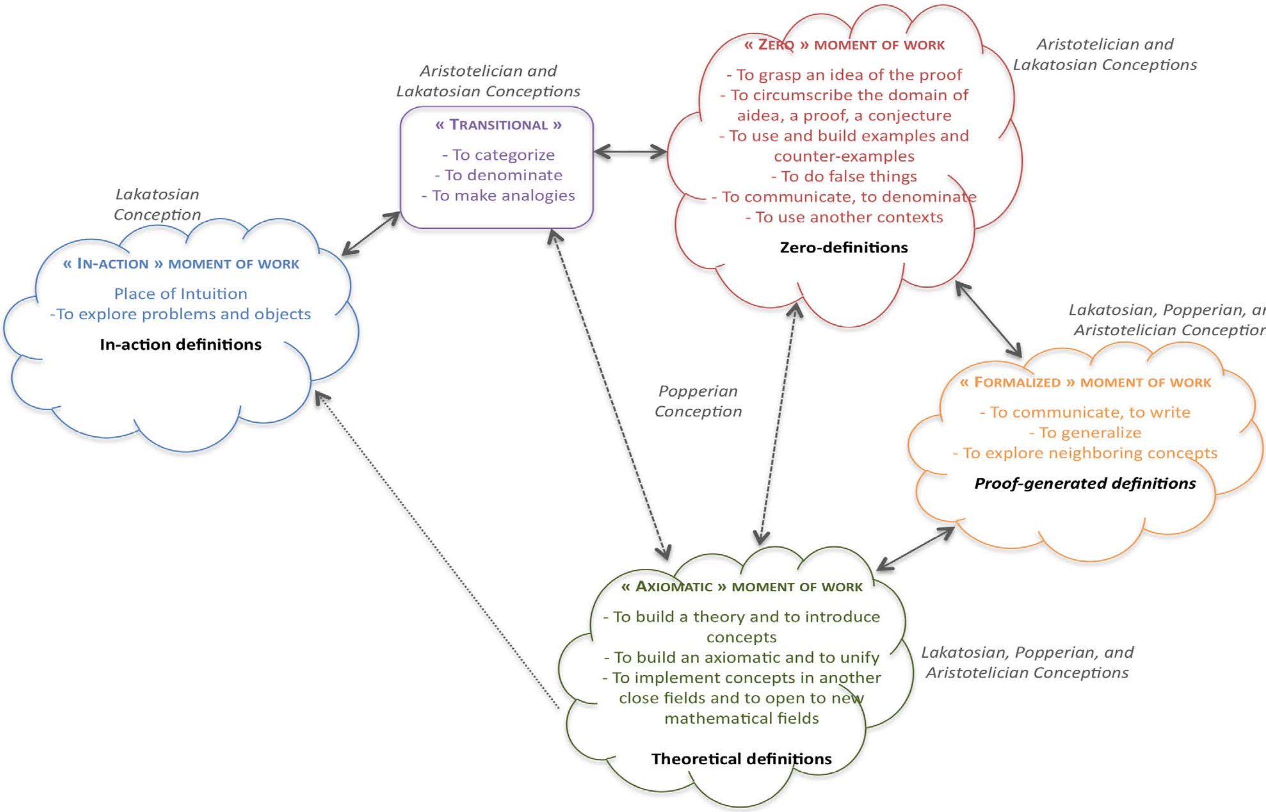

Figure 1: Overview of the defining process in mathematical research

The epistemological conceptions are operational in the moments of work

In the different moments of work on the definitions, as well as in the transition from one moment to another, the mathematicians mobilize one ore more conceptions (mainly, they express in words different elements which fit with operators and control structures of the epistemological conceptions). Then, Figure 1 synthesizes the features of each moment (in the coloured clouds), and shows the places where the epistemological conceptions are operational (in a cloud or in a transition between two clouds). The arrows mark the transition between two moments and sometimes the efficiency of a conception in such a transition. According to the interviewed researchers, one researcher cannot deal with all these moments, except for brilliant mathematicians. We can continue this research with new interviews, taking into account the different fields of mathematics.

OPENINGS

Ouvrier-Buffet (2011) has shown how a mathematical experience with a problem involving a defining activity can be conducted at university level. Such experiments also bring opportunities to reinvest the constructed concepts and the ways of reasoning in other mathematical fields. Then the question of the in-service teacher education (of university mathematics teachers) becomes crucial, as well as the definition of the contents of the university mathematics i.e. the concepts and the processes involving a real mathematical activity (and not only proof). There are clearly needs to engage collaborative research between university mathematics teachers and researchers in mathematics education (following Nardi, 2008). The interviewed mathematicians think suitable to implement defining activities at the university level, but they cannot conceptualize the way it can be implemented with students. They are very interested in the didactical research that can lead to new situations for the university. One can also extend this idea to sciences, especially with the study of the inquiry-based learning.

How do research mathematicians teach Calculus?

Georgia Petropoulou[1], Barbara Jaworski[2], Despina Potari[3] and Theodossios Zachariades[3]

1 University of Athens, Department of Mathematics, Section of Mathematics Education, Athens, Greece, enaprosena@yahoo.gr

2 University of Loughborough, Loughborough, UK

3 University of Athens, Athens, Greece

We investigate Calculus teaching at university mathematics departments and in particular research mathematicians' teaching practice in the context of lectures. We are interested in how lecturers draw mathematics students into mathematical culture. In this paper, we focus on the teaching of a lecturer of a large cohort of students that we analyse using grounded techniques and the Teaching Triad construct (Jaworski, 1994). In spite of the lecture format, the analysis suggests that this lecturer's teaching is characterized by the way he supports students' engagement in the lecture and the way he familiarises them with mathematical production. The use of the Teaching Triad brings to our insight what sensitivity to students could mean in this traditional setting and what mathematical challenge could be at the university level.

Keywords: University teaching, sensitivity to students, mathematical challenge.

INTRODUCTION

Teaching at the University level deals commonly with large groups of students and the lecture is the instructional activity within which teaching usually takes place. Arguably the lecture instruction has received a strong criticism and has been widely maligned by mathematicians and mathematics educators alike (Weber, 2004). It seems that lecture is considered as a unified, single teaching paradigm and thus a small number of studies investigated mathematics teaching in this context (Speer, Smith, & Horvath, 2010). For example, Weber (2004) addressed the nature of lecturing showing that it is not as a single teaching paradigm as it thought to be and Jaworski, Treffert-Thomas and Bartsch (2009) pointed out the tensions that a lecturer experiences in satisfying student needs and mathematical values. Yet, Speer and her colleagues (2010) in their systematic literature review argued that university mathematics teaching is "an unexamined practice" and drew attention to the need for empirical research that examines and describes the work of teaching university mathematics in detail.

Seeking to readdress this scarcity of empirical research and to gain better understandings of the actual teaching at this level, our study aims to explore characteristics of first year university mathematics teaching in Greek mathematics departments. The topic in focus is *Calculus* which is a first year compulsory course taught in a lecture format. Research concerning the learning of Calculus at the university level has shown that students experience difficulties in aligning with advanced mathematical processes and concepts when they enter into university (Artigue, Batanero, & Kent, 2007; Nardi, Biza, & González-Martin, 2009). A question is how teaching at this level and in the particular context of a lecture could deal with the above difficulties while drawing mathematics students into mathematical culture. In this respect, there is a growing body of research seeking to characterize elements of teaching practice that takes students into account (some examples will be discussed below in the theoretical background section) but not at the university level. Being aware of the complexity of teaching that has been identified by many researchers into secondary level teaching (e.g., Potari & Jaworski, 2002) and does not end with the transition to the university level, we attempt to investigate first year Calculus teaching in the, most usual for this level, format of a lecture. In particular, we focus on one lecturer's teaching actions and the rationale behind these actions to identify the characteristics of his teaching and we attempt to realise the nature of the identified characteristics in this particular context.

THE THEORETICAL BACKGROUND

Exploring characteristics of teaching deals inevitably with the fundamental question "what is teaching" addressed by some philosophical studies (e.g., Hirst, 1971). Some other studies refer to the debate whether teaching is a practice or a means to introduce students to another practice – the mathematical practice (e.g., Noddings, 2003). We see teaching as an activity following Pring (2000) who claims that: "An action might be described as 'teaching' if, first, it aims to bring about learning, second, it takes account of where the learner is at, and, third it has regard for the nature of what has to be learnt" (p. 23). Adopting a sociocultural perspective, teaching is considered not only as a product of the constructive activity of the individual teacher but also as a social practice; a complex nexus of social inter-relationships (Jaworski, 2002). Learning mathematics at this level is seen as enculturation in advanced mathematical practices (Artigue, Batanero, & Kent, 2007). Enculturation, in the sense described by Bishop (1991), is an interpersonal process so the role of people who have special responsibility for this process is emphasized. This "cultural group" of people are for us the mathematicians who teach at university level. Bishop (1991) quoted Wilder (p. 6) who wrote for the mathematicians: "Those people who do mathematics – the 'mathematicians' – are not only the possessors of the cultural element known as mathematics but, when taken as a group in their own right, so to speak, can be considered as the bearers of a culture, in this case mathematics". This view offers us a base to interpret lecturer's attempts to draw students into mathematical culture and characterize his practice since "introducing children into the culture of a mathematical practice is basically a social process" (Van Oers, 2001, p. 73).

Speer and colleagues (2010) made a distinction between instructional activities and teaching practice. According to this distinction the lecture, the context of our study, is an instructional activity while teaching practice concerns what teachers do when they are planning, teaching and reflecting on their lesson. Thus, lecture is the usual instructional activity at university level yet in lecturing different teaching practices may take place. We investigate a lecturer's teaching practice i.e. his/her teaching actions (what s/he does intentionally) and the rationale behind these actions, seeking to characterize this practice and gain deeper insights into university teaching.

Our research tool in the endeavour to interpret the nature of teaching characteristics is the Teaching Triad (TT). TT is an analytic framework that emerged from an ethnographic study of investigative mathematics teaching at secondary level (Jaworski, 1994). Its main goal was to capture essential elements of the complexity of mathematics teaching by analyzing classroom interactions. Jaworski (2002) describes that the triad consists of three "domains" of activity in which teachers engage: *management of learning* (ML), *sensitivity to students* (SS) and *mathematical challenge* (MC). ML describes how the teacher organizes the classroom learning environment (e.g., groupings, planning of tasks, setting norms). SS describes teacher knowledge of students and attention to their needs and in particular the ways that he/she interacts with individual students and guides group interactions. Sensitivity to students has been shown to relate to both affective (e.g., offering praise, encouraging students to participate) (SSA) and cognitive (e.g., judging appropriate questions, inviting explanation) (SSC) domains. MC describes the challenges offered to students to engender mathematical thinking and activity. This includes tasks set, questions posed, and emphasis on metacognitive processing. The above elements are closely interrelated as the study of Potari and Jaworski (2002) indicated. The authors claim that a balance between sensitivity to students (in both cognitive and affective domains) and mathematical challenge is an indicator of effective mathematics teaching in the sense that students can be involved in rich and meaningful mathematical activity. The triad has also been used to characterize teaching for example in a study of interactions in university mathematics tutorials (Jaworski, 2002, Nardi, Jaworski, & Hegedus, 2005) but it has not been used to characterize lecturing so far. It is a question for example, what sensitivity to students could mean in lecturing large groups of students or what mathematical challenge describes in this context. It is in our interests to reassess the elements of the Triad and define the potential meaning they gain at this level.

Nardi and colleagues (2005) also characterized teaching approaches in small group tutorials from the perspective of the tutor offering a theoretical perspective on the links between mathematics and pedagogy. Lobato, Clarke & Ellis (2005) developed a theoretical reformulation of telling, characterizing teaching actions according to their function and Anghileri (2006) characterized teaching by identifying a hierarchy of interactions that relate to teaching practices that can enhance mathematics learning. Grandi and Rowland (2013) analyzed the function of teacher interventions while Drageset (2014) characterized teachers' comments. The above studies characterized approaches to teaching and gave us the theoretical underpinnings to formulate specific criteria for coding the lecturer's teaching actions.

METHODOLOGICAL ISSUES: DATA AND ANALYSIS

This paper is a part of an ongoing study with aim to investigate the first year Calculus lecturing in two mathematics departments. Six lecturers participated in the wider study. Calculus is a proof-based, first year course in both departments and it is taught in parallel in two or three classes of approximately 100 students each (4 hours for theory and 2 hours for solving exercises per week for one semester – all in a lecture format). In this paper, we analyse data from one lecturer who is an experienced active research mathematician and university teacher, with the ultimate goal to draw students into mathematical culture. Data for this lecturer were collected through observations (3 two-hour lectures), interviews (3 interviews right after each lecture) and group discussions (5 three-hour group discussions). During the observation of the lectures, field notes were also kept and after class interviews with the lecturer conducted by the first author. Moreover, in group discussions among some of the 6 participants of the wider study and mathematics education researchers, more general issues about university teaching were discussed. The lecturer of this study participated in all group discussions. All lectures, interviews and discussions were audio-recorded (one of the lectures was also video-taped) and transcribed.

In data analysis, grounded approaches (Strauss & Cobin, 1998) and the Teaching Triad (Jaworski, 1994) were used. The analysis was conducted in three phases. In the first phase, each two-hour lecture was divided into episodes according to the accomplishment of teaching a theorem. Each episode was coded with descriptive codes according to what the lecturer did during this episode and from these descriptive codes teaching actions were identified. Codes for teaching actions were merged or refined after continuous comings and goings through the whole data and were supplemented by categories taken from Anghileri (2006), Drageset (2014) and Grandi & Rowland (2013). This process enabled us to form criteria for characterising the codes of the teaching actions. Finally, the analysis resulted in 12 codes. The rationale of teaching has been investigated through the analysis of interviews and discussions which were also coded according to the subject under discussion and in this way the lecturer's teaching practice (i.e. teaching actions and rationale) has been identified. In the second phase, teaching actions were grouped into categories and in this way the characteristics of this lecturer's teaching practice were identified i.e. characteristics are categories of teaching actions and their rationale. In the third phase we used the Teaching Triad to gain deeper insight into the identified characteristics. Thus characteristics of teaching were analysed further by using the TT to explore potentials of TT's elements in this level and in this way we gained insights into the nature of these characteristics per se.

In the next section, first we give an example of analysis to illustrate the analytical process and the related emerging issues and then we give a brief account of the results from the analysis of the whole data for this lecturer.

RESULTS

A teaching episode that appears to be typical of the way the lecturer interacts with students follows as an example of analysis. In this episode, which is about the convergence of series of real numbers, the lecturer tries to facilitate students to arrive at a conjecture.

An example of analysis: A teaching episode and its analysis

At the beginning of the lecture after the definition of a convergent series, the lecturer gave the geometrical series

$$\sum_{k=0}^{+\infty} x^k = \frac{1}{1-x},\ |x| < 1 \text{ (S1)}$$

as an example of a convergent series (a familiar example from secondary school). Subsequently, he gave the example of divergent series:

$$\sum_{k=1}^{+\infty} (-1)^k \text{ (S2)}$$

Then the dialogue below followed in Table 1.

An episode (The lecturer facilitates students to arrive at a conjecture)	Descriptive Codes	Teaching actions
L: Now, can you hypothesize, when a series may converge?	Challenging students to be engaged in mathematical exploration	Exploration
You can base on the series S1 and S2.	Prompting students to focus on the examples [(S1) and (S2)]	Focusing
(No response) The lecturer wrote again the two examples (S1 and S2) on the board (one next to the other) with the words "converges" and "does not converge" respectively next to each example.		
L: Can you see any differentiation in these two cases S1 and S2]? They are two specific cases of course but... is there any difference between them?	Asking a more focused question to compare example's characteristics	Focusing
S1: Yes. The base [of the *v*] in the first case (S1) is a positive number.	Gaining insight from a student's response	Evaluating
L: Not necessarily. If x is a negative number the sign [of x^k] changes. (he moves his hand left and right showing the alternation of the signs over an imaginary number line).	Offering a counterexample	
S2: Counting starts from different numbers	Gaining insight from another student's response	
L: No, it has nothing to do with... We could start from the same number. (He changed (in S1) the counting from $k = 0$ to $k = 1$ on the board). Now on the board the two series were: $\sum_{k=1}^{+\infty} x^k$ (S1a) and $\sum_{k=1}^{+\infty}(-1)^k$ (S2)).	Modifying the example to avoid irrelevant details	Simplification
L2: Here you are! Now the series ((S1a) and (S2)) seem comparable. Finite number of terms at the beginning of a series does not have any influence on its behaviour [related to its convergence].	Providing a reason for the modification	Explaining
S3: Is the difference that the 1st series (S1a) has a variable?	Gaining insight from a third student's response	
L: It's not a matter of variable. OK. If I set here... I don't want to confuse you. Let me take a specific geometrical series. (He writes the series $\sum_{k=1}^{+\infty} \frac{(-1)^k}{10^k}$ (S1b)). I took units everywhere. This number... I made it to look about the same.	Specifying the example	Simplification
S1: Is the difference that the 1st case (S1a) has the condition $\|x\|<1$?	Having relevant responses	
S4: Is the difference that in the 2nd case (S2) the absolute value is 1 ($\|-1\|^k = 1$)?		
L: This observation (of S4) may imply something. It's a correct observation.	Confirming	Evaluating
Your fellow student said we should take these terms (the sequence in S2) and we'd consider their absolute value. This absolute value will always be 1. This might be a difference. Whilst in this case (S1b) the absolute value of the sequence in the series is $1/10^k$. And?	Rephrasing student's talk	Drawing on students' experiences

An episode (The lecturer facilitates students to arrive at a conjecture)	**Descriptive Codes**	**Teaching actions**
S5: ... and this absolute value is less than 1.		
L: Yes. And?		
(No response)		
L: If k tends to infinity, where does $1/10^k$ tend to?	Providing a hint	Directing discussion
S1: To 0.		
Then the lecturer summarizes the result of the investigation and formulates the property.	Recapping and formulating the conjecture	Summarizing Explaining

Table 1: A teaching episode and its analysis (Translated from Greek)

In the above example we see some of typical teaching actions of this lecturer's teaching. In particular, the lecturer mainly poses a problem; calls students to express their observations; uses examples familiar to them ; evaluates students' observations by giving comments and by simplifying the examples; asks more focused questions when students do not follow; uses students' relevant observations as a basis to direct discussion and summarizes the main results.

In terms of the TT, we see expressions of his sensitivity to students and the mathematical challenge he offers to them. For example, he tries to motivate students to participate by asking questions and reassures students that their contributions are acceptable (SSA); highlights and builds on their ideas and comments (SSC). He also addresses mathematical important questions; encourages students to think deeper to identify relations (e.g. by reflecting on familiar examples) and engenders students' interpretations of relationships and representations (MC). Moreover, he organizes the content of the lecture to support students' reflections (e.g. he brings an example and later he uses it as a basis for exploring relationships) and he establishes norms of a working group (e.g. he always uses "we" in his talk) (ML). Analysing all the data from this lecturer, two specific goals were identified. The first goal was mainly affective: the lecturer tried to stimulate students to become confident in their engagement with the advanced mathematical content:

"What I do consciously is that I try to tone up students psychologically ... Speaking emphatically, I believe that, in order for someone to be engaged in the learning process he must have the appropriate psychology. I think that the 50% of learning is the learner's psychology." (Translated from Greek)

The second goal was mainly mathematical: he tried to initiate students into advanced mathematical thinking and mathematical production: "What I try to do is to teach students how to think mathematically... And I have to make them understand how someone thinks and produces mathematics." (Translated from Greek).

These goals were carried out with specific teaching actions. These teaching actions were related and grouped forming the characteristics of this lecturer's teaching which have been analysed further with the TT. Table 2 presents how all teaching actions are grouped into characteristics and how the characteristics are related to the three domains of the Teaching Triad.

We related the actions "explaining", "directing discussion" and "summarizing" because they characterise lecturer's guidance to students by informing or providing suggestions to them. In terms of the TT, we see this guidance as an indication of ML and SS as the lecturer gives explanations, suggestions or points out an idea with sensitivity to students' needs.

We related the actions "evaluating", "drawing on students' experiences" and "checking for consensus" because they characterise lecturer's supporting of students engagement. The lecturer evaluates students' contributions in a way that rewards their involvement even if the contribution is invalid and he is not moving on without their consensus. In terms of the TT, we see supporting students' engagement as an expression of lecturer's SS as the lecturer opens up students' ideas, builds on them and confirms that these ideas contribute in the learning process.

Teaching actions	Characteristics
Explaining	Guidance of students (ML and SS)
Directing discussion	
Summarizing	
Evaluating	Support of students' engagement (SS)
Drawing on students' experiences	
Checking for consensus	
Focusing	Discard any irrelevant features (MC and SS)
Simplification	
Exploration	Use of problem-solving techniques (MC)
Posing a problem	
Relating mathematical ideas	
Translating mathematical ideas	

Table 2: Teaching actions and characteristics of teaching

We related the actions "focusing" and "simplification" because they both characterise discarding any irrelevant features. The lecturer simplifies examples a strategy which he uses in his research: "This is the way I produce work." So, discarding any irrelevant features is a process of mathematical production at least for him. As he states in an interview simplifying also allows him "to include more students in the lecture", so to be more in accord with students' needs. Thus, in terms of the TT, we see discarding any irrelevant features as an expression of MC which, in this case, is related with SS.

We finally related all the actions through which the lecturer introduces students to problem-solving techniques by creating conditions for investigations ("posing a problem" and "exploring") and by encouraging connections ("relating" and "translating mathematical ideas"). In terms of the TT, we see that using problem-solving techniques is a characteristic of MC as the lecturer challenges students to be engaged in mathematical exploration and to relate and represent mathematical ideas – both important processes of mathematical thinking and production.

Summing up, we could claim that this lecturer's teaching is characterized by the way he takes students into account showing sensitivity to their needs and by the way he tries to draw them into mathematical production offering mathematical challenge.

DISCUSSION

In this paper, we studied the teaching practice of a lecturer teaching large cohorts of students and we identified characteristics of his teaching which we interpreted in terms of sensitivity to students, mathematical challenge and management of students' learning. In particular, this specific lecturer supported students to participate in the processes of advanced mathematical thinking and production bringing experiences from his research activity into his teaching.

In terms of the Teaching Triad, we see that in this case, mathematical challenge at the university level is directly related with the mathematical production. This is a different dimension of mathematical challenge than the ones may be found in secondary level and we believe that it is worth to explore what other dimensions mathematical challenge could receive at this level. We also see that in spite of the lecture format, this lecturer's teaching is characterized by his sensitivity to students since he builds on their ideas to support their engagement in the learning process. This is far from obvious in lecturing large group of students.

We tried to shed light on what takes place during the dominant instructional activity of the lecture. Our results showed that the lecture is not a unified teaching paradigm. This lecturer's teaching practice contrasts with the practices thought of as usually adopted in Calculus lectures and offers evidence that teaching can exist in a lecture format that is sensitive to the students and resembles mathematical production.

Collegiate teachers seem to work in different ways in their classrooms under the instructional context of a lecture. For this reason, as Speer and colleagues (2010) state their practice and reasoning is worthy of study because it can help others (teachers and researchers) understand how and why teaching happens in certain ways.

Obviously, many lectures at the university level are still taught in a transmissive way in the sense that the lecturer conveys information and the students listen and passively take notes. However, this study provides evidence that there are alternative ways for teaching in the instructional context of the lecture and might be used as a lecturers' self-awareness springboard towards improving teaching.

Students' concept images of inverse functions

Sinéad Breen[1], Niclas Larson[3], Ann O'Shea[2] and Kerstin Pettersson[3]

1 St Patrick's College, Drumcondra, Ireland

2 National University of Ireland Maynooth, Maynooth, Ireland

3 Stockholm University, Stockholm, Sweden, kerstin.pettersson@mnd.su.se

We analyse data from two studies in Ireland and Sweden relating to the concept of inverse function. In particular, we consider components of the participants' evoked concept images of this topic when answering open questionnaire questions. The results show that the students' concept images contain algebraic, geometric and more formal components: both Irish and Swedish students describe inverse functions as swapping x and y, as a reflection or a reversal. How various components may or may not enrich students' conceptual understanding of inverse functions is discussed.

Keywords: Inverse function, concept image, university mathematics education.

INTRODUCTION

In this paper, we aim to identify elements of undergraduate students' concept images of inverse functions. The concept of inverse function is usually covered in introductory calculus courses either at school or at university, with a well-developed conception of 'function' necessary for understanding 'inverse function' and deciding when an inverse function exists. However, as Pettersson, Stadler and Tambour (2013) argue, the function concept is a troublesome one for students and Carlson, Oehrtman and Engelke (2010) point out that students who are unable to conceive of a function as a process (rather than taking an 'action' view) have difficulties inverting functions. The concepts of function and inverses are essential for representing and interpreting the changing nature of a wide array of situations (Carlson & Oehrtman, 2005) and to describe the relationships between logarithms and exponentials for example. In this study, to enrich and broaden the data, we considered data from two projects in two countries (Ireland and Sweden). Both projects were focussed on the development of conceptual understanding of the function concept, and both involved collecting data from first year undergraduate students. The two studies included questions on the inverse function concept and we will present an analysis of these data here.

Despite the volume of research into the concept of function (e.g., Breidenbach, Dubinsky, Hawks, & Nichols, 1992), there does not seem to have been much work which concentrates on the topic of inverse function alone. One such paper is that of Even (1992) where prospective secondary mathematics teachers' knowledge and understanding of inverse function were investigated. In an open-ended questionnaire the participants were asked to find**.** Both the function () and the inverse were given. The answer is straightforward if one uses the idea of an inverse as undoing. However, the results showed that several students did not draw on their conceptual knowledge of the inverse property of undoing and instead used a chain of calculations to get the answer. This tendency to calculate instead of using the conceptual meaning of inverse function may be related to weak conceptual knowledge. However, Even (1992, p. 561) concluded that "a solid understanding of the concept of inverse function cannot be limited to an immature conceptual understanding of 'undoing'", which she claimed may result in incorrect conclusions, e.g. that all functions have inverses.

The conception of undoing is not the only way to look upon inverse functions. Vidakovic (1996) also placed importance both on composing the function and the inverse to get the identity, and on the action of swapping variables. Carlson and Oehrtman (2005) categorise three different conceptions of inverse function: inverse as algebra (swap x and y and solve for y), inverse as geometry (the reflection in the line $y = x$) and inverse as a reversal process (the process of 'undoing'). Carlson and colleagues (2010) showed that students who conceived of inverses as reverse processes were able to answer a wide variety of questions about inverses.

The algebraic and geometric views are considered in a paper from Wilson, Adamson, Cox and O'Bryan (2011). They argue that the common procedure of swapping x and y to find the inverse is confusing for students and can lead to the meaning of the result being obscured, especially for contextual or real-world problems. They contend that both swapping the variables and drawing the graph as a reflection in the line $y = x$ do not take into account the important aspect of the domain of the inverse function being the range of the function and vice versa. In particular this causes problems when the dependent and the independent variable of the function are in different units. Wilson and colleagues (2011) instead proposed the approach of solving for the dependent variable, rather than literally swapping x and y, to reduce confusion and enhance students' conceptual understanding of inverse functions. Attorps, Björk, Radic and Viirman (2013) commented on the geometric view, using GeoGebra to teach inverse functions. The results of their study indicated that several students showed an intuitive conception of inverse functions as some kind of reflection, but lacked the full comprehension of why and where the reflection should be performed.

Bayazit and Gray (2004) reported on teaching inverse functions to Turkish high school students and they observed that the students who showed a conceptual understanding of the inverse function put particular emphasis on the '1–1 and onto' conditions. They suggested that teaching should link the inverse function more explicitly to the concept of '1–1 and onto' as well as to the concept of function itself.

ANALYTICAL FRAMEWORK AND RESEARCH QUESTION

One way of studying students' conceptions is to use the theory of *concept image* (Tall & Vinner, 1981). This theory has, for a number of decades, proved to be a useful tool in analysing undergraduate students' conceptions of mathematical concepts (e.g., Bingolbali & Monaghan, 2008; Wawro, Sweeney, & Rabin, 2011). A concept image is defined to be the cognitive structure associated to a concept and includes the individual's interpretations of characteristics and processes that the individual connects to the concept. It also includes examples, intuitive ideas, mental images and, if known, formal definitions and theorems. The cognitive structure is built up successively through the individual's meetings with the concept. When meeting tasks involving the concept different parts of the concept image can be activated; the part activated at a particular time is called the *evoked concept image*.

In this study we are looking for components in the students' evoked concept images. Our research question is: What characteristic elements can be found in the evoked concept image of inverse functions of first-year university students?

METHODOLOGY

The Irish study

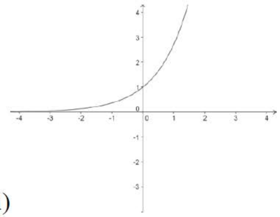
The data from Ireland involved students' responses to one of twelve questions on a concept inventory instrument designed to investigate undergraduate students' understanding of the concept of function (the full instrument can be found at http://staff.spd.dcu.ie/breens/documents/ConceptInventoryforFunction.pdf). First year Humanities, Education, and Finance students taking calculus modules (taught by the first and third authors) in two Irish universities were asked to voluntarily complete the inventory at the end of their module. 100 students took the test, 65 of whom answered at least part of Question I (see Figure 1).

The second level syllabus followed by these students mentioned inverse functions solely in the context of inverse trigonometric functions and the textbooks did not contain formal definitions or geometric representations of inverses. Inverse functions were initially discussed in both university modules (recall these were taught by the first and third authors) as reverse processes, and the role of bijectivity in determining whether an inverse exists was identified. A formal definition of inverse (for all x in the domain of f and all y in the range of f) was presented, and means of adjusting the domain or codomain of a function to make it bijective and thus invertible was discussed. The graphs of a function and its inverse as mirror images of each other in the line $y = x$ were explored, while the algebraic method of finding an inverse was acknowledged when presented by students.

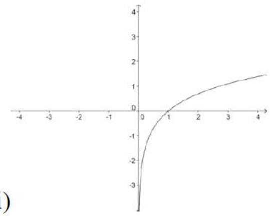
The Swedish study

The Swedish data were collected as part of a project aiming to explore students' development of their un-

I. (a) Look at the graphs (i) and (ii) below. The claim is that graph (ii) represents a function which is the inverse of the function represented by graph (i). Explain what this means and state whether you think the claim is true.



(i)



(ii)

(b) Look at the graph (iii) given below and draw, on the same axes, a graph to represent its inverse if you think there is an inverse. Explain clearly why you think there is an inverse or not an inverse.

derstanding of a threshold concept (Pettersson et al., 2013). A study group, in total 18 prospective secondary teachers who were enrolled in courses in mathematics, was observed during their second semester of teacher education. In the second level syllabus in Sweden inverses are not explicitly included although they might be mentioned. At university these students were introduced to inverse functions in the course 'Vectors and Functions'. Because of lecture observations we know that the inverse function was defined by . Both algebraic and geometric aspects were mentioned and also that the function needs to be 1–1 for an inverse to exist. In a subsequent calculus course inverse trigonometric functions were included and the need to restrict the domain of the function to ensure it is 1–1 was discussed.

The Swedish students participated voluntarily in three questionnaires relating to their understanding of the concept of function (Pettersson et al., 2013). For the present paper, focussing on the concept of inverse function, the answers on three of the questionnaire tasks were analysed (see Figure 2). In a questionnaire at the end of the course on vectors and functions, the students were given the question S1. In the questionnaire given at the end of the semester, not far from the end of the calculus course, the students were asked two questions on inverse functions, S2 and S3.

S1: Make a mind-map or a concept map with the word inverse function as starting point. Bring in other words/concepts that you can associate with inverse function. Please also indicate how you think that the words/concepts are interrelated.

S2: What is required for a function to have an inverse?

S3: In the picture (see below) you see two graphs of two different functions. What can you, based on the picture, tell about these functions?

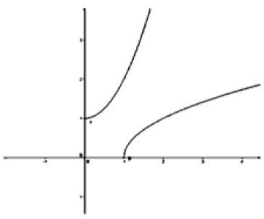

Figure 2: The questions in the Swedish study (S1, S2 and S3)

Coding

In each country the students' responses were coded using a grounded theory approach: that is the students' responses were read multiple times, codes were assigned, and these codes were then grouped into categories. At the coding stage, the responses to the tasks above were initially coded by one of the researchers, and then checked by another before the agreed codes were grouped into categories. The two sets of categories which emerged were then compared to check for consistency.

RESULTS

Results from the Irish study

We first considered the students' answers to I(a) above, i.e. the students' explanations as to what it means to say one function is the inverse of another. Only 4 students explained the concept correctly, 50 students gave an explanation which contained errors or was incomplete, while 11 answered true or false with no explanation. An example of a correct answer was:

> Let be the function in (i). Let be the function in (ii). The claim states that . It claims that is a reflection of through the line $y = x$. I agree with the claim. (Cathy)

The categories of components that arise in the evoked concept images of inverse function are shown in Table 1. Note that some students are counted more than once here if their answer referred to two or more of the concept image components identified. For example one student's answer was coded using 'opposite' and 'reflection' and so now appears under both 'Opposite' and 'Reflection' in Table 1.

We can see that the most frequent conception is 'reflection'. This category also includes responses from students who used the term 'mirror'. Its close associates of 'opposite' and 'symmetry' are also frequent. Seeing the inverse as a reverse process is common, while only 5 students gave anything resembling a concept definition of an inverse in answer to this question. There were 13 responses categorised in the 'other' category, these include: 6 responses which refer to a feature of the given graphs, 2 responses which mention 'folding', 1 response for 'domain and range interchanged', and 1 'example'. The remaining responses in the 'other' category are not mathematically relevant. We have included both correct and incorrect notions within each component of the concept image in Table 1; for instance, although 33 students used 'reflection' or 'symmetry' in their explanations, only 9 students correctly described the line of reflection or symmetry as the line $y = x$. Two referred specifically to reflection in the origin and 3 to reflection in the x-axis, while a further 6 spoke of a reflection without being specific. Students used 'opposite' when describing their concept image of an inverse in different ways: 6 of them used the word in a way that suggested reflection, and 3 mentioned graphs; 7 talked about functions being the opposite of each other; 2 spoke about opposite values. Some examples of responses in different categories are given in Table 2 below.

When asked if the claim given in I(a) was true, 41 of the 58 students who answered this question were able

Conception	Reflection	Opposite	Reverse	Symmetry	Definition	$1/f$	Swap x and y	Other
Total	27	17	10	6	5	3	1	13

Table 1: Conceptions emerging in response to I(a)

Conception	**Sample explanations given by students**
Reflection	Inverse is a reflection of the function. The inverse is that function mirrored through the line $y = x$.
Opposite	Inverse means they are exact opposites of each other, they cancel each other out.
Reverse	It is the function in reverse.
Symmetry	The inverse of a function is the function given through symmetry in the line $y = x$.
Swap x and y	When the x and y coordinates swap, e.g. here the point (1, 2) becomes (2, 1).

Table 2: Sample responses from Irish students

to correctly identify that the graphs shown did indeed represent inverse functions.

In response to I(b), 47 students attempted to draw an inverse function. 45 of these students sketched a reflection of some sort; Table 3 shows the distribution of these attempts.

Task I(b) was answered correctly by 11 students, that is, they were able to say that the function did not have an inverse and were able to give a reason for their answer. These reasons were: fails the horizontal line test (6), not 1–1 (6), inverse would not be a function (1) – illustrating a further component of the concept image held by these students. Note that two students said the function was not 1–1 and also illustrated using the horizontal line test which accounts for the numbers adding to 13. A further 4 students correctly stated that the function had no inverse but did not give a reason. Two students said that the function did not have an inverse but did not give a complete explanation, for example one of them said that "it is not just a line/angled line". The students who said that the function did have an inverse gave a variety of explanations for their answer: for instance, one said that every function has an inverse, while another said that the function was "defined for its whole domain". We saw that the conception of inverse function as a reflection in the line $y = x$ could be misleading with four students making remarks such as "There is an inverse as possible to draw line $y = x$ and reflex (sic!) images".

Students who gave correct and complete answers on I(b) offered a variety of answers to I(a) illustrating a variety of elements of concept images associated to inverse functions. These were: definition (2), reflection (3), reverse (1), opposite (2), no answer (3).

Results from the Swedish study

In the analysis of the survey, we first categorised the components of the evoked concept images that were exposed in the answers to task S1 (11 answers) and S3 (12 answers), see Table 4. The categories included also incorrect answers. Answers that contained more than one component were counted into more than one category.

To illustrate the components that arise in the students' concept images of inverse function we have picked answers from three frequent categories. In the category 'reflection' a correct answer to S3 was given by Anna: "They [and] are each other's reflections in the line ." Another student, Peter, gave through the mind map in S1 an explanation which is partly correct: "Reflection of a function in a line gives us an inverse function." Like several students Peter omitted the line in which the reflection takes place. Helena wrote correctly: "A kind of reflection of the function. Sometimes the reflection is not a function and then there is no inverse. [...] The reflection is performed in " But Helena also wrote: "A function can also be reflected in other ways, e.g. in or in the x-axis." That is of course true if you just talk about the graph, but it is irrelevant for inverse functions. Helena was the only student mentioning reflections in lines other than

The following excerpt from Anna, exposes a component of concept image categorised as 'example': " and is an example of inverse functions." Anna also drew a graph of the two functions and the line . Furthermore, Anna suggested that has no inverse. Other students also mentioned these functions and some students commented that if we restrict to , then the inverse exists. Answers which can be seen as exposing a component of concept image categorised as 'swap x and y' were given by e.g. Anna and Bob, who wrote more or less the same phrase "change places for x and y".

Type of reflection	In (0, 0)	In x-axis	In y-axis	In $y = x$	In $y = -x$	In $y = 2$
Total	22	13	3	3	1	3

Table 3: Answers to I(b)

Conception	Reflection	Example	Reverse	Graphical features	Swap x and y	Opposite	Definition	Other
Total	16	10	6	5	4	2	1	3

Table 4: Conceptions emerging in response to S1 and S3

Helena gave a more detailed version: "To get the inverse to , we switch x and y ."

The students often gave answers with several parts and each part was connected to one of the categories. To give an idea of a complete answer we present the answer from Frida, who gave a comprehensive explanation:

> The property for can be transformed into , e.g. ; . To 'raise' has the inverse process 'cube root'. is a reflection of in the line . when (inverse processes). There is a mapping of x such that the obtained value gives the original value, ; .

The analysis of task S2 (10 answers) was done with the same procedure as the other tasks. The categories of components of concept image evoked were: 1–1 (6 answers), continuous (3), reverse (2) and graphical features (1). For example, Dora stated "the function needs to be able to run backwards" (categorised as 'reverse') and continued with the following description, which was categorised as '1–1':

> A 'regular' function needs only to satisfy the requirement that each x is mapped to one y. But several x can have images at the same y. To have an inverse function it must additionally meet the requirement that each y can be traced back to only one initial x.
>
> Like most students Dora did not use any mathematical word for injectivity but our interpretation is that she understood that the function must be 1–1 and had grasped the difference between the definition of a function and of an injective function.

DISCUSSION

The data presented here come from studies in two different educational systems and as such are quite rich. The tasks given in the two studies touched on the same content but differed in several ways. In spite of that, the answers revealed similar components of the concept images evoked; in particular, the notions of reflection, reversal and injectivity were found to be important. We saw that students' concept images contain algebraic, geometric, as well as more formal components. However, very few students in either study gave a comprehensive explanation (similar to Frida's above) or attempted a formal definition of an inverse function (such as Cathy as seen previously) in response to the tasks assigned.

The intuitive conception about inverse functions as reflections noted by Attorps and colleagues (2013) emerged also in this study: 33 of 58 Irish students who stated if the claim in I(a) is true or not mentioned reflection or symmetry, and 16 instances of reflection were observed in the Swedish students' answers for task S1 and S3. In keeping with Attorps and colleagues' findings, many of the Irish participants also failed to correctly describe the reflection with only 9 students identifying it as being in the line $y = x$. It could be argued that the nature of the Irish question and, in particular, the graphs shown, prompted a reflection conception of inverses. However, it is surprising then that many students inaccurately commented on reflection in the x- or y-axis. The Swedish students showed a clearer understanding on this point and the students who mentioned a line of reflection correctly gave the line $y = x$.

None of the Irish students mentioned the necessity of 1–1 or onto properties of a function when explaining what an inverse is. But in answering task I(b), 10 of the 11 students who answered correctly were able to identify the lack of injectivity of the function (articulated as 'not 1–1' or 'fails the horizontal line test') as a reason for an inverse not to exist. However, only 2 of these 11 students had given correct and complete answers to I(a), while 6 of the students gave answers to I(a) that contained errors or were incomplete and 3 failed to give any explanation. Thus, it does not seem reasonable to argue that the students who emphasised the 1–1 property in relation to inverses had a more robust concept image or a showed a greater conceptual understanding of inverses as Bayazit and Gray (2004) may have assumed. For the Swedish data, when asked specifically what is required for a function to have an inverse, 6 students explained the necessity of a function being 1–1. We found evidence that at least Dora, despite not using any mathematical words for injectivity, understood that the function must be 1–1 and had grasped the difference between the definition of a function and of an injective function. From our experience it seems that many students find this distinction difficult; it may be that study of the inverse function concept could be used to reinforce students' understanding of function itself.

We did not find evidence in the Irish data to support Even's (1992) claim that a naïve conception of inverse functions as 'undoing' may result in incorrect conclusions, such as that all functions have inverses. Only one student revealed this particular misconception and that student did not mention reverse processes at all. On the contrary, four of the students, whose conception of an inverse was as a reflection, believed that the ability to reflect the graph of a function in a certain way confirmed it was invertible. However, Dora who used the words "be able to run backwards" gave additional requirements for a function to have an inverse as mentioned above.

The studies have, despite different tasks given to the students, evoked similar components of students' concept images. The students in both studies were in the beginning of studying mathematics at university level. Breidenbach and colleagues (1992, p. 251) remark that progress in cognitive transitions "is rarely in a single direction", thus it is not surprising that the concept images that emerged are complicated, with many overlaps between categories and variations within categories. Indeed, Bingolbali and Monaghan (2008) found that students' concept images of derivatives evolved over the course of a semester and were influenced by both the lecturer and the students' area of primary study. Learning more about students' progress in developing their concept images could inform our teaching preparation and help us to provide greater opportunities for students to gain valuable insights into the concepts of function and inverse function. At the very least, being aware of the concept images that students may hold and their likely consequences could inform teaching; for example lecturers could refer to the definition at different stages during the course as a means to develop intuition (Wawro et al., 2011), and engineer cognitive conflicts in order to give students opportunities to refine their concept images and deepen their understanding.

Trustworthiness of information about students' competencies in fundamental concepts in calculus provided by written examination

Kristina Raen

University of Agder, Kristiansand, Norway, kristina.raen@uia.no

The research reported in this paper aims to explore how students' competencies in calculus are exposed when being assessed. Several different competencies are required to achieve proficiency in mathematics. However, one problem is when the main focus of the student lies within procedural fluency because this is what pays off in the final examination. In this paper, written examination and task-based interview are used to find information about one student's competence in using formulae, fluency in written procedures, and strategies used for solving tasks. It is argued that the information about the student's competencies seen through a task-based interview is different from information gained after analysing the written final examination.

Keywords: Assessment, mathematical proficiency, higher education.

INTRODUCTION

The purpose of this paper is to provide a report from an on-going study that explores how students' competencies in calculus are exposed in a setting of assessment. The study is set in the context of a mathematics course taught as part of the first year of an engineering degree programme. Advanced engineering students are required to have knowledge of basic calculus in order to focus on their subject while using mathematics as a tool. Students in higher education tend to learn what is needed to get a good grade in the final examination, what the teacher focuses on in the lectures has less impact (Entwistle & Entwistle, 1992). Because of this, what is being measured in the examination should be of great concern, and effort should be taken in striving to measure the competence that students are required to develop.

At the University of Agder, one calculus course is compulsory for all engineering students in their first semester. This course is offered each autumn semester and has a large number of students, with around 400 to 500 students enrolled every year. This course comprises six hours of lectures and two hours with task based sessions in smaller groups each week. The assessment in this course consists of four compulsory assignments, voluntary home-work-tests every week, and the final examination. All external resources except communication are allowed because this is what is closest to what the students meet in real life, so this is an open book examination. Three of the compulsory assignments have to be approved before the students can take the final examination. The compulsory assignments and the home-work-tests are conducted using a software package called MyMathLab Global (MyMathLab, 2014) which comes with the textbook (Adams & Essex, 2010) used in the course. The students claims that they like to use MyMathlab because they get immediate feedback whether their answer was correct or not (Brekke & Hogstad, 2010).

This paper reports on the learning of one student, here named John. I explore his competencies as exposed through a task based interview and the final examination. The research question guiding my research is: What information about students' competencies in calculus is available through assessment?

REVIEW OF LITERATURE

Kilpatrick, Swafford and Findell (2001) argue that there are five strands of competence that are needed to achieve mathematical proficiency. They are interwoven and interdependent, and these skills should be a goal for the teacher when teaching in mathematics. The strands are:

conceptual understanding – comprehension of mathematical concepts, operations, and relations

procedural fluency – skill in carrying out procedures flexibly, accurately, efficiently, and appropriately

strategic competence – ability to formulate, represent, and solve mathematical problems

adaptive reasoning – capacity for logical thought, reflection, explanation, and justification

productive disposition – habitual inclination to see mathematics as sensible, useful, and worthwhile, coupled with a belief in diligence and one's own efficacy (Kilpatrick et al., 2001, p. 116)

The authors focus on children from kindergarten to eighth grade, however, I find these strands useful when it comes to being proficient in mathematics in higher education as well.

For Kilpatrick and colleagues (2001), every strand is an important competence that is necessary in achieving proficiency in mathematics. However, one problem is when the main focus of a student lies within procedural fluency because this is what pays off in the final examination. "This suggests a tension in the student's mind between learning the subject and passing the examination, with rather different strategies being involved for each" (Entwistle & Entwistle, 1992, p. 2). Brown, Bull and Pendlebury (2013) observe that the assessment defines what students regard as important. The response to this has to be that the examination measures what the student needs to know to be proficient in mathematics.

I adopt the definition of assessment used by Niss (1992): "Assessment in mathematics education is taken to concern the judging of the mathematical capability, performance, and achievement…" (p. 3). Moore and Carlson (2012) used what they called structured task-based interviews to gain insight into undergraduate pre-calculus students' difficulties experienced while attempting to solve novel applied problems in functions and graphs. In my PhD-project I explored the mathematical capability, performance and achievement of twelve students through such an interview.

METHODOLOGY AND ANALYSIS

Research design and methodology

In 2013, about 400 students participated in the calculus course for engineering students at the University of Agder. Their final examination followed a traditional form of open book examination, and was carried out at the end of the semester in December. John, who is the informant for this paper, is part of a larger study of twelve students that volunteered for the research after receiving an e-mail from the lecturer. The students were interviewed in January, as soon as possible after the examination so that their competence about these subjects would be as close as possible to their competence at the time of the examination. I did not interview them before the examination to avoid affecting their performance in the examination. Even though the students did not prepare for this interview the same way they did for the examination, I will argue that their skills were about the same. Since the communication went back and forth in the interview, I doubt quite strongly that the students knew things on the examination that he or she did not remember after some discussion in the interview. During the interview, I asked for their approval to gain access to their examination papers. The aim of this study is to make a judgment about the competence shown through the formal examination and compare this with the competence I can expose during a structured, task-based interview.

In order to explore the student's competence in calculus I used interviews which followed the methodology described by Goldin's principles of structured, task-based interviews (2000). The students were asked to think aloud when solving a mathematical task, in addition to writing. When they came no further, guiding questions were asked that would lead them into the path they needed to solve it.

Analysis

The interviews were audio recorded, and in the analysing process I have the access to the paper on which the students wrote during the interview and the papers the students handed in at the final examination. I follow Clement's (2000) methodology of analysing clinical interviews and my study is a Grounded Model Construction study. This means I have an interpretive analysis and that there are no predetermined categories into which the data will be coded.

At the end of the analysing process, the focus was about finding the mathematical competence of the student. This was also the case when analysing the written examination. As I now have two different representations of the student's competence, the discussion will be about comparing the two.

FINDINGS

This paper sets out to demonstrate that there is information about students' mathematical competence in the examination papers. To demonstrate the trustworthiness of this information I compare it to the information gained through the interview. In this paper, I will view this by focusing on three factors. The first two are about what the student can do and the last focuses on how he does it. This is only a small part of what is seen; nevertheless, I believe that the features of these factors provide a good indication of the differences of the two ways of evaluating the student. In Table 1 below I will sum up my main findings of what competencies that are exposed through the examination and through the interview, and in the following sections, I will report using excerpts of my data and some analytical arguments for my interpretation.

In the final examination I will use two part tasks, one in which John is asked to evaluate an indefinite integral, the other to solve a definite double integral, to discuss the competence revealed. These tasks are shown in Figure 1. The examination consists of four tasks with subtasks to be solved in five hours. If the assumption is that the same amount of time should be spent on each subtask, the students should spend 40–45 minutes on these two tasks.

Competence in using formulae

In the final examination there are a lot of tasks where formulae are needed in order to solve them. In order to achieve a good result the students need to find the right formulae and they need to be able to use them. In the following examples, John uses the formulae for integration by parts and substitution.

According to what we can see in the final examination John displays knowledge as to which formula he should use where, as well as how to use it in a given task. Even though there are some calculation errors, throughout the examination he uses the correct formula and he replaces the variables in the formulae with the correct terms from the task. In the first task John makes clear which formula he uses as it is named; "integration by parts" and given in the form it is shown in the formula sheet with u and v. He does not show directly what he chooses for u and v, but by reading the first line after the framed formula it is evident that he does it correctly. There is not a framed formula in the second task, but here it is evident that he substitutes xy with u and then follows the rules for integration by substitution. This is done correctly, and he integrates and replaces u with xy again before inserting the limits. Even though the calculation is incorrect, these examples show that he finds the correct formulae and uses them correctly. From these tasks it is not possible to infer anything about whether he knows the formulae by heart, that he understands what they mean or how he works when choosing a formula.

In the interview I asked John to solve two tasks similar to the two discussed above; $\int(4x + 3)e^x \, dx$ and $\int_0^\pi \int_0^y 4y^2 \cos x \, dxdy$, similar to $\int(x^2 - 5x)e^x \, dx$ and $\int_0^1 \int_0^{y^2} 3y^3 e^{xy} \, dxdy$, only one step simpler in both. At this first task he starts by saying there is a formula for

	Examination	Interview
Remembering, finding and using formulae	John can choose the correct formulae and use these when calculating, it is not possible to determine whether he knows the formulae or the rationale for choosing them.	John does not have immediate recall of the formulae, however he does know how to use them in the tasks he solves.
Fluency in written procedures	John is not fluent in procedural skills	John is not fluent in procedural skills
Showing strategies	It is not possible to know how John chooses the strategies he uses to solve a task	Some information is available about how John chooses the strategies that he wants to use when solving the task.

Table 1

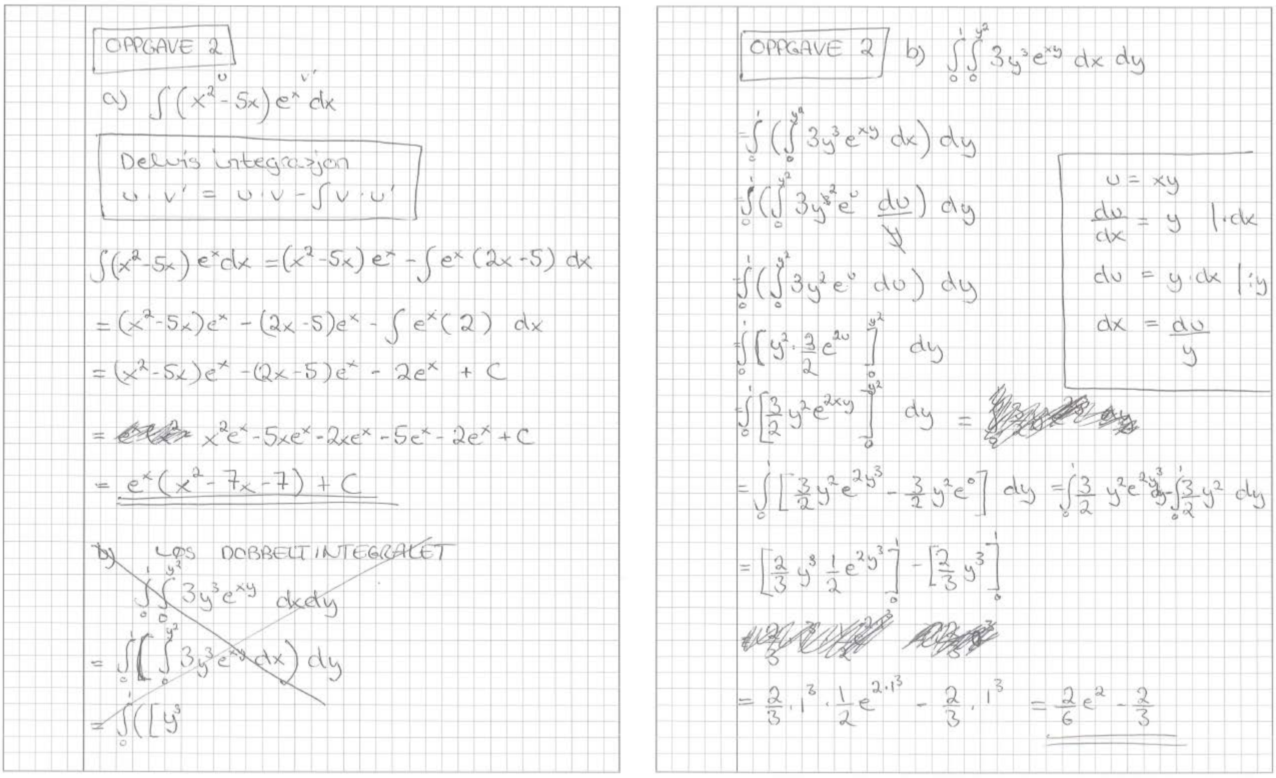

Figure 1

multiplication and division in integration and that he would attempt to use this. Below are two excerpts of the transcript from the interview where "I" is the interviewer (author) and "J" is the student. I ask how that formula looks, and his answer suggests that he is quite dependent upon the formula sheet, however, it seems that this formula is quite well known as it is almost correct.

> J: Yes, how does it look, it says in the formula sheet ... But I guess it is something like u dash v minus integral of v dash u, I think, without being able to remember it right now, I have not put too much effort into remembering any formulae, because everything is written somewhere.

This formula is almost identical to the correct formula, and I write that down. This was the formula he used himself in the examination. About picking u and v he says:

> J: And then the crucial thing is to pick more or less appropriate what should be u and v here. Because e to the power of x is the same whether you differentiate or integrate it, I would pick u as this, four x plus three, and this as v (points at e to the power of x)...

The first excerpt of the transcript is an example that shows that he does not know all the formulae by heart. Still, the fact that he says that he did not put too much effort into remembering the formula suggests that he trusts his competence to find the right one in his formula sheet when needing it, and use it correctly. In this interview I did not have the formula sheet available so I do not know how John works when finding a formula and thus how well he does it. The second excerpt shows how he substituted the letters in the formulae by the terms in the task and how he wanted to choose which factor fitted where, so by this I conclude that he knows how to use the formulae in tasks.

Procedural fluency

Procedural fluency is used as defined in the report from Mathematics Learning Study Comity, edited by Kilpatrick, Swafford and Findell; "Procedural fluency refers to knowledge of procedures, knowledge of when and how to use them appropriately, and skill in performing them flexibly, accurately, and efficiently" (2001, p. 121). To investigate procedural fluency showed in the examination, I will regard the same tasks as above. See Figure 1 for John's answers. In the first task there are two tables of errors and his answer is slightly different from what it should be, however, other parts of the examination shows correct sign after dissolving the parentheses.

The second task shows the solution of a double integral. John tries to do the inner integral by substitution even if he did not need to. Although the integration is done correctly in the first task it is not done correctly now. The limits are correctly inserted but the outer integral is incorrect. Table 2 shows excerpts of the two tasks, what is correct and what John wrote.

This indicates that John has some fluency albeit at a fairly low level when it comes to integrating the exponential function and polynomials. Even though the

Task	Correct	John
$\int e^x(2)\,dx$	$2\,e^x$	$2\,e^x$
$\int 3y^2e^u\,du$	$3y^2e^u$	$y^2 \cdot \frac{3}{2}e^{2u}$
$\int \frac{3}{2}y^2e^{2y^3}\,dy$	$\frac{1}{4}e^{2y^3}$	$\frac{3}{2}y^3\frac{1}{2}y^{2y^3}$
$\int \frac{3}{2}y^2\,dy$	y^3	$\frac{2}{3}y^2$

Table 2

two upper tasks are the same, the latter looks more complicated and it is therefore not surprising that the mistake happens in this task.

John also displays lack of fluency with respect to integration of exponential functions in the interview. Somewhere in the process of solving the task $\int(4x + 3)e^x\,dx$ he must solve $\int 4e^x\,dx$, and this gives him trouble. He says that $\int 4e^x\,dx = 4xe^x + C$:

> J: And then we can put the number four outside I think, and... no, we cannot... e to the power of becomes the same no matter how you twist and turn it, yes, it becomes four *x* e to the power of *x* then, if you integrate this, four *x* plus three minus four *x* e to the power of *x* plus C is what you get...

Here is evidence that he is unsure of the path he is allowed to take because he has to consider what to do about the number in front of e^x. After a couple of pauses he draws the wrong conclusion and ends up with a wrong answer. Nevertheless, he shows some degree of fluency because he considers the correct approach immediately, and when he realises that what he got was incorrect after a bit of prompting, the correct calculation was the only alternative left for him.

> I What would you do to check whether this is correct or not?
>
> J: Eh... differentiate it again, could you do... this is maybe not exactly right
>
> (...)
>
> J: Yes, because you only put the number four outside then?

John choosing strategies

When calculating a mathematical task, there is a need for choosing a strategy. In the final examination the students are asked to write all the calculations, and this is what provides the information as to which strategy the student might have chosen. If the sheet that the student hands in contains a crossed out section, this could indicate uncertainty in solving the task and if it is possible to read what was written before being crossed out, it might indicate which strategy was considered for solving the current task. Therefore, at best, the information available about which strategy has been used and possibly which have been considered lies in the paper, but there is nothing that indicates what influenced the student to choose that strategy or the thinking process.

In the interview the tasks were intended to facilitate John's explanation of what he normally did. In addition, my request to think aloud resulted in a certain insight into John's procedures when starting to solve a task. I have already argued that the student's competence is fairly close in the setting of the examination and the setting of the interview, and I will further argue that it is sufficiently close to say that more insight into the students' proficiency in one of the settings will tell me what is not being communicated through the other. Now returning to the task about the unlimited integral, the information made clear from John's strategy choice is from what he communicates to me when attempting to explain his thought process. He starts by saying that he wants to find a formula that suits the task.

> J: ... I would use some kind of formula for... you have this multiplication formula (...) I would try to use that... and see where I ended up

From the sections about competence in using formulae, the transcript excerpt indicates that he wants to look in the formula sheet to see if he can find a suitable formula. After examining the formula, he then proceeds to pick the appropriate *u* and *v* to fill into the formula. When looking at the transcript excerpts from the section of procedural fluency it is for instance evident that he is uncertain about which integration strategy to choose. The two alternatives he names are rules of integration which also could be located in the formula sheet. He is worried about what he is allowed to do and appears to focus on recalling it because he is not stating a reasoned cause for choosing one of them, nor does he spend time thinking it through. After realising his mistake, he asks whether the other alternative was the correct one and is satisfied with a yes or no. The information about how John chooses a formula and wants to "see where I ended up", and the fact that he expresses his uncertainty when using an integration rule yet still not explaining how he chose which rule to go for prompts my assertion that this interviewing method provides some information as to how the student chooses solving strategies.

DISCUSSION

When discussing the information about students' competence in calculus I will compare the findings from the interview and the examination. The strands needed for proficiency in mathematics are conceptual understanding, procedural fluency, strategic competence, adaptive reasoning and productive disposition (Kilpatrick et al., 2001). When taking into consideration that procedural fluency can be "in addition to written procedures, mental methods for finding certain sums, differences, products, or quotients, as well as methods that use calculators, computers, or manipulative materials such as blocks, counters, or beads" (Kilpatrick et al., 2001, p. 121), I claim that finding the correct formula and using it correctly comes into this category. The final examination shows that John has procedural fluency in formulae within this mathematical concept and I see evidence of this being the case also from the interview. He does explain to me where he would look to find the formula and he shows me that he knows how to substitute the variables in the formulae by the terms in the expression. However, this is all that is being tested in this examination. In the setting of the interview it is also revealed that John has not committed all the formulae to memory. He admits that this is not something he prioritises, which is understandable since the examination is an open book examination. There is also information about which strategies he is using when working with formulae, which I intend to review below. The questions could have been changed to gain more information around this in both ways of evaluating the student but the information provided is based on the questions posed at the time.

I concluded that there was some, albeit fairly low, written procedural fluency. My experience was that approximately the same information about the student's overall fluency was gained from the two methods of evaluating the student. The crucial step for both the methods is to provide sufficient tasks in order to establish what the students *can* do, what they *cannot* do, and what they *sometimes can* do. Yet, there is a small advantage for the interviewing method in information about what parts of the calculation are the most difficult. During the interview I could see at what steps John used the longest time, and statements he made gave information about what parts he is confident of. One problem is however presented. In the interview it seems that he is quite certain about the integration of e^x. It is the part where this is multiplied with a constant that causes trouble. In the examination it seems that he does not recall what he later states in the interview and he mixes the rule for integrating e^x with the rule for integrating x^a, at least once. I see two possible reasons for this. The first is that John actually learned this after the examination. My other possible reason is that a researcher always has to bear in mind that a student can have a "bad day" when testing him only once and that this could be a subject for the consideration of data reliability.

The last aspect explored in this paper concerns the use of strategies. From Kilpatrick and colleagues' mathematical proficiency (Kilpatrick et al., 2001) I argue that this goes into strategic competence, and then mainly about representing a problem. That part is about representing the task accurately and mathematically, and in order to do so the student should have some degree of understanding of the problem. However, I also argue that a part of this belongs to the part of procedural fluency which is about methods for finding certain sums, differences, and so on, as well as methods that use calculators, computers, or manipulative materials. This applies for instance when the student searches a formula or wishes to use a formula, expressing that he has to see where it takes him. There is very little information about this in the examination. Sometimes we see which strategy John did choose, but quite often the only way to know which strategies a student chooses is to rely on common mistakes and misconceptions revealed in previous research and compare this with what the student answered. In the interview, when John was thinking aloud, it was quite often obvious which strategy he was using, which he was considering and which he was confident about. Still, if I wanted to know why he was choosing a strategy or what else he considered I would have to ask more questions.

CONCLUSION

By evaluating students in different ways, there is different information to extract about students' competencies in fundamental concepts in calculus. In order to gain mathematical proficiency there is a need for the five competence strands; conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, and productive disposition. Of the few issues addressed in this paper, the traditional open book examination that this course uses is quite good in testing written procedural fluency of the concepts on which there is preferably more than one task of different difficulty. The interviewing method which was used provided information as to how John's confidence was displayed in the different written procedures, how fluent he was in procedural methods, and which strategies he used when solving tasks. It turned out to be the discussions, after a student got stuck on a task that really revealed a lot about these last factors.

Extreme Apprenticeship – Emphasising conceptual understanding in undergraduate mathematics

Johanna Rämö, Lotta Oinonen and Thomas Vikberg

University of Helsinki, Helsinki, Finland, johanna.ramo@helsinki.fi

Extreme Apprenticeship (XA) is an educational method that has been used in teaching undergraduate mathematics in the University of Helsinki. In this paper, we analyse the course assignments and exam questions of a certain lecture course that has recently been reformed to an XA-based course. The results show that the XA method has made it possible to move the emphasis from rote learning towards understanding the concepts behind the procedures.

Keywords: University mathematics education, Extreme Apprenticeship, conceptual knowledge, tasks, large classes.

INTRODUCTION

The pedagogical decisions in introductory mathematics courses at university-level are of great importance. On these courses the students form their first perceptions of what university mathematics is about, and most importantly, what studying mathematics in university will be like. Traditionally, the first year courses have concentrated on memorising procedures and algorithms. The procedure-centred approach can lead to problems since procedures that lack connections with conceptual knowledge may deteriorate quickly and do not transfer easily to new situations (Hiebert & Lefevre, 1986).

Over the past years many student-centred approaches have been used in mathematics teaching for facilitating conceptual understanding (Abdulwahed, Jaworski, & Crawford, 2012). These approaches include Inquiry-based learning (IBL) and Problem-based learning (PBL), in which learning revolves around real life based problems and questions that require critical thinking (Chang, 2011; Mokhtar, Tarmizi, Ayub, & Tarmizi, 2010; Retsek, 2013). Both IBL and PBL emphasise collaborative work, presentation of conclusions and development of learning skills. Another innovative and widely used approach in mathematics teaching is Flipped classroom or Inverted classroom (Jungić, Kaur, Mulholland, & Xin, 2014; Talbert, 2014). In this approach students familiarize themselves with the new information through online video resources outside of class, and class time is reserved for discussions and cooperative problem solving. Peer instruction (Lucas, 2009) and Just-in-Time Teaching (Natarajan & Bennett, 2014) are further examples of interactive teaching methods that allow teacher to adjust teaching to the needs of students. These can be used separately or with the Flipped classroom approach.

A new student-centred method for teaching large introductory courses, Extreme Apprenticeship (XA), has been adopted in the Department of Mathematics and Statistics in the University of Helsinki (Hautala, Romu, Rämö, & Vikberg, 2012; Vihavainen, Paksula, & Luukkainen, 2011). The XA method has similarities with the approaches mentioned above, as it promotes active engagement of the students and preparation prior to the class. However, the main idea of the XA method is to support students in becoming experts in their field by making them participate in meaningful activities, which resemble those carried out by professionals. This means there are neither video lectures nor screencasts. Instead, students read the course material with the help of the teaching assistants. Another difference between XA and the other novel approaches is that in XA the main method of teaching is personal instruction: students have to do a lot of work outside of the classroom, but they are offered guidance in a drop-in basis several hours a day.

Previously it has been shown that students find the XA method satisfactory, and the passing rates do not drop even though the workload is significantly increased and the requirement level raised (Hautala et al., 2012). Also, the XA method has increased student engagement and effort (Rämö & Vikberg, 2014).

In this paper, we study whether the XA method has shifted the emphasis towards tasks that promote the development of conceptual knowledge and the linking of procedural and conceptual knowledge. This is done by comparing the assignments and exams used on an XA-based course to those used traditionally. The course under study is the first year course "Linear algebra and matrices I". While this paper focuses on the linear algebra course, the XA method has been used on many undergraduate mathematics courses, including algebra, logic and probability, and our experience leads us to believe that the conclusions drawn in this paper apply more generally than just in linear algebra.

We use the definitions of conceptual and procedural knowledge by Hiebert and Lefevre (1986): Conceptual knowledge is characterized as knowledge that is rich in relationships of many kinds, whereas procedural knowledge is made up of two distinct parts: the formal language of mathematics and the algorithms for completing mathematical tasks.

EXTREME APPRENTICESHIP

The Extreme Apprenticeship (XA) method is an educational model for organising instruction in an effective and scalable manner. Its theoretical background is in situated view on learning and Cognitive Apprenticeship (Brown, Collins, & Duguid, 1989). The method was originally invented as an instrument for teaching university-level computer programming (Vihavainen et al., 2011), and later employed in mathematics courses (Rämö & Vikberg, 2014).

In XA, the amount of tasks is substantially larger and the number of lectures smaller than traditionally. Students learn skills and gain knowledge by doing tasks that offer them small and approachable goals (Vihavainen et al., 2011). Passive activities, such as sitting in the lectures, are reduced to the minimum and active work done by the students is emphasised.

The main method of teaching in XA is personal instruction, which is based on the concepts of coaching and instructional scaffolding in Cognitive Apprenticeship (Collins, Brown, & Holum, 1991; Lave & Wenger, 1991). Instructional scaffolding refers to temporary support given to students (Wood, Bruner, & Ross, 1976), and is interlinked with the concept of zone of proximal development introduced by Vygotsky (1978). Coaching refers to the broader perspective of regulating pace and difficulty of assignments in the course. A necessity for coaching students' progress is bi-directional feedback between the students and the teaching team (Kurhila & Vihavainen, 2011). The teaching team receives feedback on the progress of the students by evaluating their solutions during the course, and also from the conversations with the students during personal instruction. Students receive feedback on how they are performing, but also encouragement and support in completing the assignments.

EDUCATIONAL SETTING

University studies in Finland resulting in a Master's degree are intended to last five years with three years of Bachelor's studies and two years of Master's studies. There are no tuition fees. The students are selected by their performance in the upper secondary school matriculation examination, an entrance exam, or both.

A traditional lecture course

On a traditional lecture course, there are 4–5 hours of lectures per week, in which the lecturer covers all the theory of the course. Every week the students are given problem sheets consisting of 6–7 tasks they have to solve. The solutions to the tasks are discussed under the guidance of a teaching assistant in a group session that lasts for two hours. In each group there are approximately 20–30 students, who usually take turns in explaining their solutions to the problems on a blackboard.

Extreme Apprenticeship based course

On an XA-based course, the amount of tasks is substantially larger than traditionally, approximately 15–20 problems per week. There are relatively easy problems on new topics, but also more challenging tasks regarding more familiar concepts studied in the previous weeks. The tasks are designed to support the development of conceptual knowledge, and to aid the students in building relationships between procedural and conceptual knowledge.

Students are offered guidance by the teaching team to complete the assignments in drop-in sessions, approximately 20 hours per week. This one-on-one or small group instruction forms the main part of teaching. The purpose of the instruction is to lead the student subtly towards the discovery of a solution through a process of questioning and listening, instead of simply giving away the answers.

One or two of the tasks are selected for inspection each week. Students receive written feedback on their reasoning and also on the readability and language of the solution, and they are encouraged to improve their solutions when necessary.

New kinds of learning spaces have been created to encourage student collaboration. The main corridor of the department has become a huge drop-in class where the tables are arranged into groups and act as whiteboards, and the walls are covered with blackboards for the students to share their thoughts with each other and with the instructors.

The amount of lectures is significantly smaller than on traditional lecture courses, only 2–3 hours per week. As the assignments force the students to investigate the topics by reading the course material prior to the lectures, it is not necessary to deliver content or go through details in the lectures. Instead, it is possible for example to discuss the meaning and consequences of definitions and to address student misconceptions through various small group activities.

Linear algebra and matrices I

The course investigated in this study is Linear algebra and matrices I. It is a first year course, and for most students it is the first mathematics course they take in the university. Approximately half of the students on the course have mathematics as a major, and the rest study mathematics as a minor subject. Among these students the most common majors are computer science, physics and economy. The amount of students taking the course has increased over the last few years. In 2008, there were 394 students enrolled for the course, whereas in 2013 the number was 484.

The content of the course has varied slightly from year to year, but the main topics have remained the same. They are systems of linear equations, matrices, spanning sets, linear independence, basis and coordinates. The course lasts for 6 weeks. The workload of the course is approximately one third of the total workload of the students.

In this paper, we investigate the years 2008–2013. Two different lecturers taught the course as a traditional lecture course during the years 2008–2010, one of them in 2008 and 2010 and the other in 2009. In 2011, the course was transformed to an XA-based course (Hautala et al., 2012). Improving the implementation of the XA method continued in 2012–2013 (Rämö & Vikberg, 2014). The teacher responsible for the XA-based courses was the first author of this paper.

METHOD

The aim of this study is to compare the assignments and exams used on an XA-based course to those used traditionally. This was done by classifying the tasks using the classification scheme by Pointon and Sangwin (2003), which was modified slightly to fit the purposes of this study.

The classification of Pointon and Sangwin consists of 8 categories shown in Table 1 (categories 1–8). When the tasks of this study were analysed, it became clear that one category, namely category 9, had to be added.

The classification was executed as in the paper of Pointon and Sangwin: Each question was evaluated individually, and given equal value. If a question had multiple parts, it was classified by estimating the proportion of each category. The evaluation was done by the second author.

1. Factual recall
2. Carry out a routine calculation or algorithm
3. Classify some mathematical object
4. Interpret situation or answer
5. Proof, show, justify (general argument)
6. Extend a concept
7. Construct example/instance
8. Criticize a fallacy
9. Information transfer

Table 1: The task classification scheme

The categories are described briefly here, and more detailed descriptions with examples can be found in the paper by Pointon and Sangwin (2003).

1) Factual recall: A question that requires only the recall of some factual knowledge, usually verbatim.

2) Carry out a routine calculation or algorithm: A question that requires routine use of algebra, calculus or matrix operations. Often such tasks may be performed by a computer algebra system.

3) Classify some mathematical object: Solving the task requires recalling a definition and providing justification to show that some specific object satisfies the definition.

4) Interpret situation or answer: The task requires modelling of a physical situation or interpretation of a mathematical model.

5) Proof, show, justify (general argument): A question that requires a general argument involving abstract or general objects rather than specific examples.

6) Extend a concept: Students are asked to evaluate previously acquired knowledge in a new situation.

7) Construct example/instance: Students are required to provide an object satisfying certain mathematical properties.

8) Criticize a fallacy: Students are asked to find mistakes in supposed proofs, or criticize reasoning.

9) Information transfer: A question that requires transformation of information from one form to another, as well as processing this information. This category was added by the authors of this paper. It is explained below in detail.

Category 9: Information transfer

Category 9 did not occur in the original classification scheme of Pointon and Sangwin that consists of categories 1–8. A category bearing the same name, information transfer, can be found in the MATH Taxonomy proposed by Smith and colleagues (1996). Our category resembles theirs, but is only a subset of it. Introducing a new category was necessary, as many of the tasks did not fit in any of the categories 1–8. Questions in category 9 require transformation of information from one form to another, as well as processing this information. Typically, in these questions students are asked to draw pictures, interpret diagrams, explain something in their own words or draw concept maps.

Examples of category 9:

— Denote $v_1 = (-3, 4)$, $v_2 = (1, 1)$ and $v_3 = (\frac{2}{3}, -2)$. Draw pictures of the subspaces $span(v_1)$, $span(v_1, v_2)$ and $span(v_1, v_3)$. You do not need to justify your answer.

— The vector space $\mathbb{R}^2$ has a basis $B = ((1, 1), (2, 3))$. Determine, by drawing a picture, a vector $u \in \mathbb{R}^2$ whose coordinates with respect B to are 3 and −2.

— Explain in your own words why an elementary matrix always has an inverse matrix.

RESULTS

Course assignments

The weekly course assignments were evaluated using the classification described in the previous section. Table 2 shows that in category 2 (routine calculation), the proportion of tasks has decreased. In 2008–2010, when the course was a traditional lecture course, 36–46% of the assignments were from category 2. In 2011, when the XA method was introduced, the proportion was still high (43%), but it dropped to 28% in 2013.

In category 9 (information transfer), the proportion of tasks has risen. In 2008–2010, 1–5% of the assignments were from this category, whereas in 2011–2013, the proportion was 15–18%.

Exam tasks

Also the exam tasks were analysed in order to find out how much weight each of the categories had in the final exam. The tasks were divided into the nine categories, and the maximum score of the tasks in each category was calculated. Table 3 shows the proportions of maximum scores in each category.

It can be seen that the weight of category 2 (routine calculation) decreased when the XA method was introduced: in 2008–2010, the proportion of points that could be obtained from category 2 tasks was 42–54%, whereas in 2011–2013 when the XA method was used, the corresponding percentage was 0–25%.

The weight of category 5 (proof) has not decreased when using the XA method. A new category (7, construct example) has appeared with the introduction of XA.

Categories, %	1. Factual recall	2. Routine calculation	3. Classify object	4. Interpret	5. Proof	6. Extend a concept	7. Construct an example	8. Criticize a fallacy	9. Information transfer	No. of tasks
2008		41	22	4	15	3	12		3	30
2009		46	13	8	28		3		1	30
2010		36	22	8	15	3	12		5	30
2011	2	43	14	2	13	2	7		18	133
2012		29	21	4	21		10		15	89
2013		28	27	7	11		10		18	89

Table 2: Proportions of course assignments in different categories. In 2011 the XA method was introduced

Categories, %	1. Factual recall	2. Routine calculation	3. Classify object	4. Interpret	5. Proof	6. Extend a concept	7. Construct an example	8. Criticize a fallacy	9. Information transfer	No. of exam points
2008	8	42	25		25					24
2009	8	54		13	25					24
2010	17	42	42							24
2011	8	25	25		25		17			48
2012	6	8	33	25	27					48
2013	13		50		25		13			48

Table 3: Proportions of exams points in each category. The points are divided into nine categories according to the category of the task they are awarded for. In 2011 the XA method was introduced

	2008	2009	2010	2011	2012	2013
Number of students	307	262	280	324	345	383
Mean (%)	69	63	72	69	75	65
Standard deviation (%)	24	19	23	19	19	21
Lower quartile (%)	50	54	58	58	65	52
Median (%)	71	67	75	73	79	67
Upper quartile (%)	92	75	92	81	90	81

Table 4: The number of students taking the exam and statistical parameters of the exam scores

Exam performance

Information on the performance of the students was obtained by studying the exam scores. From Table 4 it can be seen that the average scores were 63–72% in traditional teaching and 65–75% in XA. There seems to be no distinctive change in the student performance since the XA method was introduced.

CONCLUSIONS

The aim of the XA method is to educate skilled professionals. As professional mathematicians need to understand the concepts they are working with, this should be emphasised also when teaching future mathematicians, even first year students.

The results show that when the XA method was introduced, the weight of routine calculations in the course assignments decreased and the weight of category 9 (information transfer) increased. It can be concluded that there was a change of focus from rote learning of routine procedures towards tasks that require also conceptual understanding. However, there are still categories that are almost non-existent, such as "extend a concept" or "criticize a fallacy".

Also in the course exams the weight of category 2 decreased when the XA method was introduced. Instead of routine calculations, the tasks required constructing examples or interpreting situations or answers. At the same time, there was no drastic change in the performance of the students. In the light of these results, we can draw the conclusion that the students have developed conceptual understanding. However, when interpreting the exam results, one should note that the level of difficulty of the exams may have varied slightly over the years.

Conceptual understanding is not developed at the cost of routine skills: the actual amount of course assignments in category 2 has not dropped. Since the number of tasks in XA is greater than in traditional teaching, the amount of category 2 tasks has actually risen from 12 tasks in 2008 to 25 tasks in 2013 (Table 3). This means that also in the XA method the students get plenty of practice in routine calculations.

There are many features in the XA method that facilitate emphasising conceptual knowledge. The teaching revolves around the tasks, and there are plenty of them for the students to work on. Therefore, it is easier to give students a wide range of diverse tasks. Because of the one-on-one instruction, also the weaker students have a change to fully work on the problems, and they do not need to give up if a task seems too difficult for them. The lectures support the development of conceptual understanding by focusing on motivating the concepts and discussing how they are linked together. However, not all the students take advantage of the instruction: less than half of the students who submit course work speak with the teaching assistants, and many of the students do not attend the lectures. Our next goal is to find ways to encourage students to take part in the instruction.

In this study, the tasks were categorised by the second author. The reliability of the study would be improved if the tasks were given to an independent evaluator who does not know which tasks are from which year. Also, a detailed statistical analysis would give more information about the changes that have taken place.

The tasks given to the students should be versatile and varied because mathematical competence involves knowledge of both concepts and procedures, as well as understanding the relations between them (Hiebert & Lefevre, 1986). Also, when students are offered diverse problems, they learn problem-solving strategies of experts (Collins et al., 1991). In this light, our results indicate that the Extreme Apprenticeship method is a step in the right direction.

First steps in re-inventing Euler's method: A case for coordinating methodologies

Michal Tabach[1], Chris Rasmussen[2], Rina Hershkowitz[3] and Tommy Dreyfus[1]

1 Tel Aviv University, Tel Aviv, Israel, Tabach.family@gmail.com

2 San Diego State University, San Diego, USA

3 The Weizmann Institute, Rehovot, Israel

In this report, we highlight the epistemic actions and concomitant discursive shifts of four students as they reinvent the fundamental idea and technique in Euler's method. We use this case to further the theoretical and methodological coordination of the Abstraction in Context (AiC) approach, with its associated model commonly used for the analysis of processes of constructing knowledge by individuals, and small groups and the Documenting Collective Activity (DCA) approach, with its methodology commonly used for identifying normative ways of reasoning with groups of students. In this report, we show students' first steps towards re-inventing Euler's method and explicate the theoretical and methodological commonalities of AiC and DCA.

Keywords: Documenting collective activity, abstraction in context, networking theories, Euler's method.

INTRODUCTION

Research at the undergraduate level is moving beyond the documentation of student difficulties towards the design, implementation, and analysis of innovative learning environments where students reinvent important mathematical ideas and methods. For example, in differential equations, research has documented that students are able to reinvent, given appropriate task sequences and learning environments, Euler's method, bifurcation diagrams, and even an analytic approach for solving systems of linear differential equations (e.g., Rasmussen, 2007). Such reinventions are, from our perspective, both individual and collective accomplishments. Methodological approaches for analysing such accomplishments, however, are sorely needed. In this report, we highlight the epistemic actions and concomitant argumentation of four students as they reinvent the fundamental idea and technique in Euler's method. We use this case to further the theoretical and methodological coordination of the Abstraction in Context (AiC) approach and the Documenting Collective Activity (DCA) approach (see Hershkowitz et al., 2014; Tabach et al., 2014 for initial attempts at coordinating these two approaches). The two approaches have various theoretical and methodological commonalities that we will refer to as environmental and underlying ones; the analysis in the present paper led to the discovery of additional commonalities that we will refer to as environmental and underlying internal ones. We explicate these commonalities to set the stage for the analysis of student reinvention, but first begin with a brief summary of the AiC and DCA approaches.

ABSTRACTION IN CONTEXT AND THE RBC+C MODEL

Abstraction in Context (AiC) is a theoretical framework for investigating processes of constructing and consolidating abstract mathematical knowledge (Hershkowitz et al., 2001). Abstraction is defined as an activity of vertically reorganizing previous mathematical constructs within mathematics and by mathematical means, interweaving them into a single process of mathematical thinking so as to lead to a construct that is new to the learner. According to AiC, the genesis of an abstraction passes through three stages (ibid): (i) the arising of the need for a new construct, (ii) the emergence of the new construct, and (iii) the consolidation of that construct. AiC includes a theoretical/methodological model, according to which the description and analysis of the emergence of a new construct and its consolidation relies on a limited number of epistemic actions: Recognizing, Building-with, and Constructing (RBC).

These epistemic actions are often observable as they are expressed by learners verbally, graphically, or otherwise. Recognizing takes place when the learner recognizes a specific previous knowledge construct as relevant to the problem currently at hand. Building-with is an action comprising the combination of recognized constructs in order to achieve a localized goal, such as the actualization of a strategy or the solution of a problem. The model suggests Constructing as the central epistemic action of mathematical abstraction. Constructing consists of assembling and interweaving previous constructs by vertical mathematization to produce a new construct. It refers to the first time the new construct is expressed by the learner.

Recognizing actions are nested within building-with actions, and recognizing and building-with actions are nested within constructing actions. Moreover, constructing actions are at times nested within more holistic constructing actions. Therefore the model is called the nested epistemic actions model of abstraction in context, or simply the RBC+C model. The second "C" stands for Consolidation. The consolidation of a new construct is evidenced by students' ability to progressively recognize its relevance more readily and to use it more flexibly in further activity.

DOCUMENTING COLLECTIVE ACTIVITY OVERVIEW

The methodological approach of documenting collective activity (DCA) is theoretically grounded in the emergent perspective (Cobb & Yackel, 1996), a basic premise of which is that mathematical learning is a constructive process that occurs while participating in and contributing to the collective activity of the classroom. The collective activity of a class refers to the normative ways of reasoning that develop as students work together to solve problems, explain their thinking, represent their ideas, etc. These normative ways of reasoning can be used to describe the mathematical activity of a group and may or may not be appropriate descriptions of the characteristics of each individual student in the group. A mathematical idea or way of reasoning becomes normative when there is empirical evidence that it functions in the classroom as if it is shared. The empirical approach makes use of Toulmin's model of argumentation, the core of which consists of Data, Claim, and Warrant. Typically, the data consist of facts or procedures that lead to the conclusion that is made. To further improve the strength of the argument, speakers often provide more clarification that connects the data to the claim, which serves as a warrant. It is not uncommon, however, for rebuttals or qualifiers to arise once a claim, data, and warrant have been presented. Backing provides further support for the core of the argument.

The following three criteria are used to determine when a way of reasoning becomes normative: 1) When the backing and/or warrants for particular claim are initially present but then drop off, 2) When certain parts of an argument (the warrant, claim, data, or backing) shift position within subsequent arguments, or 3) When a particular idea is repeatedly used as either data or warrant for different claims across multiple days. See Rasmussen and Stephan (2008) for an illustration of the first two criteria.

ENVIRONMENTAL COMMONALITIES

The use of both methodologies, AiC and DCA, requires very explicit classroom norms. First, they require classrooms in which students are routinely explaining their thinking, listening to and indicating agreement or disagreement with each other's reasoning, etc. If such norms are not in place, then evidence is unlikely to be found of challenges, rebuttals, and negotiations that lead to ideas where knowledge is constructed and starts functioning as if shared by the whole class. We call such classrooms "inquiry classrooms." Second, they require the intentional use of tasks that were purposefully designed to offer students opportunities for constructing new knowledge by engaging them in problem solving and reflective activities allowing for vertical mathematiziation.

Both methodologies focus on the ways in which mathematical progress is achieved and spreads in the classroom. RBC+C focuses on individuals or small groups working in the classroom and DCA focuses on group discussions. In this sense, the two methodologies complement each other in analyzing a sequence of lessons including individual and group work and in tracing how knowledge is constructed and becomes normative along this sequence.

UNDERLYING COMMONALITIES

Other characteristics of a classroom culture in which DCA and RBC+C methodologies might be enacted together are that the tasks are designed to afford inquiry and the emergence of new constructs by vertical mathematization from previous constructs; such learning materials allows for interweaving collaborative work in both small-group work and whole-class discussions, where the teacher adopts a role that encourages inquiry in the above sense.

Another underlying characteristic relates to the centrality of the shared knowledge. AiC defined shared knowledge as "a common basis of knowledge which allows the students in the group to continue together the construction of further knowledge in the same topic" (Hershkowitz et al., 2007, p. 42). This definition relates to cognitive aspects. We find its counterpart in sociological terms, in the phrase "function as if shared" used by the DCA approach. What is common between the two constructs is the point that each operationalizes when particular ideas or ways of reasoning are, from a researcher's viewpoint, beyond justification for participants. At the collective level, ideas or ways of reasoning that function as if shared have the status of accepted mathematical truths for the group. At the individual level, consolidation results in individuals accepting something as a mathematical truth.

FIRST STEPS TO REINVENTING EULER'S METHOD

We begin with the following excerpt, used also in Stephan and Rasmussen (2002) and in Tabach and colleagues (2014) but for different purposes. It is a discussion between Liz, Joe, Deb and Jeff, four students in a class of 29 STEM, first year undergraduate students, working on the following problem during group work on the first lesson:

Consider the following rate of change equation, where P(t) is the number of rabbits at time t (in years): dP/dt = 3P(t) or in shorthand notation dP/dt = 3P. Suppose that at time t = 0 we have 10 rabbits (think of this as scaled, so we might actually have 1000 or 10,000 rabbits). Figure out a way to use this rate of change equation to approximate the future number of rabbits at t = 0.5 and t = 1.

Prior to this task students received no instruction on Euler's method, but the class did develop graphical depictions of what the exact solution should more or less look like (e.g., not linear but increasing at an increasing rate). The excerpt includes a DCA analysis and an RBC analysis. The DCA analysis classifies the shaded parts according to Toulmin's model as data [D], claim [C], warrant [W], backing [B], or qualifier [Q]. For example, D2 is the Data used for Claim 2. We indicate at the end of a turn if one of the three criteria has been met. The RBC analysis is based on an a priory analysis of the activity that yielded the following knowledge elements intended to be constructed: Csy – establishing connection between P and dP/dt (if you know P you can find dP/dt); Cpit – population iteration (given P and dP/dt at a moment in time allows one to find P at a later time); and Crit – rate of change iteration (applying Csy at that later time one can find the corresponding dP/dt); and finally Cit: Cpit and Crit can be combined into a repeating loop. We conjecture that in previous courses students constructed dP/dt as a ratio (Crat) and hence they can recognize and build-with this construct. To keep things transparent we omit mentioning previous constructs to which our analysis does not explicitly refer. RBC actions were italicized in students' talk and coded in the third column as recognising (R), building-with (B), constructing (C) or consolidating (CC). This side-by-side analysis was done to facilitate coordination between the RBC+C and DCA methodologies. This coordination is then helpful for analysing student's re-invention of Euler's method.

1	Liz	*I would plug in the population of rabbits for P to determine the rate of change initially. What is the rate of change when time equals zero* [W1]. *So if we had a graph, its kind of like what we were just talking about, we are trying to determine the rate of change when this time is equal to zero* [B1].	R B
2	Joe	Oh ok. *This is where 10 rabbits at zero* [D1].	R
3	Liz	What do you think?	
4	Deb	Oh ok, *so I get the rate of change at time initially the rate of change would be 3* [sic] [C1]. Did I multiply it right?	R B Csy
5	Liz	And then I guess the simple ...	
6	Joe	How did you do that?	
7	Liz	*Okay, well this* [D2] [differential equation] *is the change in the population over the change in time* [C2].	Rrat
8	Joe	Right.	
9	Liz	Okay, and *this 3 I'm taking as being the constant or whatever you call the growth rate. And this P of t is the population at any given point of time t, but this is just short hand notation for it . So I*	

thought, if we know the population is ten when our time equals zero [D1 & D2 elaborated], *can we plug in the P(t) population at time zero and find out what initially the rate of change is* [W1]? B Csy

10 Joe It would be 10 = 3...

11 Liz *Times 10* Csy

12 Jeff *Okay I see so it would be 30* [C1]. Csy

13 Liz 30, I mean does that,

14 Jeff Yeah that does make sense.

15 Joe Well, *wouldn't 10 = 3P(t)?* [C3] *At time zero we have 10 rabbits* [D3]. (Note that his claim is incorrect) R B

16 Liz Well 10 is actually the population [D4] so I'm taking that that has to actually be the population at time t. *I don't think it's telling us how the population is changing which would be dP/dt* [C4]. CCsy

17 Liz *So if we have that [initial rate of change is 30]* [D5], *the question is how can we use that to help us figure out the population after a half unit elapsed?* [32 sec pause] (identifies a need to construct Cpit) Rsy

18 Jeff How would we work time into the equation?

19 Liz *If we think of it right now as our time equals zero*, we could say... B

20 Deb *We have the 30* [D5]. Rsy

21 Liz *We have the 30 to work* [D5] *with, so couldn't we say we don't* [5 second pause]Bsy

22 Deb You said *the population is 10 right* [D5]? B

23 Liz um hm.

24 Deb So three times ten would give us our rate of change [D5]. *Say 0.5 years passes, this is our rate of change. Then we'll take that 0.5 times the rate of change* [W5] *which will give us what, the new amount of rabbits plus the old amount of rabbits*. [C5] [Criterion 2 met for Csy, see turn 12 where this was C1] Cpit

25 Liz So *the old amount of rabbits is ten* [D6] R

26 Deb Am I making sense?

27 Jeff I think so, so *that would be 25* [C5], is that what you're saying? Cpit

28 Liz Okay I think I get what you're saying. So we're *at time zero and we have 10 rabbits, and the rate of change is 30* [D6] *so its going to grow at a rate of 30 rabbits per year* [C6]? [Criterion 2 met for Csy, similar to turn 24 by Deb] Cpit

29 Deb Right. So we'll have 30 more rabbits.[D7]

30 Liz But we only want to go a half a year.

31 Deb So it'll be *0.5 times 30*,[W7] *which is 15* [C7]. [Criterion 2 met for part of Cpit (namely that 30 is also the change over one year), claim C6 is now D7] CCpit

32 Liz And so we're really not figuring out the rate of change we figuring...*Well this is the rate of change and we're using the rate of change to figure out the number of rabbits we are going to increase by in half a year* [B5]. Cpit

33 Deb Well the new population...

34 Joe Well *if t is 0* [D8] *then we have 0* [C8]. But you said *when t is zero we have 10* [Rebuttal to Argument 1]. (note that his assertion is incorrect) Rsy

35 Liz I think it just means *initially we have 10* [Rebuttal to C8]. R

36 Joe Well according to this *when t is zero* [D8] *we would have zero rabbits. Or the rate of change would be 0* [C8]. B

37 Liz Well actually *we're going to multiply it by a half a year* [B5, continuation of turn 32]. Cpit

38 Deb This is what I did. First I looked at the fact that *this is a rate of change equation. So this is telling me how many rabbits are being produced every year* [W10]. *So If I know 3 times the original population is produced every year, then I have 3 times 10 is produced every year* [Criterion 3 met for Csy]. *But I want to know how many is produced in 0.5 years* [D10]. *So I know how many rabbits are produced per year, so if I multiply that by 0.5 then I'll know how many more rabbits have been produced. So I take that new number that I get and add it to the old population* [C10] CCpit

39 Deb Uh huh, so then *I find the one with my new rate of change* [W11], so *I just take that population and put it in for p* [D11]. *And that is 3 times whatever that is* [C11]. Bsy

40 Liz Do you get what Deb is saying?

41 Jeff Yeah *you get 25 and then you get 55* (sic) [W11]. Bsy

42 Deb I think we should make a chart like he did. [showing her paper to Jeff] But

this would be your equation. This would be your 0.5, and then rabbits per year, and that will be your new amount of rabbits that's been added, then you add that to your old amount of rabbits, and you'll get your new population [B11]. CCpit

43 Jeff I think *you can go dp/dt=30, actually your dt will be 0.5, and then you do it again for the next one* [C12]. [Criterion 1 met for Csy] Bsy

44 Liz What do you have right there?

45 Deb *You take your old rate of change which we already know is 30 rabbits per year, and how much time that has passed equals 0.5. So 0.5 times 30 will get me how many new rabbits I have* [D13]. *So I take the new amount of rabbits I have and add it to the old amount of rabbits I have and that will give me the new population. And once I know the new population I know the new rate of change because I know the rate of change is right here.* [C13] CCpit Crit

46 Liz And the reason for putting in the new population would be what? (identifying a need to build Cpit which Deb has already constructed)

47 Deb Because *now my population is larger and I know the population changes at a constant of 3 times whatever that population is* [W13]. CCrit

48 Liz Okay, so basically, I get you up into the point where you say you want to put in, what I understand is that *we found our rate of change initially at time zero and that we are using that to find out what our population is after half a year. If we are expected to grow by 30 rabbits in a year then, in a half a year we grow by 15 rabbits. So we'll have 15*, [D14]. CCpit

49 Deb No no

50 Liz I mean *25 because 15 plus 10 is 25* [D14]. CCpit

51 Jeff Then *we have to do it again* [C14]. [turns 48–51 repeat with specific values Argument 13] Crit

52 Liz Then *you start over again* [C14], so *its kind of like our new initial population, so we could label it time equals zero if we wanted to* [B14]. Crit

Since space constraints prohibit a complete accounting of the individual constructions and normative ways of reasoning evidenced in this episode we only highlight individual constructing actions associated with Cpit, the method for computing the next population value. By recognizing and building-with previous constructs (e.g., turns 1, 4, 7, 9, 20) we see Deb first construct Cpit in turn 24, followed by Jeff in turn 27 and Liz in turns 28+32+37. Per the DCA methodology we see that "knowing P means you can find dP/dt" (Csy) functions as if shared at the collective level per Criterion 2 (in turns 24 and 31 this idea was Data whereas in turn 4 it was a Claim). Even in this brief analysis we see how the coordination of the RBC+C and DCA traces well the individual and collective processes in mathematical progress.

The epistemic actions and concomitant discursive shifts resulted in these students reinventing the core idea of Euler's method, namely Cit. One way to express this core idea is in the following algorithm: $P_{next} = P_{now} + ((dP/dt)|_{now})*0.5$. Indeed, this particular formulation of Euler's method would be a viable extension of students' natural language. In particular, in turns 25–32, three of the four students essentially co-create the first step of the iterative process and then in turn 45 Deb succinctly provides a verbal summary of the algorithm. In turns 51 and 52 Jeff and Liz respectively highlight the iterative nature of the algorithm ("we have to do it again" and "then you start over again"). The use of "next" and "now" in the algorithm closely resembles students' verbal description of the process. This however, is only the first step in developing a comprehensive understanding of Euler's method.

We now further the theoretical and methodological advance for analysing individual and collective mathematical progress that was started in Tabach and colleagues (2014) and Hershkowitz and colleagues (2014). In particular, we use the previous episode to show how the various individual epistemic actions are intertwined with the collective production of arguments. This intertwining reflects the internal commonalities between the RBC+C and DCA methodologies.

RBC+C AND DCA INTERNAL COMMONALITIES

We begin by relating each of the RBC constructs to the DCA approach and then we relate the three criteria of the DCA approach to consolidation.

Relationship between Recognizing and Data. Theoretically, we argue that Recognizing actions are largely associated with Data. One uses some piece of information as Data because that piece of information makes sense to him/her. Recognizing action means recognizing a piece of information as relevant as data. Empirically, in the above example, parts of students' talk which were coded as Data were also coded as Recognizing. However in some cases, when a construction takes place, it happens that part of the argument is coded as Data (e.g., turns 21–24). In the previous example, we see that Recognizing actions are primarily associated with Data. In some cases (e.g., turn 1), Recognizing actions can be associated with Warrants, which are at times difficult to disentangle from Data.

Relationship between Building-with and Warrants. Theoretically, Warrants establish a connection between data and claim; in order to establish such a connection, one needs to build-with what one has. In the example this commonality is largely the case. Sometimes Building-with is linked to Data, because oftentimes Warrants and data are interchangeable (e.g., turn 36). While the previous excerpt also shows some slight differences in the relationship between Building-with and Warrants (e.g., Building-with may be linked to Claims for which, by Criterion 1, the Data and/or Backing drops off (see turn 43), additional data sets are needed to empirically test the conjecture about the relationship between the two constructs.

The relationship between Constructing and Arguments as a whole. Constructing requires vertical mathematization. Constructing actions are more global than Recognizing or Building-with actions; they incorporate sequences of interweaving Recognizing and Building-with actions (plus the glue between them). Similarly, arguments interweave Data-Claims-Warrants and Backings as a whole. Hence, in a line by line coding it is not feasible to indicate the holistic nature of an argument and it is typically indicated after a line by line coding (see for example Tabach et al., 2014). Moreover, arguments are usually co-constructed by several participants over several turns. Such exchanges are similarly typical for constructing actions.

Consolidating and the three criteria for identifying function-as-if-shared ideas. In processes of consolidating as well as across the three criteria for identifying when an idea functions as if shared, there is a repetition, reuse, revisiting, or repurposing of earlier ideas. To clarify, in Criterion 1 there is a repetition, but the repetition is partial in the sense that some parts of the argument (Data, Warrants) cease to be explicitly stated. In Criterion 2 there is repurposing of previous part of an argument (e.g., Claim) as either Data or Warrant. In this sense there is a repeating and reusing, but for a different purpose. In Criterion 3 there is a revisiting of either Data or Warrants to establish new Claims. In consolidation, previous constructs are recognized as relevant (i.e., revisited), and then built-with (i.e. used, possibly repeatedly) for example for solving a problem, reflecting on a situation or result, or even in the framework and for the purpose of an additional constructing action (for example, in lines 19–23, Csy is built-with as part of constructing Cpit).

Further commonalities between consolidating and the three criteria can be seen by considering characteristics of consolidation: awareness, self-evidence, flexibility, immediacy, and confidence (Dreyfus & Tsamir, 2004). Self-evidence links to Criterion 1 – the evidence is the Data, which drops off in subsequent arguments. The subsequent argument also then relates to immediacy and confidence in the validity of the idea. Flexibility links to Criterion 2 – components of an argument are being reused and repurposed (as sign of flexibility) in subsequent arguments. Similarly, Criterion 3 relates to flexibility in a different way. Flexibility lies in the fact that one is able to use an idea (e.g, Build-with) as Data or Warrant for a variety of different Claims. Hence close relationships exists between the criteria and Consolidation characteristics

CONCLUSION

Students in undergraduate mathematics classrooms are increasingly experiencing inquiry based learning and research is pointing to the strong benefits on student success in terms of grades and subsequent coursework (Freeman et al., 2014; Kogan & Laursen, 2013)[2]. While broad measures of student success are needed, there is also a need for methodologies that provide a fine-grained analysis of the individual and collective processes that make inquiry learning possible, and may have the potential to explain at the micro-level how such learning works and why it is beneficial. This report makes a contribution in this direction. The DCA analysis helps illuminate what is happening on the social or discursive plane, while the

RBC+C analysis helps illuminate what is happening on the cognitive side.

In this report, we used the case of a group of students reinventing Euler's method and we used this case to explicate the environmental, underlying, and internal commonalities between the AiC and DCA approaches. This represents considerable progress toward the call for what Prediger and colleagues (2008) refer to as the local integration of different theoretical/methodological approaches as well as contributing to our understanding of how undergraduate students individually and collectively reinvent important mathematical ideas.

Analysing university closed book examinations using two frameworks

Athina Thoma and Paola Iannone

University of East Anglia, Norwich, UK, a.thoma@uea.ac.uk

Assessment influences students' approaches to learning and conveys to the learners what the exam-setters value. Frameworks have been developed in order to understand and analyse the demands of the assessment tasks. In this paper, two frameworks are used to analyse one undergraduate closed book examination in abstract algebra. The analysis of the tasks resulting from the two frameworks are presented and discussed. Finally, some aspects regarding the applicability of the frameworks are highlighted and further steps are suggested.

Keywords: Undergraduate, closed book examinations, abstract algebra.

INTRODUCTION

Research highlights the strong relationship between assessment demands and students' approaches to learning (Ramsden, 1983; Trigwell & Prosser, 1991). Assessment also conveys what lecturers consider significant about their subject (Smith et al., 1996; van de Watering et al., 2008), thus it is important to examine and understand the demands of assessment.

In mathematics departments in the United Kingdom, the predominant method of summative assessment is the closed book examinations (Iannone & Simpson, 2011). This paper focuses on one closed book examination from a Year 2 course in pure mathematics. Three tasks from this examination are analysed using two frameworks: Mathematical Assessment Task Hierarchy (MATH) developed by Smith and colleagues (1996) and the framework introduced by Tang, Morgan and Sfard in 2012. The analysis of the tasks using both frameworks is presented and discussed. This will allow us to better understand the potential of each and to improve their use for specific research questions.

In what follows we first present the two frameworks and introduce the context of our study. Afterwards, we analyse in detail one of the examination tasks and offer an overview of the analysis of the rest. We then discuss the results, comment on the applicability of the frameworks and make some suggestions for further research.

THE FRAMEWORKS

Different frameworks exist offering ways of analysing the tasks used in assessment. One of the most common is Bloom's taxonomy of educational objectives (Bloom et al., 1956). This taxonomy examines the different educational objectives the educators set for their students and assists them in developing balanced assessments. Different adaptations of this taxonomy have been used in mathematics. One of those adaptations tailored specifically for undergraduate mathematics closed book examinations is offered by a team of mathematicians and mathematics educators (Smith et al., 1996). Smith and colleagues (1996) introduce the MATH taxonomy aiming to assist lecturers in constructing examinations demanding a range of knowledge and skills. They distinguish between eight categories of knowledge and skills and they propose three groups: A, B and C (Table 1). In solving Group A tasks, the students are asked to recall factual knowledge and fact systems, comprehend factual knowledge and be able to use basic procedures. Students have to display the ability to transfer information and apply information or methods in new situations when attempting to answer tasks belonging to Group B. Finally, in answering tasks from Group C students are asked to justify and interpret a result, offer conjectures and comparisons and evaluate results. Smith et al. argue that examinations should have items from all the groups and note that items from Group A could guide students to adopt surface learning approaches (Ramsden, 1992) whereas items from Group B and

Group A	Group B	Group C
Factual knowledge and fact systems Comprehension of factual knowledge Routine use of procedures	Information transfer Application to new situations	Justification and interpretation Implications, conjectures and comparisons Evaluation

Table 1: The MATH taxonomy

C might help them foster deep learning approaches (Ramsden, 1992).

While the MATH taxonomy was developed to assist in the creation of examinations assessing a range of knowledge and skills, the framework introduced by Tang, Morgan and Sfard (2012) was developed to characterise the discourse of school mathematics. Aiming to examine whether the nature of students' participation in the mathematical discourse changed in the last thirty years, they focused on analysing the public examinations in the UK taken at age 16 (GCSE – General Certificate of Secondary Education). This framework draws on Systemic Functional Linguistics (Halliday, 1978; Morgan, 2006) and Sfard's theory (2008) of commognition. The framework explores the mathematical discourse that the student engages with when reading and responding to an examination task. This analysis "allows a subtle characterisation of the nature of mathematics and of student mathematical activity construed through the forms of language used" (Morgan & Tang, 2012, p. 242). The framework has two components: mathematics and the student. The mathematics component characterises the mathematical discourse the student is expected to engage in when reading and solving the task. This is further distinguished using Sfard's theory (2008) in four categories: vocabulary and syntax, visual mediators, routines and endorsed narratives. The student component investigates the relation between the examination task and the student. More specifically, it examines the positioning of the student in relation to the exam-setter, the presence of human beings, in the task, engaged in everyday or mathematical activities, and finally the decisions and directions shaping the student's response.

METHODOLOGY

For the purpose of the paper, we analyse examination tasks from an abstract algebra course in a mathematics department in the UK. This is a compulsory course and focuses on linear algebra in the autumn term and on group and ring theory in the spring term. Our data consists of the coursework tasks, the examinations tasks focused on group and ring theory and their model solutions, produced for departmental use, and was collected for a doctoral study (Ioannou, 2012). The examination accounted for 80% of the course's final grade and selected coursework tasks accounted for the remaining 20%. This examination, which is the focus of our analysis, had six tasks: three on linear algebra and the remaining three on group and ring theory. The examination lasted three hours and the students had to respond to five of the tasks. Notes were not permitted in the examination and the students were told that they could use the general theorems without proof unless stated otherwise. Non-programmable calculators were permitted during the examinations. In what follows we present a detailed analysis of task 4 (Figure 1) followed by an overview of the analysis of the other tasks on group and ring theory (Figure 2).

4)

(1) Describe the group S of rotational symmetries of a solid cube in $\mathbb{R}^3$. List the possible axes of rotation and angles of rotation, and hence show that $|S| = 24$. Let l be an axis passing through the centres of a pair of opposite faces of the cube and T be the set of rotations in S which send l to itself. Prove that T is a subgroup of S and $|T| = 8$.

(2) Suppose G is a group and H a subgroup of G. Prove that the relation $\sim$ on G given by $g_1 \sim g_2$ if and only if $g_1^{-1}g_2 \in H$ is an *equivalence relation*, saying carefully what this means. In the case where G is a finite group, prove that all equivalence classes have $|H|$ elements.

(3) State Lagrange's Theorem, and use (2) to give a proof of this.

Figure 1: Examination task 4

ANALYSIS USING THE MATH TAXONOMY

Task 4 consists of three subtasks. In (4.1) the students have to describe the 24 elements of the group of rotational symmetries of a solid cube, listing all the possible axes and angles of rotation. This is classified as information transfer since the students have to visualize the cube, identify the axes and angles and describe the elements. Afterwards, in the same subtask, the students are asked to examine whether a specific set of rotational symmetries is a subgroup and to prove that the order of the subgroup is 8. Here, the students are asked to select from the 24 elements the ones satisfying the criteria of sending l to itself. This is categorised as evaluation.

In the second subtask (4.2) students have to examine whether the given relation is an equivalence relation. In the MATH taxonomy the process of deciding whether the conditions of a definition are satisfied belongs to different categories depending on the definition of the concept. If the definition is considered simple it belongs in the comprehension category and if "understanding [*the definition*] requires a significant change in the students' mode of thought or mathematical knowledge" (Smith et al., 1996, p. 69) it is considered a conceptual definition and belongs to the information transfer. Here, the concept of the equivalence relation is considered a conceptual definition and thus classified as information transfer. Then, the students need to comment on the form of the equivalence classes defined by this relation, which are actually the left cosets, and this is classified as comprehension. Finally, the subtask asks to prove that if the group G is a finite group then the equivalence classes formed from the relation have the same elements. The students have to examine whether these left cosets have the same order as the subgroup H by defining a bijective function. This is categorised as comprehension, as the students have to show understanding of the equivalence classes' concept and define the bijective function.

The students, at subtask (4.3), must state Lagrange's theorem and prove this theorem using the knowledge demonstrated previously in subtask (4.2). This subtask is classified as factual knowledge and fact systems and justifying and interpreting.

The skills and knowledge needed to respond to tasks 5 and 6 (Figure 2) are classified as factual knowledge

5)

(1) Suppose G is a group.

(a) What does it mean to say that a subgroup N of G is a *normal* subgroup? If N is a normal subgroup of G, explain how to make the set G/N of left cosets of N in G into a group.

(b) State the First Isomorphism Theorem for groups, defining the terms *kernel* and *image* in your statement.

(c) Suppose H is a cyclic group. By defining a suitable homomorphism $\phi : (\mathbb{Z}, +) \to H$, or otherwise, prove that $H \cong \mathbb{Z}/m\mathbb{Z}$ for some $m \in \mathbb{Z}$.

(2) Let R be the ring $\mathbb{Z}[\sqrt{-7}] = \{m + n\sqrt{-7} : m, n \in \mathbb{Z}\}$. In the following you may use the fact that the function $N : R \to \mathbb{Z}$ given by $N(m + n\sqrt{-7}) = m^2 + 7n^2$ satisfies $N(ab) = N(a)N(b)$ for all $a, b \in R$.

(a) Prove that the only units in R are ± 1.

(b) Give two different factorizations of 8 into irreducibles in R and deduce that R is not a unique factorization domain. You should justify carefully any assertions you make about irreducibility of various elements of R.

6)

(1) Suppose R is a commutative ring. What is meant by saying that a subset $I \subseteq R$ is an *ideal* of R? Suppose $f \in R$ and let $fR = \{fr : r \in R\}$ be the *principal ideal* generated by f. Prove that this *is* an ideal of R. Prove that, for $f, g \in R$

$$fR \subseteq gR \Leftrightarrow g \text{ divides } f \text{ in } R.$$

(2) Prove that the element $f = x^3 + x^2 + x - 1$ in the polynomial ring $R = \mathbb{F}_3[x]$ is an irreducible (where $\mathbb{F}_3$ denotes the field with 3 elements). Explain why the ideal $I = fR$ is a maximal ideal in R. What does this imply about the quotient ring R/I? Let $h = x^4 - x^2 + 1 \in R$. Is hR a maximal ideal in R? Justify your answer.

Figure 2: Examination tasks 5 and 6

and fact systems, information transfer, application to new situations and justification and interpretation.

ANALYSIS USING THE TANG, MORGAN AND SFARD FRAMEWORK

First, we present the analysis regarding the student component. Considering the student and exam-setter relationship, we examine whether the students are given commands or asked to examine mathematical questions. In this task, the students are given imperative instructions. Regarding the directions, the students are directed to present the group S in a specific way ("list…rotation"), they are also given directions, by implication ("and hence show") on how to prove that the order of the group is 24. Also, they are given directions, by instruction in subtask (4.3) as it specifically states that they should use the facts proved in (4.2) to prove Lagrange's theorem. Regarding the depth and accuracy of the expected response, the students are directed in (4.2) ("saying carefully what this means"). Examining the decisions the students have to make, we observe that in (4.1) the students can decide whether or not to provide visual representations of the rotational symmetries of the cube. Finally, in our analysis of these tasks we do not consider the presence of the human beings as the tasks do not offer descriptions of human beings engaged in mathematical or everyday activities.

In our analysis regarding the mathematics component we focus on the routines, due to space limitation. The routines discuss the patterns observed in the discursants' activity when attempting to construct and substantiate narratives endorsed by the mathematical community (Sfard, 2008). Here, according to the framework, we examine the form of student engagement and the areas of mathematics involved. The imperatives, present in the tasks, are analysed in order to examine the student's engagement which is distinguished in: engagement in material processes, construing the student's role as a 'scribbler'; and engagement in mental processes, construing the student as a 'thinker' (Rotman, 1988). Here, the students are asked to engage in material actions ("describe", "list", "state", "use") as well as in mental activity ("show", "let", "prove", "suppose"). Relating to the areas of mathematics involved we see that the students have to engage with concepts from set and group theory, but also to demonstrate knowledge from geometry when asked on the rotational symmetries of the cube. Finally, we offer a categorisation of the routines, using Sfard's theory, into: construction, resulting in new endorsable narratives; substantiation, assisting in the decision to endorse a previously constructed narrative; and recall, bringing to mind previously endorsed narratives (Sfard, 2008, p. 225). In this task, the students are requested to engage in a construction routine when asked to describe the elements of the group S and in a substantiation routine when examining which of the elements of S send l to itself. In (4.2), the students have to engage in a substantiation routine, as they have to verify the definition of the equivalence relation. Then they have to prove that all the equivalence classes have $|H|$ elements engaging in a construction routine in order to construct one of the classes and the mapping of the elements; and next in a substantiation routine where they have to examine that the mapping is bijective. In the last subtask, the students are required to state and prove Lagrange's theorem using (4.2). Consequently, the students have to engage in a recall and a substantiation routine.

In tasks 5 and 6 the students' actions are pre-shaped since they are given explicit or implicit directions regarding the presentation, the depth and accuracy of their response and the methods. There are only a few instances where the students can decide on the method and the degree of accuracy. The tasks involve number theory, set theory, group and ring theory. We also note that the student's role is construed both as scribbler and thinker. Finally, the students are asked to engage in construction, substantiation and recall routines.

DISCUSSION AND SUGGESTIONS FOR FURTHER RESEARCH

The aim of this paper was to uncover the potential of two frameworks in analysing examination tasks. To this aim we discuss the results obtained from the analysis of three examination tasks and we offer here some reflections on the application of the frameworks.

The MATH taxonomy highlights the nature of the skills needed to respond correctly to the task. The students are asked to demonstrate their knowledge of the basic concepts and theorems used in the course. They are required not only to remember but to show their understanding of them too. In order to solve these tasks the students have to demonstrate factual knowledge and fact systems, comprehension of factual knowledge, information transfer, application in new situations, justification and interpretation and evaluation. The analysis using the Tang and colleagues (2012) framework highlights that most of the students' actions are pre-shaped with the implicit or explicit directions given to them, allowing them to be autonomous in very few cases. Furthermore, the student's role is interpreted as both a scribbler and a thinker engaging with material actions and mental activity. The students are asked to engage with concepts from the following mathematical areas: geometry, number theory, set theory, group and ring theory. Finally, the students engage in recall, substantiation and construction routines in different parts of the tasks.

Both frameworks deal with the concept of familiarity through the categories of recall routine or factual knowledge and factual systems. We should point out that familiarity, a highly contextual and subjective concept, is not clearly defined in either one. A task may be considered as familiar to some students and thus require them to engage in a memory retrieval procedure, while the same task presented to students exposed to different teaching material might require them to engage in mathematical activities of a different nature. Also, familiarity can be different for the individual students belonging to the same teaching group as each one engages differently with the given material. In our analysis we classified a task as belonging to the categories above when it required stating a definition or a theorem. However, we should note that some parts of the tasks were given to the students as coursework although the model solutions of these tasks were not made available to them, as these were the ones assessed in the coursework. Here we should report that there is a framework which examines the concept of familiarity more rigorously. Bergqvist (2007) used a framework developed by Lithner (2008) regarding the reasoning expected of the students. She analysed examination tasks from a Swedish university and categorised them into tasks requiring imitative or creative reasoning. A task was classified as demanding imitative reasoning if it asked for a fact or a theory item, for which the students were clearly informed that it might be requested in the examinations; or the task occurred at least three times in the textbooks of the course. Note that the context of our study is different from the one in Sweden, as in the United Kingdom the students mostly rely on their lecture notes and not on textbooks.

In our analysis of the tasks using the MATH taxonomy we were unable to exclusively classify one task into one of the eight categories. Furthermore, we experienced difficulties when trying to position the tasks in some categories as we didn't have clear instructions regarding the effect of the background information on the classification of the tasks. However, both of these issues are related to the origin of the taxonomy. The taxonomy was developed to assist lecturers in creating balanced examinations and not as a research tool as illustrated in the quote below:

> [I]t is not our aim to be able to uniquely characterize every conceivable assessment task. Rather, the aim of the descriptors is to assist in writing examination questions, and to allow the examiner's judgement, objectives and experience to determine the final evaluation of an assessment task. (Smith et al., 1996, p. 68)

Some interesting aspects of the tasks are pointed out using the Tang and colleagues (2012) framework. More specifically by examining the areas of mathematics involved we gain information regarding students' engagement with mathematical concepts from other mathematical areas than the one that the course focuses on. This aspect is not highlighted in the MATH taxonomy as the focus is on the activity and not on the areas of mathematics. To be more specific, the tasks analysed here are assessment tasks from an abstract algebra course, but in order to solve them the students have to display knowledge of geometry (4.1), number theory (5 and 6) and set theory, which are not the focus of this course. This emphasises the nature of the mathematics involved; the prior knowledge expected from the students and also examines the students' ability to draw on different areas of mathematics.

The level of guidance given to the students and the degree of their autonomy when solving a task is also highlighted by the Tang and colleagues (2012) framework. As it examines the directions given to the student; and the complexity of the response expected of the students, namely the decisions they have to make. Examining a task in this respect might provide some information on the exam-setters' perceptions of their students, though this would need to be confirmed with interviews with the exam-setters. The explicit or implicit directions on the method may display what the exam-setters value or think that their students would be able to manage better. Similarly, by examining the directions regarding the presentation of the response we gain information on the exam-setters' perception of the depth and the accuracy of students' responses. For example we have three instances where the students are explicitly asked to provide a response with a certain degree of accuracy and depth ("saying carefully what this means" (4.2), "you should justify carefully" (5.2.b) and "justify your answer" (6.2)). On the other hand, we have the decisions the students had to make in these tasks on the degree of accuracy (5.1.a) or the presentation of their response (4.1). It would be interesting to examine how the accuracy and the depth of the students' responses in this case are assessed by their examiners. Finally, there were some decisions the students had to make regarding the method of solution. One of them was explicitly stated: "By defining ... or otherwise" (5.1.c), but having in mind the students' knowledge of the subject their methods of solution are limited to the specific methods they have encountered in the course.

The classification process of the examination tasks is highly subjective as a response to the task is taken into account. In order to position the task in a specific category in the MATH taxonomy and in order to examine the routines using Sfard's theory (2008) we have to consider a possible solution to the task. The final classification depends on the researchers' choice of response and their opinion of that response (Jolliffe & Ponsford, 1989). In our attempt to reduce the subjectivity of our classification we took into account the model solutions produced by the lecturer of the course for departmental use (Figure 3).

Choosing this response for our analysis we investigate the lecturer's expectation of the students' solution and not the actual solutions produced by the students. In order to examine the actual routines the students engage in, for the Tang and colleagues (2012) framework, and the skills and knowledge, for the MATH taxonomy, we need to examine the solutions produced by the individual students. Follow up interviews with the students are also necessary as different students can employ different routines and different skills and knowledge, depending on their background, to arrive to the same solution.

In conclusion, our analysis of the same examination tasks using two different frameworks highlights some interesting aspects regarding the two frameworks and their applicability. We should note that in our analysis of the Tang and colleagues (2012) framework from the mathematics component we took into account only the routines aspect. We intend to explore the results from the other aspects of the framework namely vocabulary and syntax, visual mediators and endorsed narratives. Finally, in the following stages of this research, we aim to seek the views of the lecturers, who

(1) S consists of the following rotations:
  (i) Axis of rotation through a pair of opposite vetrices; angle of rotation $\pm 2\pi/3$, number of this type: $4 * 2 = 8$.
  (ii) Axis of rotation through a pair of opposite faces; angle of rotation $\pi/2, \pi, 3\pi/2$, number of these: $3 * 3 = 9$.
  (iii) Axis of rotation through mid-point of a pair of opposite edges; angle of rotation π, number of these: 6.

  Together with the identity, this gives a total of $1 + 8 + 9 + 6 = 24$ rotational symmetries. T consists of 4 rotations (including the identity) of type (ii) with axis l, together with rotations about axes perpendicular to l through an angle π which 'invert' l. There are two of these of type (ii) and two of type (iii). Thus $|T| = 8$.

(2) Need to show that $\sim$ is:
  Symmetric: if $g_1 \sim g_2$ then ${g_1}^{-1}g_2 \in H$ so as $H \leq G$, $({g_1}^{-1}g_2)^{-1} = {g_2}^{-1}g_1 \in H$ i.e. $g_2 \sim g_1$.
  Reflexive: $g_1 \sim g_1$ as ${g_1}^{-1}g_1 = e \in H$.
  Transitive: if $g_1 \sim g_2$ and $g_2 \sim g_3$ then ${g_1}^{-1}g_2, {g_2}^{-1}g_3 \in H$. As H is a subgroup $({g_1}^{-1}g_2) * ({g_2}^{-1}g_3) = {g_1}^{-1}g_3 \in H$ so $g_1 \sim g_3$.
  An equivalence class is of the form $\{g_2 : g_1 \sim g_2\}$ for some $g_1 \in G$ and by definition this is $\{g_1 h : h \in H\}$
  The map $H \longrightarrow \{g_1 h : h \in H\}$, $h \longrightarrow g_1 h$ is bijective so the number of elements in the set is $|H|$.

(3) Lagrange's Theorem: If G is a finite group and H a subgroup of G then $|H|$ divides $|G|$. The equivalence classes in (2) partition G: every element of G lives in a unique equivalence class. All classes have $|H|$ elements, so $|G| = |H|x$ number of equivalence classes. Thus $|H|$ divides $|G|$.

Figure 3: Model solution of task 4

set the tasks, and the views of the students solving the tasks and relate these findings with the results from the frameworks.

The constitution of the nature of mathematics in the lecturing practices of three university mathematics teachers

Olov Viirman

University of Agder, Faculty of Engineering and Science, Kristiansand, Norway, olov.viirman@uia.no

The study reported in this paper investigates how notions of the nature of mathematical knowledge and mathematical objects are articulated in the discursive practices of three university mathematics teachers at a Swedish university. The data consists of video recorded lectures, and the analyses were informed by classifications presented by Lerman (1990) and Davis and Hersh (1981). The results indicate that different epistemological and ontological positions are indeed constituted through the discourse. Although the discourse is generally highly objectified, the ways in which mathematical objects are introduced differ. Mostly the discourse was within an absolutist paradigm, but there were also examples of how the socio-historical nature of mathematical knowledge is emphasized.

Keywords: Tertiary mathematics, university teaching, epistemology of mathematics, ontology of mathematics, mathematical discourse.

INTRODUCTION

Recent years have seen an increasing research interest in university mathematics teaching, including a growing number of studies focusing on so-called traditional mathematics teaching (e.g., Gücler, 2013; Viirman, 2014b; Weber, 2004). One aspect of university mathematics teaching, which has so far received less attention, is how notions of the character of mathematics are constituted through the teaching practices in mathematics lectures. The present paper is an attempt at addressing this issue. There are many ways of characterizing mathematics (see, e.g., Devlin's (2000) four faces of mathematics), but in this short paper I have chosen to focus on the classic philosophical questions of epistemology and ontology, that is, on the nature of mathematical knowledge and mathematical objects, and how these notions are manifested in the teaching discourse.

THEORETICAL PERSPECTIVES

The study takes it theoretical starting point in the commognitive framework of Sfard (2008). In this theory, mathematics is viewed as a discursive activity, with mathematical discourse constituted by its use of *words*, *visual mediators*, *narratives* (sequences of utterances speaking of objects, relations between and/or processes upon objects, and subject to endorsement or rejection within the discourse) and *routines* (repetitive patterns characteristic of the discourse). In the present paper the focus will be mainly on narratives and substantiation routines, that is, routines aimed at deciding whether to endorse previously constructed narratives. Mathematical discourse is also characterized by its high degree of objectification, where words in the discourse are viewed as signifying independently existing objects (ibid, p. 300).

Concerning the questions of the epistemology and ontology of mathematics, these have been central topics within the philosophy of mathematics for hundreds of years, and a more thorough discussion is far beyond the scope of this paper. For the purposes of this study the distinctions made by Lerman (1990) and Davis and Hersh (1981) will suffice. Lerman, in a study investigating the relation between views of the nature of mathematics and teaching practice, distinguishes between absolutist and fallibilist epistemologies. The absolutist sees mathematical knowledge as certain, absolute and timeless, and views the history of mathematics as "a demonstration of the errors and mistakes along the way to certain knowledge" (Lerman, 1990, p. 54–55). Fallibilism (inspired by Wittgenstein and Lakatos) on the other hand, "sees the growth of mathematical knowledge as a process of conjectures, proofs and refutations, and accepts the uncertainty of mathematical knowledge as part of the nature of mathematics" (ibid, p. 54). A similar stance is taken by Davis and Hersh, (1981), who also consider mathematical ontology. They distinguish between Platonism, where mathematical objects are seen as real, having an objective existence outside of human experience, and an alternative position, later denoted as humanism (Hersh, 1997), where mathematical objects are seen as human creations, but still objective in the sense of being external to the consciousness of any single individual. Instead they belong to the social, non-material culture of mankind.

Thus, the focus of this paper is on how the epistemology and ontology of mathematics are expressed in the teaching discourse. The question that the paper aims at answering is the following: How are notions of the nature of mathematical knowledge, and of mathematical objects, articulated through the discursive practices of the teachers?

PREVIOUS RESEARCH

Traditionally, questions about the nature of mathematics in relation to teaching practices have been handled in the context of research on teacher beliefs. That is, the focus has been on what beliefs about the nature of mathematics teachers possess, and how these beliefs might impact on their teaching practice (for overviews of the early achievements in this field, see, e.g., Pajares, 1992; Thompson, 1992). The study by Ernest (1989) can serve as an example. Ernest identifies three categories for characterizing individuals' views of the nature of mathematics: Instrumentalist, Platonist, and Problem-Solving. However, Ernest's study, like most similar studies, focuses mostly on pre-service or practicing teachers in elementary or secondary school, although there are some examples of studies of university teachers' beliefs about mathematics (e.g., Mura, 1993; Speer, 2008). Also, studying teacher beliefs shifts the focus from the teaching to the teacher, which runs contrary to the aim of the present study. Furthermore, the very notion of teacher beliefs as a topic of research has been the subject of much criticism, from a methodological standpoint – beliefs being notoriously hard to define and gain access to (Speer, 2008; Skott, 2009) as well as on a purely conceptual level (Skott, 2013). Skott suggests that we move away from the objectified construct of beliefs, focusing instead on "patterns of participation" in social practices, that is, on the processes said to give rise to beliefs (Skott, 2013, p. 549). This approach is similar to Sfard's (2008) commognitive framework, with its focus on discursive practice as a patterned activity.

Unfortunately, studies looking at how notions of the nature of mathematics, as described for instance in the literature cited above, are expressed through teaching practice are rare. The previously mentioned study by Lerman (1990) could be said to be one, although the principal focus of the empirical analysis in his (mainly theoretical) paper is on what student teachers' interpretations of a teaching episode tells us about their views of mathematics. Another example, which also happens to concern university teaching, is the study by Österholm (2010), investigating "what types of epistemologies are conveyed through properties of mathematical discourse in two lectures" (p. 241). Despite *Österholm's* paper being framed in the language of belief research, the analyses in fact focus solely on the epistemological character of mathematics as conveyed through the discourse. To this end, Österholm considers the types of statements and the type of argumentations used by the teachers. Of particular relevance for the present study is the distinction between use-statements, related to procedural knowledge; and object-statements, related to conceptual knowledge. A dominance of object-statements can be seen in the calculus lecture, indicating a focus on conceptual knowledge.

METHOD

The analyses presented in this paper are based on data collected for my doctoral thesis (Viirman, 2014a). This data consists of video recordings of first-semester mathematics lectures by seven teachers at three different Swedish universities, approximately two hours of video for each teacher. The teachers were selected among those volunteering to participate in the study, aiming for variety both in teaching experience and in topics taught. In this study, however, I am using data from lectures by three of the teachers (denoted A1, A3 and A4 in what follows, in accordance with other publications arising from this data, e.g., Viirman, 2014a; 2014b). These were chosen since the analysis conducted for the doctoral thesis indicated that they were the richest and most varied with regard to the aims of the present study. All three teachers work at the same university, one of the largest and most well-established in Sweden, and are experienced teachers, having taught university mathematics for more than 10 years. Teacher A1 is female, while the other two are male. All three lectures were given in courses aimed at engineering students, and were taught in a traditional style, with the lecturer talking and writing on the board. The number of students ranged from about 50 (teacher A1) to about 150 (teachers A3 and A4). Teacher A1 taught an introductory course, preparatory for calculus; teacher A3 taught linear algebra; while teacher A4 taught single-variable calculus. The topic in all three lectures was various aspects of the function concept. For more detail on the process of data collection, see (Viirman, 2014a; 2014b).

As part of the work on the thesis, the video recorded lectures were transcribed verbatim, speech as well as the writing on the board. For the present study, the transcribed lectures given by teachers A1, A3 and A4 were then analysed, first separately and then in comparison, looking specifically at how mathematical objects and the nature of mathematical knowledge were expressed through the teachers' discourse, focusing on word use and narratives. Regarding the teachers' use of definitions, and how new mathematical objects were introduced I looked, for instance, at how notions of agency were expressed in the discourse – whether these new objects were spoken of as originating outside of the discourse or within it. Concerning means of substantiation I looked, for instance, for utterances suggesting change in such means over time. Throughout I used the categorisations of Lerman (1990) and Davis and Hersh (1981) to guide my analyses. I want to stress that this is not a study of teachers' beliefs. I make no claims as to whether the ways in which mathematical objects and mathematical knowledge are articulated in the discursive activity in the lectures have any bearing whatsoever on the views the teachers might be holding regarding these matters.

RESULTS

Considering first the question of mathematical ontology, the discourse documented in this study is typically mathematical in that it is generally highly objectified. The mathematical objects are spoken of as being independently existing [1]:

> Teacher A4 So, it's about continuity, and that is a property that functions can have.
>
> Teacher A3 There is a transformation that we call, I don't know, id for identity, that takes every vector to itself.

In fact, functions are so much like physical objects that they can be moved around:

> Teacher A1 That is a function; it is the function x^2 that I move one step to the right and two steps upwards.
>
> Teacher A4 What happens to this function when x is bigger than one? (...) It goes down, yes, and then it will wander here, and get bigger and bigger and bigger.

However, looking at how new mathematical objects are introduced, narratives are framed in different ways, suggesting different ontological positions. Consider the following example:

> Teacher A1 for us to know what we are talking about, we have to begin by saying exactly what we mean by a function. I think that most of you already have a feeling for what it is that a function is, but maybe you haven't seen exactly a definition. Because, you know, it is like this in mathematics that all words we use, we have to say exactly what we mean by them so that we are totally agreed, if I say that all functions have a certain property, then all have to agree with me what objects we are talking about. We have to agree about what we mean by the word function.

Here, even though the functions are explicitly spoken of as objects, it is still clear that regarding the properties of these objects it is up to the participants in the mathematical activity to decide what they are. But all participants have to agree in order to be able to use them meaningfully. This way of talking is very much in accordance with the humanist philosophy, as formulated by Davis and Hersh (1981). Later in the same lecture, we find the following example. The teacher is discussing the unit circle, an example drawn on the board.

> Teacher A1 We would perhaps want this to be a function (...) but then when we insert something which isn't one or minus one

then we get- there are two y-values that fit, so the function doesn't give us exactly one, it gives more than one, and then it isn't a function.

Hence, although we, the participants in the mathematical activity, have ourselves constructed this object called function, we are not free to do whatever we want with it. Once we have decided what to mean by the word, it comes equipped with properties that are not ours to decide over. It is not enough that we want something to be a function; it has to agree with what we decided that a function should be. Again this corresponds to the humanist position, where mathematical objects, although human creations, still have objective properties.

Yet another example from the same lecture: having introduced trigonometric functions through right triangles the teacher notes that these functions are only defined on the interval $(0,\pi/2)$, and continues:

Teacher A1 We would want these functions sine and cosine to be defined for all real numbers, we would like to exchange this little piece for the whole of *R* (...) then we have to figure out how to do this, and before we do this we have to say how we are going to measure angles.

Again, it is up to us as participants to decide how to define the sine and cosine functions outside of the interval $(0,\pi/2)$. But, it can't be done any way we want. It has to agree with what has already been decided, that is, with how the functions are defined for acute angles.

On the other hand, the introduction of mathematical objects can be done through narratives framed in a very different manner:

Teacher A3 A function from R^m to R^n is called a linear transformation if it is linear, that is, if it satisfies two conditions:

The teacher then goes on to describe the two linearity conditions. After giving, as an example, a characterization of all linear transformations from *R* to *R*, he concludes:

Teacher A3 this was a very small example, and an example that has completely negligible importance for the rest of the course, but anyway it says something about that linear transformations are very rare. In any case they are very important.

As presented here, there are some things called functions, and among these a small number satisfy certain conditions, and these are called linear transformations. Indeed, these are spoken of as rare, almost as if talking about rare birds or flowers. There is nothing in the way these objects are discussed suggesting that they are anything other than objectively existing, independently of our working with them. No reasons are given for the linearity conditions looking the way they do, for instance. Looking at the example given at the start of the section about the identity transformation, the transformation is there, we as practitioners of mathematics just give it a name. Similarly, concerning the relationship between matrices and linear transformations:

Teacher A3 Every linear transformation defines a matrix which we will call the standard matrix of the linear transformation.

Again, the transformation defines the matrix; we only have to give it a name. This way of speaking about mathematical objects fits with the Platonist position.

Considering epistemology, that is, the questions of mathematical knowledge and how it is obtained, much of the discourse documented in this study is consistent with an absolutist paradigm. Claims are mainly justified using traditionally mathematical means of substantiation, for instance through mathematical proof or by reference to already established mathematical facts (for more detail on the teachers' substantiation routines, see Viirman, 2014b). Some examples:

Teacher A4 It isn't obvious that it is like this, this is not a property that all functions have, but for us it was a consequence of what? Two things. The basic properties of limits (...) and the standard limits.

Teacher A3 Why is it linear? It is linear precisely because matrix multiplication works like that.

The mathematical substantiations are mostly done through algebraic and numerical reasoning, as in the following example, where the aim is calculating the range of the function $f(x) = (x-1)^2 + 2$:

> Teacher A1 In this case, there is an even square here, plus 2. Even squares can be zero or bigger. (...) Hence it can be 2 plus something positive, so it can be all numbers that are greater or equal to 2.

Or here, part of the process of calculating the value of $\sin(\pi/4)$ from a diagram of half a square:

> Teacher A1 $[x_0^2 + x_0^2 = 1^2 \Rightarrow x_0^2 = 1/2 \Rightarrow x_0 = 1/\sqrt{2}]$

There are also examples of using geometrical reasoning to substantiate claims:

> Teacher A3 That these two vectors are perpendicular, this you can see immediately geometrically (...) If we project something which is perpendicular to *v* on *v*, then we just get zero, right? [Draws a vector pointing straight upwards, draws another vector pointing straight to the right and marks it by *"v"*, marks the angle between the two vectors as right.] Here is *v* [points to the vector *v*], here is something which is perpendicular [points to the vertical vector], if we project it down here [points to the base of the vertical vector] then we get sort of nothing.

In a similar fashion, teacher A3 shows the linearity of rotations in the plane by geometrical arguments, drawing vectors and their images under the transformation and showing why the linearity conditions are satisfied.

There are also examples of substantiations emphasizing the cumulative nature of mathematical knowledge, referring back to previously known facts, as in the excerpt quoted above, as well as in the following examples:

> Teacher A4 If someone were to twist your arm and say: How do you know that? Then it is precisely from the good old rules of limits.
>
> Teacher A4 And now it's time to reconnect this part of the brain that you have neglected for some time, namely complex numbers. Because the fundamental theorem of algebra says that a third degree polynomial has three roots, in general complex.

This is still consistent with an absolutist paradigm. There are however some examples of substantiations consistent with a fallibilist epistemology, where the historical development of mathematics is explicitly used in the teaching, emphasising the socio-historical nature of mathematical knowledge. Some examples:

> Teacher A4 In fact, this is how one often defines continuity during the 18th century, this means that the graph of this function if we are to draw it [Draws a coordinate system, and draws a connected curve] it hangs together like this; I can draw it without lifting the chalk from the blackboard.
>
> Teacher A4 This is the beginning of a line of work that is quite important within analysis, and which gained momentum during the latter half of the 19th century, when the deal was to find really pathological functions, that test our understanding of the function concept and what we can assume (...) A lot of great mathematicians spent time on this, and some people thought that it was totally nuts, such things don't exist, they are totally insignificant, can't be used for anything, and that turned out to be totally wrong.
>
> Teacher A4 I just read an article by a German mathematician from the late 19th century (...) and he spent half a page in his article explaining what this meant, it wasn't established at that time, the terminology was vague, and it isn't totally trivial what it means.

This way of using historical examples indicates how mathematical definitions are subject to change over time, and how even what is to be counted as mathematics is the subject of disagreement and controversy.

DISCUSSION

The results of the study show how different philosophical positions on the nature of mathematical knowledge and mathematical objects are articulated in the teaching discourse. The study is thus an example of how notions traditionally studied within the context of research on teachers' beliefs can indeed be studied purely on the level of discourse.

One prominent characteristic of the discourse of all three lectures documented in this study was the use of a highly objectified language, something Österholm (2010) also notes in his study. Some of the differences that could be seen, for instance, regarding the type of substantiations used for claims made, can probably be explained by differences in the courses taught. For instance, in an introductory course such as the one taught by teacher A1 one does not expect substantiation through previously established facts to be very prominent.

Still, there are other differences, more directly related to notions of the nature of mathematics, which are not obviously explained by differences in topic or level of the courses taught. For instance, the results show clearly how two different, and indeed contrasting, positions concerning mathematical ontology can be seen in the teaching discourse: a humanist position, emphasizing how the definition is something we as participants in the mathematical activity have agreed upon, and a more depersonalized Platonist position where mathematics is presented as something that is discovered, appearing fully formed.

Concerning the epistemology of mathematics, although the discourse documented in the study is generally consistent with an absolutist paradigm of mathematical knowledge, such statements may be interpreted differently depending on other aspects of the discourse. For instance, statements suggesting an absolutist position may be interpreted differently in the light of whether emphasis is generally placed on the man-made character of mathematical objects or, on the other hand, on a more Platonist way of talking about mathematical objects. Similarly, an emphasis on the socio-historical development of mathematics (humanism position) makes an absolutist interpretation of the mathematical discourse less likely. One might point out here, however, that the use of historical examples does not in itself necessarily suggest a fallibilist epistemology. As Lerman (1990) indicates, "[w]hilst it may be generally accepted that, in its external history, it is influenced by cultural determinants and social factors, the prevailing view is that the mathematical knowledge that results is self-justificatory in terms of its truth" (p. 54). It might be possible to interpret some of the statements quoted above in this way. For instance, on the topic of the classic theorems on continuous functions (the maximum value theorem, the mean value theorem etc.) when the teacher notes that "it wasn't established at that time, the terminology was vague", this could be taken to mean that mathematicians have now established the true state of affairs. Although such an interpretation might be less likely, one would have to gather more data, both in the form of further recordings of his teaching, and data on how students interpret the use of the history of mathematics in teaching, to be able to draw more certain conclusions.

Indeed, data on the students' interpretations of the teaching practices would be useful, to establish whether the notions of mathematics constituted through the teachers' discursive practices actually have any effect on student learning. It has been claimed by many within the mathematics education community that students' beliefs about mathematics affect their learning (e.g., Pajares, 1992). Even if one accepts Skott's (2013) critique of the concept of belief, increased knowledge of how notions of the nature of mathematics are constituted through teaching practices, and of how students interpret these practices, would be useful to gain further insight into the relationship between teaching and learning mathematics.

More generally, although the present study is small, the conclusion that notions traditionally considered as belonging to the field of belief research can actually be studied as features of discourse could be of importance to any researcher interested in such aspects of mathematical teaching and learning.

The transition from informal to formal understanding of the concept of order in abstract mathematics

Mustafa Akdemir, Serkan Narlı and Muhammet Kaşıkçı

Dokuz Eylül University, Faculty of Education, İzmir, Turkey, mustafa.akdemir@deu.edu.tr

This study presents an analysis of the answers given by prospective teachers to a questionnaire that consisted of 6 open ended questions. They answered the questions before meeting the formal definition of order relation and after getting familiar with the formal definition of order relation. In this context, the theoretical perspective of concept image and concept definition is used in the study.

Keywords: Concept image, concept definition, concept of order, order relation.

INTRODUCTION

Considering the theoretical perspective of concept image and concept definition by Tall and Vinner (1981), this study constitutes a detailed report regarding how and to what extent prospective teachers convert the informal information regarding order notion to formal information after the subject of order relations is taught in abstract mathematics.

RESEARCH QUESTIONS

RQ1: What are the concept images and informal definitions of undergraduate students related to the concept of order?

RQ2: After meeting the basic definitions of order relation, what type of changes happen in students' concept images?

CONTEXT OF THE STUDY

Order relation is one of the important concepts in abstract algebra. By using order relation, the elements of a set can be ordered and the maximum, minimum, supreme, minimum, maximal and minimal elements of this set can be determined. In daily life whenever a comparison is done such as big-small, thin-fat, richest-poorest etc., we can say that order relation is an intrinsic part of these comparisons. Nevertheless, it may be thought that students generally may not be aware of these associations between the daily usage and the concept of order relation which they learn in school (Narlı, 2013). In this context, it can be thought that the concept of order used in daily life informally can be associated with the concept of order relation in an academic setting.

In this qualitative study, using content analysis, a questionnaire – that aimed to inform us about students' concept images of order and was made up of 6 open ended questions – was applied to 25 first year students in the department of Elementary Mathematics Teaching at Dokuz Eylül University. The following six questions were asked to the students:

Q1.What comes to mind when you hear the phrase, "order notion?" Q2. Can the symbols "□,D,⋕,*" be ordered? If yes, show how you order them. Q3. May an infinite set be bounded? Explain. Q4. May a finite set be boundless? Explain. Q5. Is there any set where any two different elements can't be compared with each other in terms of greatness-smallness? Write your justification and exemplify it. Q6. What is order relation? Explain.

RESULTS AND CONCLUSION

Our analysis revealed some concept images (CI) as well as data that we were not able to classify as concept images (CD, as in "categorized data") – see Table 1.

If we consider our research from the theoretical perspective of concept image and concept definition, we

	Before meeting definition (with frequency)	After meeting definition
Q1	*CI-1*"Grouping of elements" *(5)* *CI-2*"Determining arbitrary criterion (rule)" *(11)* *CI-6*"Everything can be ordered" *(3)* *CI-4*"Only the numerical data can be ordered" *(6)*	*CD-2(22)*"The category points to undergraduate students who answered Q1 by associating the formal definition (order relation)", *CI-1(3)*
Q2	*CD-1(17)* "The answers that seem as unconcerned to our research questions and the answers that are left blank can be categorized as CD-1", *CI-2(8)*	*CD-2(21), CI-2(4)*
Q3	*CI-3*"Boundedness and boundlessness vs. finiteness and infiniteness" *(21), CD-1(4)*	*CI-3(15), CD-1(10)*
Q4	*CI-3 (15) CD-1(10)*	*CI-3(7) CD-1(3) CD-2(14)*
Q5	*CI-4(17)* *CI-5*"Elements should be of the same type" *(7)* *CI-7*"Infinite decimal numbers cannot be ordered"*(1)*	*CD-3(19)* "Some undergraduate students tried to answer the question by defining a mathematically convenient order relation", *CD-1(6)*
Q6	*CD-4*"this category points to the answers which have statements that are inconsistent with the formal definition" *(20)* *CD-1(5)*	*CD-5(21), "*students provided formal definition of order relation*" CD-1(4)*

Table1: Categories of concept images and categorized data

can say that concept images have a vital role in formation of the formal definitions. Prospective teachers' concept images need to be approached attentively in the instruction plan. This study may be carried forward with greater sample groups and different theoretical perspectives.

Improper integrals in a CAS environment

Francisco Javier Cortés González and Hugo Rogelio Mejía Velasco

CINVESTAV, Ciudad de México, México, fjcortes@cinvestav.mx, hmejia@cinvestav.mx

With an instrumental approach in a CAS environment, our research is oriented towards the development of instrumented action schemes. Involving concepts related to improper integral and the use of the parameter, this paper presents the tasks that aim to identify the functional relationship that fits the graph of the points defined by the parameter values and the value of the improper integral convergent.

Keywords: Instrumental genesis, improper integral and instrumented action scheme.

This paper presents part of a teaching sequence based on the *instrumentalist theory* (Verillon & Rabardel, 1995), where an *artifact* and an *instrument* are differentiated. Trouche (2005) argues that the construct called *instrumental genesis* is a complex process linked to the characteristics of the *artifact* (its potentialities and constraints) and it can be explained by the *use of schemes* and *instrumented action schemes*.

An *instrumented action scheme* is a stable mental organization which includes technical skills, concepts and theorems, supporting a way to use a device, in order to perform a class of tasks (Drijvers & Gravemeijer, 2005). Drijvers and Gravemeijer (2005) use the notion of the *instrumented technique* developed by Lagrange (1999) and consider it the visible external part of the *instrumented action scheme*.

METHODOLOGY

The teaching sequence comprises two stages: one for training in a CAS environment and another where students perform the designed activities. The CAS environment where our research is based is the Derive software. Ten engineering students voluntarily participated in the experiment.

Following the line drawn by Drijvers and Gravemeijer (2005) for the identification of an *instrumented action scheme* as a list of key elements which includes technical and conceptual aspects for a specific task involving the use of a command from the CAS environment, the *instrumented action scheme* is established as *a priori* guidance on the design of activities to be implemented.

The given functions were , ; with, , and . The task consisted of exploring the "Product of the function and the function ". Using the "vector" command of the Derive software, the requested activities were to explain the behavior of the family of curves generated by the product where runs on the interval for possible values of the parameter ; to calculate the improper integral for some values of the parameter , to complete a table with the values of the parameter and the value of the improper integral when converges; to plot the points and to consider if there was any function or piece function that fits the plotted points above.

A training for using the "vector" command allows the student to use the potential in this facility. We expect the student to use the syntax and in order to analyze different behavior when runs between and with distinct *steps*.

RESULTS AND COMMENTS

The purpose of the activity related to the use of skilled and trained software Derive "vector" command is fulfilled by students. This is observed in actions undertaken with the software and the answers given in their worksheets. Intervention for students assigned a different "*step*" to an integer value in the corresponding syntax needed.

The students require intervention to identify the improper integral as , which may be finite, infinite or not exist. They also recognize the range of real numbers of the variable for the function has an asymptotic or exponential behavior.

The students explained the asymptotic or exponential behavior of the generated family of curves, use the "vector" command and graphics software resources. They also employed the "vector" command to calculate the requested improper integral and to identify the functional relationship which conforms the graphical representation of for values of the parameter when the improper integral is convergent. The students developed the *use schemes* for CAS commands. However, those are the conceptual aspects of the commands that require intervention. We can see this in the difficulty to identify the parameter as a real number that infinitely takes many values – and thus the potential use of the "vector" command – as well as in the difficulty for the students to properly identify when an improper integral converges or diverges. The differentiation of the technical and conceptual aspects from the *scheme instrumented action* allow timely intervention on the weaknesses shown by students.

Revival of classical topics in differential geometry

Thierry (Noah) Dana-Picard and Nurit Zehavi

Jerusalem College of Technology, Weizmann Institute, Jerusalem, Israel

We present a reflection on the usage of modern algorithms and technology, in order to revive topics of classical Differential Geometry. This enables students to acquire new mathematical knowledge and provides new skills for applied science.

Keywords: Differential geometry, 1-parameter families of curves, envelopes, technology.

MOTIVATIONS

Classical topics in Differential Geometry like the study of 1-parameter families of curves and their envelopes have been abandoned in the past for various reasons: the classical theory may not be rigorous enough, it has too many particular cases, it may be so rich that it cannot be forced into a rigorous pedagogy, nothing ensures that all the "pathological" cases have been included in a catalogue, etc. (Thom, 1962).

Nevertheless, this topic has a great interest, both in mathematics and in modern applied science. It can be studied via a blended activity, i.e. pencil and paper work together with CAS work. Moreover it has many applications in science and engineering – caustics and wave fronts, i.e., Geometrical Optics and Theory of Singularities (Arnold, 1976), robotics and kinematics, rigid motion in 2-space and in 3-space, collision avoidance, etc. (Pottman & Peternell, 2000). This topic is also connected to the theory of billiards.

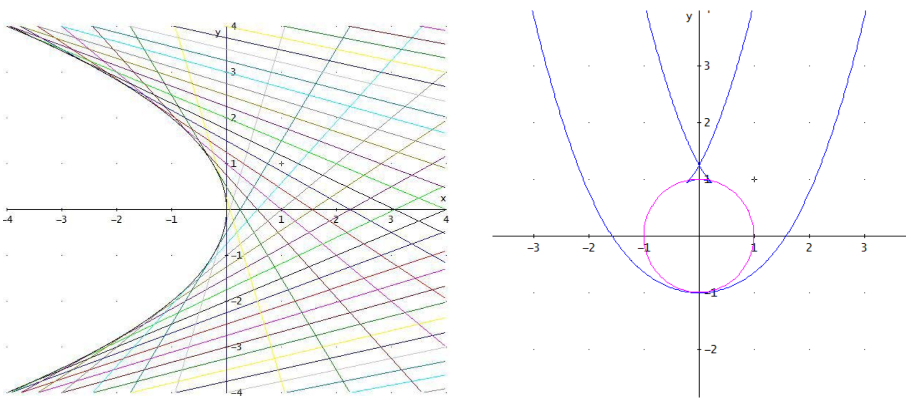
EXAMPLES

Let be given a family of plane curves by an equation $f(x, y, c) = 0$, where c is a real parameter. An envelope of the family, if it exists, is a curve tangent to every curve in the family. It can be shown that this envelope is the solution set of the system of equations $f(x, y, c) = 0$, $\frac{\partial f}{\partial c}(x, y, c) = 0$. Figure 1a shows the envelope of the family of lines given by the equation $x + cy = c^2$ (it is the parabola whose equation is $x = -y^2/4$. Figure 1b shows the envelope of the family of circles with radius 1 and centre on the parabola whose equation is $y = x^2$ (here the result has two components).

STRUCTURE OF A WORKING SESSION

We use infinitesimal methods for exploration and derivation of the equations, then algorithms based on Gröbner bases computations, first to solve the system of equations, and then to transform the obtained parametric representation into an implicit one.

This is a core issue in other fields (Pech, 2007). A similar, but non identical, scheme gives the mathematical educational frame for other topics in Differential



(a) (b)

Figure 1: Exploration of envelopes

Geometry, giving an extension of the curriculum (Dana-Picard, Mann, & Zehavi, 2014).

CORE ISSUES

Such a study provides an opportunity to discover new topics beyond the scope of the regular curriculum, sometimes together with applications to practical situations. New computation skills with technology may be developed, in particular for the experimental aspect of the work (e.g., exploring the existence of cusps, as in Figure 1b). For this, the availability in the software of a slider bar is a central issue. Moreover, ability to switch between different registers of representation may be improved, within mathematics itself (parametric vs implicit) and with the computer (algebraic, graphical, etc.). An interesting instrumental genesis may appear (Artigue, 2002) and mind-and-machine interaction is a central feature of the work.

An envelope may not exist (e.g., for a family of lines where the coefficients of the equations are affine functions of the parameter). These issues have been observed by the authors in sessions for in-service teachers at the Weizmann Institute of Science.

Tutorial teaching to enable undergraduate students to make meaning with mathematics

M. Gozde Didis[1] and Barbara Jaworski[2]

1 Gazıosmanpasa University, Faculty of Education, Tokat, Turkey, gozde.didis@gop.edu.tr

2 Loughborough University, Loughborough, United Kingdom

The poster reports from a study of teaching in one small group tutorial with first year mathematics students in a UK university. The aim was to characterise teaching that was designed to support students' meaning making in mathematics. The research was developmental in that it contributed to the development of the teaching, as well as the tutor's knowledge in teaching. Two researchers, one who was also the tutor, collected and analysed data in the form of recordings of each tutorial and reflections of the tutor. Analysis was grounded in the data and a theoretical construct, the Teaching Triad, was used to support analysis. Findings showed the tutor taking a questioning approach, seeking to probe students' meanings, but needing to prompt frequently due to students very short and tentative responses. The study points to the difficulties in encouraging students to articulate their mathematical understandings.

Keywords: University mathematics teaching in small group tutorials; teaching triad; teacher questioning; difficulty in students' articulation of mathematics.

INTRODUCTION

In this paper, we focus on teaching in a small group tutorial in the first year mathematics programme at a UK university. We studied 10 tutorials in all and focus here on one tutorial which addressed questions in linear algebra. We are interested in studying relationships between the planning for teaching and teaching approaches, and the responses of students in so far as they gave access to the students' meaning making in mathematics (Jaworski & Didis, 2014). Our three basic research questions are:

1) What is the nature of the teaching manifested in the tutorials?
2) What student meanings can we discern and in what ways?
3) In what ways can we link (1) and (2) and what issues does this raise?

We took a sociocultural approach toward the research, recognising the many factors that underpinned activity in a tutorial, contributed to the interactions between students and tutor, and to mathematical meaning-making by the students. We see that, making connections to the worlds of mathematics and beyond, and processes of socialisation into culture and values are all central to how mathematics is taught and, associated with this, how students make meaning in mathematics.

APPROACHES TO OUR RESEARCH

The tutor (the second author of this paper) planned the tutorials and worked with the students. Her co-researcher (the first author) observed and audio-recorded tutorials and transcribed the recordings. Our conversations we sat together after tutorials were also audio-recorded; capturing the tutor's teaching reflections and our analytical discussion as two researchers. In working on our data we combined a grounded approach with the application of the 'Teaching Triad', a theoretical model which has been used extensively for analyses of teaching (e.g., Potari & Jaworski, 2002).

We read and reread the data, developing a coding scheme and seeking to make sense of the data in relation to our research questions. In addition we explored the nature of the teaching using the Teaching Triad. These forms of analysis were inter-woven to provide a rich characterisation of teaching practice. Our approach was two-fold: (a) reflections on the tutor's discerning of meaning-making in the tutorial in order to guide the teaching approach; (b) the discerning of meaning making through analysis of tutorial dialogue in order to link teaching with learning.

RESULTS AND CONCLUSION

Analysis revealed many aspects of teaching and ways in which the teaching approaches "in practice" related to the approaches planned. A finer grain of analysis showed that the codes relating to "tutor questioning" were the most prevalent. Through questions, the tutor not only invited and encouraged students' participation, but also tried to control the mathematical focus of the tutorial. She asked *prompting questions* to invite students to respond and articulate students' meaning, trying to promote both individual meaning and collaborative meaning of students. The following dialogue illustrates an example of the tutor's approach.

Tutor:	Now, Julia, what is the standard basis in R^3? *[Prompting-Q]*
S: (Julia)	A matrix *[SR-short/hesitant]*
Tutor:	Is a basis a matrix? *[Prompting & Probing-Q] [Mathematical challenge]*
S: (Julia)	No *[SR]*
Tutor:	Ok, what is a difference? *[Probing-Q] [Mathematical challenge]*
S: (Julia)	Vectors (*student smiles*) *[SR-short/tentative]*
Tutor:	If I asked to write down the standard basis in R^3, what would you actually write? *[Prompting-Q]*

Students' responses were mostly short, tentative and hesitant. This led us to deduce that discerning meaning making was difficult and time consuming. University cultures and practices, in which students are rarely expected to speak their mathematical thoughts or engage in discussion, result in such engagement being uncommon. Therefore, in relating the teaching approach to students' meaning making with mathematics, we need to address further: (i) what students expect from these tutorials and what their readiness is to deal with the planned teaching; (ii) what the tutor expects from the tutorial and wants to see from students, and how this can be achieved; and, (iii) what time factors influence the depth of students' meaning making.

A geometric approach in teaching differential equations

Younes Karimi Fardinpour

Islamic Azad University, Ahar Branch, Department of Mathematics, Ahar, Iran, y-k-fardinpour@iau-ahar.ac.ir.

INTRODUCTION

This study aims at exploring the challenges that students encounter when they learn about differential equations. The study was conducted as a one-semester project with second-year students at one Iranian university. Students received nearly 9 hours of instruction in a differential equation course. In the task "What does the differential equation $dy/dt = y^2(4 - y^2)$ predict $y(t)$ for (a) $y(0) = 3$, (b) $y(0) = -1$ and (c) $y(0) = -2$" one of the students, Rogayeh, figured out the correct answers to parts (a) and (b) but she was unable to address the part (c). Why would she be able to do parts (a) and (b), but fail to part (c)? I had the opportunity to become aware of some challenges that students encounter when they learn about differential equations by conducting an in-depth one-on-one task-based interview with Rogayeh. She had arrived at correct conclusions, yet underneath lay erroneous ideas and conceptual gaps.

RESULTS AND DISCUSSION

As shown in Figure 1, Rogayeh does not plot the equilibrium solution curves. I asked "What is the limit of $y(t)$ for (a) $y(0) = 3$, (b) $y(0) = -1$ and (c) $y(0) = -2$?" She was unable to address the last of these questions, although she answered part (a) and (b) correctly as 2 and 0. So I asked "may you show me the equilibrium solutions in your solution curves?" She couldn't. So I changed my question to "What is an equilibrium solution?" She answered "… equilibrium points are −2, 0 and 2. … they are functions whit fixed values." Hopefully this answer was helpful, I continued "Excellent. Well, now where are these fixed value functions?" But she couldn't answer.

After some more conversation she said "If you ask me about $y(0) = 2$ then the answer is 2. But in $y(0) = -2$, solution curves are not convergent." By her description, I realized why she couldn't answer part (c). Because she saw the solution curves related to the $y(0) = -2$ were not converging (see Figure 1). This is a challenge that students encounter when they learn about differential equations. As a matter of fact, she thought that the differential equation $dy/dt = y^2(4 - y^2)$ predict $y(t) = 2$ for $y(0) = 2$ because solution curves are convergent. It shows that behind the students' correct answers there often lay an incorrect conception of equilibrium solution (Rasmussen, 2001).

Then it was a good time to ask "What do you predict if the $y(t)$ starts off at exactly zero?" Immediately she answered "zero" and explained that "by putting a zero instead of y in $y^2(4 - y^2)$, the answer is zero". I would expect Rogayeh's notion of equilibrium solution in zero to be a subset of her notion of a fix value function as she mentioned before. But this did not appear to be the case. Consistent with Zandieh & McDonald's (1999) findings, this incident suggests a conceptual challenge that may lie beneath a correct answer.

When I asked "What is the relationship between solution curves and the graph of the $f(y)$?" Rogayeh did not answer. So I asked "How do you see the relationship between solution curves and the phase line?" She answered "… solution curves are increasing or decreasing according as arrows in the phase line … arrows on the phase line are according as $f(y)$ sign…" Although she links the phase line and the solution curves, as well the sign of $f(y)$ in the sign chart and the phase line. But she is not able to connect the graph of $f(y)$ and solution curves.

This study is yielding new insights into the challenges that students encounter when they learn about differential equations. It seems more research into these challenges is needed so that new pedagogical strategies can be created that will help students overcome these challenges.

Aspects obstructing or facilitating examination success for first year engineering students

Birgit Griese[1], Malte Lehmann[2] and Bettina Roesken-Winter[2]

1 Ruhr-Universität Bochum, Bochum, Germany, birgit.griese@rub.de

2 Humboldt-Universität zu Berlin, Berlin, Germany

When analyzing influences on examination success in reference to learning strategies, we found that Effort played an important role. This supports the importance of affective and motivational aspects in the teaching of mathematics.

Keywords: Learning strategies, effort, affect, motivation.

Engineering students often have trouble passing mathematics examinations. Some approaches to remedy this relate to cognition, others to affect. Another one, improving learning strategies, is promising as it relates to both aspects *and* provides a perspective for interventions.

THEORETICAL CONSIDERATIONS

The obstacles students are facing when starting a course in mathematics at university can be categorized in different ways (cf. de Guzmán, Hodgson, Robert, & Villani, 1998). When the emphasis is on learning strategies, interventions can address cognitive aspects, learning resources or the metacognitive level. The design research (van den Akker, Gravemeijer, McKenney, & Nieveen, 2006) project MP²-Math/Plus is based on the hypothesis that learning strategies are the key to influencing learning behaviour (cf. Dehling, Glasmachers, Griese, Härterich, & Kallweit, 2014). Apart from providing a selected group of students with special coaching, MP²-Math/Plus researches learning behaviour and collects data on personal circumstances and examination success. In order to cover different aspects of learning behaviour, the LIST questionnaire (Wild & Schiefele, 1996) was employed. This questionnaire is divided into eleven scales covering different cognitive, metacognitive and resource-related learning strategies. Thus it is appropriate for answering the research question: *What patterns are emerging when analyzing examination success in terms of these three measures: learning strategies, participation in a project on learning strategies, and gender?*

SELECTED METHODOLOGICAL DECISIONS

LIST factor scores were calculated (N=653), yielding values between 0 and 100. Mutliple linear regression identified factors with relevant influence. Descriptive statistics were computed (N>1750), differentiating between project participation, examination success, and gender.

RESULTS AND IMPLICATIONS

Internal reliability of the scales was satisfactory ($\alpha > 0.7$). The correlations between the factors were below 0.63 (highest between *Effort* and *Metacognition*), allowing for multiple linear regression with LIST factors as predictors and the examination result as outcome. This explained 23% of variance and highlighted the importance of *Effort* ($p = 0.000$), *Using Reference* ($p < 0.001$), and *Time Management* ($p < 0.01$), with standardized $\beta_{\text{Effort}} = -0.50$, $\beta_{\text{Reference}} = 0.24$ and $\beta_{\text{Time}} = 0.18$. Interestingly, all these are resource-related learning strategies, and among these three, only *Effort* improves examination achievement. Other supportive (though not significant) influences were found in *Organizing* (structuring and summarizing subject matter) and *Learning Environment*. The hypothesized relevance of *Metacognition* is not directly mirrored in the results, but becomes evident through its relatively high correlation to *Effort*.

Gender had no detectable influence on any kind of learning behaviour, although females participating in MP²-Math/Plus achieved significantly higher pass rates than their male counterparts, e.g. in 2013, 79.31% of female but only 68.29% of male participants passed the examination. On the whole, project participation helped examination success, with some variance among project years, the most substantial success being a pass rate of 72.86% among participants, compared to 57.97% for non-participants in 2013. Moreover, achievement was significantly higher ($p = 0.007$, $t(89.928) = -2.125$, $r = 0.219$), although the MP^2-Math/Plus concept postulates deliberately choosing students with below average prior performance.

These results indicate the importance of fostering aspects covered by the *Effort* scale. These items (e.g., *I do not give up even though the subject matter is very difficult and complex* or *Whenever I have planned a certain workload, I make an effort to master it*) relate to perseverance and motivation, describing attitude rather than aptitude. It seems advisable to continue focusing on affective and motivational aspects and not relying on cognition alone. In order to gain detailed insight, the next step will be qualitative analysis, e.g. through interviews.

Language and students' conceptions of logic in undergraduate mathematics

Mercy Kazima, Levis Eneya and Patrick Sawerengera

University of Malawi, Zomba, Malawi, mkazima@cc.ac.mw

Issues of learning mathematics through a foreign language have been discussed by many researchers, however, the focus has mostly been on primary and secondary schools and not university. This poster presents findings from a study that focused on university and investigated undergraduate students' meanings for mathematical terms used in logic. The sample was 89 second year university students that had studied the topic of logic in mathematics in Malawi where English is the language of instruction but not the students' mother tongue. The students were asked to write down what they understood by a list of mathematical statements such as: if and only if, implies, and, or, and not. Findings suggest that even at undergraduate level, the mother tongue influences students' conceptions of mathematical terms. The poster presents some examples of students' responses and discusses possible reasons for the responses in relation to the mother tongue. Furthermore, the poster discusses some implications for teaching logic specifically and teaching mathematics in general, to undergraduate students' learning mathematics in English as foreign language.

Key words: Language, logic, Malawi, mathematical terms, undergraduate.

INTRODUCTION

This paper reports a study that investigated students' conceptions of meanings of mathematical terms used in Logic, which are also used and applied throughout the undergraduate mathematics courses, and their meanings are often assumed to be understood by the students. The paper focuses on four terms: *or, implies*, *if and only if*, and *there exists*. The study took a constructivist view of learning that meaning is not transferred from teachers to learners but that meaning is constructed by the learners. This construction of meaning is influenced and affected by the learners' prior knowledge (Vygotsky, 1962). From previous studies, we expected that ordinary English and the students' local languages might influence their conceptions of the mathematical terms (Kazima, 2006). Furthermore, it is well known that students face difficulties with mathematical terms that have different meanings in ordinary English from mathematical English (Orton, 1992).

METHODOLOGY

Fifty (50) undergraduate students that have studied the topic of Logic in English, which is not their mother tongue, were asked to write down what they understood by a list of mathematical statements including the following four: (i) *or*, (ii) *implies*, (iii) *if and only if*, and (iv) *there exists*. The students were also given a short test where the statements were applied, These included *True* or *False* statements where they had to provide reasons for their answers, for example, '8 = 27 *if and only if* 2 = 3' Students responses were coded

	Term	Percentage of students that gave valid meaning	Percentage of students that gave valid example
1	or	14	12
2	implies	56	42
3	If and only if	4	8
4	There exists	38	36

Table 1: Percentage of students that gave valid meanings and examples

	Term	Common meaning	Examples
1	Or	One or the other	A baby can be a girl or boy
		Not sure	I am not sure if I should go or not
2	Implies	As a result	I cook implies I eat
3	If and only if	The only way	if and only if it stops raining then I will go to town
		Only condition	I will have money if and only if my mother comes
4	There exists	Something is discovered	There exists some numbers

Table 2: Some common responses for meaning of terms

and analysed using SPSS, and common responses for each of the terms were recorded.

FINDINGS

Table 1 shows the percentages of students that gave valid meanings of each of the terms and percentages that gave valid examples for the terms. Table 2 shows some of the common responses.

DISCUSSION AND CONCLUSION

The findings suggest that even at undergraduate level, language is an issue and influences students' conceptions of mathematical terms. This is important because it affects the students' understanding of Logic as a topic in mathematics and their ability to apply logical statements in mathematics in general.

The common responses that *or* is a 'choice' from two things that cannot occur together, and that *if and only if* is emphasis on the condition for something to happen may not be new, but worth noting because these terms are used throughout the undergraduate mathematics courses, and therefore important for students to have precise meanings.

What does pedagogical content knowledge (PCK) in the context of university mathematics teaching mean?

Azimehsadat Khakbaz

Bu Ali Sina University, Hamedan, Iran, azimehkhakbaz@ymail.com

Although university mathematics teachers have an influential role on developing culture of teaching-learning mathematics in society, little is known about which kinds of teaching knowledge a future university mathematics teacher should have. Pedagogical content knowledge (PCK) provided a suitable theoretical base to study university mathematics teaching knowledge. This study aimed to find out what pedagogical content knowledge (PCK) in context of university mathematics teaching means. To answer this question, this research has done through grounded theory. Data were gathered by interviews from 27 university mathematics teachers (8 mathematics faculty members and 19 PhD students as future university mathematics teachers) and analysed through coding and categorizing. Data analysis revealed a detailed model which described PCK in context of university mathematics teaching.

Keywords: University mathematics teaching, university mathematics teacher, teaching knowledge development, pedagogical content knowledge (PCK).

RESEARCH PROBLEM

PCK was first introduced by Lee Shulman as a "missing paradigm" in teaching in the 1980s. Shulman (1987) identified seven domains of teacher knowledge, one of which is PCK: content knowledge; general pedagogical knowledge; curriculum knowledge; pedagogical content knowledge; knowledge of learners; knowledge of educational context and knowledge of educational ends. He described PCK as a special amalgam of content and pedagogy that is uniquely the province of teachers, their own special form of professional understanding. He also noted that PCK itself includes knowledge of learners, knowledge of educational context, and knowledge of instructional materials.

One of the most important conceptualizations of PCK was proposed by Hill, Ball and Schilling (2008) and was labelled mathematical knowledge for teaching (MKT). These authors divided MKT into two categories: subject matter knowledge (SMK) and PCK. SMK was described as consisting of three domains of knowledge: common content knowledge (CCK), specialized content knowledge (SCK) and horizon content knowledge (HCK). Knowledge of content and students (KCS), knowledge of content and teaching (KCT) and knowledge of content and curriculum (KCC) are defined as being included in PCK.

The MKT model has provided a useful foundation in mathematics education at lower grade. Speer and King (2009) analyzed CCK, SCK and PCK in mathematics teaching at higher levels. Their research concluded with a set of questions that they believe are important for the research community to consider as investigations of teachers' knowledge more broadly and beyond school contexts.

Speer and colleagues (2015) demonstrate that the nature of SMK, especially CCK and SCK, for university teachers are different from that of school teachers. Therefore, conceptualization of PCK in university mathematics teaching needs more study.

RESEARCH METHODS

This research was conducted through the grounded theory approach. The study took place in Iran, a country with a centralized higher education system. Two universities were selected for gathering data. In each university, participants were 8 mathematics faculty members and 19 PhD students as future university mathematics teachers. Data of this study were gathered mainly through semi-structured interviews of the participants' experiences of teaching and learning mathematics at university. Interviews were transcribed and analyzed through coding and categorizing.

FINDINGS

Data analysis revealed that we could conceptualize PCK for teaching university mathematics through relationships between four main categories of knowledge:

- Knowledge about the context of mathematical concepts
- Knowledge about students' understanding of mathematics
- Knowledge about mathematics curriculum planning
- Knowledge about creating an influential mathematics teaching-learning environment

Tackling the difficulties of the transition from school to university mathematics

Eirini Kouvela[1], Irene Biza[2] and Theodossios Zachariades[3]

1 Loughborough University, Loughborough, UK, e.kouvela@lboro.ac.uk

2 University of East Anglia, Norwich, UK

3 University of Athens, Athens, Greece

This paper reports on a study that investigates the difficulties encountered by first year undergraduate mathematics students during their transition from school to university mathematics. The research is a case study of five students who were followed regularly from the beginning until the end of the semester through questionnaires and interviews while they were attending a Calculus course. The results of the research revealed difficulties faced by undergraduate students regarding the content of the module and the social and academic context. In addition, the research suggests a categorization according to the approaches that students adopted in order to tackle these problems.

Key words: *Transition, university mathematics, first year undergraduates, calculus.*

This paper reports on a study that investigates the difficulties first year undergraduate students of a Greek department of Mathematics who attend a Calculus course face in their transition from secondary to tertiary education and how these students deal with these difficulties. The main research questions are: (a) Which difficulties do first year mathematics students face in their learning of Calculus during their transition from school to university? (b) To what extent do the social and academic environment affect the transition? (c) How do students deal with these difficulties? The results we report in this paper regard mainly the third question.

Transition problems from secondary school to university mathematics have been a recurrent issue which varies across different educational systems. Researchers note that there is a gap between school and university mathematics. School students study mathematics in a different way than the one required in university and as Clark and Lovric (2008) have indicated, mathematics courses at university focus on conceptual understanding whereas school mathematics tends to have more procedural characteristics. Advanced mathematical thinking requires students to develop working techniques that are necessary to understand and apply mathematical notions, definitions, theorems and proofs and this is a challenge for first-year students entering tertiary education (Hoffkamp, Schnieder, & Paravicini, 2013). Apart from factors related to mathematical content, other factors are also important when students are entering university. These include their mathematical background, the academic and social environment, and their study habits (Pongboriboon, 1992).

In the department of mathematics where this study was conducted, Calculus is offered in the autumn semester of the first year with four hours of lectures and two hours of tutorials. Attendance is not obligatory and students have the option to sit the exams just after the end of the teaching period in January and resit in July or September, if they fail, or transfer their assessment to the resit periods directly. Also, students have the option to drop out of the module and register in it again the following year.

The research is a case study of five students who were followed from the beginning until the end of the semester. Data collection was separated in two phases. In the first phase a questionnaire was handed out in a Calculus course consisting of general questions about students' profile (e.g., gender, grades in secondary school, etc.) and some mathematical tasks. Then five students were selected according to the criteria of gender, grades and responses to the tasks and were interviewed. The second phase of the research included three successive interviews that were spread across the first semester and were conducted by the first author. During the first two interviews students talked about their experience in the university, responded to a set of mathematical tasks and commented on their responses to these tasks. In the last interview students were asked about their overall experience in the Calculus module and their new life in university.

The results of this research revealed that students face various difficulties during their transition from secondary to tertiary education. Some of these difficulties concern the content of the taught module, in our case Calculus, and some others to the new social and academic environment that students have to adjust to. Analysis suggested three categories of students in terms of the approaches they used to tackle these difficulties. In all categories students begin their studies with great interest in mathematics. In the first category, students face difficulties mainly with the mathematical content. They consider the Calculus module very difficult. They become disappointed in the first weeks and they decide to transfer the module to the following year and pay attention to other modules which are easier to them: "It is not going very well because I am left behind, I said I would study on my own because I could not understand the first things we have done and then I just quitted and I thought of studying another module." In the second category students realize from the beginning of the semester the differences between school and university, such as the new environment, the content of the module, the way the course is taught and the study habits. Despite the difficulties, they study hard: "[...] I started dealing with it [module] more seriously, studying more and considering the whole situation in a more mature way". However this is not always effective due to their lack of mathematical understanding. In the third category, similarly to the second one, students face difficulties but mostly to the social and academic environment of university. The autonomy of university work challenges them mostly but gradually they adopt a new way of thinking. In the end they find a way to adjust to the new institution: "There are differences [from school] that make you feel insecure, it is a new environment that you have to integrate into, find your own path [...] in the beginning you feel like you are lost, but once you find your way everything works better."

Typology of incoherence due to the didactic transposition in Quebec textbooks introducing abstract algebra

Ismaïl Régis Mili[1] and Isabelle Ascah-Coallier[2]

1 University of Montréal, Department of Didactic, Montréal, Canada, ismail.mili@umontreal.ca

2 University of Montréal, Department of Mathematics, Montréal, Canada ascahc@dms.umontreal.ca

INTRODUCTION

As shown in the Quebec Ministry of Education curriculum, the first notions of abstract algebra are presented in the linear algebra class, at CEGEP level (students of 17 to 19 years old). After a census of the 13 French CEGEP of Montreal region, which offer pre-university preparation for mathematics, we found out that four textbooks (regularly re-edited) are used by the majority of teachers as guidance for this class (Ouellet, 2002; Amyotte, 2009; Charron & Parent, 2005; Papillon, 1993, 2012). Unlike high schools, CEGEP are free to choose the didactic material they propose to their students; textbooks do not have to be approved by a Ministerial commission. However, for the sake of consistency, editors try to respect ministerial guidance and organise the textbooks following objectives given by the ministry. Notably, amongst those programme objectives (MELS, 2010, p. 5), we found that the most relevant to the class of linear algebra students were:

- identify a certain amount of ideas in link with the subject to compare, classify and evaluate them;
- link pertinent ideas in a logical order;
- building a coherent argument / reasoning / proof (loose translation).

Goal of the research

It therefore seems relevant for us to inspect to what extent the organisation of didactic sequences of these textbooks permits the attainment of the ministerial objectives. In reference to the aforementioned ministerial objective, we also want to study what are the valid domains of reasoning in the different textbooks. We propose the outline of a typology of incoherence revealed following the textbook analysis.

FIRST ANALYSIS AND RESULTS

Our analysis revealed that, in terms of style in which linear algebra is taught (Dorier, 1997), the way usually chosen by Quebec authors consists of building on previous notions, already introduced to the students, to present their generalisations [1]. However, when the notion with a high level of abstraction is presented, very few references are shown with a low level abstraction. We can observe here a first breach in the presentation since these references could serve as examples and these passages could allow to work on the comparison and classification of ideas as mentioned in the ministerial objectives. More generally, by making a crossing between the typology of abstraction levels and the notion of didactic transposition (as in Chevallard, 1985), three categories of incoherence were identified:

1) Breach in the generalisation process: This includes elements such as the circular generalisations (lack of distinction between the didactic transposition levels) and the lack of examples (either prior to introduce generalisation, or to verify the coherence of the previous knowledge of low level of abstraction in this generalised theory). We also include here breaches in the deductive structure (presentation order of notions.)

2) Unnecessary generalisation and presentation of mathematical concepts of low relevance within the deductive sequence: This includes elements such as the introduction of concepts which are never revisited or in only in an artificial and

technical way, solely to achieve technical ends. This category can also generate breach in the deductive structure.

3) False concept and creation of didactic obstacles (in the sense defined by Brousseau, 1998): This includes elements such as the introduction of mathematical concepts by failing to mention their range of validity. These concepts turn out to be incorrect once they are evaluated out of this implicit range. For example, to consider a vector and a scalar quotient only makes sense in real vectorial spaces.

ENDNOTE

1. In reference to a term used by Aristotle (and notice by Cleary, 1985), notions from low level of abstraction are generally used as foundation for the presentation of high level abstraction notions.

An international comparison between final secondary assessments: Detected differences through an a priori analysis of tasks

Charlotte Derouet[1], Carolina Henríquez[2], Romina Menares[2] and Monica Panero[3]

1 Université Paris Diderot, LDAR, Paris, France

2 Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile

3 Università degli Studi di Torino, Dipartimento di Matematica, Torino, Italy, monica.panero@unito.it

This paper presents a comparative study of the final secondary assessments in France, Italy and Chile, through the a priori analysis of tasks involving functions. We detect particularities in each expected resolution process, and we focus more specifically on the "availability" level of a piece of knowledge, which corresponds to activating it without any help or indication. At the core of the comparison, we distinguish between two degrees of availability: as "object" and as "tool".

Keywords: Function, international comparison, transition high school/university.

CONTEXT OF THE STUDY

The aim of this paper is to have insight into what is expected from students at the end of secondary school. This can be a way to study the prerequisites "at the entrance" to university courses in mathematics. Analysing the tasks proposed in the secondary school final assessment seems to be a first possible approach. In this study, we want to present a comparison between three countries: Chile, France and Italy. France and Italy are two European countries with similar school systems, which have already been the object of a comparative study about the teaching of functions (Derouet & Panero, 2014). Including Chile allows us to enlarge and to enrich the comparison by considering a country with a different educational system. The Chilean secondary school ends at grade 12. The final assessment, called "Prueba de Selección Universitaria" (PSU), is a test that ranks students for accessing to university. However, it does not evaluate all the notions studied at secondary school. The PSU test in mathematics is a multiple-choice test. In France, the secondary school goes from grade 10 to grade 12. At the end of this period, students have to pass an exam, called "Baccalauréat", which is compulsory to enter university. The "Baccalauréat" varies according to section. In the scientific section, the exam in mathematics is composed of four exercises, with detailed questions. Finally, the Italian secondary school ends at grade 13 (so it lasts one year more than the Chilean and the French secondary school). The final exam is called "Maturità" and, as in France, it is necessary to access to university. In scientific section, the exam in mathematics consists of two problems, of which only one has to be solved, and 10 questions (the candidate chooses and solves 5 of them).

Clearly, preparing students for the final assessment represents one of the main aims of the last year of secondary school in each country. In our study, we focus on the tasks involving functions. And we wonder what mathematical activity is expected from students at the end of the secondary school in Chile, France and Italy.

A PRIORI ANALYSIS OF TASKS

We focus on one representative task on functions for each of the three countries and, through an *a priori* analysis, we try to detect particularities in each resolution process. We partially refer to the methodology of analysis of tasks introduced by Aline Robert (1998). Specifically, we wonder if the question is open or closed, we focus on the activated frames (Douady, 1986), working frames and registers (Duval, 1995). Moreover, we consider the adaptations to do (introducing steps, choosing a method, recognising the modality of application) as well as the expected level of activation of knowledge (Robert, 1998). We focus on the "availability" level, which corresponds to activating knowledge without any indication in the statement. We can distinguish two degrees of availability. On the one hand, a certain notion/property can be recalled and employed as "object": for example, the memorisation of a formula to directly work on the involved notion. We call it "availability as object". On the other hand, a notion/property can be recalled and introduced by the students themselves as "tool", to solve a question that does not involve directly the notion. We call it "availability as tool". The degree of availability of knowledge is at the core of our comparison.

CONCLUSIONS

This analysis allows us to notice some remarkable differences between the assessments of the three countries. Our main result is the observation of a great dissimilarity at the level of availability and of autonomy expected from the students, linked to the degree to which the tasks are guided. Chilean students appear to be required to activate knowledge at a high level of availability as object. French students seem to be expected to mobilise some pieces of knowledge at the level of availability as tool, but the availability as object prevails, with little space left to autonomy. Italian students appear to be given more autonomy in solving tasks and in mobilising knowledge at a high level of availability as tool.

Student noticing of exponential and power functions in university financial mathematics

Natalie E. Selinski

Hochschule für Wirtschaft und Umwelt Nürtingen-Geislingen, Nürtingen, Germany
University of Kassel, Nürtingen, Germany, nselinski@hotmail.com

Exponential functions are critical for university study of financial mathematics, yet they persist as a challenging mathematical topic within finance and in the mathematics classroom. My research examines students' initial conceptions of exponential functions and student noticing regarding exponential functions in an inquiry-oriented instructional sequence taght in a university mathematical bridging course. My analysis identifies a strong tendency for students to initially not distinguish between power functions and exponential function, but, with carefully designed tasks, students were able to identify the characteristics of exponential and power functions that make these types of functions distinct.

Keywords: Exponential functions, student mathematical noticing, university students.

INTRODUCTION

Exponential functions are critical for the university study of financial mathematics, yet they persist as a challenging mathematical topic within finance (e.g., Stango & Zinman, 2009) and in the mathematics classroom (e.g., Strom, 2008). While researchers and educators alike traditionally perceive exponential functions as a remedial topic for university students, the multitude of courses covering "remedial" topics suggest students are still actively developing their conceptions of these topics during their university studies (Bausch, Biehler, Bruder, Fischer, Hochmuth, Koepf, Schreiber, & Wassong, 2014). In this paper, I add to the literature regarding exponential functions, by addressing two research questions. First, in the context of university financial mathematics, what are students' initial conceptions of exponential functions? And during the instructional sequence I developed, what do students notice about exponential functions?

SETTING AND DATA SOURCES

Data was collected in the summer semester of 2013 at a university in southern Germany during a voluntary remedial mathematics course running parallel to the students' required first semester financial mathematics studies. In particular, data was drawn from two sources: (a) a written survey on students' initial conceptions of exponential functions prior to the instructional sequence (16 participants), and (b) fully transcribed and translated video recordings of the remedial classroom (2–8 participants). The analysis in this paper focuses on one day of the instructional sequence, in which students explored the distinction between exponential and power functions. Only two students, Alisa and Heidi, were present in the class on this day.

RESULTS

An initial survey was used to identify students' initial conceptions of exponential functions. When asked "What is an exponential function?" 10 (of 15) students claimed it was function containing an exponent. When asked about their conceptions of exponential functions as used in financial mathematics, 7 (of 14) students stated that exponential functions are used "to construct cost, revenue, and profit functions," often giving as examples polynomials such as .

Following the results of the survey, I developed an instructional sequence that included tasks guiding students in distinguishing between exponential functions and power functions. Specifically students were prompted to model two scenarios for borrowing 100€, one with a fixed interest rate i and variable time n

(known as the Brother's Situation, represented by the formula $K_n = 100 \cdot 2^n$) and another situation with a variable interest rate i and fixed time n (known as the Cousin's Situation, represented by the formula $K_n = 100 \cdot (1+i)^2$).

Analysis of the transcript from the day that the instructional sequence was conducted drew on the Student Mathematical Noticing Framework (Lobato, Hohensee, & Rhodehamel, 2013). Lobato *et al.* define noticing as "selecting, interpreting, and working with particular mathematical features or regularities when multiple sources of information compete for one's attention" (p. 809). For the purpose of this paper, I worked with only two primary components of the Student Mathematical Noticing Framework: centers of focus, which are the properties, features, regularities or conceptual objects which students notice, and focusing interactions, which are the discourse practices including diagrams and talk that give rise to the centers of focus.

Three centers of focus were identified:

1) Positive input values lead to similar graphs showing increasing growth;

2) Including negative input values lead to dissimilar graphs, a parabola for the Cousin's Situation and an exponential curve for the Brother's Situation;

3) Differences exist in parameters and variables in algebraic representation when comparing the Brother's Situation and the Cousin's Situation.

This last center of focus was best summarized by Alisa: "For parabolas [points to Cousin's function]... the exponent is always known and for [points to Brother's function]... there it is unknown, the, the exponent." It was by identifying the difference of a "known" parameter in the exponent versus an "unknown" variable that permitted Alisa to distinguish between the Brother's exponential function and the Cousin's power function. This finding suggests that there is room, and necessity, for an expansion of Strom's (2008) Exponential Functions Framework, particularly to include how distinguishing from non-linear functions, especially power functions, is critical to students' conceptions of exponential functions.

3 Slovak University of Agriculture in Nitra, Nitra, Slovak Republic

The aim of the project outlined in this paper is to launch a new performance tracker of students' mathematical performance. Our project consists of two parts – data collection and analytical assessment – both of which will happen over three academic years. The data collection will result in a detailed database of students' math grades. This will provide us with a solid basis for understanding the overall performance of our students and any links between students' secondary education background and their university grades. More broadly, we aim to gain more insight into approaches to students' motivation, and, over time, we aspire to track the impact of any changes to lecturing materials or assessment framework on students' performance. As lecturers this will also add an indirect feedback loop for the quality of our teaching. for students from various types of schools. We aim to publish our findings by 2017.

Keywords: Student performance tracker, mathematical literacy, motivation.

INTRODUCTION

The aim of the project outlined in this paper is to launch a new performance tracker of students' mathematical performance. This database will serve as a platform for analysis and understanding of determinants of student performance, their motivation, and background and indirectly we can quantify the impact of changes of syllabus. Whilst the tracking of student performance is common in Slovak pedagogical universities, we are the first group to research and propose a performance measurement tool in a setting of an economics faculty. The project proposal is focused on university education. We aspire to factor the relevant information into our ongoing live project. Our project consists of two parts – data collection and analytical assessment, both of which will happen over three academic years. The data collection will result in a detailed database of students' math grades. This will provide us with a solid basis for understanding the overall performance of our students and any links between students' secondary education background and their university grades. More broadly, we aim to gain more insight into approaches to students' motivation, and, over time, we aspire to track the impact of any changes to lecturing materials or assessment framework on students' performance. As lecturers this will also add an indirect feedback loop for the quality of our teaching.

RESEARCH PLAN

Our envisaged broader plan of action is the following: Our data collection begins in the current academic year of 2014/15, where we are able to track and store mid-term student scores, end of term exam grades as well as secondary education information. At the end of the current academic year, we will have sufficient data to draw simplified conclusions. We are particularly interested in the link between students' secondary school mathematics performance and their exam scores in our faculty. We are also keen on exploring the progression determinants of the students' first year mathematical performance: starting from mathematics admission test at our faculty, through any mid-terms test scores up to the final exam grade.

We have developed theoretical hypotheses about determinants of students' university performance using a variety of available literature sources.

Our statistical analysis of the collected data will provide a test for validity of these assumptions in the context of a Slovak university setting.

We also aspire to be able to draw broader practical conclusions about student motivation based on factors such as composition of tutor groups, student geographic background and the type of secondary school and the graduation score from mathematics. We would like to identify the motivation of students by short pre- and post- questionnaires or interview from a random sample of students. Research (Anderson, 2007; Rock, Gregg, Ellis, & Gable, 2008;) suggests that, if we would like to support differentiated classroom practices, we will have to continually assess, reflect and adjust content, process, and product to meet students' needs. On a more personal note, our own competence as lecturers can be greatly improved by having more data points and statistical evaluation at hand.

In the academic year 2015/16, we will use the same data collection and analytical approach and this time with a new set of first year undergraduates and the same process will be repeated in 2016/17 as well. Of note, the students at our faculty only have first year undergraduate mathematics; because after this first year of study they have only optional mathematics and statistics is provided by the department of statistics at our university. Hence our data set is different each academic year.

RESEARCH EXPECTED OUTPUTS

With a three-year data set, we will then be ready to draw more robust conclusions and identify the causality between mathematical performance and prior education background as well as the teaching framework at our faculty. We have to be very careful when working with data. For example, we need to be attentive to the complexities generated by the type of secondary school students come from. However, we would propose creative uses of pedagogical propositions that accommodate for differentiated learning. Tomlinson (1999) offers a caveat: "For all its promise . . . effective differentiation is complex to use and thus difficult to promote in schools. Moving toward differentiation is a long-term change process" (p. 6). It would be simpler and less invasive form of introduction of specialized mathematical seminars for students from various types of schools.

We aim to publish our findings by 2017, with a publication that highlights the determinants of the quality of education in our university.

Student understanding of linear independence of functions

Megan Wawro and David Plaxco

Virginia Tech in Blacksburg, Blacksburg, USA, mwawro@vt.edu

We present findings regarding student understanding of linear independence of vector-valued functions, a concept common in linear algebra and differential equations. Data were collected from written homework questionnaires and a paired interview, prior to any formal instruction about the definition of linear independence of functions. Grounded theory was used to categorize student approaches, resulting in five main categories: Function Combination, Focus on t Values, Focus on Graphs, Focus on Scalars, and Previous Rule. Results suggest that students' transition from linear independence of vectors in Euclidean space to linear independence of functions in function space is not trivial and that fostering an object view of function may facilitate students more readily operating with functions as elements of a vector space.

Keywords : Linear algebra, linear independence, funcion space, Euclidean space.

Linear algebra and differential equations are important courses for mathematics and engineering students, and research shows that students tend to struggle with these courses (e.g., Dorier, 2000). While a growing body of literature exists about student understanding of linear independence of vectors in $\mathbb{R}^n$, few empirical studies report on student understanding of linear independence of functions. In one report, Harel (2000) contended that students might struggle to determine A = $\{x, x^2, x^3, x^4\}$ is linearly independent if they "have not formed the concept of function as a mathematical object, as an entity in a vector space" (p. 181). The focus of this study is on how students make sense of linear independence of vector-valued functions, a concept common in linear algebra and differential equations. In particular, we investigate students' initial notions of how linear independence in Euclidean space might extend to linear independence in function spaces.

THEORETICAL FRAMEWORK AND METHOD

This study is framed by Cobb and Yackel's (1996) emergent perspective, which coordinates the individual cognitive perspective of constructivism and a sociocultural perspective based on symbolic interactionism. Within our analysis, we assume that learners acquire knowledge from their daily experiences, that prior conceptions affect interaction with new ideas, and that knowledge structures are contextually dependent.

Data were collected during the Fall 2012 semester in an honors linear algebra and differential equations course for first-year mathematics or engineering students. Data sources include a semi-structured pairwise interview and written responses to two homework surveys collected prior to students' encounter with the formal definition of linear independence of functions. This timing allowed us to capitalize on a unique opportunity to investigate how students initially make sense of linear independence of vector-valued functions with only their prior understanding of vectors in $\mathbb{R}^n$. Questions analyzed in this study, written exactly as they were presented to students, are given in Figure 1. Grounded theory (Strauss & Corbin, 1990) was used to analyze student responses, which led to five categories of student approaches.

SUMMARY OF RESEARCH RESULTS

We analysed two aspects of student responses: their problem solving approach and their answer for if the given functions were linearly independent (LI), linearly dependent (LD), or something else. For the first aspect, we found student approaches could be sorted into five main categories: *Function Combination, Focus on t Values, Focus on Graphs, Focus on Scalars,* and *Previous Rule*. The *Function Combination* approach, for example, which is typified by a primary focus

1. Consider the functions $f(t) = 2$ and $g(t) = \sin t$ with $f\colon \mathbb{R} \to \mathbb{R}$ and $g\colon \mathbb{R} \to \mathbb{R}$. Would you say these functions are linearly dependent or independent for all $t \in \mathbb{R}$? Explain.
2. Consider the functions $F(t) = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$ and $G(t) = \begin{bmatrix} \sin t \\ 0 \end{bmatrix}$ with $F\colon \mathbb{R} \to \mathbb{R}^2$ and $G\colon \mathbb{R} \to \mathbb{R}^2$. Would you say these functions are linearly dependent or independent for all $t \in \mathbb{R}$? Explain.
3. Consider the functions $F(t) = \begin{bmatrix} t \\ 1 \end{bmatrix}$, $G(t) = \begin{bmatrix} t^2 \\ 2 \end{bmatrix}$, and $H(t) = \begin{bmatrix} t^3 \\ 0 \end{bmatrix}$ with F: $\mathbb{R} \to \mathbb{R}^2$, G: $\mathbb{R} \to \mathbb{R}^2$, and H: $\mathbb{R} \to \mathbb{R}^2$. Would you say these functions are linearly dependent for all $t \in \mathbb{R}$? Explain your reasoning.

Figure 1: Questions analysed about linear independence of vector-valued functions

on whether or not the functions could be written as a linear combination of one another, supported the correct answer (LI) across the three questions. The *Focus on t Values* approach, which never supported a correct answer in this data, is characterized by first evaluating the functions at specific t values and then making conclusions about vectors in $\mathbb{R}^n$ rather than about functions in a function space. For the second aspect, we categorized student answers for each question. For instance, for Question 2, twelve students stated correctly LI, six stated LD, and four stated LI at some t values and LD at others. A description of all results, with examples, can be found in the poster presented and discussed at the conference at meganwawro.com/presentations.

We acknowledge that the students' ways of reasoning captured in both their approach and final answer may have been influenced by the formulation of the questions in Figure 1. For instance, the phrase "for all $t \in \mathbb{R}$" was included to align with the formal definition for linear independence of functions the instructor had used; however, this may have led to more approaches aligning with the *Focus on t Values* category than if the questions had not included that phrase. Similarly, students who stated linearly independent at some discrete t values but dependent at others may have been influenced by the inclusion of that phrase.

This preliminary work illustrates that students' transition from linear independence of vectors in $\mathbb{R}^n$ to linear independence of functions in function spaces is not trivial. The *Function Combination* approach, however, not only led to correct answers but also seemed within reach for these novice students; as such, it deserves consideration as a fruitful approach to be leveraged as students encounter linear independence of functions. This further suggests an importance of fostering an object view of function so that students can more readily operate with them as elements in a vector space.

TWG15
Teaching mathematics with resources and technology

Introduction to the papers of TWG15: Teaching mathematics with resources and technology

Jana Trgalová[1], Alison Clark-Wilson[2], Iveta Kohanová[3] and Mirko Maracci[4]

1 University of Lyon 1, Lyon, France, jana.trgalova@univ-lyon1.fr

2 University College London, Institute of Education, London, UK

3 Comenius University, Faculty of Mathematics, Physics and Computer Science, Bratislava, Slovakia

4 University of Pavia, Pavia, Italy

The technology working group continues to increase in size since its inclusion at the first CERME congress in 1999. During CERME 9, for the first time the group was divided from the beginning, giving birth to two separate groups: TWG15 focusing on issues related to the teaching mathematics and teacher education and professional development, and TWG16 focusing on students' learning with technologies and software and task design issues (see Weigand, Lokar, Robutti, & Sinclair, 2015).

TWG15 builds on the legacy of the group work at previous conferences. A number of important issues related to technologies and resources and their use by teachers and teacher educators emerged from the group discussions, such as the need to elaborate specific methodologies for analysing and evaluating the efficiency of teacher education programs, or the construction of models that facilitate analyses of the evolution of teachers' practices related to their ICT use. The research presented in the group contributions tended to be: local, focusing on a particular aspect of teaching mathematics; short-term; and often conducted in controlled laboratory conditions, which prevented general conclusions being drawn about the benefits of ICT in mathematics education. The group concluded that it was necessary not only to learn more about "real" uses of ICT in classrooms and beyond, but also to understand why ICT is not used and to conduct long-term studies with "ordinary" teachers in "ordinary" classes in order to explore the impact of the ICT on students' learning and on teachers' practices (Trgalová, Maracci, Psycharis, & Weigand, 2013).

The call for contributions thus proposed to deepen the community's understanding of these issues by addressing themes such as: the specific knowledge and skills required for an efficient use of ICT; teacher education programs embedding these knowledge and skills and assessment of their impact on teachers' practices; theoretical and methodological approaches to the evaluation of the evolution of teachers' practices, "best practices" with using technologies, among others.

WORKING GROUP IN A FEW NUMBERS

The group involved 31 participants from 13 countries: Cyprus, Czech Republic, France, Germany, Greece, Israel, Italy, Poland, Portugal, Slovakia, Sweden, Turkey, and United Kingdom. 17 papers and 6 posters were presented and discussed during the working group sessions.

REPORT OF THE WORKING GROUP DISCUSSIONS

For each session, the group Co-leaders defined a particular theme that was discussed in relation to a group of a few papers and posters. The discussions were framed by two or three questions raised after the paper and poster presentations. In what follows, we give a brief overview of the themes discussed and the main outcomes. We conclude with an outline of some emerging perspectives for consideration at the next conference.

Teacher professional knowledge and frameworks for its analysis

Various frameworks are used to analyse teachers' practices with technology and digital resources in math classrooms: *Bozkurt and Ruthven* refer to the Structuring Features of Classroom Practice (SFCP) (Ruthven, 2009) that "identifies key aspects of the craft of teaching that indicate the corresponding professional reasoning and craft knowledge that teachers must develop about these aspects in order to successfully incorporate new technologies". *Robová and Vondrová* draw on the technological pedagogical content knowledge (TPACK) framework (Mishra & Koehler, 2006) to analyse teachers' specific skills needed for work with dynamic geometry software. *Rocha* introduces a new framework, Knowledge for Teaching Mathematics with Technology (KTMT) that she applies to analyse teachers' practices with the use of graphing calculators.

The participants were invited to discuss the specificities of these frameworks and their usefulness both for the observation of teachers' practice and knowledge and for structuring teacher education programs.

Fostering creativity in mathematics

Creativity in mathematics is a new issue raised within three contributions to TWG15. *Papadopoulos Papadopoulos, Barquero, Richter, Daskolia, Barajas and Kynigos* raise the issue of the design of resources fostering the development of students' creative mathematical thinking (CMT) based on teachers' representations of CMT. *Kynigos and Kalogeria* propose an analysis of a collaborative design of resources for CMT within a specific technological environment. *Jančařík and Novotná* discuss scaffolding strategies in an e-learning mathematics course attended by gifted students and their effectiveness in supporting the students' problem solving.

These contributions promoted the issue of how ICT supports creativity in the students. Two main aspects have been highlighted in this respect: encountering different registers of semiotic representations through technology, and linking communication about mathematics between teachers, students and students and teachers.

Design, appropriation, orchestration of teaching situations

Contributions to these issues include both studies on local, short-term projects focusing on particular aspects of teaching mathematics alongside studies involving teacher development within large-scale projects concerning mathematics teaching with technology. *Benacka and Ceretkova* present the results of a survey evaluation of a course involving 28 pre-service mathematics teachers centred on the use of spreadsheets. *Sollervall and de la Iglesia* investigate how a co-design methodology can support teacher's orchestration of a didactical situation aimed at fostering so-called "logos-oriented discussions" among students and between students and teachers. *Turgut* presents the results of a pilot study of a larger research project involving the design and orchestration of teaching interventions within a linear algebra course with the use of ICT. *Clark-Wilson, Hoyles and Noss* elaborate a conceptual framework and methodological approach for research aiming at evaluating the success of the professional development part of a large-scale intervention. *Fahlgren*'s study aims at identifying those elements of activities involving students in scaling coordinates system in dynamic software that can affect the process of instrumental genesis. *Lavicza, Juhos, Koren, Fenyvesi, Csapodi, Kis and Mantecón* outline the theoretical framework, the different stages and highlight initial results from the first phase of a Hungarian national project promoting technology integration into Hungarian schools.

The theme of design, appropriation and orchestration of teaching situations appeared a really multi-faceted one; hence the issues proposed for the discussion concerned a lot of different aspects: the educational objective which can be pursued through the use of ICT, and how the choice of educational objectives influences the teacher's use of ICT in her/his practice; the principles which can inform the design of tasks or teaching situations and their "teach-ability"; what is needed from theories to inform the design of teaching activities, situations or sequences centred on the use of ICT; and the conditions under which short, local experimentations could be scaled, and the methodology through which scaling can be monitored and evaluated.

Assessment issues

Within the context of TWG15, the term assessment, and the role of technology within assessment, incorporates two perspectives: the assessment of teachers' individual knowledge and practice concerning their classroom technology use; and technological tools and approaches to facilitate the summative and formative assessment of students' learning. From the perspective of teachers, the paper by *Karatas and Tutak* describes a Turkish study that adopts the TPACK M Scale by Handal, Campbell, Cavanagh, Petocz, and Kelly (2013) to assess a group of 138 secondary teachers' technological, pedagogic and content knowledge, raising important methodological questions concerning the reliability and validity of such scales. The remaining papers (and poster) focus on the assessment of students' learning. *Chenevotot-Quentin Chenevotot-Quentin, Grugeon-Allys, Pilet, Delozanne and Prévit* describe the design and uses of a diagnostic assessment tool *Pépite* for the assessment of algebra at different grade levels in France. At the classroom level, *Aldon* focuses on how *critical incidents* arising from the students' uses of *TI-Nspire* technology provide the context for teachers' formative assessment of students' mathematical conceptions. In her poster contribution, *Juskowiak's* study concerns the assessment of students' mathematical outcomes with non-standard problem solving tasks involving the use of graphic calculators.

The discussions that arose from these contributions prompted questions concerning the different approaches to the assessment of students' learning with technology and the role of technology in supporting teachers to assess students' mathematical learning and, ultimately make decisions based on this assessment.

Teachers' support of students' conceptualisation in mathematics

Contributions to this issue explore the ways in which instrumented activities, orchestrated by a teacher, can benefit students in meaning-making of mathematics concepts. *Psycharis* presents two computational systems and discusses their potential in helping students conceptualize the notion of functions, based on both an *a priori* analysis of the systems affordances and on empirical studies of students' interactions with them. Likewise, *Stoppel* shows how the use of different media, providing different functionalities and command syntax, may lead the students to applying different methods in a problem solving activities. *Diamantidis, Economakou, Kaitsoti, Kynigos and Moustaki* explore the emergence of meaning of a concept of angle in 3D space in students working collaboratively in computer-based environment. Their study highlights the importance of technology supporting communication, collaboration and joint mathematical thinking. The learning potential of a video with mathematical content shared on the web is studied by *Palatnik*. His study evidences that Web2.0 resources can become a new source for generating interest in mathematics amongst a public audience. *Bagdat*'s study highlights the role of a teacher in helping students make sense of the concept of variable while working with spreadsheets.

The discussions of issues related to this theme brought forward two main ideas: the ability to assess affordances of technological tools as one of the basic skills teachers need to develop in order to successfully integrate technology in their practices, and the awareness of the importance of social learning, either in classrooms or informally through open Web2.0 resources.

CONCLUDING REMARKS AND PERSPECTIVES

The papers and posters presented and discussed within the group encompass a wide variety of research topics. Several convergent concerns emerged from the exchanges among the participants. First, an important role of teachers in the design of appropriate instrumented tasks was acknowledged, as the expression from one of the participants "*teachers as designers of students' learning with technology*" documents. A need was expressed to redefine teachers' skills enabling them to support students' collaborative learning not only in a classroom, but also while working online or offline, and subsequently to elaborate education programs embedding these skills. The discussions brought forward a complexity of meaning-making processes in mathematics, which requires from teachers the ability of analysing affordances of computer-based tools in order to avoid situations in which the students can succeed to solve a given problem without understanding the underlying mathematics. Also, articulating syntax-related issues inherent to digital tools with mathematics appears as an important aspect in teaching and learning with technologies, which is in line with the theory of semiotic mediation (Bartolini Bussi & Mariotti, 2008).

What perspectives can be outlined for the next CERME10 congress? There is still a need to develop a more comprehensive theoretical framework to address "old" but still topical themes, such as task design and methods for large-scale dissemination of "good practices" with digital technologies use. The role of technologies in formative assessment, of networked classroom technologies and e-learning appear among the emergent issues that require further theoretical and methodological development. Finally, some topics, which are under-represented, would deserve researchers' interest: touch technology, 3D technology, including 3D printers, virtual reality in mathematics education, Massive Online Open Courses (MOOCs) and web2.0 or web3.0 environments, and technology for educational special needs.

The parable of the broken pencil or syntactic incidents and their consequences

Gilles Aldon

ENS de Lyon, EducTice-S2HEP, Lyon, France, gilles.aldon@ens-lyon.fr

When using technology, the translation of a mathematical concept into a particular technology brings syntactic difficulties that may lead to problems that can either be an excuse to withdraw from knowledge construction or a starting point for a mathematical reflexion. The boundary between the two attitudes is directly linked to the situation and to the integration of technology within the classroom. In this paper, I'll present the notion of syntactic incident and show in a particular class situations how students react in front of the consequences of such an incident.

Keywords: Technology, didactical incidents, formative assessment, theory of didactic situations.

INTRODUCTION

When Evelyne decided to begin her novel after a long reflexion about the characters she wanted to introduce, the context in which they will evolve and the general scenario of the story she wanted to share with the world, she sat down in front of her desk, laid down a sheet of white paper, verified that her eraser was on the desk and took a pencil. "Once upon a ti..." she wrote. And her pencil broke. She first searched for a pencil sharpener but she didn't find one (she remembered having given it to her nephew for the beginning of the school year); after a thundering cry of anger, she decided:

1) to write with a pen instead of a pencil even if it will not be possible to erase her writing,

2) to take a knife and to try to sharpen her pencil even if the lead will not be sharp enough for her writing,

3) to stop writing of the first page of her novel and to go shopping (buy a pencil sharpener, she thinks)

4) to sit down in her chair thinking about the incipit of her novel and remembering the most famous incipits of the literature... "Longtemps, je me suis couché de bonne heure...", "Call me Ishmael.", "The sun shone, having no alternative, on the nothing new", "I have never begun a novel with more misgiving"... [1]

5) to call a friend asking for a pencil sharpener,

6) to abandon this adventure which is not for her, even the things are against her,

7) to go and buy a computer, it will surely be safer to write her novel and she has always thought that it is high time to understand computer science,

8) ...

An incident occurred thwarting her intentions and this incident is directly linked with the tool she wanted to use with precise intentions: she wrote with a pencil because she wanted to erase her clumsiness and to keep a clean manuscript. The next episode of this story may be very different regarding the different attitude she would adopt.

In the first case, a direct consequence will be that she will not be able to erase the first draft. If she wants to keep the idea of a clean manuscript, she'll have to think more carefully to the sentences she'll write, otherwise she'll have to strike through her draft but, in doing so, she'll keep in memory her different trials. The choice of the tool she'll use has consequences on the organization of the content. In the same time she loose properties of the first tool, she gains new ways of writing.

The second attitude will modify the potentialities of her tool: she chose a pencil instead of a pen or a quill for some reasons, rational or irrational. But she surely had built for a while schemes of utilization of this particular tool and the combination of an unprecedented sharpness of detail and smoothly flowing movement will disappear.

In the third case, there is a break in the continuity of her work. She perhaps will come back to this particular state of mind that allows to begin the writing of a story, but for the moment, the incident stopped her progression. This important disturbance modifies deeply the next step of the story: instead of writing, she goes shopping and perhaps, she may come back to her task later.

The fourth case is also a break in the progression of her writing, but in that case, the new direction she takes, brings her in a deep reflexion about her own writing in the literature's world. She stays in the general context of her task but still work on the first sentence in another way she did initially.

In the fifth case, there is an externalisation of the procedure. The solitude of the writer is broken by an external component. She will have to explain and perhaps to justify her will of writing a novel, she'll surely have to summarize her first ideas, to introduce the theme of her novel... The first environment that she designed is deeply modified.

This sixth case is surely the most radical case where the incidents lean to an abandonment of the realization of the task. It is certainly because the project was not deep enough within the writer's mind, and using didactical words, that the devolution of the task is not made.

The seventh case is also a very radical transformation of the writing conditions. A result of the incident is to consider that the tool is not appropriated for the task and that the learning of a new way of writing is a precondition to complete the project successfully.

There are surely other developments of this story, but the lesson of this parable is that, regarding the conditions, the actors, the environment, a same event can lead to different scenarii that may modify the continuity of a story. Taking into account this parable in the field of mathematics learning can give interesting tools to analyse the mathematical activity of students in front of a specific task.

More theoretically, when students are learning in a digital environment that is the result of a construction of the teacher who has specific intentions and of students' knowledge regarding both technology and mathematics, the questions relative to the syntactic knowledge and interpretation are crucial for the construction of mathematical knowledge at stake.

More precisely, a question that can be addressed and that will be developed in the paper concerns the conditions that allow students to overcome syntactic incidents in order to transform them into mathematical questions and lean to knowledge construction.

THEORETICAL CONSIDERATIONS

In order to answer such questions, the first approach is to precise in which context the answers will be searched. In our case, the methodology is based on the theory of didactic incidents (Aldon, 2011) which took its founding principles in the theories of didactic situations (Brousseau, 2004) and of instrumental genesis (Rabardel, 1995; Artigue, 1997; Trouche, 2004; Drijvers & Trouche, 2008).

The theory of didactic situations takes, as a starting point, the relationship between an interaction of a player in a particular game with his/her *milieu*, and knowledge. The didactic situation is for an observer the modeling of the environment of the game, and is the game itself for the student. From the point of view of students, the environment of the game is integrated within the game and knowledge construction results from the interaction of the player with the entire environment including his/her own knowledge, mathematical situation given through a specific wording, the interactions with the teacher and available artefacts at this moment. Interactions of the player with the environment produce knowledge through the experiences build with the different parts of this environment. An important point is to consider in this environment the different available artefacts and the process of transformation of these artefacts into instruments useful for winning the game. The instrumental genesis theory that initially comes from ergonomic studies considers the artefact as a thing without any intentions. The use of the artefact in specific context transforms it slowly into an instrument that can be considered as the combination of an artefact and schemes of utilization. The integration of technology into the classroom is of the same nature and can be considered as a slow process in which the given technology (the artefact) becomes an instrument through the double movement of instrumentation and instrumentalization. The instrumentation is the process where the artefact modifies the subject's activity and the instrumentalization is the process where the subject modifies the artefact for her own use.

A didactic incident is defined as "an event of the didactical system that occurs sporadically, that is unforeseen, and that requires an appropriate answer of the actors" [2] (Aldon, 2011, p. 26). A didactical system is the implementation of a didactic situation in a particular context. In the different didactic incidents that have been picked out, some of them are directly linked to the digital environment of the didactic situation. A syntactic incident is a problem that occurs in the conversion from a register of representation in another. The term *syntax* refers to the units that make up rules to accomplish an action. For example, the drawing of a line in the "language" of paper and pencil can be done using a ruler and a pencil (place the ruler on the paper, place the pencil along the ruler and follow the ruler with the pencil) and, this same drawing in the language of a GDS will be to choose the menu create a point, to show with the mouse the place of the point, to click with the right button of the mouse, to choose the menu line, etc.

Especially, when there is a translation into a digital representation, syntactic incidents can *a priori* be triggered by two factors: the operation is not foreseen by the software and must be built or the operation is provided but doesn't work due to a misunderstanding of the syntax of the command or, is not known by the operator, in a particular environment. The perturbations that follow can be short in the case of an assistance provided by an actor of the situation (teacher, other student, element of the *milieu*...) or by understanding of the phenomenon by the subject (which is part of his/her instrumentation). But, they may also have long-term consequences, as shown in the parable of the writer who breaks her pencil: a disengagement of the subject locally (3) or globally (6) leading to a new instrumental genesis, a loss of devolution of the situation (3, 6, 7) that may lead to a disengagement of the student, a questioning of the relevance of the artefact in achieving the task (1, 2, 7) that may come out to a reflection about the pertinence of a tool relatively to a mathematical task or a mathematical concept, a modification of the working environment (5) and a reorganization of the way to approach the problem (4) whose consequence could be either the beginning of a new learning different from the teacher's intention or a new approach allowing knowledge construction.

We took the opportunity of a wide introduction of handheld technology in different classes to study the impact of such a technology on teaching and learning of mathematics. The example that is developed in the next paragraph comes from a class which is equipped with TI Nspire calculators. The teacher (J.L. in the following) worked in this class in a perspective of inquiry-based learning and proposed to his students (16 years old, in a scientific major) problems that allow a personal and collective reflection. The example of this paper has been designed, observed and discussed in the context of the European project EdUmatics [3] and illustrate a syntactic incident leading to different perturbations.

EXPERIMENTATIONS

The context of the experimentation is a mathematical problem that is proposed to the students. The general context of this problem is the study of the relationship between the distance of a walker to a given point according to his/her position on a path. In this study, we follow students who are searching the following problem:

Pjotr moves at constant speed along a square $ABCD$ with center O (intersection of the two diagonals) and given side L, starting from vertex point A.

Pjotr wants to describe how his distance from the center O of the square changes while he is moving along the square. How can you help him/her? (If you wish, you can choose any positive real number as the length L of the side of the square).

The observed group worked either on their own calculators or on a computer with the software TI Nspire. The different illustrations of this paper show the camera viewpoint for this group of four students who are working both with their own calculator and with the software available on computer. The first analyzed episode comes after a first episode of work with paper and pencil that leads students to explicitly calculate the relationship of the distance that Pjotr covered along the first side of the square and his distance to the center as shown on the Figure 1.

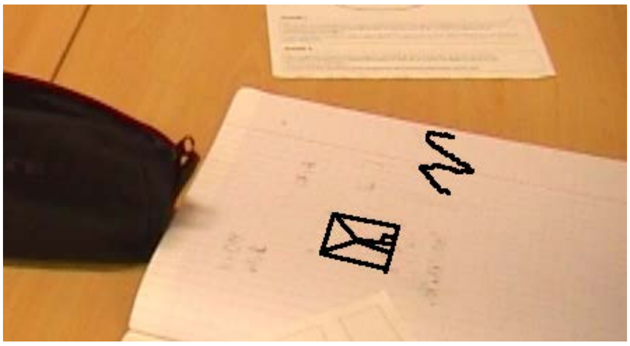

Figure 1: The first approach of the problem with paper and pencil

It is interesting to notice, that a freehand drawing of the behaviour of the function (which has been stressed on the Figure 1) has been made on the paper before any calculation: "*it'll be like that, it'll make a wave*" a student said drawing the freehand drawing. The second episode of work consists in a transposition of the mathematical situation to the software. The idea developed by the four students was to capture in the spreadsheet the values of the distance of *P* (the position of Pjotr on the square) to the centre of the square and to represent on a graphic these values according to the covered distance of point *P* from his starting point *A*. The syntactic incident comes from the translation of this idea in the language of the software. It is indeed possible to measure the distance of two points but there is no menu giving the distance from a point to another on a given path (here the square *ABCD*). The first trial was indeed to consider the abscissa of the graphic representation as the distance of *A* to *P*. The resulting graphics appeared to be in contradiction with the idea expressed previously and drawn on the paper. In that case, the syntactic incident associated with the previous mathematical reflexion led one of the students (S1) to think differently the parametrization of the point *P* in this task. Students are here in the fourth situation of the parable: the incident is the starting point of a new mathematical reflexion that comes to a definition of a piecewise function:

J.L.: And how did you do to obtain the second arch?

S1: In the next drawing, I made BP but each time I added six because six is the length AB...

In the same time and in front of the same situation, the second student (S2) working on his handheld tried to solve the same problem. However, his mastery of the technology or the mathematical reflexion are not sufficient to allow a transformation of his research strategy. In the contrary, most of his time was spent to try to solve the syntactic problem using the function "distance of two points" and without referring to the mathematical situation. The result was in contradiction with the former reflexion but this student tried to solve the problem without the good tool. He was exactly in the situation of the second choice of the parable: the tool is not adapted to a precise goal but can give the illusion to work well. The result of the work is illustrated on the handheld screen of the Figure 2. In the didactic situation, there was, in that case, what Margolinas (2004) called a didactic bifurcation where the problem that try to solve the student is no more the problem that the teacher wanted to be solved. It is also an illustration of the seventh choice of the parable: there is a knowledge construction or a trial of knowledge construction but out of the intentions of the teacher. Even if this knowledge participates to the instrumental genesis of the student, the lack of institutionalization leads the student to consider this trial as a failure. It's not sure that the different trials and errors done by this student lead to a better understanding of the technology and, in the contrary it could be a pretext to abandon this technology which is "*a waste of time*" as expressed by another student in an interview:

Interviewer: [...] and do you remember the time you said, oh no, I do not want any more this calculator?

Student: It was very early, yes because we had to go to the menu, go to this location there, finally, Click everywhere, we had quite a

Figure 2: Two different consequences of the same syntactic incident

> journey to make a calculation you could do very easily with our old calculator, in fact faster. [4]

In this paper, we only study one example of syntactic incident in a particular episode, but, it is by studying different observations that we have been able to determine the types of behaviour described in the parable of the introduction.

MAIN FINDINGS AND CONCLUSION

One syntactic incident and its consequences on two different students has been detailed in the previous section showing that the perturbations following an incident may differ regarding the choice that follows the incident. The question that we posed in the introduction was to analyze the reasons why one or another consequences occur and more precisely why and when an incident is a starting point of a re-organization of knowledge or not. Answers to these questions are interesting for the student as well as for the teacher in a perspective of formative assessment, defined by Bell and Cowie (2001, p. 536) as "the process used by teachers and students to recognize and respond to student learning in order to enhance that learning, during the learning". The European FP7 project FaSMEd [5] "aims to research the use of technology in formative assessment classroom practices in ways that allow teachers to respond to the emerging needs of low achieving learners in mathematics and science so that they are better motivated in their learning of these important subjects." The incident analysis is part of the toolkit that allows to understand better the behavior of students in a digital learning environment.

In the different observations in teaching and learning digital environment, the analysis of syntactic incidents and the perturbations that follow show different cause that can be clues for students and for teachers in order to understand when and why knowledge at stake in a particular mathematical situation is not reached.

Incidents lead to perturbations that prevent knowledge construction when:

- Technology is external to mathematics, that is to say technology is not included in the set of mathematics tools useful in the resolution of a mathematical problem for a given student at a certain moment.
- The knowledge of the syntax overcomes mathematical knowledge: in that case learning the syntax (in the sense defined in the second section) adds technical or conceptual difficulties that lead students to forget the mathematical notions at stake.
- The technological knowledge is more difficult that math knowledge at stake in a given situation: in that case, it is important to think about the adapted technology.
- Technology that is used doesn't supplies potentialities that are necessary in the mathematical situation most of the time because of a bad initial choice of technology.

In the contrary, incidents lead to construction of knowledge when:

- The class culture takes into account the experimental part of mathematics, and technology is used internally in different mathematical situations.
- The instrumental genesis is sufficient to give adapted technological skills in the learning situation.
- The knowledge of the syntax of a particular technology is either sufficiently natural or trained before having to use it in a complex mathematical situation

A continuation of this study will be to make this kind of analysis operational both for teachers in a perspective of formative assessment and for students in a perspective of auto-evaluation. This work is part of the FaSMEd project.

Graphing functions and solving equations, inequalities and linear systems with pre-service teachers in Excel

Ján Beňačka and Soňa Čeretková

Constantine the Philosopher University in Nitra, Nitra, Slovakia, jbenacka@ukf.sk

The article presents the results of a survey on using Excel for graphing functions, solving equations and inequalities without and with a parameter, and solving systems of linear equations with pre-service mathematics teachers. The experimental group were 28 master students of teaching mathematics. The aim was to ascertain that the methodology can benefit teaching the topics and make mathematics more interesting.

Keywords: Spreadsheets, modelling, constructivism.

INTRODUCTION

The spreadsheet is a tool that enables access to ideas and concepts through a computational experiment without any need for programming. It allows using inquiry and heuristic methods and the immediate feedback provokes into experimenting and discovering.

The use of spreadsheets in mathematics education has been researched for decades, however, mainly on primary and lower secondary level (Healy & Sutherland, 1990; Rojano & Sutherland, 1993; Hošpesová, 2002ab; Haspekian, 2005, 2011, 2014; Ainley, Bills, & Wilson, 2005; O'Reilly, 2006; Wilson, 2006; Tabach, Arcavi, & Hershkowitz, 2008; Tabach & Friedlander, 2008; Tabach, Hershkowitz, & Arcavi, 2008; Drake, Wake, & Noyes, 2012; González-Calero, Arnau, & Puig, 2013; Watson & Callingham, 2013; Geiger, Goos, & Dole, 2014). There is a considerably smaller number of articles written on the use of spreadsheets in mathematics education at upper secondary level (Molyneux-Hodgson, Rojano, Sutherland, & Ursini, 1999; Sivasubramaniama, 2000; Neurath & Stephens, 2006; Forster, 2007; Topcu, 2011; Benacka & Ceretkova, 2013).

Research of Molyneux-Hodgson and colleagues (1999) with 16 to 18 years old students from England and Mexico showed that the mathematical culture in the country affected the choice of the means when the students solved tasks with spreadsheets. Research of Sivasubramaniam (2000) with student of age 14 and 15 showed that the use of spreadsheets had a positive impact on understanding Cartesian graphs. Forster (2007) researched a group of 17 and 18 years old girls on the use of technology when investigating the trend of a set of data from jewellery. Projecting graphs created in spreadsheets had a positive effect. Topcu's (2011) research with 16 years old boys showed that the boys who used spreadsheets to solve algebra tasks were considerably more confident as they were aware of the possibility of checking and correcting errors. Neurath and Stephens (2006) researched the effect of integrating Excel into teaching of algebra with 14 to 17 years old students. The students' opinion of the lesson was surveyed by a questionnaire. The result was that 69% were interested in solving tasks with Excel and understood algebra better, and 77% of the students enjoyed the course because solving tasks with Excel made algebra more interesting. Just 8% disapproved in both cases. Benacka and Ceretkova (2013) gave account on an experiment in which 16 to 19 years old students developed Excel applications to graph functions, find extremes, solve systems of linear equations, calculate the area of a planar figure by the rectangle method and Monte Carlo method, and simulate motion of a projectile in a vacuum. The students' opinion of the lesson was surveyed by a questionnaire. The result was that 100% of the students found the lessons interesting, 35% understood all and 65% understand most of the mathematics.

This article presents the results of a survey on using Excel in mathematics teachers education. The experimental group were 28 first year master students of

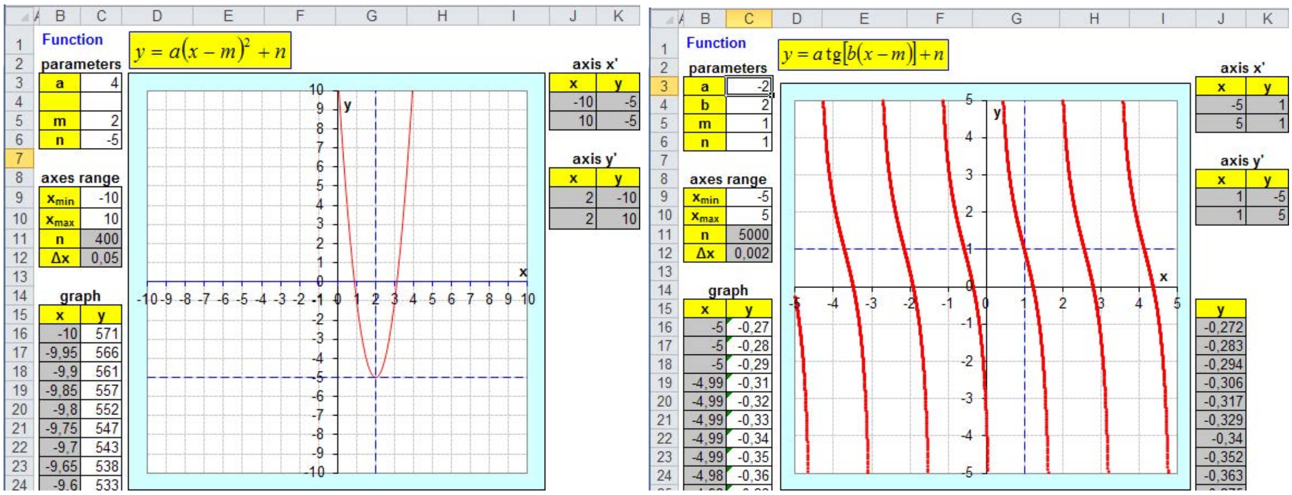

Figure 1: Graph of a function with definition domain R (left) and not R (right)

teaching mathematics. There were 6 men and 22 women in the group. The topics were Graphing functions, Solving inequalities, Solving equations with a parameter, and Solving systems of three linear equations with three variables. Aplications developed by the first author were used. The aim was to ascertain that the applications, the tasks and the presented teaching methodology can make teaching mathematics at upper secondary level attractive, benefit the teaching of the topics and contribute to the technological and pedagogical knowledge (TPACK) of the pre-service teachers. Each topic took a 90 minute lesson. A questionnaire survey with the following questions was carried out at the end of each lesson:

A) *The lesson was (1 = very; 2 = quite; 3 = little; 4 = not) interesting.*

B) *I understood (1 = all; 2 = most; 3 = little; 4 = nothing) of the mathematics involved in the activity.*

C) *The lesson contributed to my TPACK*

D) *(1 = a lot; 2 = quite a lot; 3 = little; 4 = not at all).*

E) *The applications benefit the teaching of the topic*

F) *(1 = a lot; 2 = quite a lot; 3 = little; 4 = not at all).*

G) *Developing the applications helps comprehend the core of the topic*

H) *(1 = a lot; 2 = quite a lot; 3 = little; 4 = not at all).*

I) *I am a man (1 = yes; 2 = no).*

Answers 1 and 2 in questions A–E were considered positive. Altogether, 96 questionnaires were evaluated. The survey summary is in the last section.

GRAPHING FUNCTIONS

The application on the left side of Figure 1 graphs functions if the definition domain is R. The graph is produced from 100 points in range B16:C116. Cell C12 contains the formula =(C10-C9)/C11. Cell B16 contains =C9, Cell B17 contains the formula =B16+$C$12. Cell C16 contains the formula =$C$3*(B16-$C$5)^2+$C$6. The two formulas are copied down as far as row 116. The application on the right side of Figure 1 graphs functions if the definition domain is not R. The graph is made over 5000 points in range B16:B5016 and J16:J5016. Cell C16 contains the formula =$C$3*TAN($C$4*(B16-$C$5))+$C$6. Cell M17 contains the formula =IF(ISERROR(C16);NA();C16). The two formulas are copied down as far as row 5016. The points that are out of the definition domain are skipped by function NA().

Lesson and survey: There were 28 students in the lesson, 6 men and 22 women. The students downloaded the template (Figure 1 with empty white and grey cells) from a website and developed the application with the teacher's help. The shape of the graph, definition domain, range and symmetry of elementary functions $y = x$, $y = x^2$, $y = x^3$, $y = 1/x$, $y = 1/x^2$, $y = \sqrt{x}$, $y = \sin x$, $y = \cos x$, $y = 2^x$, $y = \log_2 x$, $y = \tan x$ and $y = \cot x$, was discussed and visualized by the applications. The effect of the sign and absolute value of the parameters on the orientation, steepness, period and shift of the graph were checked. The following algorithm for graphing functions $y = af(a - m) + n$ or trigonometric

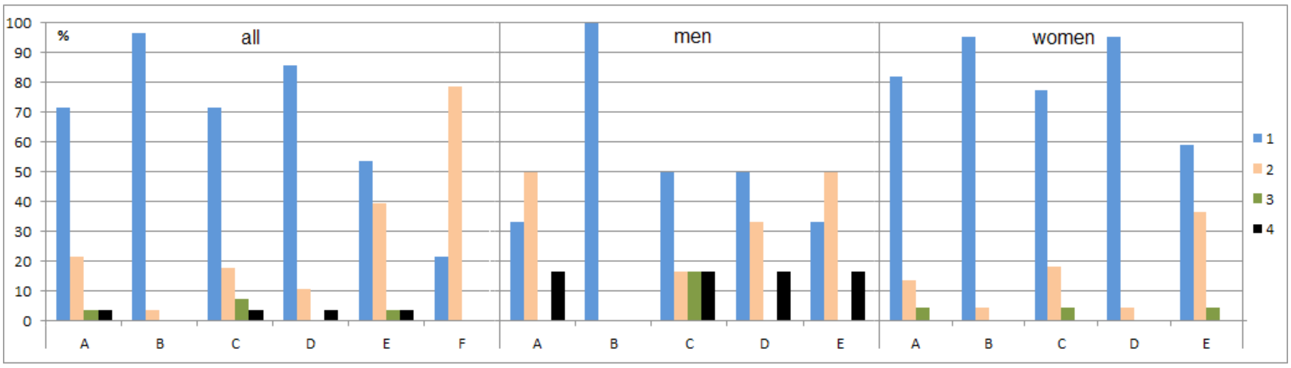

Figure 2: Relative frequency of the answers

$y = af(b(a - m)) + n$ by hand was deduced and exemplified by graphing the functions $y = (2x - 4)^2 - 5$ and $y = 2\tan(2 - 2x) + 1$ (Figure 1). At the end of the lesson, the students answered the questionnaire. The result is graphed in Figure 2.

The result is: (A) 92% found the lesson interesting (71% very, 21% quite); (B) 100% understood the topic (96% all, 4% most); (C) 89% had the feeling that the lesson contributed to his/her TPACK (71% a lot, 18% quite a lot); (D) 97% found the applications to be benefitting (86% a lot, 11 % quite a lot). (E) 93% were of the opinion that the developing helped comprehend the core (54% a lot, 39% quite a lot). The women found the lesson more interesting and benefitting than the men.

SOLVING INEQUALITIES

Solving an inequality analytically may be an intricate process that takes many minutes. With Excel, the solution is quick, transparent and credible. The inequality $\frac{|3-5x|}{x-2} \geq -x - 2$ is resolved by using the application in Figure 3 and 4. The solution is clear from the position of the graphs.

Lesson and survey: There were 21 students, 5 men and 16 women. The analytical solution to the inequality was quickly gone through. Then the students developed the application from the application on the right side of Figure 1 and resolved the inequality in two ways. First, the intersection point was found by iteration (Figure 4). The maximum and minimum of axis x (cells C9:C10) were set up to be close to the intersection point from both sides. Then, the x coordinate of the intersection was found in the first column of range B16:D5016 in the row in which the values in the second and third column were equal (cell B3090). The other way of solving was by using Goal Seek (Figure 3, range K12:N13). The solution is $x \in [-0.19, 1.14] \cup (2, \infty)$. The exact solution is $x \in [\frac{5-\sqrt{29}}{x-2}, \frac{-5+\sqrt{53}}{x-2}] \cup (2, \infty)$; however, the bounds have to be converted into decimal numbers for practical use, which is the form shown above. At the end, the students answered the questionnaire. The result is graphed in Figure 5.

The result is: (A) 96% found the lesson interesting (67% very, 29% quite); (B) 100% understood (90% all, 10% most); (C) 96% had the feeling that the lesson contributed to his/her TPACK (67% a lot, 29% quite a lot); (D) 100% found the applications to be benefitting (71% a lot, 29% quite a lot). (E) 100% were of the opinion that the developing helped comprehend the core (81% a lot,

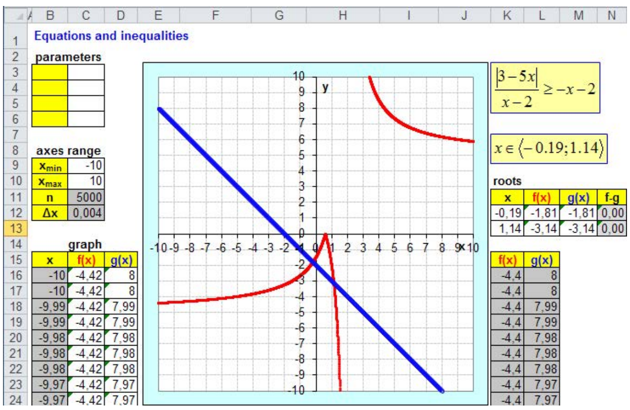

Figure 3: Solution with Goal Seek

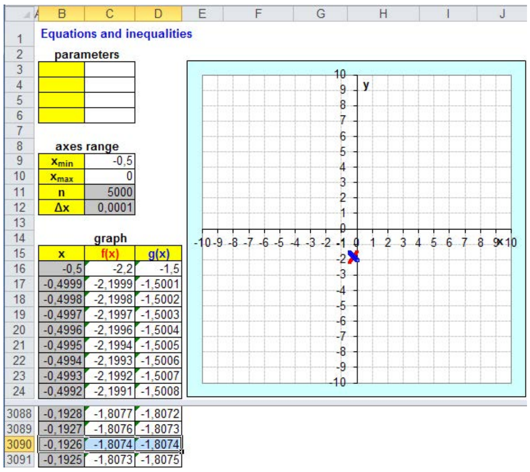

Figure 4: Solution by iteration

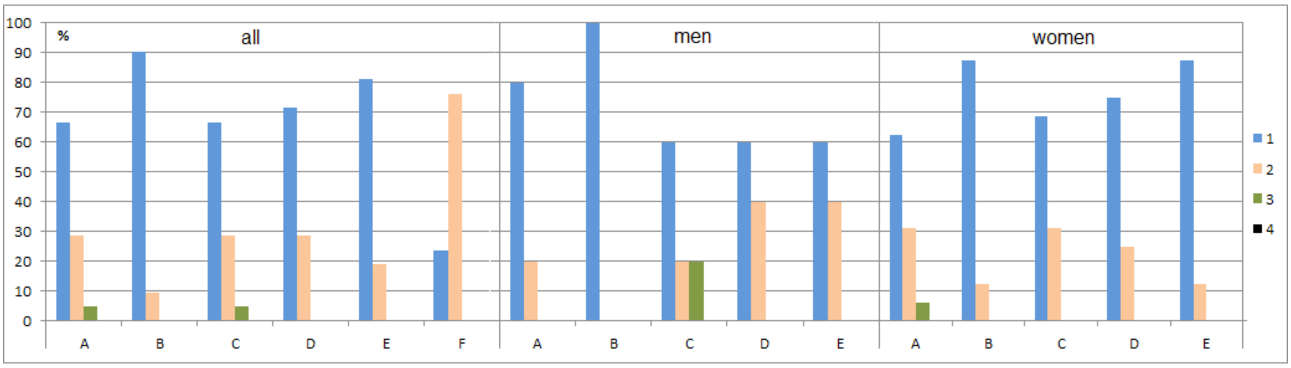

Figure 5: Relative frequency of the answers

19% quite a lot). The men found the lesson more interesting while the women found it more benefitting.

SOLVING EQUATIONS WITH A PARAMETER BY USING ANIMATION

Solving an equation with a parameter is a hard task at upper secondary level. The graphical interpretation helps. If the parameter is changed quickly, the relation between the parameter and the solution can be easily revealed. The left side of the equation $(p + 1)x^2 + px + |p| = 0$ is graphed in the application in Figure 6. Parameter p is controlled by a spinbutton. Clicking it and holding down animates the graph. The positions at other values of parameter p are depicted in Figure 7. The solution is:

$$p \in (-\infty, -1) \cup (-1, -0.8): \quad x = \frac{-p \pm \sqrt{p^2 - 4(p+1)|p|}}{2(p+1)}$$

$$p = -1: \quad x = 1$$

$$p = -0.8: \quad x = 2$$

$$p = 0: \quad x = 0$$

$$p \in (-0.8, 0) \cup (0, \infty): \quad x \in \{\}$$

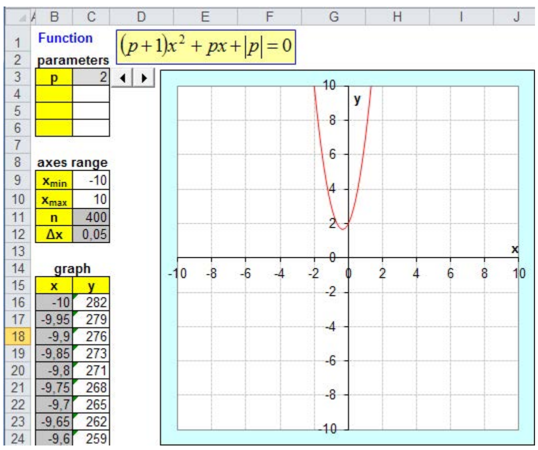

Figure 6: Position of the graph at p = 2

Lesson and survey: There were 23 students, 4 men and 19 women. The analytical solution to the equation was quickly gone through. The students developed the application from the application on the left side of Figure 1. They found that the graph is in a special position if p = 0, −0.8 or −1. The solution at these boundary values was obtained by substitution. The solution for the values inside the intervals given by the boundary values was obtained by applying the quadratic equation. At the end, they answered the questionnaire. The result is graphed in Figure 8.

The result is: (A) 87% found the lesson interesting (61% very, 26% quite); (B) 96% understood the topic (83% all, 13% most); (C) 83% had the feeling that the lesson contributed to his/her TPACK (57% a lot, 26% quite a lot); (D) 83% found the applications to be benefitting (65% a lot, 18% quite a lot). (E) 87% were of the opinion that the developing helped comprehend the core (65% a lot, 22% quite a lot). The women found the lesson more interesting and benefitting than the men.

INTERACTIVE SOLUTION TO A QUADRATIC EQUATION AND TO A SYSTEM OF THREE LINEAR EQUATIONS WITH THREE VARIABLES

Solving quadratic equations and systems of three linear equations with three variables are skills that are often applied in solving tasks at upper secondary level. The following task requires applying both skills:

A projectile was fired in a vacuum. Three points of the trajectory were detected by radar. The trajectory is a parabola. Find the points of shot and impact.

Substitution of the coordinates of the points in the equation $y = ax^2 + bx + c$ yields a system of three linear equations with variables a, b, and c. In Figure 9, the system is solved by using the Gaussian elimination method (GEM).

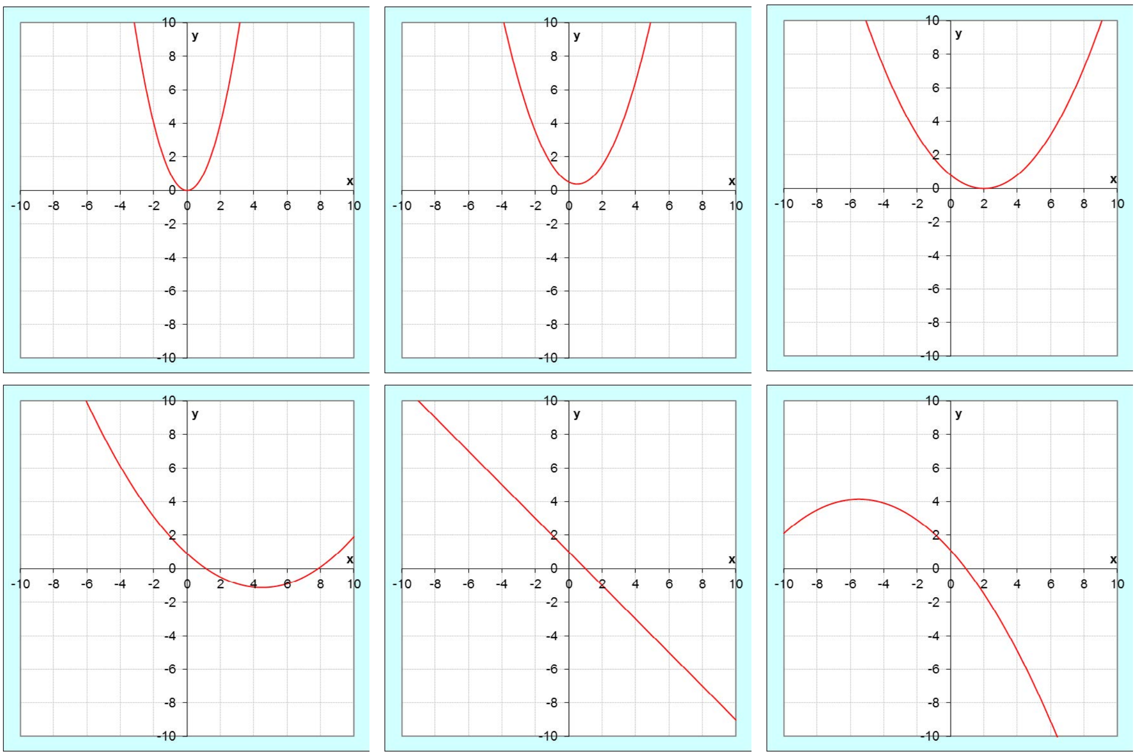

Figure 7: Positions at p = 0; -0.5; -0.8; -0.9; -1; -1.1 (left to right by rows)

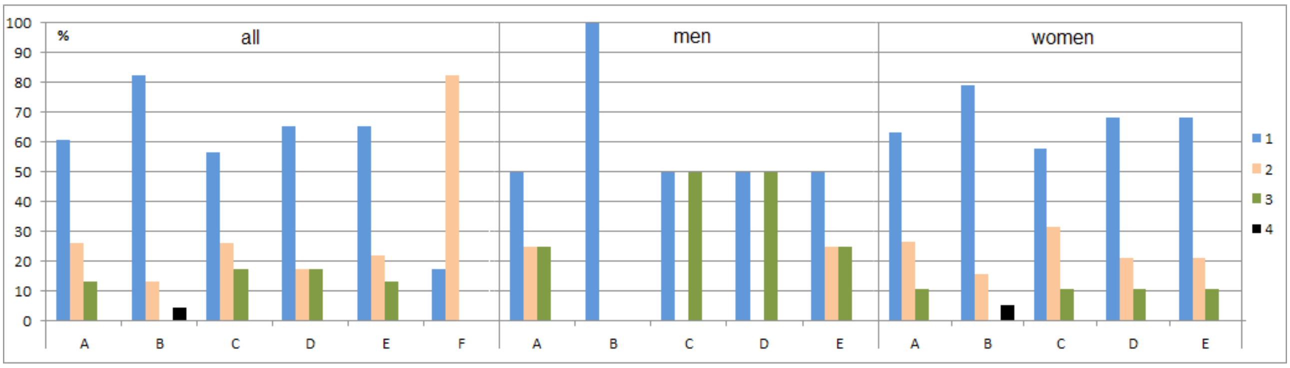

Figure 8: Relative frequency of the answers

The matrix is in range N5:Q7. The upper triangular matrix is obtained in four steps over ranges N9:Q11, N13:Q15, N17:Q19 and N21:Q23. Variables a, b and c are calculated in range C3:C5. The system always has a unique solution, which stems from the physics of the task. The discriminant of equation $ax^2 + bx + c = 0$ is in cell L10. It is always positive.The roots are in cells L13 a L14. The vertex coordinates are in cells K18 a L18. The application is interactive – if the coordinates of the points in range K5:L7 change, the point of shot and impact (L13, L14) are recalculated.

Lesson and survey: There were 24 students, 4 men and 20 women. The solution to the systems of linear equations by GEM was gone through. The students developed the application in Fig 9 from the application on the left side of Figure 1 and resolved the task. At the end, they answered the questions. The result is in Figure 10.

The result is: (A) 92% found the lesson interesting (54% very, 38% quite); (B) 100% understood the topic (83% all, 17% most); (C) 92% had the feeling that the lesson contributed to his/her TPACK (54% a lot, 38% quite a lot); (D) 92% found the applications benefitting (63% a lot, 29% quite a lot); (E) 96% were of the opinion that the developing helped comprehend the core (50% a lot, 46% quite a lot). The men found the lesson more interesting while the women found it more benefitting.

SURVEY SUMMARY

Altogether 96 questionnaires were answered, 19 by men and 77 by women. The result is graphed in Figure 11.

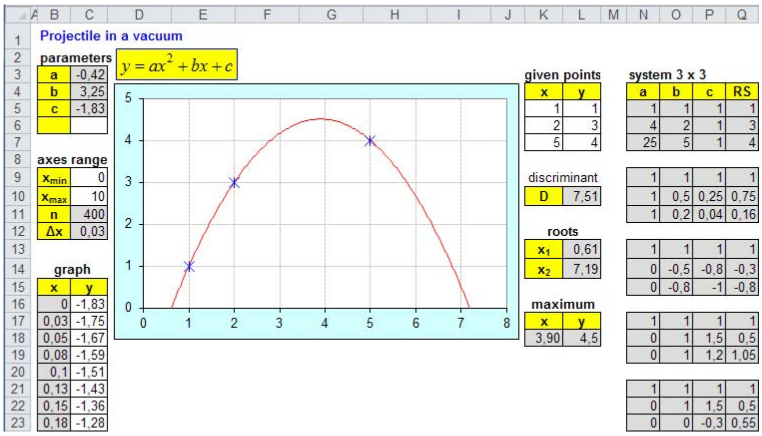

Figure 9: Trajectory of a projectile in a vacuum

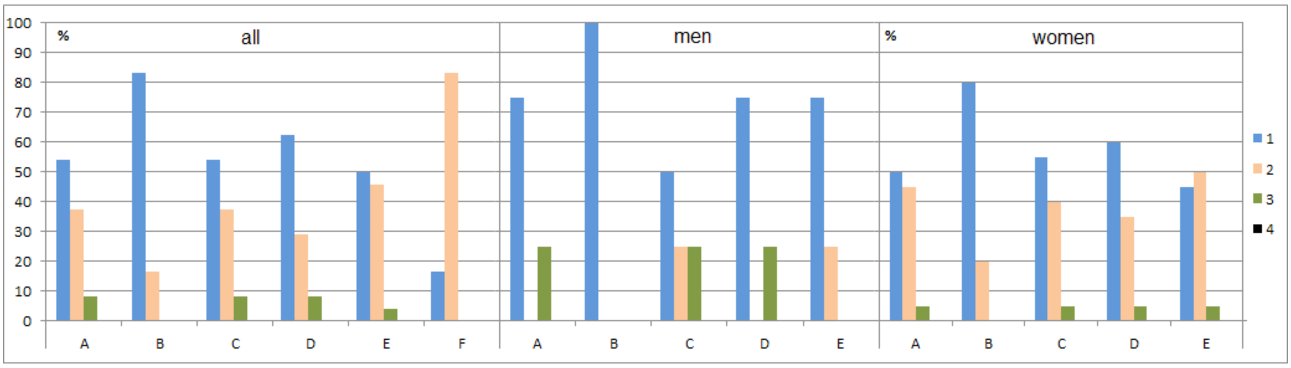

Figure 10: Relative frequency of the answers

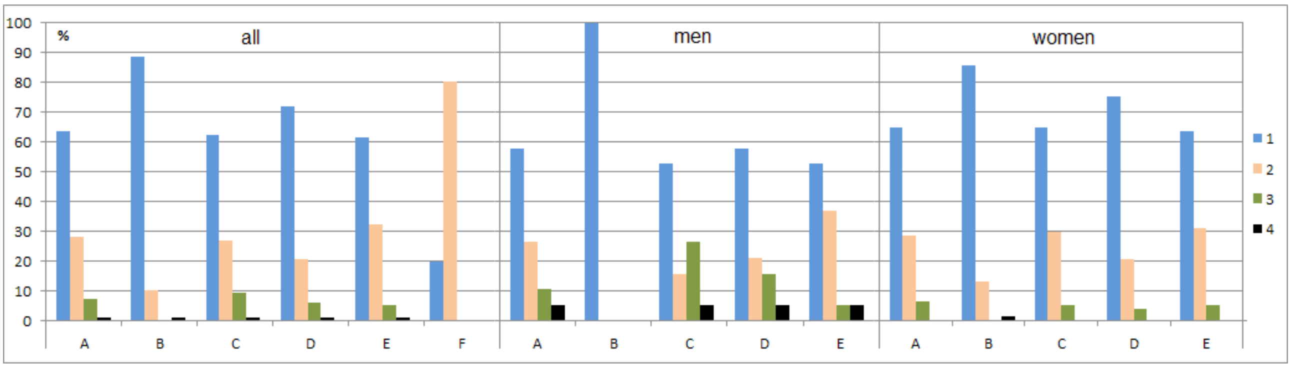

Figure 11: Relative frequency of the answers in total

The result is: (A) 92% found the lesson interesting (64% very, 28% quite); (B) 99% understood the topic (89% all, 10% most); (C) 90% had the feeling that the lesson contributed to his/her TPACK (63% a lot, 27% quite a lot); (D) 93% found the applications to be benefitting (72% a lot, 21% quite a lot). (E) 94% were of the opinion that the developing helped comprehend the core (62% a lot, 32% quite a lot).

The outcome for all, men and women was:

A) *The lesson was interesting: 92%, 84 %, 94 %*

B) *I understood of the mathematics involved: 99%, 100 %, 99 %*

C) *The lesson contributed to my TPACK: 90%, 69 %, 95 %*

D) *The applications benefit the teaching of the topic: 93%, 79 %, 96 %*

E) *Developing the applications helps comprehend the core: 94%, 90 %, 95 %*

F) *I am a man: 20%*

The lessons contributed considerably more to the TPACK of the women than men (difference of 26%). The women found the applications more benefitting the teaching of the topics and more interesting than the men (difference of 17% and 9%). The women were stronger of the opinion that developing the applications helps comprehend the core of the topic (difference of 5%).

The result implies that the presented method of teaching mathematics through developing spreadsheet applications that model and solve tasks is of interest to pre-service teachers, benefits the teaching of the topics and contributes to the technological and pedagogical knowledge of the teachers, mainly women. The outcomes correspond well with the result of the authors' research with high school students (Benacka and Ceretkova, 2013). That suggests that "learning by doing" with spreadsheets has a potential in promoting mathematics at upper secondary level.

Expert and novice teachers' classroom practices in a technological environment

Gulay Bozkurt and Kenneth Ruthven

University of Cambridge, Faculty of Education, Cambridge, UK, gb408@cam.ac.uk

This case study compares the teaching practices and craft knowledge of two secondary mathematics teachers using GeoGebra to teach the same geometrical topic. It forms part of a programme of research aimed at developing a more comprehensive understanding of technology integration in classrooms, by providing a model of key structuring features of classroom practice (Ruthven, 2009) which shape the use of technology in lessons and the kinds of professional knowledge required. In accordance with this conceptual framework, the classroom practices of an expert technology-using teacher are analysed in contrast to those of an experienced but technologically novice teacher, so shedding light on the character of expertise and the process through which it develops.

Keywords: Classroom practice, mathematics teaching, dynamic mathematics software, technology use, teacher knowledge and thinking.

INTRODUCTION

There has been considerable recent interest in issues of the integration of new technologies into ordinary classrooms in which the particular focus is on the teacher dimension. Researchers have suggested that teachers are faced with the need to consider a range of classroom management issues. They need not only to develop new types of interactions (Monaghan, 2004; Drijvers et al., 2010) but also to manage different kinds of time in their classrooms (Assude, 2005). They must establish a relationship between a technological environment and a paper and pencil environment in order to "build connections with the official mathematics outside the microworld" (Guin & Trouche, 1998, p. 200). Furthermore, some researchers (Monaghan, 2004; Lagrange, Dedeoglu, & Erdogan, 2006) have shown how technology can affect the emergent goals of the teacher during the lesson. When a teacher integrates Dynamic Geometry Software (DGS) in order to make students engage with the task, s/he must consider not only a mathematical learning trajectory but also the instrumental aspect of this including the operation of the tool (Lagrange et al., 2006). In this light, it is not surprising that the process of orchestrating technology-integrated mathematics learning is not straightforward, in particular for teachers who are novice in technology-use, since the use of digital resources calls for "change in teachers' professional knowledge and development" (Gueudet & Trouche, 2009, p. 199). In this respect, Tabach (2012) showed that classroom practices of teachers in relation to technology-use influence their knowledge and thinking and vice versa. Similarly, a number of studies (e.g., Monaghan, 2004; Drijvers, 2012) have shown that, over time, teachers' practices with technology generate professional growth as teachers revise and adapt their teaching in relation to technology through feedback from their experiences. In other words, teachers build up knowledge from their reflection on their own classroom experiences and strategies they develop when, in the course of using the technological tools available, unexpected issues occur in the classroom.

Two fundamental questions, then, need to be addressed: "What aspects of classroom teaching shape the ways in which teachers integrate new technologies?" and "What kinds of professional knowledge do teachers need to teach with them?"

THEORETICAL FRAMEWORK

The recently conceived Structuring Features of Classroom Practice (SFCP) (Ruthven, 2009) was the framework chosen for this research on teachers' classroom practices with the use of new technologies. This framework takes a naturalistic approach, focusing on constructs that are directly related to teachers' classroom practices. Drawing from prior research on teaching and schooling in general, it identifies five constructs which have already been developed to analyse what happens within classrooms and which bear crucially on incorporation of technology within classroom practice. These are working environment (e.g., Horne-Martin, 2002), resource system (e.g., Cohen, Raudenbush, & Ball, 2002), activity format (e.g., Burns, 1984), curriculum script (e.g., Putnam, 1987; Leinhardt, Putnam, Stein, & Baxter, 1991), and time economy (e.g., Assude, 2005).

Working Environment: Using new technologies typically requires adaptation of the working environment, either through moving teaching to a specialised computer laboratory or re-organising the ordinary classroom.

Resource System: New technologies increase the range of tools and resources available in classrooms, and pose a challenge for teachers to create a coherent resource system.

Activity Format: Technology-based lessons may require the adaptation of existing activity formats from non-technology based lessons or the development of some new format which "structures the activity and provides the organizational means by which learning tasks will be accomplished" (Burns, 1984, p. 103). Grouping arrangements, delivery system and interaction patterns define the activity format.

Curriculum Script: Mathematics teachers who are integrating new technologies in their classrooms need to develop their curriculum script in order to have a structure for planning and interpreting classroom teaching of a topic with technology. Curriculum script was developed by Putnam (1987) and defined as "a loosely ordered but well defined set of skills and concepts students were expected to learn, along with the activities and strategies for teaching this material" (p. 13).

Time Economy: Assude (2005) argues that time related issues in classrooms stem from time management difficulties in the classroom. Following Assude, Ruthven (2009) uses the concept of time economy to denote "how teachers seek to manage the 'rate' at which the physical time available for classroom activity is converted into a 'didactic time' measured in terms of the advance of knowledge" (p. 14).

The SFCP framework identifies key aspects of the craft of teaching that indicate the corresponding professional reasoning and craft knowledge that teachers must develop about these aspects in order to successfully incorporate new technologies. Ruthven (2009) explained the interaction of these aspects in teaching decisions and activities: for example, "Each of these modifications of an established activity format calls for the establishment of new classroom norms for participation, and of classroom routines to support smooth functioning" (p. 10). Employing this framework, the research reported here studies teachers' use of technology in classrooms and the associated expertise teachers use in their everyday practice.

RESEARCH CONTEXT

This study examines classroom practices of two secondary math teachers' use of GeoGebra (GGB) for math teaching, working within the English school system. GGB was of particular interest due to its accessibility. Although there is a lot of interest in GGB, difficulties arose when looking for suitable lessons, which indicated that in practice its use still remains quite rare. The most popular topics are concerned with graphing functions, geometrical transformations and angle properties in a circle.

After teachers agreed to participate in the research, the first author visited their schools to discuss their timetable and to find out when they were planning to make some significant use of this technology. Observations took place at a time agreed in advance with each teacher. Thus, this study involved no attempt to control or influence teachers' lessons. In particular, the researchers did not participate in the lessons planning, although it is clearly possible that a teacher's planning was influenced by the knowledge that a lesson would be observed. To try to forestall this, the research protocol made clear to teachers that they themselves should choose the topic, using GGB however they saw fit, and in any manner they wished.

Both teachers in this study chose to teach the topic referred to in the English curriculum as "Circle Theorems". One (pseudonym Chris) is an Advanced Skills Teacher (a recognised grade of classroom teacher within the English school system, also taking special responsibility for leading professional development). He has around twenty years of teaching experience and is an expert technology user who utilises new technologies in a progressive way in math instruction. He taught the topic over a series of four lessons to a top set Year 11 class. The other teacher (pseudonym Susan) also has around twenty years teaching experience, but is a novice technology user. Although Susan was experienced in teaching Circle Theorems, it was the first time she had integrated GGB into her teaching of this topic to this extent. She taught the topic over two lessons to a lower set Year 10 class.

Teacher Interviews: Semi-structured post-lesson interviews were conducted in order to clarify the professional thinking behind the observed lessons according to the SFCP framework key themes. Interview questions mainly focused on how using technology in the lesson might make it rather different to organise and run from a similar lesson without technology. These interviews were audio-recorded.

Classroom Observations: A semi-structured, non-participant observation approach was adopted for which the SFCP framework as an interpretative lens provided guidelines. In this regard, observation data aimed to provide evidence about teachers' classroom practices in relation to use of technology, with a focus on pre-specified aspects of the SFCP framework. All observed lessons were recorded and transcribed verbatim. To do this the teachers were asked to wear a microphone during lessons to capture all speech during individual teacher-student interactions.

RESULTS

The data acquired from this study are presented in detail due to space constraints. Instead some of the main findings are outlined and compared with other research.

Working environment

Chris's lessons took place in a Computer Lab where the computers for students were arranged in a U shape around the back and sidewalls, so that students working at them were facing away from the front of the room. There was also sufficient seating in the centre of the room to accommodate the entire class being taught as a group facing the front. At the front of the room there was a computer connected to a data projector for the teacher, and a Smart-board. Susan's lessons took place in a normal classroom where the seating consisted of rows of tables with chairs. There was a Smart-board as well as an ordinary whiteboard at the front. The teacher provided students with laptops on which GGB was downloaded, which they used at their normal tables in the classroom. In order to ensure that students would have a functioning computer system she spent a considerable amount of time in preparation.

Chris was satisfied with the working environment since the layout allowed him the most convenient method of monitoring students, which in turn supported interaction between teacher and students.

> I can see all of their screens. So if I stand in the middle and turn my head I can see everybody's screen which means that I know immediately if somebody isn't doing what they should.

He also appreciated the availability of software that allowed the teacher to control students' screens.

Although Susan made an active choice to use laptops because her class had too many students to fit into the available computer room, she described her ideal layout as being a bigger U-shaped computer room where she could monitor students in a more straightforward way.

> I'd rather have a bigger room. My ideal would have been a big U shaped computer room with big screens that they can see and that I can walk around easily. You can position yourself to see 3 quarters of the screen to scan the room. And I suppose this is where for me I am always thinking about the classroom management issues particularly in these lessons where I'm a bit out comfort zone.

Resource system

Chris as an expert technology user had a full command of the software. He was aware of difficulties that might arise with students' use of the resource and preempted these through use of technical demo (Drijvers et al., 2010). For instance, he made sure that students all knew how to measure an angle with GGB. This was because, over the years, he had noticed that students often "measure" without clicking in the anti-clockwise order (a convention embedded in GGB).

> For example measuring angles, you can click on the three points and depending on which order you click. If you click one two three, then it will

> measure the interior angle (he shows on the paper). If you click them the other way round it measures the reverse angle. That was just a matter of try clicking in a different order.

However, Susan was a novice in using GGB and did not have a full knowledge of it. So she was learning some aspects of the software during the lessons. While she was doing a technical demo at the beginning of the first lesson she wanted to show how to measure an angle on GGB; however she was not aware that GGB measures anti-clock wise and she got the measure of an obtuse angle a number of times while wanting to measure an acute angle. But during students' work on laptops, a student told her about clicking in the anti-clockwise direction.

> I was learning on the hoof this bit where it measures it anti clockwise; I had not really tweaked that. As I say Mike *(a student)* helped me with that one. I mean, yeah yes I did learn during the lesson. So then I could show the students. But the only way I have got now that in my head is by going through that pain and then teaching the students.

Similarly, she did not know how to set GGB to measure to the nearest whole number, which she thought created some confusion for students in this lower set since they had difficulties in seeing the relationships between angles.

Both teachers allowed students to use GGB by themselves for around half of each lesson as their aim was for students to discover some CT rules (Susan) and to explore some mathematical ideas, i.e., proof through CT (Chris). During students' use, teachers' role was to walk around and make sure that students engaged with their task. The teachers also used GGB for whole class teaching to explain or discuss problems. However, the two teachers had prepared rather different sets of tasks for students. Chris used more open-ended tasks, which aimed to encourage students to use GGB as tools or representations to help thinking. With this particular class, which is a high ability group of students, Chris pointed out that they have established this way of working over several years. His aim was to show students that there were many paths to reach the same mathematical solution; in particular he saw the topic of Circle Theorems as a vehicle for developing ideas about mathematical proof by focusing on different ways of proving. He also thinks that students have to learn to interpret the diagrams through building them up by themselves. On the other hand, Susan asked students to set up the diagrams shown on the worksheet by using GGB and then to explore triangles inscribed into circles and try to formulate four different CT rules through using dragging techniques.

> I expected them to discover the circle theorems. That was the aim of it. I wanted them to have that moment of awe and wonder, when they notice that special things happen in the diagrams. And I think the GGB lent itself to that.

During her reflections, Susan indicated that she used GGB to add 'fun' to lessons and to help students engage with more examples through using dragging techniques and to facilitate noticing the relationships between angles in circles. In comparison with undertaking the same worksheet on CT by hand, she considered that GGB assisted investigating CT through its accuracy, speed and manipulative ease.

Activity format

SFCP does not suggest specific activity formats, however Instrumental Orchestration (e.g., Drijvers et al., 2010; Drijvers, 2012), which also focuses on teachers' classroom practices in technological environments, has particularly focused on how activity structures relate to particular ways of making use of the technological component of the resource system, and has provided operational descriptions based on a combination of data- and theory-driven analysis (Ruthven, 2014). We will make use of the six activity format types identified for Instrumental Orchestration research; Technical-demo, Explain-the-screen, Discuss-the-screen, Spot-and-show, Work-and-walk-by and Sherpa-at-work (Trouche, 2004; Drijvers et al., 2010; Drijvers, 2012)

Chris' lessons broadly broke down into 3 segments. Initially the teacher introduced lessons in a whole class when he gave information about the lesson agenda and projected student work from a previous lesson to remind students what they had done and what direction to take from there. In the second segment, students went onto the computers and worked to discover for themselves in groups of at least two while the teacher walked around to monitor their progress and guide when necessary. Work-and-walk-by activity format comprised about 50% of a lesson. This format gauged students' involvement and engagement with the task, and also determined whether they had any difficulties during tasks. The teacher also guided the students to think in different ways during this format. Therefore, elements of Discuss-the-screen and Explain-the-screen were apparent in the teacher-students interaction during Work-and-walk-by. Finally, the teacher gathered the students in the middle of the room in order to discuss important points of the lesson primarily to create collective knowledge. Chris often made use of a Spot-and-show activity format during each segment of his lessons perceiving it as a means to enhance student involvement and discussion. He spotted students' examples, in particular different approaches, and showed them to the whole class in order to make pupils think of different ways of doing things. Another activity format that Chris made use of was Sherpa-at-work (Trouche, 2004): he spotted an example while circulating in the classroom, and stopped the students to project this spotted example on the IWB for whole class discussion. However the difference from the Spot-and-show format was that the teacher let the student, whose example he spotted, run the example from her computer and at the same time he was explaining/discussing the screen of what was going on. In other words, the Sherpa-student was the owner of the spotted example and she was in charge of the technology. Predict-and-test was another activity format used during the middle segment. The teacher encouraged students to make their own conjectures and then test them out on the computer.

The activity formats for Susan's lessons consisted of whole class teaching as well as student work at computers with the teacher moving around to monitor and provide support. The former was mostly to demonstrate some tool techniques, and to outline what the lesson was about. Since she was teaching this topic with GGB for the first time and most of the students had never used GGB, she spent half of the first lesson using a Technical-demo format to show some tool techniques that they could use for angle properties. She demoed briefly what she expected students to do, and to exemplify she used GGB in modelling on the IWB how to tackle the first question from the printed worksheet. During this, she showed the specific tools in GGB that students would need for constructing the shapes shown on the worksheet. Susan's activity formats were still influenced by non-technology patterns, and not fully instrumented by the technology. For instance, when she made use of Spot-and-show, rather than using GGB on the IWB she would hold up a student's worksheet in order to show others how this student had done the question.

Curriculum script

Examining the tasks sequences used in these cases provided a starting point for looking at how technology featured in the curriculum scripts (CS) of the two teachers, and how these scripts were developing in response to using technology. In particular, post lesson interviews focused on aspects where teachers reported change/development in their thinking about teaching the topic and/or structuring the lesson related to using GGB. Striking contrasts appear, with the CS of the technologically expert teacher being richer and more detailed in this respect than that of the technologically novice teacher. On that note, it was much easier to elucidate information from more experienced teacher about his CS. This richness was also evidenced by the differing nature of, and the degree of emphasis on, CS against resource system. The novice teacher's focus tended not to be on the CS, but was more about developing instrumental knowledge to make it part of the resource system, first for herself personally and then also for her students. For instance, Susan's reflections on what issues came up in lessons that she did not expect focused more on her lack of knowledge of GGB such as measuring acute angles and rounding measurements. These issues have already been raised in the section on resource system and they are more about GGB not yet being part of a functioning personal resource system for the teacher. In that sense she did not have a well-developed aspect of her CS for the topic that is specific to technology, which combines content and technology knowledge. Her CS consisted of following the sequence of her worksheet (prepared for teaching this topic in a non-technological environment) and she was at the stage of learning and adapting. However, Chris, who had been teaching with GGB for many years, had layers of accumulated knowledge about how to teach this topic with GGB.

Time economy

It became clear in post lesson interviews how the use of DGS contributed to time efficiency in lessons. Both teachers indicated that GGB – in particular the angle-measuring tool and the edit/undo option – enabled students to progress faster compared to measuring/calculating angles by hand.

> It will let us do lots of measuring without needing to do measuring or calculating so it will measure without us needing to do those by hand. That is a huge time saver. That saves a lot of time over drawing them out. (Chris)

This speed helped the students to produce and engage with more examples without spending as much time capital, therefore, maximised the didactic time.

> The speed is that they can see lots of versions of it and all the weird versions. (Susan)

As an expert technology user, Chris's use of working environment and available resources such as control software for showing examples led to efficient use of instructional time. Also, instrumented use of Spot-and-show during students' work at computers provided 'intermediate syntheses' (Assude, 2005), which helped him save time capital. However, the fact that Susan was not aware of some tool techniques introduced some time diseconomy in her lessons.

While students worked at computers in groups, both teachers walked amongst students and guided them through making 'authoritative contributions' (Assude, 2005, p. 201) and posing leading questions in order to increase the didactic time during activity by avoiding students dissipating the limited time capital available.

CONCLUSION

As a novice technology-user, Susan believed that students need more monitoring during technology lessons, and that some room arrangements offer better scope for monitoring and interaction. Both teachers were very conscious of the degree to which GGB formed part of a functioning resource system for their class: in Susan's case, that she was just embarking on establishing such a system; in Chris's case, that he could count on such a system having already been established. In terms of activity formats, most of the orchestration types characterised in Drijvers and colleagues (2010) and Drijvers (2012) studies featured in this study but with more variants. However, an additional type of activity format, Predict-and-test, was identified in my study (resembling an activity format already noted in Ruthven, Deaney, & Hennessy, 2009). The interaction becomes between the teacher, class and computer, with the students making a prediction and then testing it out on the computer rather than teacher validating – or invalidating – it. That shifts the role of the teacher towards becoming an organizer/observer of this process. Also, this activity format appears to be specific to technology use, depending crucially on its use. Therefore, it could be said that the results of this study also contribute to extending the Instrumental Orchestration framework to some extent. There was a notable difference in the way in which teachers instrumented activity formats through the use of technology. The novice teacher tended to customize existing (and more generic) formats for implementing activity. The expert teacher believed that Sherpa-at-work was distinctive to technology use where the involvement of the computer uniquely influenced the nature of the interaction-taking place.

This study makes a threefold contribution. Firstly, it provides a further empirically-based test of the usability and usefulness of the SFCP conceptual framework (Ruthven, 2009) as a tool for advancing research on technology integration. Secondly, in focusing on the teacher dimension (Lagrange et al., 2003) this case study provides an illuminating comparison which math teachers and teacher educators engaged in professional development on the issue of the integration of technological tools could employ to build a holistic understanding of the conditions of technology in ordinary classrooms and shed light on how teachers can adapt new technologies to their teaching. Finally, there might be a third type of contribution through presenting the report of these teachers' teaching with technology in ways that could be directly accessible and useful to other teachers, by reporting practical solutions to concrete problems that a teacher commencing integrating technology into their teaching would encounter.

The diagnostic assessment Pépite and the question of its transfer at different school levels

Françoise Chenevotot-Quentin[1], Brigitte Grugeon-Allys[1], Julia Pilet[1], Elisabeth Delozanne[2] and Dominique Prévit[2]

1 Université Paris Diderot, Laboratoire de Didactique André Revuz (LDAR), Paris, France, chenevotot.francoise@neuf.fr

2 Université Pierre et Marie Curie, Laboratoire L'UTES, Paris, France

This paper deals with the question of the transfer of the diagnostic assessment Pépite at different grade levels. First, we present the theoretical foundations and the modalities of the diagnostic assessment Pépite. Then, we characterize the model of the diagnostic test and we study how this model is compatible according to different grade levels. We detail the response analysis and also we explain how to transfer it to different grade levels.

Keywords: Diagnostic assessment, Information and Communication Technology (ICT), elementary algebra, student's profile, teaching suggestions.

CONTEXT

Teachers are looking for tools in order to help their students. In fact, to allow each student academic progress, teachers need detailed diagnosis about individual student's learning. However, teachers also need to manage the whole class by proposing differentiated activities which are adapted to groups of learners with close competences or who require the same teaching strategy.

This paper addresses the TWG15 "Teaching mathematics with resources and technology". Our research concerns the development and the use of online resources for diagnosis and differentiated learning in the field of elementary algebra. It takes place into the *Pépite* project whose objective is to design and implement a web-based application to support mathematics teachers in managing the cognitive diversity of their students in school algebra classes (Delozanne, Prévit, Grugeon-Allys, & Chenevotot-Quentin, 2010).

Since 2011, we spread our research tools on *LaboMep* (Pilet, Chenevotot, Grugeon, El-Kechaï, & Delozanne, 2013), the online databank developed by *Sésamath*, a French mathematics teachers association. The success of the *LaboMep* platform shows us that such online resources may answer to the teachers' needs (Artigue & Gueudet, 2008): they are looking for valuable information about consistency and misconceptions in student's algebraic activity. First, we implemented the diagnostic assessment *Pépite* for $9^{th}/10^{th}$ grade students (15–16 years old). Second, we implemented a tool providing automatically teaching suggestions according to the learning objectives aimed at by the teacher and adapted to students' diagnostic assessment (Pilet et al., 2013).

This paper deals with the question of the transfer of the diagnostic assessment *Pépite* at different grade levels. First, we present the modalities of the diagnostic assessment *Pépite* and the theoretical elements mobilized. Then, we characterize the model of the diagnostic test and we study how this model is compatible according to different grade levels. We detail the response analysis and we also explain how to transfer it to different grade levels. Last, we conclude with some research perspectives.

THE DIAGNOSTIC ASSESSMENT PEPITE

The theoretical foundations

The modeling presented here is not based on a psychometric approach. The *Pépite* diagnostic assessment is based firstly on an epistemological and anthropological approach and secondly on a cognitive approach of elementary algebra in order to define a reference (Artigue, Grugeon, Assude, & Lenfant, 2001).

In its *tool* dimension (Douady, 1986), the algebra field covers traditional arithmetic problems, problems of generalisation and proof, problems where algebra appears as a modelling tool, problems to put into equation, algebraic and functional problems (Chevallard, 1989). In its *object* dimension, algebra is a structured set of objects with specific properties, semiotic representations and treatment modes taking into account both their semantics and their syntax (Kieran, 2007; Vergnaud, Cortes, & Favre-Artigue, 1988). The diagnosis *Pépite* relies on a multidimensional analysis of the algebraic activity (Grugeon, 1997; Kieran, 2007 [1]) which allows identifying consistency in student's algebraic activity and following its evolution.

According to the anthropological approach, mathematical knowledge strongly depends on the institutions where it has to live, where it has to be learnt or to be taught. Mathematical objects do not exist per se but emerge from practices, which are different from one institution to another one. Chevallard (1999) analyses them in terms of praxeology, i.e., in terms of type of tasks, techniques used to solve these tasks (praxis), technological discourse developed to explain and justify particular techniques, and last, theories which structure the discourse (logos). Here, the diagnostic assessment *Pépite* depends on the curriculum at the end of compulsory education. At each grade level, diagnostic tasks are characterized by a type of tasks, the complexity of algebraic objects involved and the level of involvement of tasks in the resolution.

Pépite diagnostic tasks

The *Pépite* test is composed of ten diagnostic tasks that cover the algebraic field grouped into four sets of types of tasks: calculus (developing or factoring algebraic expressions, solving equations), production (of expressions, formulas or equations), translation or recognition of mathematical relationships from one register of representation to another, solving problems in different mathematical frameworks (numeric, algebraic, geometric, functional) with algebra in order to generalize, prove properties, model or put into equation. The diagnostic tasks may be multiple-choice questions or open responses with multistep reasoning.

The conceptual IT model of classes of tasks developed by Prévit (Delozanne, Prévit, Grugeon, & Chenevotot, 2008) allows characterizing equivalent tasks on a diagnosis point of view. Prévit developed *PépiGen*, software that automatically generates the tasks and their analysis. It uses *Pépinière* software that generates anticipated student's correct or incorrect responses, according to a priori analysis of the tasks.

We work on two main points to transfer *Pépite* assessment at several grade levels. On the didactic modelling side, we have to define a set of tasks that cover the mathematical field at the grade level considered and the associated didactical variables. On the IT modelling side, we have to build generic tests in order to have a same framework for each test.

The response analysis

The diagnostic assessment *Pépite* includes three stages:

- The *local diagnosis* (on a single exercise) analyses each student's response on several dimensions and not only in terms of correct/incorrect and the diagnostic system provides a set of codes that characterize this response according to types of anticipated responses;

- The *individual global diagnosis* (on a set of exercises) collects similar codes on different exercises to build the student's cognitive profile expressed by a level at three scales of skills, success rates and personal features (relative strengths and limitations, false rules and correct rules);

- The *collective global diagnosis* defines groups of students who have close cognitive profiles.

In order to transfer the response analysis, for every task, we need to anticipate the different types of responses and their different forms and study if the computer algebra system *Pépinière* allows automated analysis. At last, we have to build the algorithm to calculate the student's profile.

We now expose the issue of the transfer of the diagnostic assessment *Pépite* at the $7^{th}/8^{th}$ grade level and define some conditions to succeed.

THE TRANSFER OF THE DIAGNOSTIC TASKS

The first step of the transfer of *Pépite* concerns the design of diagnostic tasks with two necessary conditions: theoretical foundations and institutional constraints.

Types of tasks	Number of items	Test item
Calculus	4 / 27	5.1 / 5.2 / 5.3 / 5.4
Producing algebraic expressions	6 / 27	3.1 / 8.1 / 8.2 / 8.3 / 9 / 10.2
Translation or recognition	16 / 27	1.1 / 1.2 / 1.3 / 1.4 / 2.1 / 2.2 / 2.3 / 3.2 / 4.1 / 4.2 / 4.3 / 4.4 / 4.5 / 6 / 7 / 10.1
Problem solving in different mathematics frameworks	3 / 27	8.3 / 9 / 10.3

Table 1: Organization of the 9th/10th grade level test in terms of types of tasks

Types of tasks	Number of items	Test item
Calculus	4 / 22	7.1 / 7.2 / 8.1 / 8.2
Producing numerical expressions	1 / 22	5
Producing algebraic expressions	3 / 22	3.1 / 5 / 6
Translation or recognition	14 / 22	1.1 / 1.2 / 1.3 / 2.1 / 2.2 / 2.3 / 3.2 / 4.1 / 4.2 / 9.1 / 9.2 / 9.3 / 9.4 / 10
Problem solving in different mathematics frameworks	1 / 22	6

Table 2: Organization of the 7th/8th grade level test in terms of types of tasks

A tasks transfer that ensures the mathematical coverage area

To ensure that the test takes into account all types of tasks involved in the algebraic field, we characterize each item of a diagnostic task by one or more of these types of tasks (Chenevotot-Quentin, Grugeon, & Delozanne, 2011). We consider that the diagnostic test covers the types of tasks in the field if all types of tasks are involved. As shown in Table 1, the ten diagnostic tasks of the initial test (9th/10th grade level) cover the algebraic field. The test for the 7th/8th grade level is also composed of ten diagnostic tasks. The Table 2 shows that they are spread across all types of tasks. As at this grade level, numeric skills play an important role in the entry into the algebraic activity, we add a new type of tasks to our list: *Produce a numerical expression*. We assume that the question of whether a student may or may not produce a numerical online expression with correct parentheses is an important indicator of its interpretation of algebraic expressions. We illustrate this task in the following text.

A transfer by adapting existing tasks or adding new tasks

To comply with the curriculum experienced by students in grade 7th in France, the transfer of the test

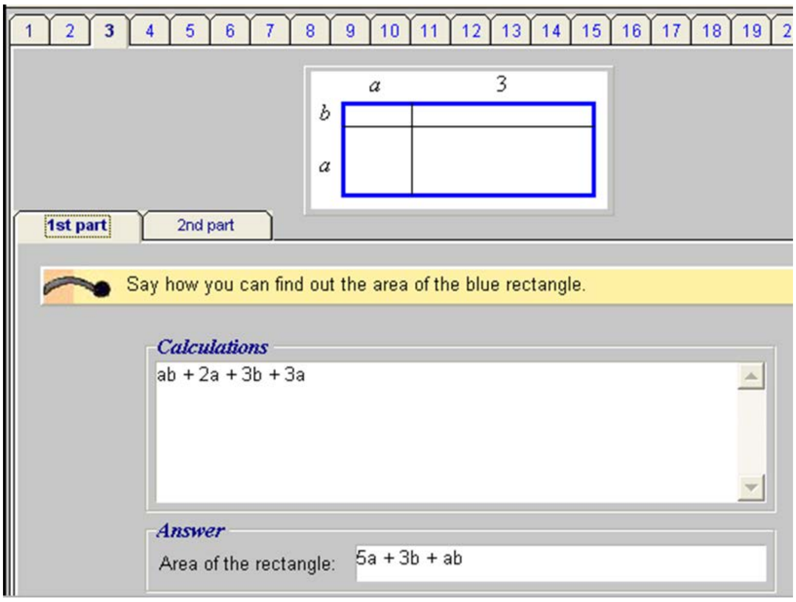

Figure 1: Item 3.1 of the initial test

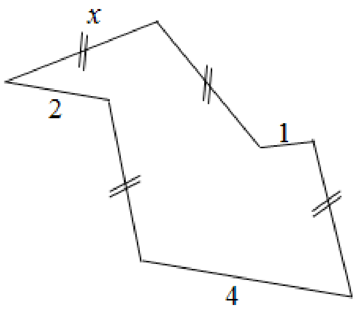

Shows how to calculate the perimeter of the figure	
Draft for calculations	Perimeter of the figure

Figure 2: Item 3.1 of the 7th/8th grade level test: an example of an adapting task

13 girls and 15 boys go to the movies. Each pays his ticket € 6.80, buys one soda 3 €, popcorn € 3.20 and also one glass € 2.50. Write one line expression to find the amount spent by the group without doing calculation.
Expression of the amount spent by the group

Figure 3: Item 5 of the 7th/8th grade level test: an example of a new task

requires a specific work on tasks. We distinguish, on the one hand, characteristic tasks of the algebraic field that are transferred with adaptations from the 9th/10th grade to a lower grade, and, on the other hand, tasks of the numerical field, specifically designed for 7th/8th grade level. We adapt the tasks of the algebraic field by adjusting the values of didactical variables such as the structure of algebraic expressions or the choice of numbers. These adaptations are justified by both the curriculum and the algebraic activity expected at this grade level. We present an example of adapting item: adapting the item 3.1 of the initial test (Figure 1) for the 7th/8th grade level test (Figure 2). In both cases, the type of tasks is *Produce an algebraic expression in the geometric setting*. In the initial (resp. new) test, the task relates to the area (resp. perimeter) of a rectangle (resp. figure). The area of the rectangle is a second-degree expression and the structure is too complex for the 7th/8th level. That is why we have chosen for this grade level a figure leading to a first-degree expression. Moreover, this choice allows identifying students that concatenate all terms (11x response) or those who are still in a repeated addition (x + x + x + x + 7 response).

To take into account the numerical skills of students who just discover algebra, we design new tasks. Figure 3 shows one of these tasks which belongs to the type of task: *Produce a numerical expression*. This task assesses if students can correctly produce one numerical expression with parentheses or if "step by step" reasoning persists.

THE TRANSFER OF THE RESPONSE ANALYSIS

We expose the issue of the transfer of the response analysis in the diagnostic assessment *Pépite* by successively visiting the three stages of the process: local diagnosis, individual diagnosis and collective global diagnosis.

First stage: Local diagnosis

The whole process of the diagnostic assessment *Pépite* relies on the quality of this first step: assessment of each student's responses. Students' responses are not only evaluated in terms of correct/incorrect. They are also coded in terms of consistency in the student's algebraic activity, determined by *a priori* analysis (skills, recurring errors). We define six analysis codes found-

Tick the correct equation			
$\frac{1}{2}+\frac{1}{3}=\frac{3}{2}$	$\frac{1}{2}+\frac{1}{3}=\frac{2}{5}$	$\frac{1}{2}+\frac{1}{3}=\frac{2}{6}$	$\frac{1}{2}+\frac{1}{3}=\frac{5}{6}$

Choice	A priori analysis	Code
1	Incorrect calculation based on the cross product	V3 EA5
2	Addition of numerators and of denominators	V3 EA42
3	Addition of numerators and product of denominators	V3 EA33
4	Correct	V1 EA1

Figure 4: Local diagnosis of the item 1.4 for the 9th/10th grade level test

Tick the correct equation			
$\frac{2}{3}+\frac{1}{6}=\frac{3}{6}$	$\frac{2}{3}+\frac{1}{6}=\frac{3}{9}$	$\frac{2}{3}+\frac{1}{6}=\frac{3}{18}$	$\frac{2}{3}+\frac{1}{6}=\frac{5}{6}$

Choice	A priori analysis	Code
1	Addition of numerators without putting the same denominator	V3 EN33
2	Addition of numerators and of denominators	V3 EN42
3	Addition of numerators and product of denominators	V3 EN33
4	Correct	V1 EN1

Figure 5: Local diagnosis of the item 1.1 for the 7th/8th grade level test

ed on theoretical study: validity of the response (V), meaning of the equal sign (E), use of letters as variables (L), algebraic writings produced during symbolic transformations (EA), representations used during translating a problem (T) and level of justification (J). Figure 4 and 5 show the responses of a 9th/10th and 7th/8th grades student to the task exposed in Figure 1 and 2 and their analysis.

Are these six analysis codes adequate to transfer the assessment to 7th/8th grade student? It is necessary to complete the six previous codes by adding two new codes to study the numerical writings produced during symbolic transformations (EN) and the skills with negative and decimal numbers (N). The EN code is created to take into account that the algebraic skills are built from numerical skills. As the EA and the EN codes have a close structure, we do not distinguish EA and EN in the initial test.

The local diagnosis is based on the anticipated responses obtained both by a didactical analysis and a corpus of responses; it produces the analysis grid. This method is adapted to the IT designing and computer programming. The two pieces of software *PépiGen* and *Pépinière* automatically generate tasks, their analysis and anticipated students' responses. The computer programming of the multiple-choice questions is easier than the one line open responses. In this case, the analysis is effective and generic. Around 10 to 15% of the open responses are still not analysed because of the complexity of the algebraic reasoning, sometimes written with a French text. The analysis of open responses needs specific treatments.

Second stage: Individual global diagnosis

The individual global diagnosis operates on the set of the ten exercises. The system analyses student's responses and calculates the student's cognitive profile through a transversal analysis of the codes of all their responses.

To build the student's cognitive profile, we define a scale of skills with three components founded on theoretical study: Use of Algebra for solving problems (coded UA); flexibility in translating different types of representations (geometric figures, graphical representations, natural language) into algebraic expressions and vice versa (coded TA); ability and adaptability in various uses of algebraic calculation (coded CA). For each of the three components, we identify a scale with different modes, and appropriate criteria for each (Delozanne, Vincent, Grugeon, Gélis, Rogalski, & Coulange, 2005). Figure 6 shows the individual global diagnosis for a 9th grade student with CA3-UA3-TA3 (Figure 6). This student does not give much sense to algebraic activity and does not use it as a tool for solving problems.

To transfer assessment to other grade levels, we also need to complete the algorithm to compute the profile by adding a fourth component to evaluate the various

Components	Personal features	Level
Algebraic Calculation With few signification	Success rate for the technical questions	2 / 12
	Success rate on the meaning of the algebraic expressions	7 / 23
	Mastery of the algebraical calculus	Failing
	Mastery of the rules	Failing
	Interpretation of the expressions	Failing
Usage of Algebra Not motivated and not understood	Success rate for the mathematisation questions	1 / 9
	Mastery of the algebraical tool	Failing
	Type of justification	
Algebraic Translation To schematize	Success rate for putting in equation	5 / 24
	Mastery of the translation	Insufficient
	Translation of the mathematical relationships	Abreviative

Figure 6: 9th grade student's cognitive profile

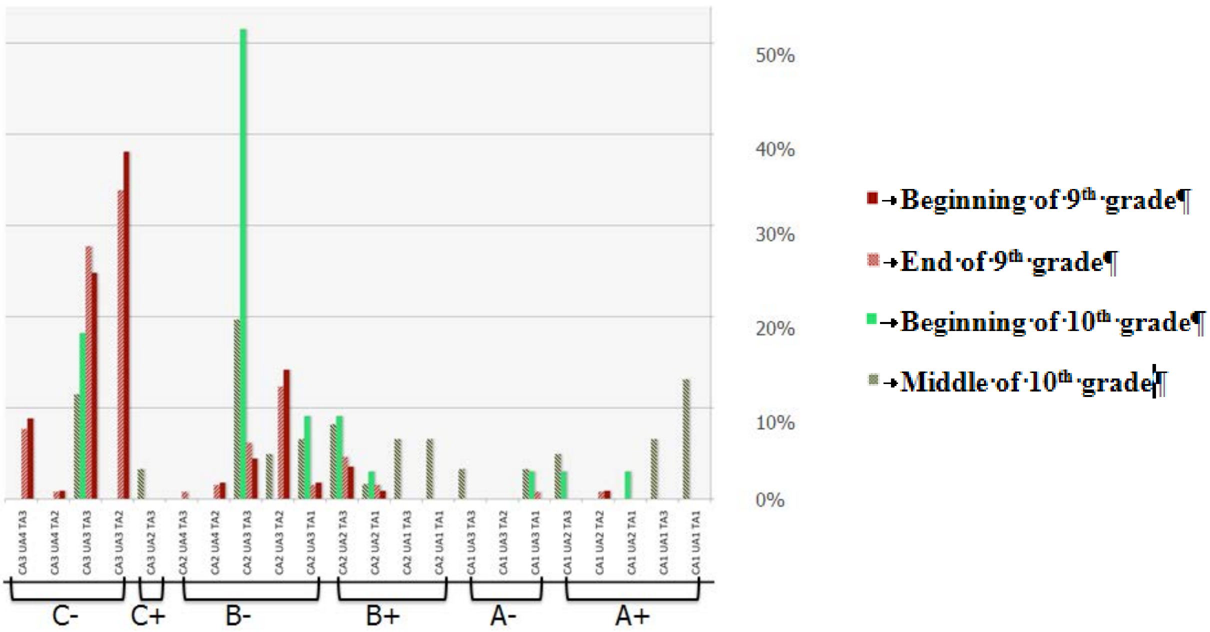

Figure 7: Collective global diagnosis for 9th/10th grade students (191 persons)

uses of numerical calculations (coded CN) and modes on the literacy scale. The CN component is created to take into account that the algebraic skills are built from numerical skills. This is the reason why the computation of the modes on scale on the CA and CN components has a similar algorithm.

Third stage: Collective global diagnosis

Teachers request that the diagnosis allows defining groups of students according to their skills in algebra with the aim of setting up strategies of differentiation. *PépiMep* software automatically calculates three groups of students (groups A, B and C) who have close profiles in algebra (Grugeon-Allys, Pilet, Chenevotot-Quentin, & Delozanne, 2012). For 7th/8th grade, the algorithm to calculate groups takes into account the new CN component.

CONCLUSION

Different studies comparing diagnostic assessment *Pépite* to other forms of assessment show that *Pépite* is reliable and valid, even with open questions (Delozanne et al., 2008, Delozanne et al., 2010). Overall, it provides a tool to save time and to avoid a very tedious work of a human being.

Since 2011, we implemented in *LaboMep* one test for 9th grade students (14–15 years old) and two tests for 9th/10th grade students (15–16 years old). We realized the model of the diagnostic tasks and we designed test and *a priori* analysis for 8th/9th grade students and 7th/8th grade students. We are now programming them in *LaboMep*.

From the theoretical foundations, we define a scale related to the algebraic activity. We can thus follow the evolution of the algebraic skills of the students on different grades. 191 students passed the 9th test and the 9th/10th test and we have already observed that the skills of the students increased. We project to validate this result from the 7th grade to the 10th grade (Figure 7).

What are the research perspectives? We project to extend the tool providing automatically teaching suggestions according to the learning objectives aimed at by the teacher and adapted to students' diagnostic assessment (Pilet et al., 2013), from 7th to 10th grade.

Do the following three calculation programs give the same result?		
Program 1	Program 2	Program 3
Choose a number, Multiply that number by 4, Add 3 to the product obtained.	Choose a number, Multiply that number by 7.	Choose a number, Multiply that number by 4, Add the product obtained triple the number selected.

Figure 8: Learning situation about equivalence of expressions

The first step, transfer of the diagnostic assessment to 7th/8th grade, is already realized. The second step will be to adapt learning situations already defined to study some epistemological algebraic aspects, often not sufficiently explained in curricula: sense of algebraic tool for solving problems of generalization, equivalence of expressions (Grugeon-Allys et al., 2012). The example given in Figure 8 illustrates a situation adapted to the target goal. This research is part of the NéOPRAEVAL project from the French *Agence Nationale de la Recherche*.

ENDNOTE

1. Using a synthesis of international researches in didactics of algebra, Kieran (2007) proposed the GTG model which differentiates three complementary algebraic activities: (1) Generative activities involve producing various algebraic objects (expressions, formulas, equations and identities), (2) Transformational activities involve the usage of transformational rules (factorization, expansion of products, rules for solving equations and inequalities…), (3) Global/meta-level activities involve the mobilization and use of the algebraic tool to solve different types of problems (modeling, generalization, proof).

Scaling mathematics teachers' professional development in relation to technology – probing the fidelity of implementation through landmark activities

Alison Clark-Wilson, Celia Hoyles and Richard Noss

University College London, UCL Institute of Education, London, UK, a.clark-wilson@ioe.ac.uk

This paper reports research into aspects of 'scaling' classroom access to technology within the context of an English teacher development project, 'Cornerstone Maths'. The aim of this multi-year project is to address issues of underuse of dynamic mathematical technologies by lower secondary students in classrooms through: specially designed web-based software; teacher and student materials; and professional development. The paper proposes the construct of a landmark question as a means to assess the degree of fidelity of the resulting classroom implementations at scale and reports emergent data on this theme.

Keywords: Mathematics, technology, teacher development, scaling, implementation fidelity.

INTRODUCTION

Despite multiple studies over many years that have concluded positive effects of student interaction with transformative digital technologies in mathematics education, teachers and schools find it difficult to integrate such resources within 'normal' mathematics lessons (Clark-Wilson, Robutti, & Sinclair, 2014; Gueudet, Pepin, & Trouche, 2012; Hoyles & Lagrange, 2009). By 'transformative technologies' we mean 'computational tools through which students and teachers (re-)express their mathematical understandings, which are themselves simultaneously externalised and shaped by the interactions with the tools' (Clark-Wilson, Hoyles, Noss, Vahey, & Roschelle, 2015). (For a more substantial elaboration of this, see Hoyles & Noss 2003). The reasons for this lack of engagement include: insufficient time and opportunity for sustained professional development; weak alignment with institutional practices; difficulties installing and maintaining software access; teachers' mathematical knowledge and beliefs, and insufficient access to teaching materials that exploit the affordances of well-designed technologies. The Cornerstone Maths (CM) project has been developed to respond to these concerns.

Cornerstone Maths began in 2009 as a design-based implementation study (DBIR, Kelly, 2004) that seeks to implement a replacement curriculum for hard to teach topics (linear functions, geometric similarity and algebraic expressions), which included professional development, and, research the resulting classroom implementations. This paper concerns the first curriculum unit on linear functions, which evolved from work in the USA. It is organised as a 'curriculum activity system' (Vahey, Knudsen, Rafanan, & Lara-Meloy, 2013) and comprises: web-based interactive software, teacher guide and student workbook [1] and face-to-face/at distance professional development support. Adaptation and pilot studies in England established the efficacy of the materials – a more expansive elaboration of the previous work is reported elsewhere (Clark-Wilson et al., 2015; Hoyles, Noss, Vahey, & Roschelle, 2013).

This paper extends this earlier work by elaborating a theoretical frame and methodological approach for research aiming at assessing the success of the professional development part of a large-scale intervention. Central to the approach is the question of how a teacher's classroom practice comes to align (or not) with the epistemic goals of the CM materials. We will limit this discussion to outcomes relating to classroom implementations of the CM curriculum unit on linear functions.

THEORISING ABOUT SCALING

We have drawn heavily on the work of Hung, Lim and Huang (2010) who, from the context of technology enhanced educational innovations within the Singaporean system, have defined the 'products' and 'processes' of scaling. By products, they mean the mainly quantitative measures such as the number of schools, teachers, and classrooms, the geographical reach and the (school-derived) measures of increased student attainment [2]. The processes describe the means through which such products are achieved, which will differ according to each project. For CM, the processes included the development of a localised PD offer led by a CM project lead who could provide ongoing peer support for teachers to embed CM within local of schemes of work.

However, whilst these products and processes indicate the extent of teachers' and schools' access to (and use of) the CM materials, they mask the more fundamental information about *how* the materials were implemented in classrooms and, crucial to our research interest, whether or not these implementations retain any fidelity to the design principles of the CM innovation. Existing literature on research into the enactment of the mathematics curriculum offers a range of methodologies to this end (Heck, Chval, Weiss, & Ziebarth, 2012 ; Polly & Hannafin, 2011). However, few studies have addressed how to research classroom implementations during large-scale projects involving hundreds of teachers over a timeline of years (Wylie, 2008).

Defining success at scale

Our earlier work (reported in Clark-Wilson et al., 2015, and summarised here) revealed a set of criteria or 'success indicators' at the level of an individual teacher's engagement with CM. These were:

1) Expression of satisfaction with the professional development and teaching materials;

2) Alignment between the professional development and teaching materials and their goals as a teacher;

3) Use of materials and the extent to which they create legitimate adaptations (which align to the design principles of the innovation);

4) Positive outcomes in their classroom;

5) Activity and engagement within the professional community and with the project team.

Ultimately, we were keen to uncover the extent to which teachers redefined powerful learning of their students in the light of the innovation. As our earlier work had concluded that legitimate adaptions [3] enhanced the epistemic value of the tool use (Hoyles et al., 2013), we viewed adaptation as an essential part of teachers' actions as they made sense of (and began to use) the CM materials. However, we were aware that some teachers could adapt the CM materials to produce 'lethal mutations', i.e., implement the materials in ways that are inconsistent or detrimental to the design principles such that they no longer retained their intended epistemic value. For example, an important design principle was for students to have some control of their interactions with the software. Consequently, a teacher who chose to always lead the use of the software from the whole-class display could jeopardise student autonomy in this respect.

As the project scaled to 113 schools (and over 200 teachers) it was evident that observation and interview was no longer a viable methodology. Therefore we chose teachers' self-reports to provide an insight into the teachers' perceptions of the epistemic value of the CM teaching materials and their associated classroom practices.

METHODOLOGICAL DESIGN

The CM unit on linear functions comprised 14 'Investigations', divided into sub-tasks, most of which required direct student interaction with the specially designed web-based software. In this paper, we focus on the first 7 investigations, which address the following mathematical ideas:

Representational:

> Equations, algebraic expressions, graphs and tables are forms of mathematical representation.

> Motion can be represented on a graph of distance versus time.
>
> On a position-time graph, multi-segment graphs can represent characters moving at different speeds.

Relational:

> Linear equations can be derived using differences of position and time in a table or by using the y-intercept and speed/gradient of a graph.
>
> Speed can be determined from different parts of graph and simulation.

Contextual

> For equations of the form $y = mx$, in motion contexts, m is the speed of a moving object.
>
> For equations of the form $y = mx + c$, in motion contexts, c is typically the starting point and m is the speed of a moving object.
>
> Graphs of motion show characters' start position, speed (relative) and places and times where characters meet.

Landmark activities

The notion of a 'landmark' activity originates in the concept of cognitive breakdown, or a 'situation of non-obviousness' (Winograd & Flores, 1986, p. 165), in which established routines are 'replaced by conflict, disagreement or doubt' (Hoyles & Noss, 2002). This resonates with the role of 'contingent moments' within the development of mathematics teachers' knowledge and practice (Turner & Rowland, 2011). In the context of the technology-enhanced mathematics classroom, it is anticipated in the design that the technology would disrupt routine practices in a transformative sense, and that the ensuing breakdowns would provide insights into developing practices.

We define landmark activities as those which indicate a rethinking of the mathematics or an extension of previously held ideas – the 'aha' moments that show surprise – and provide evidence of students' developing appreciation of the underlying concept. Our challenge was to develop a methodological approach that enabled us to research *at scale* teachers' perceptions and use of previously identified landmark activities. There is a blurring as to whether such activities are landmarks for the teacher or for their students. They are derived in fact from the perspective of the teachers although, as will be seen later, teachers' perceptions are invariably influenced and substantiated by their students' responses to tasks, supported by day-to-day formative assessment practices. We recognize the temporal nature of landmark activities in that the teachers' initial selections of landmark activities resulting from their first teaching of the CM unit might evolve and, we conjecture, stabilise over time. At this point, we start from the assumption that, if teachers show awareness of landmark activities that align with the design principles, and foreground [4] them for their students, they have 'got it' with respect to the design principles of the unit.

The process of identification of landmark activities went through several stages. First, the research team (the authors of this paper) made their own selection from the student workbook. Then they discussed their selections and agreed a list of eight activities that were highly aligned to the design principles of the CM curriculum unit under discussion. The tasks included some that were mediated by the software and some that were paper-and-pencil tasks. This process was repeated face-to-face with a focus group of three teachers, selected as they had provided thoughtful reflections to the online surveys, who provided their rationale for their choices. We would have preferred that all teachers gave a wholly open-text response in justification for each landmark question. However, as hundreds of teacher would be responding to the questionnaire over a timeline of years, the project resources did not extend to the resulting qualitative data analysis process. The data gathered from the focus group of teachers, supplemented by responses from the Cornerstone Maths professional development team informed the development of a set of answer prompts that were used within the wider online survey. These prompts are given in Table 1 alongside the teachers' survey responses.

As part of the final questionnaire to teachers, administered after they had completed their first teaching of the CM unit, we asked teachers to report their three most memorable landmark questions and justify their choices by selecting one or more of the answer prompts and/or by selecting 'Other' and providing their own reason.

Rationale for choice of landmark question	**% of total number of selections (n=601) [6]**
Most students were engaged and motivated to complete the activity.	22
It provoked rich mathematical discussion.	46
Most students were able to record their explanations.	20
It revealed important misconceptions.	35

Table 1: Summary of teachers' reasons for their identification of landmark questions

We conjecture that the teachers would be able to identify particular tasks in the CM materials that could be described as landmark with respect to students' mathematical learning and engagement. The teachers' justifications would be based on their: observations of their students engaging in the various CM activities (with and without the technology); questioning of students about their work (individually, in small groups and during whole-class teaching); and reviews of students' written responses in the workbooks.

FINDINGS AND DISCUSSION

Our initial analyses of 98 of the 111 [5] teachers' responses suggest that there are some trends emerging from the data that offer an insight into the teachers' perceptions and classroom practices with respect to landmark activities. Table 1 summarises the teachers' responses for all of their justifications of their chosen activities as landmark.

Almost half of the responses related to teachers' evaluation of their chosen landmark activities as being important for their role in: provoking rich mathematical discussion; revealing important misconceptions; and revealing progress in understanding. This suggests that the construct of a landmark activity is relatively well-defined.

The 'Other' responses, of which there were 31 comments that related to a particular landmark activity, could be classified as expanding on the particular: mathematical content (i.e., 'stationary= flat line'); mathematical process (i.e., 'it enabled the students to reflect on the connections between the graph, the table and the equation'); and highlighted the particular mathematical difficulties that the students had overcome (i.e., 'students found it difficult to fill in the table from the information given').

We highlight two contrasting findings that lead us to critique the validity of our approach with respect to our underlying aim to develop a methodology that might be appropriate for large-scale studies that seek to research implementation fidelity.

Firstly, we report on the frequency of teachers' alignments with one of our *a priori* landmark activities, supported by qualitative data provided by teachers for their choices. We focus on one landmark activity, as selected by 17 teachers (shown in Figure 1), taken from Investigation 3, which required students to interact with the software to respond to a series of questions that were designed to develop their understanding of the mathematical concepts.

This question was one of a series of sub-questions that required students to generate an appropriate graph by interacting with the software. The teachers' most common justifications for this choice of landmark question were: it provoked rich mathematical discussion (n=7); it revealed important misconceptions

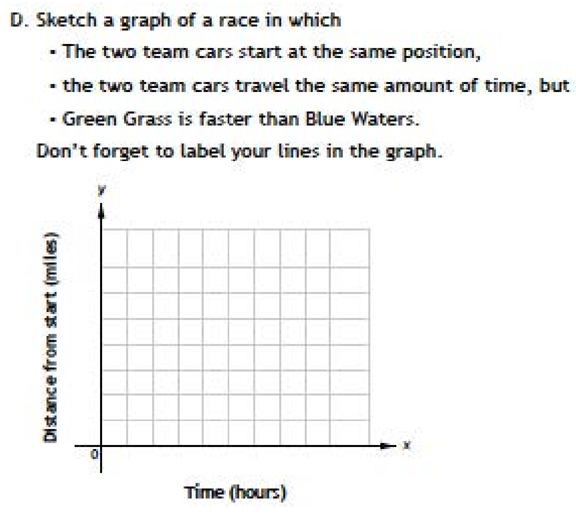

Figure 1: A landmark question from Investigation 3

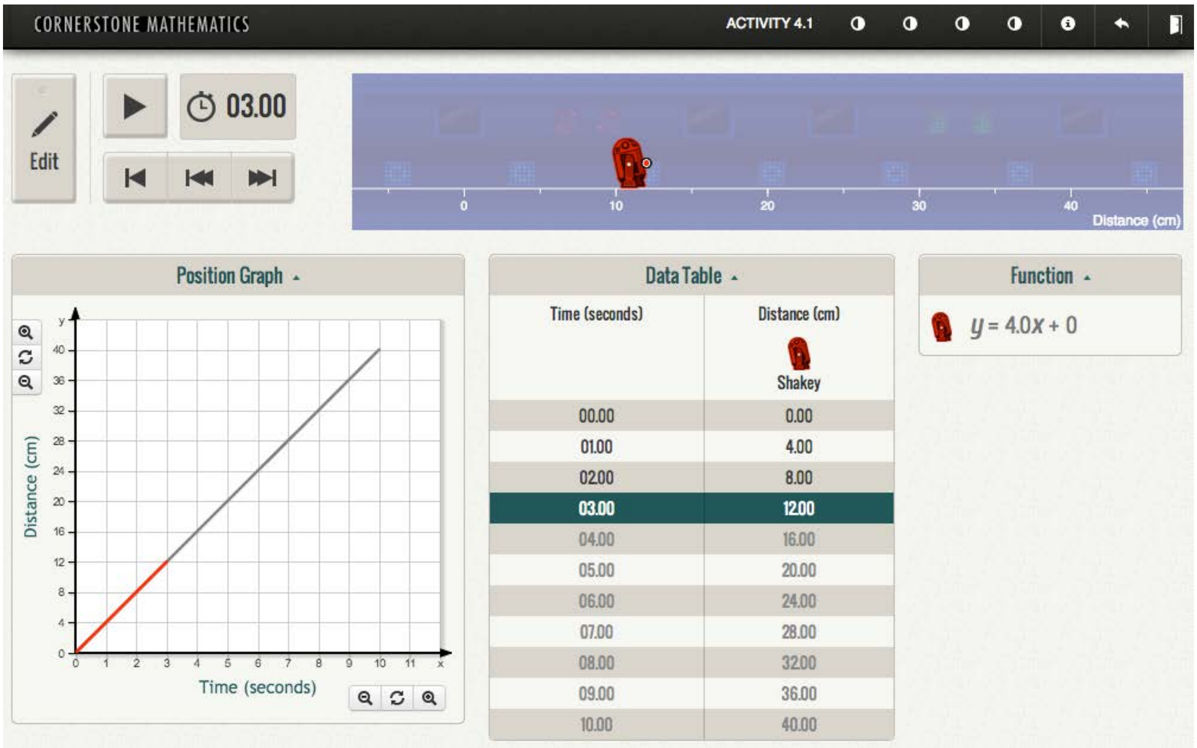

Figure 2: The accompanying software environment

(n=10); and it revealed progress in understanding (n=9). One teacher offered the additional comment,

> When answered together they showed immediately whether a pupil had understood the nature of the graphs, the different axes, the similarities and differences.

Another reported,

> I could easily see which students had a deep understanding of the concept specifically how the position and time were placed on the graph and the meaning of these axes.

By contrast, we were surprised by one landmark question that was identified by 28 teachers, as we had interpreted this activity as simply recording what students were seeing in the dynamic multiple representations and it did not, in itself, highlight any relational concepts. However, our teachers viewed it differently.

This question related to the software screen shown in Figure 2.

In the activity, the students were asked to edit the graph and play the resulting simulation in order to determine how time, position and speed were each represented in the graph, table and equation respectively. They were required to record a written response in their workbooks.

Fifteen of the teachers reported that this question had provoked rich mathematical discussion and fourteen stated that it had revealed important misconceptions on the part of their students.

One teacher justified her choice by saying,

> Because if students understand and can articulate the representation, then everything else follows.

CONCLUSION

Research on the successful scaling of educational innovations, with an emphasis on aspects that impact upon mathematics teacher development, is of primary importance given the funding constraints that many countries are experiencing (see Blömeke, Hoyles, & Rösken-Winter, 2015; Thompson & Wiliam, 2008). Furthermore, innovations that involve mathematical technologies are known to be slow to integrate and scale (Organisation for Economic Co-operation and Development, 2010).

The developing methodology reported in this paper offers a way to ascertain the fidelity of the resulting implementations with a large number of teachers. Although needing further elaboration, the construct of the landmark activity appears to resonate with teachers and their views captured in an online survey methodology with high response rates over time. Follow up interviews would certainly enrich the findings if this could be undertaken with some sample.

We will also explore how the observation of teachers' responses to landmark activities *during* the CM face-to-face professional development might shed further light on teachers' own knowledge development in our ongoing research.

The construct of landmark questions promises to be a productive way to probe teachers' interpretations of the CM unit of work and the mathematical outcomes for their students. Our ongoing work will seek to extend and validate the construct and its application within our studies.

ACKNOWLEDGEMENT

We gratefully acknowledge funding by the Li Ka Shing Foundation and Hutchinson Whampoa. The research has been an intensive collaboration between teams at the London Knowledge Lab, Institute of Education, University of London and at the Center for Technology in Learning, SRI International, Menlo Park, USA.

ENDNOTES

1. The student workbook is a consumable book that contains the task instructions. Students record their responses to interactions with the technology and other related questions in the workbook.

2. We conjecture that, whilst the efficacy of the Cornerstone Maths materials have been established by its pilot research projects, individual schools and teachers will seek to validate the materials to (re-)establish its efficacy within their institutional settings as an important component of the process of scaling.

3. We adopt the ideas of 'legal' and 'legitimate' mutations of an innovation to describe the extent to which classroom implementations adhere to its original design principles. This is not a bipolar scale.

4. As all teachers have access to the same set of teaching materials, they make individual decisions about which mathematical content and processes to emphasise (or foreground) in their teaching.

5. 111 teachers had completed their teaching of the CM curriculum unit by the end of September 2014.

6. Teachers could make multiple selections. This represents the total number of responses across the teachers' choices of three landmark questions.

Social creativity and meaning generation in a constructionist environment

The use of digital tools for "doing mathematics" has been studied both from the meaning making perspective and from the point of view of social interactions. In this study, we discuss how the use of digital tools that support collaboration, exchanging ideas and artifacts among students in a dense and intense way fosters the mechanism of meaning making in a group of 9th grade students that interact with a half-baked microworld. We reemploy the UDGS model to describe meaning making, but this time from a social aspect, using the notion of social and sociomathematical norms. In this context of analysis, we search for instances of social creativity, while investigating the connection between creativity and students' joint mathematical thinking.

Keywords: Digital tools, meaning generation, social creativity, theory integration, Logo-turtle geometry.

THEORETICAL FRAMEWORK

The use of digital tools for creative mathematical thinking has mostly been studied from two different perspectives, focusing respectively either on meaning generation or social interaction. Nonetheless, the availability of digital tools that support both math meaning generation and communication among students has recently highlighted the value of drawing from both perspectives. Following this strand, we attempt to investigate meaning generation itself as a social interaction process. In this paper, we study shared meaning making in a context where the focus is on the social interactions among students. The students worked in groups with a digital medium designed to support tinkering with a 3D Turtle Geometry tool using dynamic manipulation and Logo programming. At the same time, this medium allowed students' online collaboration and communication through shared workspaces.

For this study, we have chosen two theoretical tools. Firstly, the notion of social and sociomathematical norms (Yackel & Cobb, 1996; Kynigos & Theodosopoulou, 2001), which we found useful, as it helped us interpret the social interaction of the students during their communication, in terms of "microcultures" and taken-as-shared behaviors of each group. We found especially useful to consider meanings generated through interaction and the taken as shared as work progressed.

Secondly, the UDGS model (Hoyles, 1987), which although it was first used back in the mid eighties, we found it useful for our research, as it is a tool that describes students' meaning making process while they engage in mathematical exploratory activities with digital media. According to this model, there are four phases of the meaning making process: Using, Discriminating, Generalizing and Synthesizing. At first, students use mathematical and non-mathematical concepts, without much attention to their actual meaning. In the next phase they discriminate elements of mathematics in their constructions and the way they use them. Through the observation of patterns in relations or properties of the Logo commands they use, students generalize their ideas. Finally, they make synthesis of these generalized ideas with typical mathematics that these ideas are based on. In this framework a mathematical meaning is the way that a student understands, uses and thinks of a certain mathematical concept.

In this paper, we discuss a classroom study where different group configurations of students experimented with the "Twisted Rectangle" half-baked microworld (Kynigos, 2007). Half-baked microworlds are incomplete by design, challenging students to explore the reason for the buggy behaviour they show, engaging them in the process of mathematical meaning-making.

The Twisted Rectangle's buggy procedure creates an open skewed rectangle, intriguing students to try to fix and express their own mathematical ideas on how to reconstruct it (Figure 1). To conduct their experiments as they tried to find the bug and then work out the mathematics necessary to fix it, the students needed a medium able to support collaboration, joint planning, argumentation and meaning making.

The Metafora Platform (Dragon, Mavrikis, McLaren, Harrer, Kynigos, Wegerif, & Yang, 2013) was built to encourage students to "learn how to learn together". Group members have tools to make plans, to act as designers, and to publish, argue over and discuss their constructions. This act of designing and publishing (Kafai, 2006) is an externalization of an individual's tacit knowledge, or a group's knowledge, in the case of a joint construction of more than one individual. We were interested in studying how meanings were shared and argued over as an integral part of the students' activity. Artifacts were available at all times for inspection and reconstruction, starting from discriminations of the ideas embedded in the procedure by the designers (Kynigos, 2012). It has been a long time now that Papert and Harel (1991) suggested that when artifacts are published intensively and densely in a learning collective, meaning making process happens naturally. We wanted to study this process in detail, to capture the process of shared meaning making and the kinds of socio-mathematical norms generated, as groups of students jointly tried to fix a buggy artifact and use it to build their own.

In this context of social interaction and building on our previous work (Kynigos & Moustaki, 2013), we wanted to give particular focus on creativity in mathematical thinking. Since we talk about groups, we put emphasis on social creativity. We found Fischer's approach as a good tool for us to think with. Arias and Fischer (2000) emphasize that externalization supports social creativity as students move from vague mental conceptualizations of an idea to a more concrete representation of it. It also allows students to interact with, negotiate around and build upon an idea as the diversity of voices and minds increases. Fischer's group approaches creativity as a social process which has four elements: (1) originality: people or, in this case, students have novel ideas or they are capable of applying prior knowledge in new contexts, (2) expression: students should be able to express and externalize these new ideas, (3) social evaluation: students with different perspectives should be able to evaluate these novel contributions, reflect upon them and improve them, and (4) social appreciation: refers to the credits and acknowledgment from the other participants of the group motivating further creative activities (Fischer, Scharff, & Ye, 2004). Fischer, Giaccardi, Eden, Sugimoto, & Ye (2005) have described the characteristics of situations that, in their approach, support this social aspect of creativity: they are *open-ended* and *complex* so that students will be led to unpredictable results and eventually to experiences of *breakdowns*. Breakdowns offer opportunities for reflection and learning, through the procedure of the back-talk of situations (Fischer et al., 2005). Another form of social creativity is *co-creation* which is a situated experience leading to emerging and sharing creative activities with no explicit goal and meanings in a socio-technical environment through synchronization and improvisation as students share emotions, experiences and representations (ibid).

Although there seems to be a connection between aspects of social creativity and the meaning making process when students work in groups, we found research on these two approaches to be rather fragmented with respect to emphasis on one or the other. In our study we tried to see if these separate views can be usefully integrated in a situation where co-constructing students work in groups that communicate with each other exchanging ideas and different versions of the original figure.

TECHNOLOGY

The Metafora platform brings together students from various backgrounds to solve problems of fixing models which we faulty by pedagogical design (Kynigos, 2012). It hosts three types of tools available to the students at all times: a 3D Turtle Geometry environment, an argumentation tool and a shared workspace for students to make shared plans of their actions as a

Figure 1: The half – baked microworld "Twisted Rectangle" in 3D Math

group. The 3D Math tool (Figure 1) affords Logo-based Turtle Geometry with a feature for dynamic manipulation of variable procedures once executed with a set of values (Kynigos & Psycharis, 2003).

THE STUDY

Research design and methodology

In the study we used the methodological tools of "design research" (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003), which is an empirical study of human activity in real settings. In the implementation of the research, students and teachers were engaged, for several sessions, in an activity with the use of digital tools. This research framework is suitable in the classroom, where the learning ecology is described by means of collaboration and effectiveness in addressing tasks that challenge students to take initiative in specific situations (Collins, Joseph, & Bielaczyz, 2004).

Ten 9th grade students, three mathematics teachers of a public Experimental School in Athens and four researchers participated in the research. The implementation took place in the school pc lab, after-class, in the frame of the school Math Club activities, for twelve sessions of two teaching hours each (about two and a half months). Most of the students were not novice users of 2D Turtleworlds. In the time of the study, students had been taught trigonometry, but not stereometry. They were separated in two groups, and each group was divided in two subgroups. The subgroups of the same group were communicating through Metafora communication tools.

Task analysis

The bug in the procedure given to the students was the absence of a relation between a turn and a length of one of the rectangle sides. This resulted in the procedure producing an "open" figure and the students were faced with the challenge of fixing the bug so that it 'closed' no matter what the variable values were. The challenge required students to find simple sin and cos relations between angles and sides in two triangles lying respectively in two different planes joined only by one common side. Once figured out, the students would have to express these relations with functions allowing for the rectangle to be built with one variable for twist around a vertical axis (wmega), one for a horizontal axis (theta) and one for side length. To do that, the students would have to think about the concept of angle in 3D space.

A useful tool for us to recognize the meanings that students generated was the approach of Henderson and Taimina (2005) of students' conceptualization about angle: as a static geometrical figure, as a number that expresses a magnitude, or as a result of turning. These perspectives of an angle correspond to the static or dynamic definition of it (Mitchelmore & White, 1998). Our hypothesis is that ninth grade students mostly conceptualize angle as a static geometrical figure, which corresponds to the static definitions of angle. In Turtle Geometry however, angles are dynamic turns, rather than static direction relations.

Data collection method

Data collection included conversations between teachers and students, or groups of students, their gestures during their discussions, their constructions on the screen or artifacts that they made by hand. For these reasons we used voice recorders and a camera. A screen-capture software (HyperCam2) was used to record students' interactions with the Metafora tools. We also collected students' manuscripts and drawings. The data corpus was completed by the researchers' field notes.

RESULTS

Episode 1: Elements of social creativity in the phase of discrimination used in the process of generalization

The students of the subgroup 1 used dynamically the variation tool in order to find out which variable of the code corresponded to which spatial characteristic of the "Twisted Rectangle". Founding it difficult to come to a conclusion, they had the idea of reconstructing the figure. They decided to use drinking straws, although there were no straws available till then. The sequence of commands "forward(:length) right(90+:theta/2) up(:wmega) forward(:width)" made the turtle go forward for a distance equal to the variable "length", turn right "90+theta/2" degrees, then pitch up "wmega" degrees and go forward for a distance equal to the "width" variable. Turning right "90+theta/2" degrees seems to be complicated, but "theta" was a structural feature of the figure, related with its buggy behavior. Discriminating the role of "theta" was necessary, so that the students could focus on what was missing to fix the bug. Following this sequence of commands, the turtle drew an angle of the figure. Comparing the two representations of this angle, the one on 3D Math

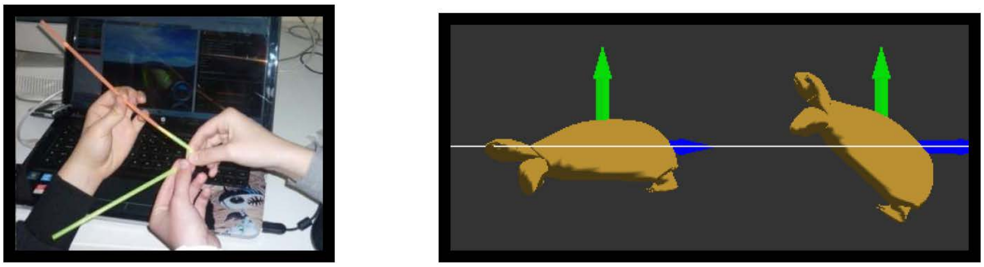

Figure 2: (a) the construction made of drinking straws, (b) the result of command up( )

and the other on the construction of straws, students realized that they are not the same.

Student 1: After fd(:length) it turns right.
Teacher: How much it turns?
Student 1: 90 + theta/2.
Student 2: And after that?
Student 1: up(:wmega). So it goes like this, it has gone up and then goes fd(:width), nice!
Student 2: The figure shouldn't have been like that. Let's do it again...

In this dialogue, the students use interchangeably three representations of the shape: the figure inside 3D Math, the logo code and their construction (Papert & Harel, 1991). Trying to represent the geometrical result of a right turn of "90+theta/2" degrees, they constructed an obtuse angle (Figure 3). This construction of the artifact seemed to be a result of their conceptualization of the angle as a static geometrical figure (Henderson & Taimina, 2005; Mitchelmore & White, 1998). According to the UDGS model, this is the phase of "using", as the students used the mathematical concept of angle without having a complete image of it (Hoyles, 1987).

Furthermore, there seems to be a breakdown in their effort. Thinking that their construction of straws was not totally correct, the students decided to explain the logo code step by step.

Student 1: I have second thoughts about this command...
Teacher: Why?
Student 1: If it turns right 90 plus something, then it goes here (she shows 90-theta/2). But it is not right; the figure ends up being wrong.
Student 2: Thanks God that I do not trust the logo code! (Laughing)
Student 1: Just a moment, give me the straws and the eraser. Ah, it goes here.
Student 2: 90+theta/2 to the right.

In the dialogue above, Students 1 and 2 seemed to evaluate their initial construction and improve it, using an eraser (pointing somewhere) as a representation for the turtle. This modification was revealing of the students' thinking. It seemed that in the first model (without the eraser), the straws were not a signifier for the trace of the turtle. They used the straws as a semantic simply for the sides of the angle. Their idea to use an eraser, in order to add a signifier of the turtle to the model, led to an "improvement" of the use of the straws. The straws instantly became not just the signifier of angle edges, but of the turtle's trace, as well. This "improvement" came up as a more concrete representation of an angle, than their initial conceptualization (the angle as a static geometrical object). The extended model (straws and eraser) was the result of "expressing a new idea" (use an eraser as a turtle), after they interacted with the logo code and the figures. The students reflected upon their model and evaluated it due to the distrust to the code.

The novelty of the students' idea to use the straws, the construction of their model, and the reflection upon it, which led to the evaluation and improvement of the model, according to Fischer's approach, can be interpreted as three of the four elements of social creativity; originality, expression and social evaluation.

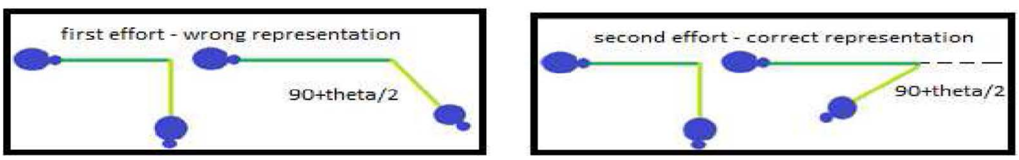

Figure 3: The two representations of the result of the logo command rt(:90+theta/2)

Using their improved model as an instrument (Artigue, 2002), the students started to generate new meanings for the concept of angle, which corresponded to the dynamic definition of it as a turn (Mitchelmore & White, 1998) (Figure 3). In this way, they discriminated the element of turn under their construction and the way they improved it (Hoyles, 1987). Later, as they tried to construct the rest of the figure using straws, they found that the logo commands were following the same pattern.

Student 1: You see? It is fd(:length) lt(90+(:theta)/2) dp(:wmega) fd(:width) instead of fd(:length) rt(90+:theta/2) up(:wmega) fd(:width). Left instead of right and down instead of up.

Student 2: This part of the figure is an angle like the other we have already done.

The students appeared to transfuse a property of the logo code to the figure. They made an abstraction, using a certain pattern of logo commands as a representation of the angle. This observation of patterns of the logo commands is a main characteristic of the "generalization" phase in the UDGS model. When they discovered the same pattern of logo commands elsewhere in the logo code, they recognized it as the symbolic representation of a similar angle, and searched for this angle on the eraser-straw model. In this way, they generated an abstraction, generalizing the concept of an angle and using it. We also suggest that this joint mathematical thinking can be explained through the lens of sociomathematical norms. To be more specific, the argument that a pattern of logo commands defines a certain geometrical figure had been a norm of an accepted mathematical explanation within the group of students.

Episode 2: Creative ideas for synthesizing concepts across context

At the end of the previous session the group managed to address the challenge (Figure 4a). Subgroup 1 and subgroup 2 had different perspectives of the solution (geometrical and algebraic), but they reached to a common solution. The students, reconstructing the code, created a formed and closed "Twisted Rectangle". In this session, the subgroups using the Twisted Rectangle as a building block created their own constructions with 3D Math. Subgroup 1 had constructed a figure that reminded them a logo of a chain store, while subgroup 2 had constructed a "flower". They used the communication tool in order to exchange and combine logo codes and ideas:

Subgroup 2: You could test the code "flower" that we have already tested. We'd like to tell us what you think about it and what you have done... in order to make a combination of our codes!!!

Subgroup 1: We created the code "stem" and combined both codes so we created a new code called "flower with a stem"!

Subgroup 2: Ok. We wanted to make a bigger flower, so we added more variables... We should combine this code now with yours again...

Subgroup 1: Ok! We sent you the new combined code: "The flower with a stem"!

Then, they used the logo of the chain store as a "vase" to put the flower in (Figure 4b).

According to the UDGS model, using the generalized "Twisted Rectangle" as a building block is an instance of meaning making. Observing the students' interactions we notice a dense publishing of their own constructions and an intense exchanging, reflection, combination and improvement of their logo codes (which represent their ideas). Based on the approach

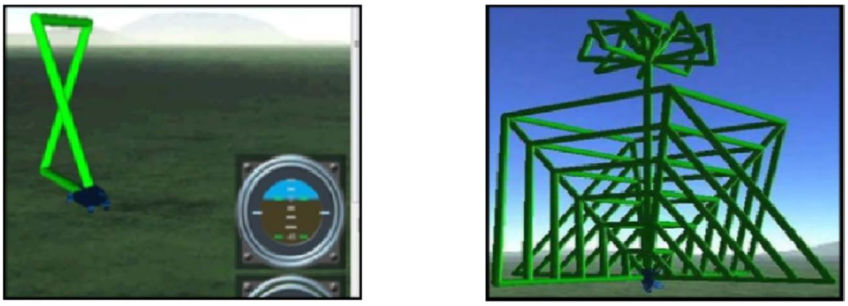

Figure 4: Students' construction: (a) The twisted rectangle, (b) The flower in a vase

of social norms we suggest that this taken-as-shared behaviour was a basis for their communication, which indicated the group "microcultures" (Yackel & Cobb, 1996). This kind of microcultures was characterized by externalization of original ideas and social evaluation of them (through reflection and improvement). According to Fischer and colleague's (2004) approach these are elements of social creativity. Moreover, during the construction of the artifact we noticed the development of taken-as-shared understanding of what was an "appropriate" logo code in order to create a common construction; the two subgroups used variables instead of numbers in their codes.

From our point of view, this shared behaviour of "using variables" is related to the embodiment of the power of generalization that occurs during the meaning making process and indicates a sociomathematical norm. We suggest that this common behaviour was crucial for addressing a task with no explicit goal, like this one. According to Fischer and colleague's (2005) approach and taking under consideration that students used a digital tool which supports communication and sharing of ideas, this situation can be characterized as co-creation which is a form of social creativity.

DISCUSSION

The study discusses two episodes where meaning generation was evident in a context of social creativity in mathematical thinking. In the first episode students of subgroup 1 realized by tinkering with the model of straws that it was not an accurate representation of the Twisted Rectangle because it was static and they improved it using an eraser. Taking a close look at the students' activity, we suggest that they were trying to rebuild their model to be the closer to what the Logo code represented, which was a construction of the Twisted Rectangle, rather than a static result. This novel idea came up early, during the phase of discrimination (of UDGS model) in the meaning generation process. It seems that this idea was shared by the students and used in their attempts to make sense of angle in space which were perceived as joint. The eraser semantic initiated a developing of a socio-mathematical norm about how to think of dynamic angle in space which was then taken as shared in subsequent generalizations of angle and trigonometric relations to twisted rectangle sides.

In the second episode, the students of each subgroup used their shared resolved procedure of a generalized twisted rectangle as a building block to build their own constructions. The two subgroups exchanged their constructions through the Metafora argumentation tool in a dense process focused on negotiating meanings to explain and exchange developing complex models. The ideas of what to build and how it behaves were shared between the two groups which were operating as a new group to show the class what they had done. They were thus conceived and used in a social setting from the beginning and the language developing in the groups seemed to create an atmosphere of social creativity and sharing of these ideas. We take these shared practices and behavior as situated in interaction with the medium of this particular collaboration. From this point of view, we can argue that the Metafora Platform afforded and fostered the emergence of social creativity in the group activities.

In both episodes the learning process seemed to be fostered by social practices, such as the making of shared meaning, common argumentation and beliefs of what is accepted as a solution. Although we were looking at socially emerging meanings, we found the use of UDGS shows helpful to describe meaning generations but this time to try to understand if this meaning making process can be described with these tools as a collective process in emergence of social creativity. More precisely, we found elements of social creativity emerging within the phases of the UDGS model. This study made us reflect that it may be worth readdressing the problem of meaning making in new kinds of collectives now that we have digital media that support communication, collaboration and joint mathematical thinking.

Instrumental genesis concerning scales and scaling in a dynamic mathematics software environment

Maria Fahlgren

Karlstad University, Department of Mathematics and Computer Science, Karlstad, Sweden, maria.fahlgren@kau.se

It is recognized that the process in which an artefact becomes an instrument for a user, denoted as instrumental genesis, is a complex process. The aim of this paper is to identify elements of the process of instrumental genesis when students are dealing with scales and scaling issues in a dynamic mathematics software environment. This study involves four upper secondary school teachers and their classes. By observing the students' instrumented techniques while working with tasks designed with a hypothetical instrumental genesis in mind, some key elements are identified.

Keywords: Instrumental genesis, scaling of axes, dynamic software environment.

INTRODUCTION

Several decades ago, researchers recognized the affordances provided by graphical technologies, in particularly in the field of functions and graphs (e.g., Goldenberg, 1988; Leinhardt, Zaslavsky, & Stein, 1990). For instance, in comparison to the corresponding work with paper and pencil, they emphasized the ease, and thereby the speed of changing the scales of the axes to obtain several different views of a graph. However, some difficulties have also been identified relating to the issue of scales and scaling of axes (Hennessy, 1999; Mitchelmore & Cavanagh, 2000; Yerushalmy, 1991).

The availability of different kinds of technology in mathematics classrooms is increasing and more and more students are provided with a computer of their own (Valiente, 2010), which entails new possibilities for the integration of technology in mathematics education. However, there is a need for students to learn how to use the technology appropriately so that it becomes an instrument for them. Several researchers use the notion of *instrumental genesis* to describe this process by which an artefact [1] becomes an instrument for a user (e.g., Artigue, 2002; Drijvers & Gravemeijer, 2005; Trouche, 2004). However, there is agreement that the complexity of this process has been underestimated and may have contributed to the recognized difficulty of integrating technology into mathematics teaching and learning (Artigue, 2002).

To address the challenge of integrating technology into the mathematics classroom, Trouche (2005) introduces the notion of *instrumental orchestration*, which also takes account of the social dimension of the instrumental genesis within a classroom. Although many researchers associate instrumental orchestration primarily with the organisation of classroom interaction (e.g., Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010), the original notion also involves the customization of an artefact in order to create a particular task environment (Ruthven, 2014). This paper concerns the customization of a dynamic mathematics software environment, especially the tools associated with scales and scaling. The tasks were designed with a particular instrumental genesis in mind. The aim of this paper is to pinpoint some elements affecting the process of instrumental genesis in relation to scale and scaling issues within a dynamic mathematics software environment, in this case *GeoGebra*.

INSTRUMENTAL APPROACH

One important aspect of this approach is the process of *instrumental genesis* (Verillon & Rabardel, 1995). Through this process an artefact becomes an instrument for a user. An artefact is an object, material or abstract, available to the user and aimed at performing a certain type of task. For an artefact to become an instrument for a user, there need to exist a meaningful relationship between them (Drijvers & Trouche, 2008). In this way, "...the instrument consists of both the artefact and the accompanying mental schemes..." (p. 367), developed by the user.

It is recognized that the process of instrumental genesis has two directions, one towards the artefact (*instrumentalisation*) and one towards the user (*instrumentation*) (Trouche, 2004). The user shapes the artefact by his/her knowledge and former method of working while the artefact shapes the subject by its constraints and potentialities. However, the fact that the process of instrumental genesis is a rather complex and thereby a time-consuming process has been underestimated (Artigue, 2002). One reason for this, Artigue argues, is the predominant role as a pedagogical tool given to technology.

> Suggesting that instrumentation may be a complex and costly process does not fit visions that consider technology mainly as an easy tool for introducing students to mathematical contents and norms defined independently from it. (2002, p. 253)

Regarding what could be considered as an artefact depends on the situation under consideration. For instance, a symbolic calculator could be considered as a collection of artefacts (Trouche, 2004). Accordingly, this provides students with the possibility to develop several types of instrument while working with this kind of technology. Besides the artefacts, the kinds of instrument being developed depend on the students and the accompanying tasks (Maschietto & Soury-Lavergne, 2013). Hence, it is important for a task designer to be aware of, among other things, the potentialities and constraints of an artefact (Artigue, 2002; Trouche, 2004).

Concerning the mental schemes students develop through the instrumental genesis process, researchers (e.g., Drijvers & Gravemeijer, 2005; Trouche, 2004) distinguish between two categories, *usage schemes* and *instrumented action schemes*. The usage schemes are basic and relate closely to the artefact while instrumented action schemes focus on actions upon objects such as graphs or formulas. In this way "Instrumented action schemes are coherent and meaningful mental schemes, and they are built up from elementary usage schemes by means of instrumental genesis." (Drijvers & Gravemeijer, 2005, p. 167). However, it is not always obvious how to distinguish between these kinds of scheme; it might be a matter of level of capability of the user (Drijvers & Gravemeijer, 2005).

Drijvers and Gravemeijer (2005) argue that instrumented action schemes involve both technical and conceptual aspects. Even if it is the development of conceptual knowledge that is the most interesting, it is the technical activities that are visible and thus the observable part which can be the object of investigation. The technical activities that are developed through instrumental genesis are denoted as *instrumented techniques* (Artigue, 2002) or just *technique* (Lagrange, 1999). In this way, it is the technique that is the "...gateway to the analysis of instrumental genesis." (Drijvers & Gravemeijer, 2005, p. 169).

SCALES AND SCALING WITH TECHNOLOGY

Several decades ago, researchers were already discussing the influence that new technology would have in the field of functions and graphs (e.g. Leinhardt et al., 1990). This section introduces some issues relating to scales and scaling of axes.

In traditional paper-and-pencil work, for example, textbook tasks, graphs often are presented as static diagrams with the coordinate axes scaled in an appropriate way (Zaslavsky, Sela, & Leron, 2002). When working with a graphical technology, on the other hand, the scaling of axes is often left for students, which has proved to cause them some difficulties (Hennessy, 1999; Mitchelmore & Cavanagh, 2000). Further, Leinhardt and colleagues (1990) assert that students' ability to deal with scaling of axes is often taken for granted and argue that "...the construction of axes requires a rather sophisticated set of knowledge and skills." (p. 43). As an example of elements of instrumental genesis observed in a CAS environment, Artigue (2002) discusses "framing schemes":

> When students use function graphs in a computer environment (or a graphic calculator), they are faced with the fact that a function graph is "window-dependent" and they have to develop specific "framing schemes" in order to cope efficiently with this phenomenon. (p. 250)

Mitchelmore and Cavanagh (2000) argue that one reason for students' limited understanding of scaling might be their lack of experience in dealing with graphs where the axes are unequally scaled. In line with this, Goldenberg (1988) discusses students' preference for "symmetric scaling", i.e., *x*- and *y*-axis are equally scaled. He refers to an example where students who had received an appropriate view of a graph, still changed the scales to obtain symmetric scaling. In this way, the students received a visual appearance obscuring important features of the graph. To receive a better visual appearance, they changed the scales of the axes by the same factor, i.e. they used a zoom operation. Goldenberg (1988) argues that one reason for this might be that students' intuition about scale changes is closely connected to real-world experiences: "... our almost automatic approach is to change both scales by the same factor..." (p. 36). However, since usually different units on the axes are required to see the graph in an appropriate way, Goldenberg (1988) stresses the importance for students to deal with unequally scaled axes.

Mitchelmore and Cavanagh (2000) found that students in their study showed limited understanding of the zoom operation. The students used the zoom operation as a magnifying glass but "...were unable to link the operation of zooming with any change in the scale of the graphs displayed in subsequent viewing windows." (Cavanagh & Mitchelmore, 2003, p. 14). As an example, they refer to a case were students who zoomed in on the vertex of a parabola were surprised to see a linear shape of the graph.

Concerning how unequal changes of the scales of the axes (i.e. not zooming) impact on the visual appearance of the graph, Yerushalmy (1991) emphasizes the importance of understanding the difference between the properties of a function and its picture in a graphical view. In her study, students showed difficulties when interpreting the same function graphed in two different scale systems, since the visual appearance differed (Yerushalmy, 1991).

Godwin and Sutherland suggest graphing software as a mean to provide students with experiences of this kind since it provides "The ability to change the scale easily and hence the 'frame of view' of a function..." (p. 134). Further, Hennessy (1999) emphasizes the importance for students not only to realize what will change but also what remains constant as the scales change.

METHOD

This study is embedded within a form of design research project involving two researchers and four upper secondary school teachers with one class each. The focus of the project was on a sequence of three lessons, taught over the course of a school year, in which some use was made of *GeoGebra* to tackle tasks concerning functions and graphs. The researchers and teachers had meetings before and after each lesson. In total, three worksheets, one for each computer lesson, were designed. Although the responsibility for the design was the researchers', the teachers provided valuable information regarding the participating students' capabilities and their current practices.

Each worksheet consists of a sequence of related tasks, denoted as a *task sequence, TS*. The first and the third worksheets concern exponential functions, while the second worksheet is mainly about linear relationships. This paper focuses on issues concerning scale and scaling which are mainly addressed in the task sequences for the first and second lessons. A more comprehensive report of the project will be provided in another paper by the author.

The overarching aim of the task sequences is to enhance both students' conceptual knowledge about functions and graphs and the scope for the dynamic mathematics software to become an instrument for the students (Verillon & Rabardel, 1995). Therefore, on the worksheets the task sequences were intertwined with computer instructions. As noted earlier, the way in which this was done constitutes an instrumental orchestration of the task environment.

The participating students were tenth grade students with no previous experience of working with either dynamic software or graphical calculators. Altogether, 85 students participated in the study. The students were to work in pairs with *one* computer per pair. The purpose of this is that the computer screen should provide a shared object for discussions between students.

The empirical data reported in this paper were mainly collected during the two relevant lessons with the four classes. Each lesson lasted about 60 minutes. In each class one pair of students was video recorded and all teacher-student interactions during the lessons were audio recorded using a microphone attached to the teacher. When necessary in the analysis process, copies of the written responses from the students were used.

In the analysis process, the video recordings were the primary source since these data made it possible to observe students' instrumented techniques which are the observable part of the instrumented action schemes (Drijvers & Gravemeijer, 2005). The audio recordings provided further insight into the frequency of some student responses.

The scope of this paper is restricted to only dealing with aspects concerning scale and scaling in relation to the process of instrumental genesis. Thereby the tools addressed in this paper are those associated with the coordinate system, and particularly the tools needed to obtain appropriate visual graphical appearances.

RESULTS

This section introduces some prototypical observations regarding how students deal with scales and scaling of axes. The first task in the first task sequence (TS 1) was intended to be a routine paper-and-pencil task which introduces the context of TS 1:

> The height of a sunflower is 50 cm when it is measured for the first time (June 1). After that the sunflower grows so that it becomes 30 % higher each week. Calculate the height of the sunflower one week after the first measurement.

The first task is followed by computer instructions and the students are expected to use the software to enter the points known so far. Regarding the first point (0,50), we decided to provide students with both conceptual and technical guidance as follows:

> When the first measurement is performed, $x = 0$ (since 0 weeks have passed) and $y = 50$. The corresponding point in a coordinate system is (0,50).
>
> Insert this point by entering *(0,50)* into the "*Input Bar*": Input: **(0,50)**
>
> *NOTE!* To be able to see the point you must adjust the scale on the *y*-axis. This can be done by "dragging" the *y*-axis. (first mark ✥)

Since we anticipated that several students might be confused when they cannot see the point in the Graphics View [2], we decided to add the note above to draw attention to the scaling of the *y*-axis. However, this note proved to be insufficient since utterances like "Should we not get a point there?" appeared several times both in the audio and video recordings. The video recordings indicate that the reason for this might be students' eagerness to start using the computer and not to spend time reading the instructions. Consequently, the teachers often had to draw students' attention to the *y*-axis making them aware of its scale. Further, since the students tended to use the zoom operation when changing the scales, the teachers frequently had to demonstrate the possibility to only adjust the *y*-axis.

Next, the students were expected to enter the point corresponding to their calculation in Task 1, i.e. the point (1,65). To make students aware of the possibility of adjusting the *x*-axis, i.e. adjusting one axis at time, to obtain an appropriate graphical view, we added the following note:

> If appropriate, adjust the scale on the *x*-axis!

However, this note seemed to be ignored by most of the students. Maybe the note came too early, and by this stage the students could not see the point of it. The empirical data reveal that even students who had adopted the technique of adjusting one axis at a time tend to focus on the *y*-axis and not use this possibility when it comes to the *x*-axis. Both the audio and video recordings reveal that the teachers frequently had to draw students' attention to the grading of the *x*-axis to get a more appropriate visible view of the coordinate system.

The second task sequence, TS 2, introduces a context problem where the students are encouraged to formulate a linear function formula to insert into *GeoGebra*:

> To get money for a class trip, the Class 9b at Sugar School decided to rent a table and sell candy at the market place. The rent for a table is 100 SEK. They purchase candy for 40 SEK per kg. Determine a formula that describes how the total cost depends on the weight in kg of the candy purchased.

As in TS 1, the *y*-axis has to be adjusted to see the object, in this case a graph, in the coordinate system. Therefore, we decided to give the following note:

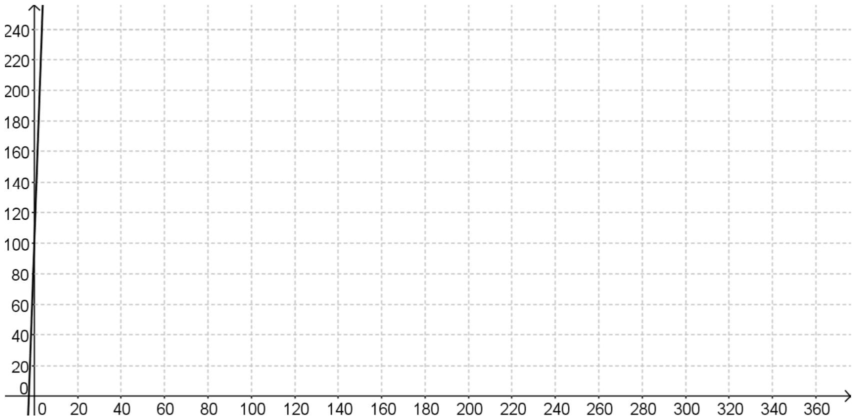

Figure 1: One example of a Graphics View obtained by students

> *NOTE!* To be able to see the graph (the line) there might be a need to adjust the axes.

As in TS 1, both audio and video recording show that several students could not see the object due to the scaling of the y-axis. In their attempts to find out the reason why they cannot see the graph, one pair of students discussed whether they have to type a sign (*) for multiplication between 40 and x. Thus, they did not reflect on the scales. Reminded by the teacher of the scaling of the y-axis, they used the zoom operation, and obtained a graphical view like the one in Figure 1.

The empirical data reveal that graphical views similar to the one in Figure 1 were frequently obtained by students. Actually, all the video recorded pairs obtained a similar view. This, in turn, caused difficulties when they were encouraged to attach a point at the graph and (a) describe how they could use the point to check their calculation in the preceding task, in this case moving the point so that its x-coordinate becomes 10 and read off the corresponding y-value and (b) decide the value of x for a specific value of y. With a graphical view like the one in Figure 1 it turned out to be impossible to use the Graphics View to read off the corresponding value of y when of $x = 10$ without changing the scale of the x-axis. One of the video recorded pairs of students expressed their confusion:

Student 1: It looks like we have done wrong.
Student 2: mm
Student 1: Go back!
Student 2: We check a little more...lock from the start. There is nothing wrong with the equation.

Having convinced themselves that the formula is correct and that they understand what the point presents, they felt that they got stuck and asked the teacher for help. Notably, they did not reflect on the scales of the axes. Reminded of the possibility of changing the x-axis, these students solved the task.

The audio recordings also revealed this kind of confusion on several occasions. Consequently, the teachers often had to remind and instruct the students how to scale the x-axis to receive integer marks and to obtain a better visual appearance of the graph.

However, it was observed how one of the video recorded pairs tackled the problem caused by inappropriate scaling of the x-axes (see Figure 1), by only observing the Algebraic View while solving the task. They moved the point along the graph until the x-coordinate of the point shown in the algebraic view became 10.

Although the participating students when entering the first two task sequences seemed to lack experience of adjusting one axis at a time, to obtain an accessible graphical view, the video recordings indicate an enhanced ability among the students to perform this when tackling the third task sequence.

CONCLUSION AND DISCUSSION

The aim of this paper was to identify elements affecting the process of instrumental genesis concerning appropriate scaling of the coordinate system in a dynamic mathematics software environment. During their work with the tasks, the participating students encountered situations which required rescaling of the axes; to see an object in the coordinate system and/or to obtain an appropriate visible appearance of the object(s). The following closely related elements of instrumented action schemes were recognized:

1) Knowing how to change the scale of the axes, both by using the zoom operation and by adjusting one axis at a time.

2) Realizing when it is necessary to adjust the y-axis to see an object, for example, points or a graph.

3) Realizing when it is appropriate to change the scale of the x-axis to obtain a better visible picture of the objects.

It is possible to distinguish between the technical and conceptual character of the elements (Drijvers & Gravemeijer, 2005). While the first item primarily requires technical capabilities the other two items primarily demand conceptual knowledge. In this study, the mathematical knowledge required to be able to rescale the axes in an appropriate way is about the range and domain of functions representing real world situations. Concerning the instrumented techniques of changing scales of the axes, the result indicates that students are disposed to employ the technique of zoom operation, which aligns with the findings already reported by Goldenberg (1988) more than two decades ago. This sometimes gave rise to obstacles when the visual appearance of an object, for example, a graph, made it hard or even impossible to solve problems graphically.

One reason for students' preference for using the zoom operation technique might be that students already are familiar with this technique from the use of other screen based technologies, for example, smart phones. In comparison, they did not adopt the technique of adjusting one axis at a time so easily. The reason for this might be that students lack of prior experiences of this kind of technique.

Another reason might be the features of this kind of tool in the particular software under consideration, i.e., *GeoGebra*. While the zooming tool, and the associated zoom operation technique, is readily available, the technique of scaling one axis at a time is more demanding, probably because the associated usage schemes involve knowledge of tools with limited accessibility in *GeoGebra*.

A further observation made in this study is that students tend to neglect the written instructions on using the computer, at least when they do not see any immediate need for them. When, later on in the task sequence, they encountered problems due to their inattention to the instructions, they asked the teacher for help. The reason why students tend to disregard such instructions may be that they do not usually read instructions while using digital technology.

To summarize, the findings highlight various obstacles which arose in the course of instrumental genesis under the instrumental orchestration of *GeoGebra* use provided by the teaching sequence and task environment as originally designed. These findings suggested ways in which that orchestration might be redesigned in order to better support students' development of the desired instrumentation schemes. In particular, they highlight the potential importance of taking account of students' previous experiences both regarding the use of technology in mathematics and the use of every-day technology, e.g., smart phones. Furthermore, these findings emphasize how students draw on existing instrumentation schemes, developed in relation to what they perceive as similar tools, when they start to work with a new tool; instrumental orchestration needs to plan for such transitions, taking account both of the continuities and discontinuities between tools.

ENDNOTES

1. In this paper, the terms of 'tools' and 'artefacts' are used interchangeably.

2. We assume that students have obtained an equally scaled coordinate system showing y-values between 0 and 16 and x-values between 0 and 28.

Scaffolding in e-learning course for gifted children

Antonín Jančařík and Jarmila Novotná

Charles University in Prague, Faculty of Education, Prague, Czech Republic, antonin.jancarik@pedf.cuni.cz

The paper presents partial results of research focusing on teacher-pupil communication in e-learning courses. The authors of the paper study the form of possible teacher's help to a pupil using soft scaffolding methods. The text presents examples of the use of scaffolding in the form of specific instruction in courses for talented pupils run within the frame of the Talnet [1] project. Most of the coursework in this project has the form of off-line discussions.

Keywords: Scaffolding, off-line communication, e-learning, specific instructions.

INTRODUCTION

Information technology and modern technologies have considerable impact on all aspects of our lives, including education. The use of computers in mathematics and in mathematics classroom has been subject to a number of researches and research studies. The goal of the here presented paper is to point at one of the aspects that has not entered the spotlights in research yet, namely the social aspects of the use of modern technology and its impact on communication in mathematics education. Most attention is paid to the teacher-pupil communication and communication in small groups of pupils. The authors want to show the similarities and differences between communication on a computer network and face to face communication in the classroom. Most emphasis is put on what form of support the teacher can offer to their pupils in this communication that result in achieving the desired solution – scaffolding.

Communication offline when compared to face to face oral communication has some specific features. An important difference is the time delay in reactions to other participants' communications. The participants of the communication have the time to search for missing information in other sources (internet, printed documents etc.). No information is lost, as any information can be retraced (on the condition that it was not permanently deleted). This makes group communication easier as all its participants can access the preceding course of the discussion and then find it easier to react.

SCAFFOLDING

It is impossible to imagine *scaffolding* as one specific activity. In literature, we come across a number of similar definitions of scaffolding. For example, Boblett (2012) states that "*Scaffolding* as a metaphor in teaching and learning describes a system of temporary guidance offered to the learner by the teacher, jointly co-constructed, and then removed when the learner no longer needs it." In other words, the concept of scaffolding in education means strategies and methods that help pupils overcome barriers in learning, and techniques that allow pupils to master knowledge and skills. In a broader sense, scaffolding can be understood not as a single activity but as a process that offers clues and strategies to pupils until they are able to cope with the activity on their own (Tejkalová, 2010).

Scaffolding may come in many various forms. Brush and Saye (2002) distinguish between two types of scaffolding: Soft forms of scaffolding (or contingent scaffolding (Li, 2001)) are those activities that come out of situations and have not been planned in advance, they evolved while solving a problem. These activities are, for example, a discussion between teachers and pupils in which the teacher reacts to the pupils' needs and provides support in the extent required by the given situation (Simons & Klein, 2007). In contrast, in hard scaffolding, the teacher tries to foresee the possible problems and plans additional tasks and problems or clues for their pupils.

Tejkalová (2010) presents a detailed list of methods that can be used as scaffolding in a CLIL [2] classroom. Her list includes activation of existing knowledge, decomposition of a more complex task to a single, more easily viable subtasks, showing an example of the expected outcome, a teacher's "thinking out loud", offering hints, use of key words, reformulation, use of models, illustrations etc., use of internet resources, use of mnemonics, use of gestures and pantomime. Of course, the list is not and cannot be exhaustive but offers a better insight into what methods can be included under this umbrella term. It is obvious that some of these methods can be easily transferred to teacher-pupil communication in an e-learning environment (e.g., decomposition of a more complex task to single, more easily viable subtasks, or using of a motivating context). Other methods can be used in work in small groups (e.g., activation of existing knowledge by brainstorming to make a mind map of associations). However, Tejkalová's list also includes methods that cannot be transposed into the e-learning course environment, either because they are not related to mathematics or cannot be applied in an internet course.

Palinscar and Brown (1986) distinguish between four basic types of "scaffolding construction": predictions that are based on existent knowledge, posing questions that arouse interest in the text, summary in which pupils present the text in a somewhat condensed form, and final clarification in which attention is paid to the elements that obstruct comprehension.

Wood and Middleton (1975) differentiate between three categories of scaffolding that can be provided to pupils: general encouragement, specific instructions and direct demonstration.

The goal of the presented study was to analyse communication that took place within the course Talnet in 2010–2014 and to find those phenomena in communication that are characteristic for situations in which a teacher's intervention contributed to solution of the problem and to pupils' progress in the course. When analysing the conversations, elements from Grounded theory (Strauss & Corbin, 1990) were used; the different phenomena were labelled and grouped into broader categories. With respect to literature, it seemed most appropriate to use the classification of scaffolding presented by Wood and Middleton (1975). However, this classification was too rough in the area of specific instructions, which is why more subtle were introduced by the authors of this paper. This classification is still in the process of development, which is why only two subcategories will be presented – moving the limits and revealing the right answer.

OFF-LINE COMMUNICATION – THE COURSE TALNET

The following text demonstrates and develops possible uses of scaffolding in e-learning courses. The descriptions and analyses are based on classification of scaffolding categories of Wood and Middleton (1975). The illustrative examples are from e-learning courses for pupils with talent in mathematics that are run within the frame of the Talnet project and come out of teaching practice of one of the authors (Jancarik, 2013).

The Talnet project offers not only mathematics but also educational, inquiry and communication activities from other disciplines – physics, chemistry, biology, geography and technology. The activities are tailored to the needs of inquiring youth. One of the authors of this paper is involved in designing and implementing the course Mathematics within this project. The course Mathematics is run for a small number of participants (5–10 pupils). Secondary school pupils from the whole country enrol in the course voluntarily, based on their interest.

The course Mathematics introduces the pupils to combinatorial game theory and is structured in such a way to allow pupils discover and prove statements on their own. The goal of this course is not to introduce pupils to a comprehensive theory. Questions and tasks guide pupils to independent discovery. The course is divided into two parts. In the first part the pupils are introduced to different variants of the game NIM [3]; the aim of this activity is to guide the pupils to discovery of the winning strategy of this game (see Bouton, 1901). In the second part, the pupils are introduced to the game Hackenbush [4] and their goal is to assess different positions (see Conway, 1976).

Most of the coursework has the form of off-line discussions. The pupils enter these discussions at their leisure and according to their time possibilities. Thus sometimes the communication is very fast and sometimes there are long time intervals between the individual contributions. This depends on the current possibilities of the pupils and the lecturer. While analysing the conversations, the methods of scaffolding used by the lecturer were identified and then further studied. The following text offers illustrations of some of the methods suitable for e-learning courses. All of them are from the category of soft forms of scaffolding. Examples [5] from practice will be used to demonstrate the use of specific instructions. In analyses of the use of scaffolding in the form of specific instruction, hive categories have been identified and described. This text focuses only on two of these – Moving the limits and Revealing the right answer.

Specific instructions: Moving the limits

Moving the limits is one of the soft forms of scaffolding. The teacher reacts to the conditions that limit the pupil's thinking and tries to motivate the pupil to extend and generalize his/her thoughts. The goal of this form of scaffolding provided by the teacher is to turn the pupil's attention to those aspects of problems the pupil has not noticed or to guide them to relationships they have not realized. This form of scaffolding requires the teacher to carefully follow hints of deeper thoughts in the pupil's statements and to channel the pupil's attention to these rudiments of knowledge.

Let us again demonstrate this by an example from the course. It is a situation from the discussion of the one pile NIM game with extended conditions. The core of the discussion focuses on general characteristics of the winning and losing positions in this game (see Jančařík, 2007).

Example 1 – Moving the limits

Let us start this example by an extract from discussion between the lecturer and pupil A. The goal of this discussion was to clarify the task. It is presented here as introduction to the problem.

Lecturer (06/10/2010, 18:17): Hi, you've asked too many questions in your answer. I'll reply by a counter question. Is it possible that there would be neither winning, nor losing strategy in a game with no element of chance?

Pupil A (07/10/2010, 15:03): Yes, I think that the Tic-Tac-Toe [6], if played according to the official rules, is a perfect example – otherwise there wouldn't be championships in the game, would there?

Lecturer (07/10/2010, 15:22): Are there better moves in Tic-Tac-Toe? If so, how will the game turn out (I'm not requiring here a specific answer but the principle – I can explain this to you later), if you make these moves. Is it determined, or not?

Pupil A (07/10/2010, 16:03): Hmm... I'm a bit ashamed. Determined? I don't quite understand and I don't know the concept. Anyway, what rules are you asking about? Classical or official?

Lecturer (07/10/2010, 16:06): Determined – fixed, stated. Do they matter?

Pupil A (07/10/2010, 16:10): Yes, I think they matter – the official rules are meant to break the advantage of the player who starts. There's no doubt about this advantage.

The goal of the discussion in the following extract is to guide the pupil to the discovery that in games with no element of chance, the result is given if both players play well.

Lecturer (07/10/2010, 19:29): Let me repeat the question: Is it possible that in a game with no element of chance there would be neither winning, nor losing strategy?

Pupil A (07/10/2010, 16:33): Hm... well, simple logic tells me it's not possible (if there's neither winning, nor losing strategy, it's possible to win only by chance, so it can't be without an element of chance), but I can't say how this works in reality. And I think I'm not able to determine this as the number of various combinatorial games is enormous.

Pupil A is aware that it is logical that the result in such games is determined from the beginning; however, he refuses to apply this knowledge generally. As he says, "there are many games and have different rules". The pupil is trying to overcome the obstacle that is preventing him to generalize this knowledge.

Lecturer (07/10/2010, 20:02): Try to think about what you've written. Are you ready to trust logical arguments?

Pupil A accepted the argument, which is evident from his subsequent work in the course. Pupil B, who is solving the same problem, enters the discussion.

Pupil B (27/10/2010, 20:36): I think that if there's no strategy in a game, it's only a matter of chance, or maybe of the skill to take advantage of the opponent's mistake.

Lecturer (27/10/2010, 20:45): Hi, try to reverse the question. Ask when there can be (or must be) a strategy in a game. It's a bit abstract question but sometimes it really helps to start by solving things generally and then apply the general solution to a specific situation.

The teacher reverts the pupil's consideration and hands it back to the pupil in the form of a counter-question. Thus he opens space for new considerations. The teacher makes use of his experience from previous courses and tries to guide the pupil to the point that is the cognitive obstacle, i.e. the fact that in certain kinds of games there must be an optimal strategy, even if we do not know it. This is a high level of abstraction – a non-constructive proof. The course of the following discussion showed that the pupil managed to overcome this difficulty successfully.

Specific instructions: Revealing the right answer

This is again a soft form of scaffolding. Its basic principle is described in its name. Let us illustrate this by two examples.

Example 2 – Hinting at the correct answer, the game TIC TAC TOE

Pupil A (10/10/2010, 19:59): If both players play well, it must be a draw. But only if player two plays as he should. Already in his first move, if he makes the nought/cross incorrectly, then there is a winning strategy for player one.

Pupil A presents the right solution but does not provide any justification or support of this solution. Pupil B, who joins in the discussion later, does not agree and attaches a detailed counterexample.

Pupil B (10/10/2010, 21:08): Hello, I've played this game several times and it seems to me there's a sequence of moves in which the other player has no chance to win. But I may be wrong. Please, look at the attached file:

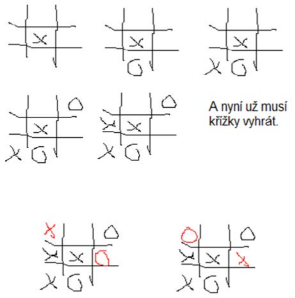

Figure 1: Students' solution to TIC-TAC-TOE game

Player One starts from the most advantageous central field.
Player Two can now make any move, none of them is much more advantageous in his situation. So, he chooses the bottom middle field.
Player Two can now make any move, none of them is much more advantageous in his situation. So, he chooses the bottom middle field.
Player One takes the corner point so that...
Player Two is now forced to prevent the next move which would make three crosses on the diagonal but...
Player One forms scissors, which Player Two cannot beat and so...
Player Two loses.
In my opinion both players play the best moves. However, if we play 'just for fun', Player Two is often the winner...

Lecturer (10/10/2010, 20:49): So, who will tear this argument to pieces?

The teacher does not provide the right solution here but points out that the presented solution is erroneous (which gives a clue to the right answer) and at the same time motivates other pupils to join in the solution.

Pupil B (11/10/2010, 15:09): Well, thinking about it I can see that Player Two is not playing ideally. In fact, his move is quite silly. He does not foresee more moves in advance. If he places his nought into a corner, the described trap disappears. In that case I'd even say that the game will lead to a draw. But I'd better think about it for a while, not jump to a wrong conclusion again.

The clue provided by the teacher was enough to make Filip reconsider his solution, find there a mistake and correct his procedure. Nothing more than a clue was needed.

The primary goal of providing a counterexample is not to draw attention to a pupil's mistake but to give him/her the chance to discover the mistake on his/her own. It is good to find such a counterexample that draws attention to the problematic passages in the pupil's solution. Guiding the pupil to discovery of the mistake accelerates the solving process and also facilitates the communication.

Example 3 – Hinting at the correct answer, Cat and Mouse Game (Tapson, 1977) [7]

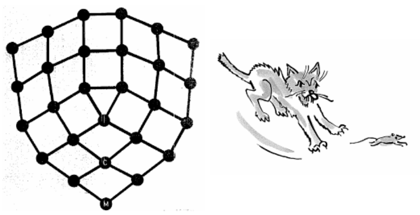

Figure 2: Cat and Mouse Game (taken from Jančařík, 2007)

Pupil A (6/10/2010, 21:27): So far I haven't got into studying situations that could happen if the mouse chose a different direction than the one I'm talking about, or if the same strategy would work if the mouse did not go one field back. So far I perceive as "chance" the fact that the mouse moves in a convenient direction.

Lecturer (6/10/.2010, 21:30): Fine, I'll leave all of you some time to think about the answer once more and to refine it.
Just a question, do you play chess?

Pupil A (06/10/2010, 21:34): To be honest I know the rules and moves of the figures but I'm by no means an outstanding player. I've won a few games with my relatives. But to be good at the game I'd need some training, which is not my case.

Lecturer (6/10/2010, 22:19): This has much to do with the position in chess which is referred to by the beautiful Czech word zugwang. But you need some skill in chess to know. May be there is a better chess player among us. And this hint could help him. :-)

The teacher provides a clue that can be used to solve the situation. This is leaving the move to the opponent and taking the advantage of an unfavourable move. For more information see http://en.wikipedia.org/wiki/Zugzwang.

Pupil B (07/10/2010, 15:00): I'm sorry but I had to google the term Zugwang (Zugzwang) up and now I've grown a bit smarter.: -P But still I can't see any satisfactory solution in the Cat and Mouse – they can be running round and round as mad and the mouse will never be cornered. But how to describe in mathematical terms that it can be caught?

In this case the pupil learnt a new concept but failed to apply it in the situations. An additional hint was needed for the correct solution. The use of hints in this case gave birth to the knowledge that results can be transferred from one game to another, which was very important later in the course.

Example 4 – Hinting at the correct answer, Cat and Mouse Game

Lecturer (14/10/2014 18:10): A very simple idea (I've stepped down a bit): Be the cat, forget about the mouse, go directly to the centre of the board, run around the triangle in the centre and then start chasing the mouse (which has been running somewhere so far), how will this end?

Student (28/12/2014 12:29): I was wondering about this comment and the comment "Has anybody noticed a triangle has three sides and rectangle four sides?" for a long time, so I tried to play in the way that I run around the triangle with the cat and then I got it – if I run around the triangle I'll get to the same place in three turns. There are rectangles everywhere else so that it takes four moves. So I get one turn ahead, which was mentioned by Dominik: "If a mouse is to lose from this position, it must be its turn (if it is the cat's turn, the mouse will simply move to a free field)." In contrast to the starting situation when it was the cat's turn, it will be the mouse which has to move one field and the cat will be able to get to this field in the next move.

The last example borders on specific instruction and direct demonstration. After a lengthy discussion in which the pupils had not been able to get closer to the solution the lecturer almost gave up and described the way that leads to victory. The only thing he did not do was tell the pupils it was the correct solution. It took two and a half months for the above quoted reaction of one of the pupils who then managed to combine all the hints from the discussion and discover the right solution and especially the reason why it worked.

Methods of direct demonstration were scarcely used as soft scaffolding in the course. One of the reasons is the specific nature of the course, whose goal is not the solution of particular problems but development of abilities to experiment and find solutions. Another reason is the pedagogical beliefs of the lecturer that only valuable is only knowledge that is discovered and justified by the pupil on their own.

DISCUSSION

Communication in digital environment resembles common communication in the classroom but at the same time is very different. It is not a face-to-face communication. Neither the teacher nor the pupils have the chance to use non-verbal means of communication – gestures, expressions or intonation. The "dialogue" is not continuous. There are many disruptions and time delays. It is often very concise or abbreviated. Writing of mathematics expressions may be difficult.

The listed aspects clearly show that off-line communication deserves special attention. What is very important is the effort to understand the individual utterances and the teacher's provision of effective support and help.

CONCLUDING REMARKS

The goal of the presented study was an analysis of the scaffolding tools in offline communication. As stated in the introduction, offline communication when compared to face to face communication is specific in that it affect the success of the used form of scaffolding. It became obvious that specific instruction may come in various forms; the paper presents only two types – moving the limits and revealing the right answer. The significant role they play in support leading to successful solution of problems in offline communication is illustrated on selected example situations from the course.

One of the tasks for future research is to study the patterns in off-line communication, to describe basic phenomena that are connected to this communication, and to identify its efficient methods. The examples above are not meant to illustrate the complete range of the different methods of scaffolding that can be used in offline communication. The goal of presenting them was to show the characteristic features of this type of communication and problems its participants (teachers and pupils) must face. It is more a pioneer research indicating the directions for future research in the area.

Another important question to be addressed in our future research is to what extent the studied methods of soft scaffolding can be generalized and modified in such a way to make them implementable into courses in the form of hard scaffolding. Translation of soft scaffolding into the form of hard scaffolding will also enable us to transfer research results also into courses with greater numbers of students.

One of the key questions that is of crucial importance for the educational process and that every teacher must ask is how to state the current pupil's knowledge and the horizon where it can be developed. In this paper, we discussed benefits, based on examples, of the use of scaffolding in an e-learning course for gifted students.

The examples are taken from highly specialized courses for talented pupils. However, the authors of the paper are convinced that the shown methods can be successfully applied not only in e-learning, but also in regular courses of mathematics where there is communication between the teacher and their pupils, as they are helpful at every moment when the pupil faces difficulties trying to overcome obstacles in the cognitive process.

ENDNOTES

1. See, for example, http://en.wikipedia.org/wiki/Talnet. Talnet is a project for gifted children and teenagers interested in natural sciences and technologies, as well as for their teachers from all country.

2. Content and Language Integrated Learning (CLIL) refers to any teaching of a non-language subject through the medium of a second or foreign language. CLIL suggests equilibrium between content and language learning.

3. See, for example, http://en.wikipedia.org/wiki/Nim.

4. See, for example, http://en.wikipedia.org/wiki/Hackenbush.

5. In case of the above presented forms of scaffolding, it seems that a discussion in the internet environment is in many aspects similar to the usual classroom interaction. The authors deliberately present the examples with dates as they very nicely show how much time elapsed between the different contributions.

6. The game TIC-TAC-TOE is a simplified version of the game Noughts and crosses played on a board with a 3 x 3 square grid. Originally, TIC-TAC-TOE is a paper-and-pencil game for two players, X and O, who take turns marking the spaces in the 3×3 grid. The player who succeeds in placing three respective marks in a horizontal, vertical, or diagonal row wins the game. There are applets on the internet for this game in which we can play the computer. These applets are deliberately not offered within the course as they seduce the pupils to use heuristic strategies. What is expected for the participants is a systematic analysis of all possibilities. And applets do not develop this.

7. The cat and the mouse are represented by tokens that move in the fields connected by a net (the squares represent mouse holes). The cat and the mouse can only move to the nearest field. The goal of the cat is to catch the mouse, the goal of the mouse is to escape. There is a very simple winning strategy for the cat. Still, most pupils are convinced at the beginning that the mouse will always escape and the cat has no chance to catch the mouse if the player plays well.

An examination of secondary mathematics teachers' technological pedagogical content knowledge

Firdevs İclal Karataş[1] and Fatma Aslan Tutak[2]

1 Middle East Technical University, Ankara, Turkey, iclal.karatas@metu.edu.tr

2 Bogazici University, İstanbul, Turkey, fatma.tutak@boun.edu.tr

This paper aims to examine secondary mathematics teachers' technological pedagogical content knowledge (TPACK) and diversities in it due to teachers' gender, age and years of experience. The participants of the study were 138 secondary mathematics teachers in Istanbul, Turkey. An adapted TPACK-M scale with three constructs (TCK, TPK and TPACK) was used to collect data. Results showed that TPACK level of teachers was moderate. According to demographic results, there was no significant difference in TPACK perception of male and female mathematics teachers. Also, small negative correlation was found between age and teachers' TPACK. Furthermore, there was no significant difference in TPACK perception and teaching experience of teachers.

Keywords: Technological pedagogical content knowledge, secondary mathematics teacher, integrating technology in mathematics education.

INTRODUCTION

In accordance with scientific and technologic developments in the world, technological opportunities of schools have increased in Turkey recently. Ministry of National Education (MoNE) has some attempts to integrate technology in schools. The FATIH project (Increasing Opportunities and Improvement of Technology Movement) is among the most significant educational investment of Turkey. The aim of this project is to enable equal opportunities in education and to improve technology in schools for the efficient usage of information and communication technologies (ICT) tools in the learning-teaching processes through providing tablets and LCD interactive boards (MoNE, 2013). However, putting latest technologies into classroom without well trained teachers is not really technology integration (Dockstader, 1999). It can be achieved when technology is used effectively and efficiently in the different content areas to allow students to learn how to apply technology skills in meaningful ways. Although technology has relationship with many domains, it has prominent place in mathematics education due to many reasons. In the last century, technology integration into mathematics education has brought many innovations in the mathematics classroom in terms of development as well as accessibility. According to technology principle of National Council of Teachers Mathematics (NCTM, 2000), "technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students' learning. " (p. 11). Moreover, the effective use of ICT is strongly emphasized in Turkish mathematics education curriculum (MoNE, 2013). From this point of view, mathematics teachers' role in the integration of technology into instruction is crucial. They need to acquire the ability to use technology resources effectively. On the other hand, integrating technology is not just adding technological knowledge in curriculum; it needs a complex mixture of technology, pedagogy and content knowledge. In order to effectively integrate technology in instruction, teachers should have an adequate technological pedagogical content knowledge (TPACK) (Mishra & Koehler, 2006).

LITERATURE REVIEW

The knowledge needed for teachers to use technology strategically in mathematics instruction is a topic that has recently gained much attention (Neiss, Lee, Sadri, & Suharwoto, 2006; Mishra & Koehler, 2006). TPACK, described by Mishra and Koehler, "represents a thoughtful interweaving of all three key sources of knowledge – technology, pedagogy, and content" (2006, p. 14). The TPACK framework describes good teaching with technology by including the components of content, pedagogy, and technology. Shulman's (1986) idea of pedagogical content knowledge (PCK) is the basis for this framework with the inclusion of the domain of educational technology. Technological pedagogical content knowledge (TPACK) provides a useful framework for understanding teacher perceptions and practices of technology integration into curriculum and pedagogy. To integrate technology into their pedagogy and curriculum successfully, teachers must develop confidence in their abilities to integrate technology in the classroom because the integration of technology affects how students learn in the classroom. TPACK for teaching with technology means that teachers should know how particular mathematics concept might be taught with technology so that students understand the concept (Niess, 2005).

After Mishra and Koehler (2006) introduced their TPACK model, it was used in many researches. This framework has been widely adopted for the planning of teacher ICT education (Cox & Graham, 2009) and used as a theoretical underpinning for the development of surveys to measure teachers' TPACK. In terms of measurement, all of the instruments were focused on teachers' self-report, in other words their perception on use of technology. Also, conducting research about development and measuring of TPACK is an important and hard challenge. Since TPACK is a complicated construct and comprises many components, measuring the effectiveness of TPACK depends on the relationships of these components with each other (Koehler, Mishra, Bouck, DeSchryver, Kereluik, Shin, & Wolf, 2011). As a result of the complexity of TPACK, getting reliable and valid results after assessing the TPACK is an important process. Researchers encounter some problems while they are measuring the TPACK of teachers. They face different problems in each different measurement tool of TPACK. Two main problems occurring during the measurement process are understanding the effects of teachers' domain knowledge on their current teaching practices and reliability, validity concerns of TPACK measurement methods (Abbitt, 2011). So, researchers try different methods to measure TPACK because of its dynamic characteristic.

The definition of TPACK concept looks like settled but it continues to be studied. So, most of the studies focused on the definition of TPACK and developing instruments to measure it (Mishra & Koehler, 2006; Koh, Chai, & Tsai, 2010; Schmidt, Baran, Thompson, Mishra, Koehler, & Shin, 2009). Also, many TPACK studies are conducted with pre-service teachers. Similarly to a general trend in TPACK studies in international arena, in Turkey most of the studies focused on adapting surveys or developing new ones to measure TPACK (Öztürk & Horzum, 2011; Yurdakul, Odabasi, Kilicer, Coklar, Birinci, & Kurt, 2012).

Also, the adaptation studies in Turkey did not focus on any specific content. According to the results from a pilot study of the FATIH project, teachers do not feel themselves adequate and confident in their knowledge. Therefore, the purpose of this study were to examine technological pedagogical content knowledge of secondary mathematics teachers at FATIH project schools and their possible gender, age and years of experience diversities related to TPACK by adopting mathematics specific scale (TPACK-M). The specific research problems addressed in this study are the following:

— What are the levels of secondary mathematics teachers' TPACK as measured by TPACK-M scale?

— Is there a significant difference in perception of Turkish secondary mathematics teachers' TPACK in terms of gender?

— Is there a significant relationship between TPACK and age of secondary mathematics teachers?

— Is there a significant difference in perception of Turkish secondary mathematics teachers' TPACK in terms of years of experience?

METHODOLOGY

This study contains the combination of survey and correlational research methodology (Creswell, 2012). In this study, all secondary mathematics teachers at FATIH project schools in Istanbul were identified as the target population. The reason why FATIH project teachers were determined as participants in this study is that they have already been equipped with technological devices such as interactive board and tablets. However, it was not practical to visit all schools to meet the teachers. So, multistage cluster sampling was used in the study. FATIH project schools in Istanbul were considered as clusters. Six districts (three from Anatolian side and three from European side) were chosen from 39 districts. When selecting each district, the ratio of students per teacher and school size in all districts were considered. Firstly, all districts ranged according to the ratio of students per teacher. Then, those districts separated into three groups (low, middle and high). The participants of the study were 138 secondary mathematics teachers working at FATIH project schools in Istanbul. Among the participants, 62 (44.9 %) of them were male and 76 (55.1 %) female, aged between 29 and 62 years (*M=41.1, SD=6.04)*. When teaching experience of teachers was considered, majority of the teachers had teaching experience between 11 and 15 years. As demographic information, it was also asked to participants to indicate whether they had their personal electronic devices (desktop, laptop, tablet and smartphone). The majority of teachers have their own laptop (76.1%), smartphone (73.9%) and tablet (70.3 %), while teachers showed lower percentage of desktop ownership (42.8%).

Technological pedagogical content knowledge of secondary mathematics teachers (TPACK-M) scale was used in the study after an adaptation into Turkish. For the adaptation of the study, the scale was translated into Turkish using a standard protocol. Also, both versions of the test applied twenty five pre-service mathematics teachers who are native in English and fluent in Turkish. The TPACK-M questionnaire was designed by (Handal, Campbell, Cavanagh, Petocz, & Kell, 2013) to identify teachers' TPACK in terms of technological content knowledge (TCK), technological pedagogical knowledge (TPK) and technological pedagogical content knowledge (TPACK). It focuses on secondary mathematics teachers and involves three parts. A 5-point (from 1-strongly disagree to 5- strongly agree) Likert type scale contains a total of 30 items. Each construct has 10 items. Technology knowledge (TK) was not included in the questionnaire because of the research emphasis on discipline related technology. The questionnaire deliberately focused on the concept of ability as a measure of a respondent's capacity to carry out a particular task, rather than focusing on the enactment itself. Hence the examples of the items are, "I am able to use dynamic geometry software (e.g., GeoGebra, Geometer's Sketchpad, Autograph, Cabri)" (for TCK), "I am able to teach a concept using an interactive whiteboard" (for TPK) and "I am able to use technology to demonstrate mathematical models or concepts through learning objects (e.g., animations, simulations, online applications)" (for TPACK). Data was gathered through self-report. Non parametric statistical techniques were used to analyze the data.

RESULTS

Table 1 indicates mean values and standard deviations of participants' TPACK level for three constructs TCK, TPK, TPACK and for whole instrument.

According to Table 1, the whole TPACK mean score is 3.38 *(SD=.83)* in a range of 1 to 5. When three components of scale are examined, the highest mean subscale score belongs to technological content knowledge (*M=3.48, SD=.92*) while the lowest mean subscale belongs to technological pedagogical knowledge *(M=3.28, SD=.77)*. Three dimensions as low, moderate

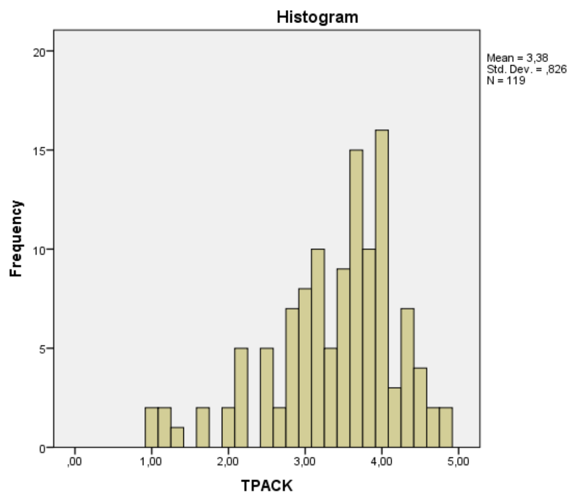

Figure 1: Distributions of TPACK Mean Score

	N	Mean	Std. Deviation
TCK	127	3.48	.92

	Total	118				

Table 4: Kruskal- Wallis test for TPACK and teaching experience

and high were determined to interpret the findings. If mean scores of tests are between 1 and 2.33, the level of perception is considered as "low". If mean scores of tests are between 2.34 and 3.67, the level of perception is considered as "moderate". If mean scores of tests are between 3.68 and 5.00, the level of perception is considered as "high" (Yurdakul et al., 2012). Considering these values, it may be inferred that secondary mathematics teachers' perception on their TPACK level is moderate. Also, their perception level for three constructs (TCK, TPK and TPACK) can be considered as moderate. The distributions of the mean TPACK score is illustrated in Figure 1.

In order to explore possible gender differences of secondary mathematics teachers' technological pedagogical content knowledge, non-parametric Mann-Whitney U test was used because of the violation of normality assumption. A Mann-Whitney U test results, shown in Table 2, revealed no significant difference in the TPACK levels of male and female mathematics teachers (*U=1557, z= -1.11, p=. 27*).

Furthermore, the relationship between participants' age and TPACK perceptions was examined using Spearman rho correlation. As shown in Table 3, there were small negative correlation between age and technological pedagogical content knowledge of teachers (= −.16, p > .05)

In order to answer whether there is a difference in TPACK levels across five teaching experience levels, Kruskal-Wallis test was used. Teaching experiences of teachers were categorized as less than 10 years, 11–15 years, 16–20 years, 21–25 years and more than 25 years. Chi-square value, the degrees of freedom (df) and the significance level are shown in Table 4. So, there is not a significant difference in TPACK levels of mathematics teachers across five different teaching experience groups (*6.56, p= .16*).

DISCUSSION AND CONCLUSION

According to the results, the mean score of each construct and the whole instrument showed that secondary mathematics teachers generally rated themselves as moderate. The moderate mean score in TPACK (and three constructs) may be explained by the familiarity with technology in daily life and in-service education on using technology. Overall, the participants reported using various technologies in their personal life to communicate or obtain information. According to study conducted by Menzi, Çalışkan and Çetin (2012), teachers who have personal technological devices see themselves more competent in the field of technology than those who do not have. So, this may explain why participating teachers' perception is moderate in technology related knowledge in this study. However, as shown in other studies (Harris, Mishra, & Koehler, 2009; Lei, 2009), use of technology for communication and information does not necessarily translate into technology integration in the classroom. Teachers used technology to communicate daily but lacked expertise or vision to translate this technology knowledge into use in instruction.

Moreover, in the scope of the FATIH project, teachers took in-service education related to technology use in education. This education is mainly focused on functionality of the hardware and software, but not on content (choice of appropriate media, functionality of the media) or pedagogical integration of the content in strategic ways, including interaction between tablets, interactive whiteboards, teacher and student (ERI, 2014). So, this may be the reason of teachers' moderate perception on technology related knowledge. However, how and in what degree they use technology is a questionable issue. Teachers may still think pedagogical knowledge, content knowledge and technological knowledge separately. This does not mean technology integration.

Considering the specific subscale mean scores, the highest mean value of the teachers' perception corresponds to technological content knowledge (TCK). This means that mathematics teachers feel more competent in content-related technology. According to the report of 2000 National Survey of Science and Mathematics Education, high school mathematics teachers are significantly more likely than middle school teachers to report feeling qualified to teach a number of mathematics topics (Weiss et al., 2001). Therefore, mathematics teachers may prefer to use technology mostly in their good-at construct, content. On the other hand, among the TPACK sub-constructs, the least mean value of the teachers' perception corresponds to technological pedagogical knowledge (TPK). It can be concluded that mathematics teachers do not feel themselves sophisticated use of technology for pedagogical purposes as well as in other constructs. According to the report of 2000 National Survey of Science and Mathematics Education, high school mathematics teachers reported well prepared to use various instructional technologies in their teaching. As yet another lens on teachers' perceptions of pedagogical preparedness, they are least likely to feel prepared in technology-related areas (Weiss, Banilower, McMahon, & Smith, 2001). This result may stem from teachers' lack of general knowledge about technology-related pedagogy.

Based on the existing literature on teacher integration of technology into classroom, gender, age and teaching experience were possible predictors of technology integration. So, demographic diversities of TPACK were discussed in terms of gender, age and teaching experience in this study. Within the sample studied, there were no significant difference between secondary mathematics teachers' TPACK and gender. North and Noyes (2002) suggested that the prevalence of computers in schools could provide both males and females with equal opportunities for computer use, thereby equalizing their perceived differences with respect to computer use. Therefore, if the FATIH project reaches the aim of providing equal technological opportunities to schools, the impact of gender differences on TPACK may become less significant on teachers. Also, teachers in the FATIH project school took in-service education which was constructed on similar content. This may be the reason why male and female teachers perceive themselves similar in terms of TPACK.

Furthermore, weak negative correlation was found between TPACK and age in this study consistent with previous studies (Koh et al., 2010; Öztürk, 2013). When teaching experience of participants was considered, there was no significant difference in TPACK levels of teachers across five teaching experience groups. In this study, the respondents had an average of seventeen years of teaching experience and the categorization was centered on 11–20 years of teaching experience. Therefore, the results of this study may not be generalized because of small numbers of teachers in some teaching experience categories. Previous study showed that age, gender and teaching experience all affect the teachers' response to implementing new ideas in the classroom (Fullan, 2001). Since FATIH project is a new implementation, such demographic information of teachers which can be effect on technology integration was discussed in the present study.

Boundary crossing in a community of interest while designing an e-book with the aim to foster students' creativity

Chronis Kynigos and Elissavet Kalogeria

University of Athens, Educational Technology Lab and CTI & Press Diophantus, Athens, Greece, kynigos@ppp.uoa.gr, ekalog@ppp.uoa.gr

This paper investigates the process in which teachers of different experiences and subjects collaboratively designed an e-book unit around 'Windmills', aiming to foster students' creativity (call c-book, c for creativity). Our aim was to identify the characteristics of this innovative design, as well as if and how this process can enhance teachers' creativity. We found that the design evolved in four phases incorporating learning mechanisms–indicators for teachers' creativity: Searching for mathematical ideas/concepts, implementation of the raw ideas, pedagogical and /didactical contextualization, transition to the c-book. The c-book was the boundary object around which the participants interacted, reflected and finally transformed their knowledge regarding the way it should be designed to support creativity.

Keywords: Boundary crossing, community of interest, resource design, expressive media.

INTRODUCTION

The present study refers to the process during which designers of different expertise and interests collectively designed digital educational resources in the form of e-books, aiming to challenge and foster its users' creativity in posing and solving mathematical problems through constructionist, exploratory and investigational activity with the use of digital media. Creativity is expected to be at the core of both the process of jointly developing a c-book and the product itself (called c-book, c for creativity). Since this kind of resource constitutes an innovative approach to mediating mathematical content, we were particularly interested in studying both the process of developing as well as the affordances of the product itself, in order to identify their characteristics and their potential for the math teaching and learning.

The designers' online discussions and outcomes that we analyzed here, took place in the context of a European R&D project called 'MC Squared' focusing on technologies affording creativity both in collaborative designs and in using the media to engage in mathematical thinking. The project aims at developing the 'c-book', a technology supporting collaborative authoring, diverse constructionist widgets and data-analytics configurable by its authors for the design of creative educational resources for creative mathematical thinking (CMT) (the c-book units). This technology has been thought to go along with the generation of some specifically generated collectives of designers characterised by their diverse disciplinary backgrounds, expertise, history and membership in different communities of practice, which are defined in literature as Communities of Interest (CoI) (Fisher, 2011). Four such CoIs were formed in the project whose members were as diverse as developers of math digital media, publishers of math educational materials, researchers specialized in creativity or in math education, creative math teachers and students. In this paper, we discuss a group within one of these CoI from Greece.

THEORETICAL FRAMEWORK

We perceive mathematical creativity at the school level "as a process that results in unusual (novel) and/or insightful solution(s) to a given problem or analogous problems and/or as the formulation of new questions and/or possibilities that allow an old problem to be regarded from a new angle" (Sriraman et al., 2011). Novelty is interpreted as having a local character, i.e.

something that may not be novel to experienced mathematicians but from the perspective of the learners it can be judged as novel and therefore as creative (Askew, 2013). This issue brings to the fore the distinction (Craft, 2000, 2001) between 'high' and 'ordinary' creativity. The former (big C) describes 'great works' by experts or gifted persons which change knowledge and/or our perspective on the world. The latter (small c) recognizes that all pupils can be creative and arises – for example – when a student creates a solution to a novel problem or connects together two seemingly disparate ideas.

Our view on the creativity of educational designers of math resources is in accordance with Ervynck's (1991) who considers as creative math activity every designer's attempt aiming to reform or improve the network of concepts of a math curriculum for pedagogical reasons, even if new mathematics is not generated. According to Bolden and colleagues (2010) some of the creative opportunities that might be offered in the math classroom are the need for mathematical expression and communication (the social aspects of creativity), the construction of meaning and development of personal understandings, the generation of ways for solving problems, hypothesizing about math situations and outcomes, constructing tests of those hypotheses and formulating plans for solving complex problems. In this paper, we sought for creativity in both the process and the products of collaboration among teachers so as to produce material which is expected to offer students some of the above creative opportunities. The kind of creativity which is developed in collectivities through joint enterprises is described as 'middle c' creativity and is needed to create strategies, to find ways to make the differing views of individuals capable of existing together and to produce collective learning outcomes, including an elaborated understanding of the learning topics addressed (Eteläpelto & Lahti, 2008). In MC2, the engagement of teachers in this kind of collaborative design targeted the empowerment of students' creative mathematical thinking (CMT). Although the use of digital media can facilitate the engagement with CMT in unprecedented ways (Healy & Kynigos, 2010), there is a lack of both pedagogical designs targeting CMT and corresponding technologies supporting them. Even in the case of digital tools with great potential for enhancing CMT, such as e-books, the pedagogies that accompany those tools are often outdated, following the traditional teaching and learning models. Moreover, the process of designing them is rather restricted and limited to the authors, instead of being open to collective design that leaves space to the designers for sharing creative ideas. Designing digital educational resources for CMT can be therefore viewed as a 'squared' creativity challenge, since it requires not only fostering students' mathematical creativity but also situating the design process itself within a socio-technical environment that can boost educational designers' creative potential (Kynigos, 2014). In the context of MC2, learners' engagement with CMT was planned to be designed in collectives with the use of digital media, resulting in a new genre of authorable e-book, the *'c-book'*. The technology of a c-book differs from the one of an e-book as it includes dynamic widgets and interoperability, anticipates collective design incorporating an authorable data analytics engine with appropriate interface, drawing on end-users' and resource designers' interactions. This environment is aiming to enhance and stimulate *social creativity* in designing for CMT through the generation of *Communities of Interest* (CoI) (Fischer, 2001). A CoI has a heterogeneous character, as each of the participants of a CoI represents a group of practitioners from different domains or communities while all of them target to resolve collectively a problem and achieve common understandings overcoming their cultural differences. The "symmetry of ignorance" in the process of framing/solving design problems and creating new artifacts/understandings, triggers the emergence of social creativity (ibid). In this context, such CoI is anticipated to operate as a *socio-technical environment,* i.e. a living entity where everyone might be, at the same time, "designer" and/or "consumer", in the process of co-designing dynamic re-useable and re-constructible educational materials for CMT. Interconnectedness, different perspective-taking, knowledge exchange and integration between diverse domains are features of this environment expected to provide more opportunities for creative thinking and learning. The members of a CoI in order to integrate these features in their communication need to cross the boundaries between the different sites and the c-book is anticipated to operate as boundary object by fulfilling a bridging function (Star, 2010). The process of *boundary crossing* entails four learning mechanisms (Akkerman & Bakker, 2011): a) identification of the intersecting practices, b) coordination of both practices through establishing routinized exchanges to facilitate transitions, c) reflection leading to perspective-making and perspective taking and d) transformation that provoke changes in practices or even the creation of a new in-between practice. We perceive these mechanisms as indicators for teachers' creativity, thus in our study we sought for them during the design process.

The present study is a first attempt to describe in detail this kind of innovative design and identify its characteristics as well as if and how this process can enhance teachers' creativity. Particularly, we investigated: (a) designers' ideas in the process of formulating mathematical problems as well as the way they designed and foresaw students' CMT (b) the product of this process in terms of novelty and usefulness as well as its characteristics (c) the potential of the c-book for operating as boundary object between the CoI members.

METHOD

In this paper, we study the development of the c-book unit 'Windmills' which was meant by the researchers to operate as a sparker for social creativity. It was planned to be jointly created by the following 9 members of the Greek CoI: Tom (Computer Science developer), Dimitris (experienced math teacher, designer in math education with the use of digital tools, master degree in the didactics of math), Katerina and Areti (master degrees in math education with technology, but limited teaching experience in math classrooms), Popi (experienced math teacher and teacher educator for the pedagogical use of digital tools in math, with deep knowledge of the available tools), Marios (phd-student and Informatics teacher), Foteini (teacher in engineering education, phd in the pedagogical use of digital tools for the vocational education), Yannis (university teacher) and Elissavet (moderator of this discussion, experienced math teacher, PhD in the domain of math teachers' education with the use of digital tools). Our data were: (a) the 75 contributions in the CoICode, (b) the files attached in the CoICode (c) the pages in the platform of the c-book (the widget instances and the respective narratives). For analysing the content of CoICode, we adopted the data grounded approach (Strauss & Corbin, 1998).

THE C-BOOK ENVIRONMENT

The c-book provides space (CoICode) for organized discussions in two parallel interfaces: a threaded forum discussion view and a mind-map view (Figure 1) and gives user the possibility of switching from one to the other. Users can characterize the nature of their contribution by selecting between different semantics (alternative, contributory, objecting, off task and management) in which they can write text, links, attach files or widget instances (a software such as Geogebra is a widget factory and a microworld of this factory is a widget instance). The platform (Figure 2) is the space for authoring where the students interact with the c-book. It incorporates pages with dynamically manipulated widget instances accompanied by corresponding narratives.

RESULTS

The analysis of the 75 contributions posted in CoICode during the first cycle of MC2 showed that 16 of them were related to technical and organizational issues, 4 were off-topic and the majority (55) concerned the development of the c-book unit. It should be noted that Tom and Marios did not participate in this cycle of the design. From the analysis of our data we identified that the process of developing the c-book unit was evolved in the following four phases incorporated different characteristics:

1) Searching for mathematical ideas and concepts

2) Implementation of the raw ideas

3) Pedagogical and didactical contextualization

4) Transition to the c-book: texts accompanying the constructions

These phases are interconnected and sometimes not clearly limited, as one of them may penetrate or overlap the previous and evolve together overtime. Below, we describe them regarding their characteristics in terms of both processes and products.

Phase 1: Searching for mathematical ideas and concepts

This phase starts with the exchange of files depicting different types of windmills all over Greece (Elissavet and Katerina) or the way they function (Foteini), aiming to operate as starting point and trigger the subsequent expression of the first ideas. The shapes of the windmills and their operation turn the participants' attention on the kind of software that should better integrate those characteristics. Their first ideas are

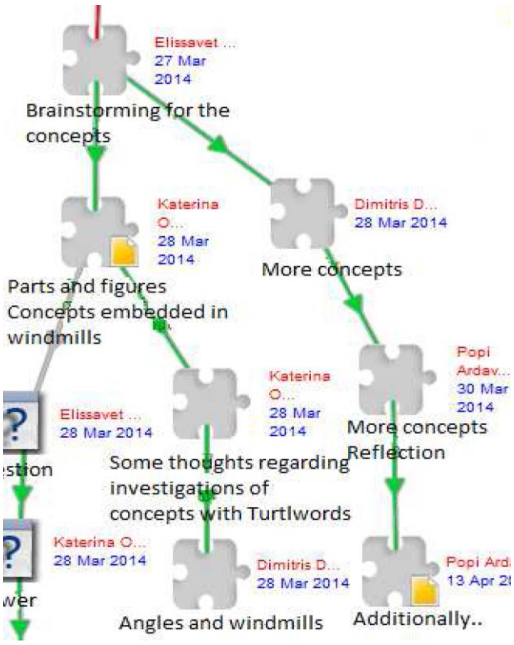

Figure 1: ColCode map

related to Turtlewords (Dimitris, Elissavet and Areti), as they were all fully aware of its functionalities for rotation with the variation tool. Then, Elissavet (Figure 1, 27/3) proposes a brainstorming concerning the concepts embedded in a windmill and mentions some of them: regular polygons, isosceles triangle and rotational symmetry of k grade (depending on the number of sails) for the wheel as well as cone and cylinder for the main building. Dimitris (Figure 1, 28/3) adds some more complicated ideas, for example, when an ant is walking on a wing of a windmill as it turns the ant's orbit might look like a helix. Katerina (Figure 1, 28/3) adds concepts such as parallelograms, rectangles, angles, turns and curves in 3d space. She proposes ways of connecting them and the use of Turtlwords to investigate the properties of parallelograms and of different kinds of triangles as sails of the windmill. Popi (Figure 1, 30/3) raises some questions about the mechanics and architecture of windmills, the locations which favor their operation, the time required for a complete rotation of two similar windmills with similarity ratio ½, the way the sprockets work etc.

In this part of the discussion we observe that most of the concepts come from geometry and have to do with the perceptions of windmill and its parts as geometrical figures. Popi, who is experienced in both mathematics teaching and technology introduces the time parameter and searches for a context where a windmill would be integrated. At the same time, the participants start thinking which of the available software should better be related to those concepts. The discussions of this phase seem to be focused rather on ideas than on actions.

Phase 2: Implementation of the raw ideas

At this point the CoI members start implementing the ideas expressed during the 1st phase. The constructions are individual and we note a lack of intervention in the other members' constructions. Simultaneously new ideas are invented concerning mathematical concepts, technological tools and problems. Elissavet gives a logo-code in Turtleworlds that initially constructs an equilateral triangle and then rotates it in order to take the shape of a six sails wheel. Taking this perspective, Dimitris and Katerina give half-baked logo-codes constructing an equilateral triangle using trigonometry and a parallelogram for representing the sails respectively. Areti also attaches a file with a half-baked code in Turtlwords (variables a, b, c) that initially constructs an open jagged line of two equal sides of length a, turns depended on c and the third side of length b. The dynamic manipulation of variables with the variation tool, constructs an isosceles triangle. Subsequently, the triangle turns and it is rotated n times with the variation tool, so as to give the impression of the sails of the wheel. At the same time, Dimitris and Popi start expressing their ideas with the use of Geogebra. Dimitris constructs a dynamic figure of a sail and Popi a simple model of the wheel in which she has incorporated the time parameter manipulated by a corresponding slider. The dynamic manipulation of time, brought to the fore algebraic concepts and relationships. The investigation of the model led to direct proportional amounts, linear and multiple branch functions. Dimitris makes a further refinement of the concepts and classifies them into: (1) structural relationships and construction of a windmill as a 2d shape and (2) movement of the windmill with the slider. Elissavet adds to this distinction a third group: the view of the wheel from different perspectives as a solid 3d shape, i.e. its transformation from a plane to a solid shape. She also emphasizes on the complementarity of the activities with Turtlewolds and Geogebra: the former needs a constructionist activity from simple mathematical concepts as structural units to more complicated ones, while the latter requires a de-construction of the model, resulting in the embedded concepts.

The discussions of this phase include both the expression of ideas and their implementation individually. The mathematical concepts are classified according to the way they are used, while they are also related to the functionalities of specific software tools. As the CoI members exchange their constructions we observe their smooth transition from one practice to another, effortlessly, just crossing the boundaries, without reconstructing them.

Phase 3: Pedagogical and didactical contextualization

In this phase the majority of constructions in the form of widget instances has already been completed and the next step was to put them on the platform as different pages. The CoI members discussed the optimal sequence of the activities encompassing their constructions, the targeted students' ages, the relation to the official curriculum and the kind of activities regarding their openness.

Foteini believes that this c-book unit should be addressed to specific school grades, while Dimitris' opinion is to put 'neither floor nor ceiling' in the targeted ages. From this disagreement the following dilemmas emerged: "*How can we expect our students to do creative mathematics with the use of the c-book, without having previously defined their ages?*" or "*Did defining in advance the ages of students limit our own creativity?*" Finally, they decided to include in the c-book a wide range of activities, starting from the simpler and gradually address them to students 12–17 years old, with the structure of the concepts not aligned to the official curriculum. Then, they had to choose which of the constructions should be incorporated in the c-book as well as their sequence on the different pages. They all agreed to start from the constructive activities with Turtlewords, giving students the opportunity to explore separately the figures – and the concepts of isosceles, equilateral triangle, parallelogram – which represent the sails of the windmill and then to continue towards more complicated concepts (for example rotational symmetry), using the initially investigated ones as structural units. The investigations of the model with Geogebra were decided to be posted after the 6th page, with the aim to offer students the experience of understanding functional relationships through their use (for example multiple branch functions, representing the operation of the windmill in different time intervals). We note that the multiple branch functions are taught in the 4th grade of secondary education; however, the investigation of the model could lead students of lower grades to understand this notion through its use (a typical example of mathematics-in-use). At the end of this phase Dimitris expressed the following alternative opinion: "*It does not really matter which activities we'll choose from Turtlewords or Geogebra. The widget will change when we start writing the texts. I believe that text and widget are a unit and not two different pieces*". The interrelation of widgets and texts was an issue of less importance till then and Dimitris' contribution revealed his conception of the c-book as a whole, integrating both instances and texts. Another issue was the form of the activities around these concepts, i.e. their openness and the

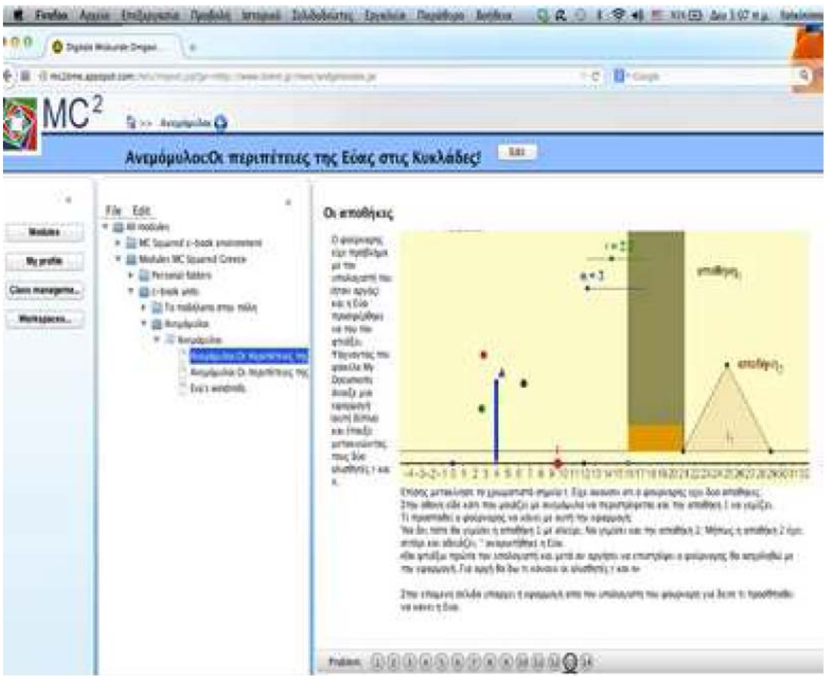

Figure 2: Screenshot of the c-book

level of instruction. Since most of the constructions involved activities on given microworlds the participants expressed the need for thinking up ideas that would give students the opportunity to create their own constructions around windmills. Thus, for the last page of the c-book unit they chose to ask students to construct their own windmill.

Summarizing the content of this phase, we observe that the conversations are rather oriented to pedagogical and didactical ideas than in action, which was prominent in the previous phase. The CoI members are facing dilemmas regarding the pedagogy of their constructions (widget instances) and have to think of ways to stimulate students' creativity without decreasing their own creativity in design. The coherence of the activities had also provoked a number of contributions, since till this phase the constructions were products of individual work and, at this point, the need to be synthesized emerged. These constructions expressed different pedagogical and didactical approaches of the embedded mathematical concepts and the participants had to deepen on these concepts, their interrelations with the available tools and the way they should be communicated through corresponding activities. The CoI members made clear their perspectives (perspective making) and extended or synthesized the ideas and perspectives of the others (perspective taking). Now, the artifacts are accompanied with pedagogy and the participants start thinking about the form of the c-book, expressing ideas alternative to their traditional way of designing.

Phase 4: Transition to the c-book

This phase begins when the CoI members' constructions have just been put on the platform as widget instances, with the sequence which had already been discussed in phase 4. Now the participants are discussing the number of available tools and the kind of functionalities they should provide to students. They are also trying to connect them through narratives and real life situations, so as to make more attractive the students' involvement with the c-book. 'Eva's adventures at Cyclades!' was the title of the c-book unit, in which Eva, her father and a local windmill owner were some of the heroes of the story. The difficulty in connecting widgets and texts is evident in the following discussion:

Areti: Dimitris, how would you find a hypothetical scenario, such as 'a boy trying to construct with a logo-code the windmill's wheel doesn't finally manage it, can the students help him?'

Dimitris: I believe that we don't need to ask something. If you have a story and a widget connected to it, the text needs to be challenging, otherwise the student would not use it, even in case he is asked to. I don't know if it's better to ask clearly students what we want them to do or not. If not, do we lose the story's coherence, as we continuously interrupt it with questions?

Areti: I'm confused. Do you disagree on the way me and Katerina changed the texts?

Dimitris: Texts resulting in a question are ok and constitute a safe teaching method. My objection is that I imagine the c-book unit as a book with texts, which is also a tool, something like the interactive books in Harry Potter. This kind of books does not need any questions in order to attract you... Trying to correct the texts of Popi's model in page 6, I inspired a new activity and put it on the twelfth page, in the form 'text-widget' (Figure 2).

Foteini: It seems that the texts have the potential to re-formulate the widgets.

In this part of the discussions, the CoI members seem to reconceptualise the use of the c-book unit: Areti expresses the need for framing the widget with a real problem to stimulate students' interest. This approach differentiates the c-book from a microworld accompanied by a formal mathematical problem. The development of the c-book unit was an unknown and unfamiliar territory for all and the perspective of the experienced Dimitris favoured the development of new understandings and practices around its use. In this process, the c-book was the boundary object around which the participants interacted, reflected and finally transformed their knowledge. At the same time, new ideas incorporating both a story and a widget instance are generated. For example, Yiannis proposes to give students a photo of a ruined windmill or without sails or roof and ask them to repair or complete it or to put inside its conic roof a rectangular parallelepiped reservoir of maximum volume, for water storage. Furthermore new widget factories are introduced: Katerina exploits available tools of the platform and creates a widget instance with the respective story in which students starting from a 2d plan are challenged to create a 3d building with a windmill. These ideas reflect a new holistic perception of the c-book and the need for making their constructions more attractive using 'non-mathematical' material (photos, plans) in challenging situations.

RESULTS

The results of our research reveal that co-designing the c-book unit was a process evolved in four phases that incorporated different characteristics and underlying learning mechanisms for the CoI members. The ideas about the product and the product itself were modified over time. Phases 1 and 3 include discussions rather concentrated on ideas, while phases 2 and 4 are oriented to practice. In phases 1 and 2 the CoI members coordinate their work, collecting individual ideas and widget instances respectively, which become objects of pedagogical and didactical reflection in phase 3, in order to be synthesized as a coherent whole. Before the end of phase 3 and at the beginning of phase 4, the form of the c-book is outlined and the participants gradually acquire a more precise picture of what the c-book unit might be. Holistic perception of the c-book and the importance of the narratives are the outstanding characteristics of phase 4. At the end of this phase the c-book hybrid form is progressively crystallized and the transformation of the CoI members' knowledge on how to design a c-book aiming to stimulate students' CMT is evident, due to the contributions of the more experienced members. In conclusion, our findings showed that the c-book was the boundary object around which the participants coordinated their activities, reflected on their pedagogy and transformed their knowledge about how to design for creativity.

ACKNOWLEDGMENT

The research leading to these results has received funding from the European Union Seventh Framework Programme (FP7/2007–2013) under grant agreement n° 610467 – project "M C Squared", http://mc2-project.eu. This publication reflects only the author's views and Union is not liable for any use that may be made of the information contained therein. The c-book technology is based on the widely used Freudenthal Institute's DME portal and is being developed by a consortium of nine partner organisations, led by CTI&Press 'Diophantus'.

What can be learned from online public-generated mathematical content? A case-study of the comments on a viral mathematical video

Alik Palatnik

Technion – Israel Institute of Technology, Haifa, Israel, umapalatnik@gmail.com

The study explores the phenomenon of "viral mathematics", providing insights about the availability and the structure of mathematical content in public-generated media (in particular in comments on videos). The study offers the research methodology, relying on original mix of qualitative, quantitative and data mining paradigms. The findings show that communication using scientific argumentation can occur in comments on a recreational mathematical video; the growth of public interest in mathematical themes can be triggered by the viral video; and the arguments used by the comment-makers contain mathematical derivations, terminology and views on science. Public-generated content can be harnessed as a unique open educational resource and a new source for engaging mathematical problems.

Keywords: Public-generated content, viral video, web cloud analysis, argumentation, divergent series.

INTRODUCTION

My first account with the video in question occurred in February 2014. My 10th grade students were intrigued and asked for my opinion about the "*one plus two plus three plus four video*". The challenge was accepted and I designed the subsequent lesson to discuss the mathematical ideas in the video. For me it was an example of blurring the boundaries between the classroom and out-of school learning. In turn, I was intrigued by the thought that a You Tube video succeeded to engage my students in university level mathematics. At that time, the video "Astounding: 1 + 2 + 3 + 4+… = -1/12" had about two and a half million views and about four and a half thousands comments, which defines it as a viral mathematical video. In general, can public interest in such a video facilitate learning of mathematics? What can students learn from the comments on a video? To answer the above questions we have to understand the nature of communication through the comments, the structure of the comment and to anticipate its application to education. This research is an exploratory study that used a mixed methodology approach in a relatively new field of learning.

THEORETICAL BACKGROUND

The advent of personal computers, electronic mobile devices and the Internet has increased the blurring between formal (institutional) and informal education in the 21st century. Blogs, wikis, multimedia sharing sites, podcasting, and social networks facilitate individual production and user generated content, harnessing the power of the crowd through an architecture of participation (Andersen, 2007). Hossain and Quin (2012) argue that the interactive features of Web 2.0 technologies enable mathematics teachers and students to create collaborative learning environments inside and outside of the classroom, providing new type of resources and ways of instruction.

Educational resources, their design, sharing and implementation receive a renewal attention from the mathematics education community (see, e.g., Ruthven, 2013 for a comprehensive review). One of the growing tendencies, closely associated with online sharing is a development of open educational resources (OER). Theoretical lens of instrumental approach was used by Trgalova, Soury-Lavergne and Jahn (2011) and Trgalova and Jahn (2013) to study the particular OER (dynamic geometry content repositories) and members of their communities. Kynigos (2014) urges to study new types of OER, which are able to "generate more powerful and relevant sociotechnical communities for the learning of mathematics" (p. 252).

One of the social phenomena related to Web 2.0 is the 'viral video': a video clip content which gains widespread popularity through the process of Internet sharing ("Viral video", n.d.). This particular type of media can be harnessed as a unique OER. As shown in 2011 by "The periodic table of videos" channel, educational videos explaining basic notions in chemistry can become viral – garnering millions of views. The impact of the channel awarded its creators with a *Science* Prize for Online Resources in Education (Haran, & Poliakoff, 2011). This explores the potential of a general public interest, manifested in public-generated content, as an educational resource in a mathematical classroom.

Research questions

This study aims to explore the phenomenon of "viral mathematics", providing insights about the availability and the structure of mathematical content in public-generated media (in particular in comments on videos with a mathematical topic). It raises following research problems. First, little is known about the nature of comments on mathematical video. Whether they consist mainly of expressions such as: "lol" or contain a valuable mathematical component? Second, within the interest on the viral video itself, the public interest in the mathematical concepts and ideas mentioned in the video has to be isolated. Third, the characteristics of comments on the mathematical videos are unclear and have to be typified. To do so, a case study of the comments on the "Astounding: 1+2+3+4… = -1/12" video (Haran, 2014) was undertaken.

The research questions, following from the research problems are:

1) What mathematical content can be found in public-generated online resources, such as comments on a video?

2) Can viral video elevate public interest in the underlined mathematical content?

3) What is the structure of comments on a mathematical viral video?

RESEARCH METHODOLOGY AND APPROACH

Viral videos and comments are an unused resource in mathematics education and to date have not been the subject of mathematics educational research. Therefore, one of the objectives of this study is to propose suitable research methodology, which relies on original mix of qualitative, quantitative and data mining paradigms.

The video "Astounding: 1 + 2 + 3 + 4 + 5 + … = -1/12" was published on YouTube on 9/01/2014 and is one of 232 (while writing this article) videos of Numberphile channel. Nearly all of those videos have hundreds of thousands of views. The "Astounding…" video introduced the paradoxical result: $1 + 2 + 3 + 4 + \ldots = -1/12$ through a manipulation with series (divergent and convergent) and infinity. The creators of the video present the following "proof". First, the following sums were denoted: $S_1 = 1 - 1 + 1 - 1 + \ldots$; $S_2 = 1 - 2 + 3 - 4 + \ldots$; and $S = 1 + 2 + 3 + 4 + \ldots$ Then the presenter claims and explains that $S_1 = 1 - 1 + 1 - 1 + \ldots = 1/2$. Based on this result he proves that $S_2 = 1 - 2 + 3 - 4 + \ldots = 1/4$. Through further manipulations the presenter derives that $S - S_2 = 4S$ and hence $S = -1/12$. In short, the paradoxical result is obtained due to inconsistencies of various natures: different meanings of "=" sign in mathematics; attribution a numerical value to a divergent series; rearrangement of infinite series using the commutative property of addition, etc. Quoting Niels Henrik Abel:

> The divergent series are the invention of the devil, and it is a shame to base on them any demonstration whatsoever. By using them, one may draw any conclusion he pleases and that is why these series have produced so many fallacies and so many paradoxes. [1]

To answer the research questions different methodologies were applied:

> To answer the first question and to identify the main themes of the discourse in comments on videos, *word cloud* analytics were applied. A word cloud is a special visualization of text where the more frequently used words are highlighted by their proportional size (Feiberg, 2013). Use of word cloud as an analytical tool is still rare in educational research, however it appeared to be a fast and visually rich way to overview the data (McNaught & Lam, 2010). Those features make a *word cloud* especially suitable for preliminary analysis and for validation of previous findings (ibid). Wordle and Tagxego programs were applied to obtain word clouds, containing 50 most frequently used words [2] out of 38452 words

1a 1b

Figure 1: Word clouds containing 50 most frequently used words in all the comments on the "Astounding..." video (2a- out of 38452 words; 2b- out of 5332 words of the sample)

in all the comments to the video. Comparison revealed no significant differences between the word clouds. The further analysis was made using Wordle software (Figure 1).

The data was prepared for analysis in the following way [3]: To open all of the pages of comments I selected "Show more" at the end of each page; to open all replies to each of the comments I selected the "View all N replies" notifications (58); to show all the lines in lengthy comments I selected "Read more" notifications (340). The obtained HTML document was copied to the MS Word using "Keep text only procedure" resulting in a 209 pages document. The utility phrases (e.g., Hide replies; Show less) were deleted from the text file before the data mining stage.

To answer the second question, namely to estimate the impact of the video on public interest to the featured scientific content, the changes in information seeking behavior as expressed by *Google Trends* were used. The methodology, using Google Trends tool was proposed and applied by Segev and Baram-Tsabari (2012). The mathematical concepts Grandi series and Cesaro sums were chosen as the subjects of investigation for the several reason:

— Grandi series and Cesaro sums are the key concepts of the video. The Cesàro sums method using the limit of the average of the first n partial sums of the series, as n goes to infinity, enables "summation" of the divergent series, thus Grandi series $1 - 1 + 1 - 1 + \ldots$ has Cesàro sums of 1/2.

— Terms Grandi series and Cesaro sums were not mentioned explicitly in the video and were mentioned in the comments

— Grandi series and Cesaro sums are usually unknown to the lay public and for the non-mathematical academic audience unlike other key concepts of the video (e.g., those present in the university curriculum or related to Riemann or Euler).

The hyperlinks to mathematical sites and blogs in the comments are additional indicators of the video's impact. The standard Find function of Word with "http" argument was used to find the external links. Each link was labelled according to its content (e.g., Blog, Wiki, scientific paper).

Descriptive statistics of the data sample and qualitative analysis of argumentation in the comments was applied to classify the comments and arguments, to answer the third question. Out of 209 pages of comments 25 pages (≈12 % of pages) were randomly selected. The sample contains 85 comments. An additional instrument for establishing the representativeness of the sample is a word cloud, produced from 5332 words of the sample (≈14 % of text) (cf. Figure 1a with Figure 1b). The main themes and topics (e.g., sum, infinity, series) are intact. All the comments in the sample was numbered, and coded according to whether they contain the following indicators: presence of mathematical derivations/ scientific terminology; characteristics of scientific enquiry/ epistemology; attitudes toward science or scientists; emotions in support or against the video. In addition, each comment was analyzed in order to locate the essential parts of an argument: a claim, a data and a warrant (Toulmin, 1958/ 2003). For example, comment #80 on the "Astounding..." video: "*Assumption: the sum of an oscillating sequence is its arithmetic mean. Conclusion from assumption: the sum of a set of positive integers*

Mathematical derivations/ scientific content	Characteristics of scientific enquiry/ epistemology	Attitudes toward science and scientists	Emotions	Argument
1	1	0	0	1

Table 1

is negative. You've just proved by contradiction that the sum of an oscillating sequence cannot be its arithmetic mean." was labelled as shown in Table 1.

The claim: the sum of an oscillating sequence cannot be its arithmetic mean, thus the main statement of the video is false; the data: a fragment of the video, where the statement $1-1+1-1\ldots=1/2$ is proven; the warrant is a proof by reduction ad absurdum. Consequently, the abovementioned comment is an argument, which uses mathematical calculations and terminology and free of emotion. First stage of the research will provide a list of key words, which are the core of scientific communication established in community of commenters on the video. The data collection was completed by simple filtering technique using the key words. The comment-makers use pseudonyms and usually do not share any personal details such as gender, age, occupation and level of expertise in mathematics. However, in some cases it was possible to make grounded suggestions about the comment-maker's background. For example search phrases: "teacher", "class", "students" revealed math teachers/ students among the comment-makers. I read the mathematical derivations line by line and checked the mathematical terminology used by comment-makers to find the experts in mathematics among them.

RESULTS

What mathematical content can be found in public-generated online resources, such as comments on a video?

The word clouds (Figure 1) show that the comment-makers were involved in scientific discussion, which main topics and themes were connected to a sum of infinite series. The word count confirms this finding. 30 words out of top 50 in the word cloud belong to mathematical/ scientific terminology (general or specific to the content of the video). See Table 2 for the details.

#	Word	Frequency in the comments		#	Word	Frequency in the comments
1	sum	233		16	average	72
2	series	220		*17	shift (technique)	72
3	infinity	213		18	positive	67
*4	S	191		19	negative	59
5	number	184		20	adding	55
*6	S2	161		21	theory	55
*7	1/2	142		22	mathematics	54
*8	1/12	134		23	sums	51
9	numbers	127		24	prove	51
10	infinite	113		25	physics	50
11	value	100		26	equation	50
12	answer	92		27	divergent	48
13	proof	92		28	sequence	47
*14	S1	80		29	summation	43
15	math	76		30	converge	41

Table 1: Word cloud frequency (* indicates the words specific to the video)

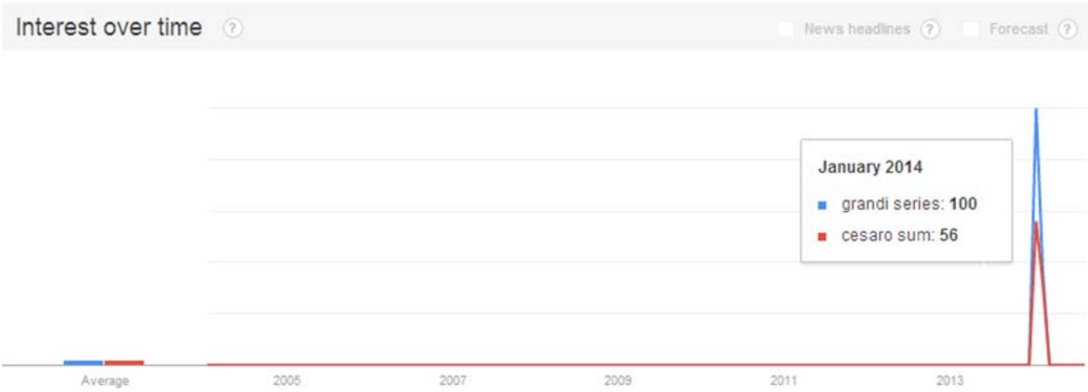

Figure 2: Google trends graph showing a percent of searches on Grandi series and to Cesaro sum

Can viral video elevate public interest in the underlined mathematical content?

Figure 2 indicates the growth of public interest in Grandi series and Cesaro sum (abstract and unknown to the lay public mathematical concepts which are explicitly mentioned in the comments and not in the video). The peak of interest to the concepts in question was registered in January 2014, corresponding to the release date of the video–9/01/2014. It is of note, that there are 37 different hyperlinks pointing to 32 different mathematical sites in comments (Figure 3). Most of the links led to various Web 2.0 platforms: Wikipedia articles about mathematical concepts related to the video (e.g., Divergent series, Riemann zeta function), mathematical blogs, social network, question and answer site or YouTube. Publication of the video has created a teachable moment and new resources for learning were generated/ brought into account.

What is the structure of comments on a mathematical virus video?

The analysis of the sample shows that the comment-makers use mathematical derivations and scientific terminology to the broad extent (28% and 36% of comments resp.) The data analysis process revealed that 73% of the comments contained arguments (63 out of 85). These arguments were categorized according to the possible roles that they play within the discourse [4]. In short the most-used categories of argument were: common sense; mathematical laws; mathematical intuition (based on non-infinite mathematics); counterintuitive thinking, proof; and authority. More than half of the comments (52%) in the sample contained indicators of positive or negative emotions toward video and its creators. For example: the fragment of comment #28: "*You know what is more amazing? WHY anyone would ask for the result of 1+2+3+4... ? It is obvious it is infinity!! You must be a genius to think that maybe not.*" Table 3 shows the distribution of the arguments/ emotions in the comments.

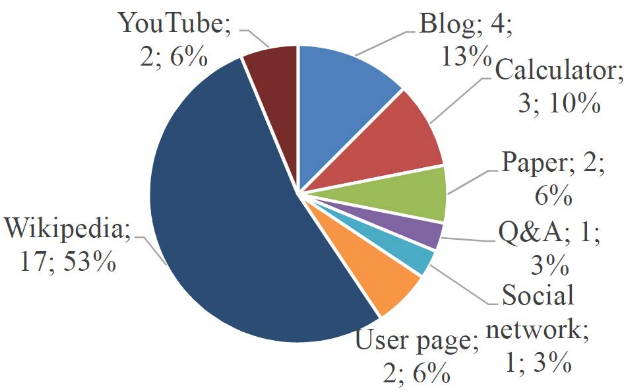

Figure 3: Distribution of hyperlinks in the comments

The next step was to apply the filtering technique to the text file of all the comments. It revealed data, which the two previous techniques could not disclose. There were evidences of various stakeholders to the "viral math" phenomenon. The math teachers/ lecturers were among the comment-makers. Most of them were concerned with misconceptions which students may develop as a result of watching the video. Comment-maker X wrote: "*My complaint is, this video is leading my students to believe that 1-1+1-1+... converges to 1/2, and is encouraging them to work with limits of sequences without knowing if they converge, which is a huge problem...*" Nevertheless, most of the teachers appreciate the "*arousing interest in discussing the problem*". The reading of the mathematical derivations line by line reveals mathematicians/ physicists among the comment-makers. Some of the comments were mathematically perfect and could be a part of a textbook, as previously cited in the Methodology section comment #80.

The comment contains:	Emotional expressions supporting / refuting the result	No emotional expressions supporting / refuting the result
Argumentation supporting / refuting the result: 1+2+3+...=-1/12	33	30
No argumentation supporting / refuting the result: 1+2+3+...=-1/12	11	11

Table 3: Argumentative/ emotional component in the sample of the comments on "Astounding…" video

There were some emotionally loaded comments toward the video creators and comments expressing attitudes towards science. The following excerpt of the comments should raise the awareness of mathematics educators, willing to use this resource to the issue of public understanding of the science and its role in society:

— *Mathematicians are frauds (in Russian)*

— *this equation means infinity is different from what we believe, or perhaps our whole concept of mathematics is wrong*

— *Why are you bashing on this channel? Blame the mathematicians who derived this and use it*

— *Unbelievable that scientists make "science" based on fallacies.*

DISCUSSION

This study explores a viral mathematical video and a corpus of corresponding comments as an open resource which was adapted for the needs of (mathematics) education. Trgalova and Jahn (2013) studied more conventional OER (web-based repository specifically designed for the educational needs) and registered a relatively small number of reviews and modifications of the content by users. The authors suggest that lack of tools for communication and collaboration in the repository may decrease users' motivation to contribute. In the list of key ideas of Web 2.0 application to education Andersen (2007) named individual production and user-generated content in first place. The current study, through analysis of the comments, makes a step toward better understanding of the learning in dynamic web environment with active user participation. The findings show that comment-makers on a recreational mathematical video can create, share, and communicate mathematical content using scientific argumentation. The active public participation through embedded tools of communication and engagement provided an educational component to an open resource.

The arguments used by the comment-makers contain mathematical derivations, terminology and views on science and scientists. The high presence of arguments in the comments advocates the further study of arguments as a promising direction in the research of mathematical communication based on Web 2.0 platforms as file sharing sites, social networks and blogs. This study treats learning from comments as a special case of learning through argumentation. Learning from argumentation has been shown by Asterhan and Schwarz (2007) to lead to students' conceptual gains where the introduction of the dialog of disagreeing discussants proposing reasons for their views about a problem resulted in the students' discussion becoming more argumentative. Lachmy and Koichu (2014) use their analysis of students' arguments to understand the interplay of empirical and deductive reasoning when proving in a computer-enhanced environment. To this end the categories that originated in the comments can facilitate the critical thinking of the students when applying to the public-generated content. For example, the most "innocent" step in the underlying proof is the implicit claim that the sums 1-1+1-1+...; 1-2+3-4+...; 1+2+3+4+... can be denoted and the numerical values can be attributed to S_1, S_2 and S. The argument belongs to a common sense category and must be revisited.

The growth of public interest in mathematical themes triggered by the viral video was shown in this study and is a phenomenon that should be studied intensively as a part of wider vein of research on a public interest in science (e.g., Baram-Tsabari & Segev, 2013).

Despite the study's limitations (it is a case study of the comments on one video), the claim is that this particular type of media can be harnessed as a unique open educational resource. First, it embodies the cyber-social learning opportunities typical of the Web 2.0 environment. Second –it combines the benefits of multimedia learning with mathematically rich content in public-generated comments on the video.

ACKNOWLEDGMENT

The author would like to thank Dor Abrahamson, Ayelet Baram-Tsabari and Boris Koichu for the valuable help. This research was partially supported by the Technion Graduate School, the Mandel Leadership Institute and the Israeli Science Foundation (grant 1596/13).

The study presented here focuses on the representations of creative mathematical thinking (CMT) held by two Communities of Interest (CoI) before and after designing educational resources with an innovative tool affording diverse expressive media for creativity in classrooms. Our analysis revealed similarities but also distinct differences in the way these communities operationalized their CMT representations in their products. Both CoI (Greek and Spanish) appreciated the novel affordance of diverse expressive media to foster CMT in students through open, real life, interdisciplinary problems amenable to multiple solutions. However, the CMT affordances appreciated by the CoI members were distinctly different with respect to contextual factors involving personal and schooling issues as well as influences by the research culture of the two corresponding teams.

Keywords: Creative mathematical thinking, technology.

INTRODUCTION: CMT AND TECHNOLOGY

Various definitions regarding mathematical creativity have been proposed during the last decades. Poincaré (1948) viewed mathematical creativity as the interplay between a period of conscious and unconscious work, in which any choices in terms of mathematical reasoning and proof are made in the pursuit of elegance and usefulness. Recently, Sternberg and Lubart's (2000) identified mathematical creativity as the ability to predict some 'non-predictable' conclusions that are at the same time useful and applicable. More recently discussion on math creativity has been led towards sorting out whether to approach it in terms of a *product* or a *process* (Shriki, 2010), as a *general ability* (associated with applying analogous problem-solving processes from one field to the other) or as some *domain-specific* skill (exemplified within a particular disciplinary or other activity field and taking into account the logico-deductive procedures already developed in it) (Lev-Zamir & Leikin, 2011). More particularly, the three most prominent strands in the research tradition of math creativity are as follows: the first and most popular is situated in the so-called the 'genius' approach of creativity (Sriraman, 2005); the second, represented by Silver (1997), is based on the claim that mathematical creativity is susceptible to instructional and experiential influences and gives equal emphasis on problem posing as on problem solving, with preponderance on the use of ill-structured and open-ended problems; finally, a more recent but rather under-researched approach is that of 'techno-mathematical literacies', the focus of which is on identifying and addressing mathematical creativity in out-of-school contexts and in out of mathematics (non-disciplinary) situations, such as looking for and applying mathematical concepts and relations in technology-based workplace practices (Noss & Hoyles, 2013).

Only the latter of these approaches tightly addresses the use and role of digital media for CMT. Although often implied, the development of CMT with the use of exploratory and expressive digital media has not often been centrally addressed in providing users with an access to and a potential for creative engagements with mathematical concepts (Healy & Kynigos, 2010). During the last decades several digital tools, applets and authoring systems have appeared designed to foster CMT affording dynamic manipulation, interconnected representations (inc. mathematical formalism), simulations of phenomena and situations embedding mathematical rules, visualisations of data representations and handling of probability. Some of these technological advances have been developed within the frame of approaches with a constructionist, argumentational, inquiry-based, problem-based, experimentation origin, all connected but not centrally matched with creativity. Nevertheless, even though research points to the potential of expressive digital media to foster CMT, the uses of these same media in educational practice at large are conversely frequently instrumented towards contexts of traditional lecturing and demonstration of exercise solutions (Ruthven, 2008). This looks like a paradox situation where digital media are being used very differently with respect to their potential for providing users with access to mathematical ideas hitherto obscure and inaccessible, and at the same time allowing them to creatively engage with experiential constructionist, dialogical and social generation of mathematical meanings, understandings and social norms has long been elaborated (Hoyles & Noss, 2003).

Our paper therefore addresses a real wide-scale problem and it is within that context we attempt to contribute to our understanding of teachers designing of affordances for CMT. No doubt, the clarification of shared understandings of the essence of CMT and the spreading of respective activity in education are slow and non-linearly developing processes. New media affording *collaborative* designs for CMT may provide us with the means to generate socio-technical environments (Fischer, 2011) more conducive to addressing these issues and designing for learning cultures cultivating CMT. This paper studies designers' representations of CMT (in the context of a European project called 'M C Squared') as they became operationalized in the collaborative production of materials with an innovative e-book author aiming to afford CMT (we call it the 'c-book', 'c' for creativity) to the end users. The designer communities have been orchestrated by four research teams so as to ensure the diversity among the members in relation to the disciplinary backgrounds, expertise, history and membership in different communities of practice which are defined in literature as Communities of Interest (CoI) (Fischer, 2011). Four such CoI (English, French, Greek and Spanish) were thus formed in MC2 project. The CoI were put together to include a variety of expertise involving designers and developers of digital resources for math education, publishers of mathematics educational materials, researchers in (and outside) math education or in creativity, teacher educators, school math teachers and students.

Given the diverse approaches to CMT outlined above, and the relative lack of connection to math activity with expressive digital media, the concept remains fuzzy in the literature. So, the aim of research is to illuminate how a shared understanding of CMT can be generated in CoI using technology specially built to afford collaborative design for CMT. Such research may contribute in crafting ways to orchestrate and moderate teacher communities of practice potentially playing a role in spreading the use of expressive media for CMT related activities in classrooms. Our research focus was thus twofold: (a) to illuminate the designers initial representations of CMT in two (of the four) CoI, and (b) to illuminate the process of operationalization of these representations during collaborative designs of such technologies for students which would be done by examining how the CoI members evaluated their product in terms of CMT affordances. In the sections to follow we briefly outline our research method, and then discuss the CMT representations of the two CoI so far revealed by our analyses (the Greek and Spanish respectively) in two ways. Firstly as they were expressed in their responses to two semi-structured questionnaires before they were engaged in the design, and subsequently, as they were manifested in their evaluation of the CMT affordances of their collaboratively produced c-book units. Finally, through a synthetic analysis we aimed to identify common patterns and differences in the ways the two CoI approached the CMT criteria with regards to their task at hand with the c-book technology.

DESCRIPTION OF THE STUDY AND METHODOLOGY

The decision to work with four (here two) CoI was a methodological one for two reasons: The first one was that we aimed to obtain diversity in relation to the expertise of the CoI members within each CoI. The second was that each CoI would correspond to a particular educational context. This decision would contribute to deepening our awareness of the role of the context diversity both by the exercise of de-contextualising our findings and by using our synthetic knowledge to later try to develop methods to re-contextualize generic findings (Lagrange & Kynigos, 2014) by distinguishing between commonalities and differences in the operationalized representations of the members of the two CoI.

In order to identify the CoI members' initial representations of CMT, an exploratory approach was chosen independently by the two research teams, mainly based on the use of questionnaire as the main instrument for data collection. Each research team developed its own questionnaire and followed a different but nevertheless comparable procedure. In the Greek case the questionnaire was administered to the 17 participants in the Greek CoI. It consisted of: (a) open-ended questions aiming to explore the CoI members' personal definition of CMT, and (b) a list of 17 statements concerning the nature and characteristics of CMT, based on a 6-point Likert type scale (ranging from 1=completely disagree to 6=completely agree). The Spanish research team developed a different questionnaire, which was administered to the 17 members of the Spanish CoI. This questionnaire consisted of: (a) a list of 26 statements (which respondents were asked to respond to by using a 5-point Likert scale, ranging from 1=completely disagree to 5=completely agree) concerning the nature of creativity and CMT, the characteristics of creativity in their professional background and the profile of a creative student and a creative math teacher; (b) three open-ended questions to collect features, criteria and examples of tasks and activities that could foster CMT. The qualitative data from the open-ended questions were subjected to thematic analysis (Braun & Clarke, 2006). This is a method for identifying, analysing, and reporting patterns (themes) within data and goes through the following six phases: (i) familiarizing yourself with your data, (ii) generating initial codes, (iii) searching for themes, (iv) reviewing themes, (v) defining and naming themes, and (v) producing the report. Quantitative data from close questions were statistically analysed, calculating, for each item, the median and the Inter-Quartile Range (Mogey, 1999). Then, a configuration of members from each CoI produced one c-book unit each, the '*Windmills*' [1] c-book unit (jointly created by 7 members of the Greek CoI), and the '*Viral behaviour of the Social Networks*' [2] (designed by 8 members of the Spanish CoI). After completing these c-book units, the two CoI were asked to evaluate the CMT affordances of their c-book units on the basis of specific criteria previously defined by them. Responses from the CoI were subjected to thematic analysis and the criteria identified were organized according to whether they (a) were aligned with established criteria already suggested in the literature, (b) were specific to the CoI, (c) were shared between the two CoI, and (d) were in accordance to the two CoI initial CMT representations. Finally, comparative analysis was employed to trace similarities between the criteria proposed by the two CoI.

INITIAL REPRESENTATIONS OF CMT IN THE TWO COI

The analysis of the data gathered from the Greek CoI responses to the open-ended question asking them to provide a definition of CMT revealed a set of themes ascertaining that the participants conceptualised CMT both in terms of *process* and *product*.

The first theme matched CMT with the 'construction' of either math ideas or some concrete mathematical 'objects'. This is in line with a 'constructionist' approach to creativity giving emphasis to the learners' creative expression and learning through the active exploration, modification and creation of digital artefacts (Daskolia & Kynigos, 2012).The next two themes that emerged are in accordance to what literature identifies as the criteria of novelty/originality (Liljedahl & Sriraman, 2006) and usability/applicability (Stenberg & Lubart, 2000). The former relates CMT to 'mathematical productions' that are new/unusual, and/or new or unexpected ways of applying mathematical knowledge in posing and solving mathematical problems. The latter was perceived by the Greek CoI as the purposeful combination of math knowledge from different math domains or with knowledge from other scientific areas. Some other themes identified in the Greek CoI representations of CMT were those pertaining to fluency, flexibility and imagination. The literature views all three of them as characteristics of a creative mathematical process (Silver, 1997; Leikin, 2009), interconnected but not necessarily all present at the same time (Baer, 1993).

The analysis of the close questions showed that almost all Greek CoI members seemed to agree that mathematical creativity entailed that is an ability which can be fostered through interaction with other people in a collaborative context (*Mdn=6, IQR=1*) and within a milieu which is rich in many alternative –and even contradictory- ideas (*Mdn=6, IQR=1*), which allows openness to other disciplinary fields (*Mdn=6, IQR=1*), and includes problems inspired from real life (*Mdn=6, IQR=0.25*). Most Greek CoI members agreed that CMT has to be based on a deep and well-rooted mathematical background, and that it can emerge from the people's ability (a) to use many, different and unusual ways to solve a problem (*Mdn=5, IQR=0.25*), (b) involving many and diverse mathematical representations for approaching a math problem (*Mdn=5, IQR=1.5*).

In the case of the Spanish CoI, thematic analysis was also employed for the analysis of the data from the open-ended questions. The analysis revealed the key traits which could trigger CMT in students: a) allowing for multiplicity in the approaches and techniques to resolve questions (16 respondents out of 17); b) promoting multiple representations of a particular mathematical concept (16 / 17); c) engaging students in math problem situations close to their reality (13 / 17); d) situating math problems in interdisciplinary contexts, by combining math knowledge with other disciplines and showing its functionality in other domains (13 / 17); and e) including communication tasks within the activities to share students proposals and opinions (10 / 17).

Concerning the nature and characteristics of CMT, most Spanish CoI members consider creativity being a quality that can be developed through instruction (*Mdn=4, IQR=1*) and that interaction with people with different perspectives can enrich the creative process (*Mdn=5, IQR=1*). Most of them consider themselves as creative professionals to a great extent (*Mdn=4, IQR=0*), and acknowledged that mathematics help promoting creativity in other disciplines (*Mdn=4, IQR=1*). In describing a creative student, they emphasised as requisites the ability to: (a) formulate questions and initiate investigations (*Mdn=4.5, IQR=1*); and (b) find different ways to solve problems combining different tools and representations (*Mdn=4.5, IQR=1*). The Spanish CoI members claimed that, in order to foster CMT, the teacher has an essential role, by holding a deep mathematical background (*Mdn=5, IQR=1*), and by encouraging the advent of diverse students' responses when approaching the mathematical questions (*Mdn=4, IQR=1*).

Comparing the two cases it seems that both CoI shared several criteria, which the literature identifies as closely related to CMT. To mention some: the belief that CMT can be fostered in the classroom, through appropriate education (Silver, 1997), the recognition that the interaction between the learning actors is important (Leikin, 2009) and the connection of creativity with mathematics (Silver, 1997). The promotion of CMT is understood through tasks of an exploratory nature (Mann, 2006), through open problems amenable to multiple solutions (Lev-Zamir & Leikin, 2011), through situations that demand the combination of various tools and/or representations, or through interdisciplinary tasks (Perry-Smith & Shalley, 2003).

EXTRACTING THE COI CRITERIA OF CMT

The CoIs' initial representations of CMT allowed researchers to build a shared understanding and 'vocabulary' on how to address CMT within their CoI, which helped them reflect on and develop their own criteria for assessing the c-book units' CMT potential impact to prospective students. The two CoI have designed and produced a series of c-book units until now. However, from a research point of view we were interested in identifying whether and how these CMT representations were employed by the two CoI immediately after they had completed their first c-book unit. In the following paragraph, we offer a short description of these two first c-book units, namely 'Windmills' and 'Viral Behaviour of Social Networks'.

The main idea of 'Windmills' was to challenge students to explore, identify and use the mathematical concepts underlying the construction and operation of Greek windmills, an integral part of the Greek islands' scenery, quite familiar to the students. The CoI intention was to design a c-book unit that would invite students to foster 'unexpected' mathematical ideas, surprising even to the initial designers of the activities. The construction of the c-book unit was initiated with the CoI members developing and exchanging through CoICode (the c-book author collaboration tool), Turtleworlds (a Logo-based Software), Geogebra (Dynamic Geometry Software) and DME Draw3D widget [3] instances (3D grid using cubes as building blocks). The rationale was to start addressing simpler and gradually move to more complex mathematical concepts. This 'low threshold – high ceiling' rationale adhered to the idea of making the c-book unit appropriate for students within a large range of school grades (lower to higher secondary). The first four pages included activities with Turtleworlds targeting the construction of geometrical figures – parts of a windmill (triangles, parallelograms, regular polygons, solid shapes) and use them to create a windmill. The following pages used GeoGebra to engage students in exploring the operation of ready-made models of windmills and identify the underlying mathematical concepts (linear functions, direct proportional amounts, multi-branch functions, periodic functions, co-variation of geometric magnitudes). Finally, students would have to repair a deserted windmill to explore geometric figures.

The Spanish c-book unit focused on fitting mathematical tools and models to describe and understand the 'Viral Behaviour of Social Networks'. Mathematical modelling was thought central to allow students to: a) formulate assumptions on different phenomena related to social network users, b) use mathematical tools to analyse relations and patterns on real data, c) look for, fit and test mathematical models to forecast social networks behaviour, d) use math (and its models) to obtain responses about reality, and e) be able, if necessary, to reformulate assumptions and models. The CoI wished to put forth an interdisciplinary approach where math (mainly arithmetic and pre-functional modelling) would provide tools for analysing social phenomena. The c-book unit consists of 3 parts: The *first part* focuses on introducing students to a sequence of questions about how the number of friends evolves depending on the degree of friendship, in order to explore exponential properties acting under social networks. The *second part* presents the 'theory of the six degree of separation', by asking students to estimate the number of friends a teenager can have and, then, forecast how this evolves depending on the degree of friendship. Finally, the *third part* allows students to work on their own data by asking them to search their friends and connections in Facebook and estimate up to what degree of friendship they are connected with any other person in the world. The c-book unit was developed in 14 pages and includes widgets from 3 different widget factories: GeoGebra, DME (probability tree, answers box, tables, etc.) and a special Cinderella widget to visualize and compare graphs of points using linear and algorithmic scale.

After completing the two c-book units, the CoI members were invited to evaluate the potential of the units as educational resources fostering users' CMT. Each research team conducted a separate analysis of the data gathered from their CoI evaluation. This analysis examined whether the criteria used by each CoI were in alignment with their initial CMT representations, with the criteria identified in the literature review, and with the educational traditions of the specific CoI. A comparative analysis between the two cases brought evidence about commonalities and differences between the two CoI. The findings of this analysis are as follow:

a) *A focus on exploring 'real' problems and questions*: Both CoI emphasised the use of real-life situations (close to students' reality) in their c-book units. This is recognized as a characteristic of mathematical creativity and many mathematicians describe it as an invaluable aspect of their craft (Sriraman, 2005). The same criterion was traced in the initial CMT representations of both CoI (a, c, d [4]).

b) *Promote openness, exploration, and diversity in the approach taken:* According to their initial representations the two CoI appreciated the fact that the activities included in the c-book units were based on open questions allowing the students to suggest their own answers. Silver (1997) suggests that such open questions encourage the development of students' creative fluency, associating fluency with exploration as a way of thinking. On the first hand, there is an explorative nature in the questions included in both c-book units. The students are prompted to explore a problematic situation using different mathematical tools and also including simulation of different mathematical models. On the second hand, both c-book units include specific widgets to collect the diversity of students' proposals, in a more open format as windows to write down their answers to be collected or as interactive widgets. For instance, the Turtleworlds widget allows students to build and work with their windmill construction with different blade's forms; the Cinderella widget facilitates that each user can work with their own Facebook data, combining the point table with the graphical representation in different scales (a, c, d).

c) *Enable multiplicity of mathematical approaches/ representations/techniques/ solutions:* According to both CoI, one of the strongest didactical qualities of the c-book units was the one of multiplicity. This refers to the case of embedded activities that promote multiple solutions for a problem or multiple paths toward the solution of a problem (Leikin, 2009). The technology involved in the two c-book units facilitates the students to work with, and combine, different representations of mathematical concepts. One example might be the variety of numerical and graphical representations (trees, point graphs, etc,) of geometrical sequences (a, c, d).

d) *Promote inter/intra-disciplinarity:* According to Perry-Smith and Shalley (2003), a person's exposition to diverse contexts and functional areas may lead to the production of different and unusual ideas. Such manifestation is an indication of novelty/originality, which is considered an inherent characteristic of CMT. The Greek c-book unit deals with mathematics through some pure engineering and environmental issues, such as the preservation of old windmills, the use of alternative energy sources, etc. The Spanish c-book unit connects mathematics with social and technology issues such as the use of Facebook. Both c-book units combine a variety of mathematical topics belonging to different mathematical domains. 'Windmills' constructions invite students to apply knowledge from trigonometry (angles, construction of triangles, etc), functions, coordinates, and graphs, whereas the 'Social Networks' promotes the construction of models based on exponential and logarithmic properties, geometric sequences, and combines diversity of representations: probability trees, point tables and graphs with ordinary and logarithmic scale (a, c, d).

e) *Promote a progressive modelling process:* Mathematical modelling penetrates the whole activity in the Spanish c-book unit. The c-book unit starts with an initial generating question that was broken into some derived questions placed along the unit (and complemented with the most appropriate widget instances). Each of its three phases leads to consider different mathematical models (more complex at each step) that appears from the analysis of real data about social networks, at the same time models evolve thanks to its evaluation and contrast with reality (a, b, d).

f) *Involve a constructionist aspect:* In the case of the Greek c-book unit the students are invited to create their own windmill or to complete half-constructed ones. This constructionist aspect is very much based on the previous experience and educational tradition of the Greek CoI members. All of them were involved in two wide-scale initiatives of the Ministry of Education in Greece. In the first, the aim was to expose mathematics teachers (amongst others) to constructionist epistemology, technologies and activity designs. The second project concerned the digital enhancement of the traditional textbooks which was also penetrated by the flavour of constructionism (a, b, d).

CONCLUSIONS

The study was carried out in the context of a growing realisation that large scale use of digital media in educational practice is widely dis-aligned from CMT affordances. Understanding and promoting CMT representations in designer communities has had a dual purpose of suggesting a strategy to spread CMT cultures and illuminating our own understanding of the fuzzy notion of how CMT is represented amongst designers. We thus tried to identify some initial CMT representations amongst diverse designers and then to illuminate how these representations were operationalized in the process of collaborative design. Both CoI appreciated the potentiality for the c-book units to foster CMT in students appreciating the potential for integrating real-life problems that are open and amenable to exploration, multiple solutions and the combination of various disciplines and/or various mathematical topics. But equally important were the operationalization of representations of CMT linked to a specific context. The Greek CoI associated the chance to foster students' CMT with the ability of the c-book technology to support constructionist activities. The Spanish CoI made a corresponding association of this technology with its ability to support a progressive modelling process.

ACKNOWLEDGMENT

The research leading to these results has received funding from the European Union Seventh Framework Programme (FP7/2007–2013) under grant agreement n° 610467 – project "M C Squared", http://mc2-project.eu. This publication reflects only the authors' views and Union is not liable for any use that may be made of the information contained therein. The c-book technology is based on the widely used Freudenthal Institute's DME portal and is being developed by a consortium of nine partner organisations, led by CTI & Press 'Diophantus'.

Formalising functional dependencies: The potential of technology

Giorgos Psycharis

University of Athens, Department of Mathematics, Athens, Greece, gpsych@math.uoa.gr

This paper proposes "formalising functional dependencies" as an approach to address critical aspects of the potential of digital technologies for the teaching and learning of functions. This approach focuses on the role of the available tools in supporting students' transition from experiencing dependencies in terms of non-algebraic digital representations to expressing these dependencies formally. To illustrate the approach, data from two studies based on the use of two distinct computational systems are analysed. Key aspects of their potential include: work with dependencies at the level of magnitudes, specially designed functionalities and dynamic interplay between symbolic and non-symbolic representations of functions.

Keywords: Functions, dependency, formalism, digital technologies.

INTRODUCTION

The notion of function occupies a central position in school mathematics curricula but it constitutes a rather difficult topic for many students. Evidence identified by research concerns issues such as students' difficulties in understanding function as covariation and dealing with algebraic symbolism (Kieran, 2007). The development of new modes of representation within specially designed technological tools that allow considering functional dependencies through the use of non-standard representations (including non-algebraic ones) has generated further interest as regards their potential to deal with the above mentioned difficulties. One distinct feature of these tools is that they are designed to make the symbolic aspect of function more accessible and meaningful to students, especially through multiple linked representations including some sort of combination of visual or geometric representations (e.g., dynamic geometry) and algebraic multirepresentation, possibly including Computer Algebra Systems (CAS) or other symbolic forms (e.g., algebraic-like formalism) (Mackrell, 2011). The interactive and dynamic character of the corresponding digital representations have brought to the fore the need to acknowledge both the transformative potential of the corresponding technologies and the opportunities provided for meaning generation. This need was reinforced by the fact that such systems encourage different levels of interplay between symbolic and non-symbolic representations (e.g., direct manipulation of mathematical objects) and different kinds of algebraic expression that can be aligned or not with standard mathematical notation. In this study, I am particularly sensible to the possibility offered by particular computational environments to students to make sense of function through modelling dependencies in a non-algebraic/symbolic (e.g., geometrical, iconic) setting before passing to formal expressions of these dependencies and to mathematical functions. In this process, there is always a transition from experiencing dependencies through the use of non-algebraic/symbolic digital representations to recognising which of these dependencies constitute functional ones and expressing them formally using the available symbolic representational forms. This transition is far from trivial for students. Apart from the novelty of the used representations, well-known problems that students face with functions and algebra are also brought to the fore (Kynigos et al., 2010). Thus, the potential of the corresponding technologies needs to be addressed. This is the general goal of this paper. Based on the integrated framework developed by Lagrange and Psycharis (2014), I adopt a similar approach – I call it *formalising functional dependencies* – to address such potential.

FORMALISING FUNCTIONAL DEPENDENCIES

The approach formalising functional dependencies is developed around the need to address the following issues as regards the students' transition from non-symbolic/algebraic to symbolic/algebraic representations of function and the coordination between them in technology enhanced mathematics: (1) the role of the available tools in supporting different levels of students' work with dependencies (e.g., modelling, exploration), (2) the students' activity to 'translate' the modelled functional relations in symbolic language and to conceptualise the connections between different representations of function, and (3) critical aspects of the students' difficulties with functions (i.e., covariation, symbolism). Below, I present briefly the three parts of the theoretical work that underlie these issues and constitute the approach.

Levels of students' work with dependencies. Lagrange and Artigue (2009) developed a conceptual framework for functions and algebra in order to address students' work with dependencies. Taking an epistemological point of view, they situated students' activities for approaching functions at three levels: (1) activity in a physical system (e.g., dynamic geometry, a simulation): students can experience dependencies sensually in a physical system through observation of mutual variations of objects; (2) activity on magnitudes: the idea of function is linked to dependencies between magnitudes which is expected to support students' consideration of functions as models of physical dependencies; (3) activity on mathematical functions: students work with mathematical functions of one real variable, with formulas, graphs, tables and other possible algebraic representations.

Situated abstraction. Noss and Hoyles (1996) introduced the notion of situated abstraction to address abstraction within computational media as a meaning generation process in which mathematical meanings are expressed as invariant relationships, but yet remain tied up within the conceptual web of resources provided by the available computational tool. In this perspective, a 'situated abstraction' approach to students' conceptualisation of function within a particular computer-based setting involves meaning generation evident in the concretion of generalized relationships by students through the use of the available tools and structures.

Function as co-variation and the role of symbolism. The essence of a co-variation view of function is related to the understanding of the manner in which dependent and independent variables change as well as the coordination between these changes (Thompson, 1994). However, this dynamic conception of simultaneously variation between magnitudes is rather difficult for the students especially when mathematical symbolism is involved. Research has been showing rather conclusively that the idea of independent variable, the algebraic expression of functions and its connection to other representations constitute obstacles for many students even for those beginning to study more advanced mathematics (Kieran, 2007).

In order to concretize the approach, I consider here two computational systems, both dealing with functions through innovative representations and functionalities, but different in many other aspects. One is *eXpresser*, a microworld designed to support 11–14 year-old students in their reasoning and problem-solving of generalisation tasks (Noss et al., 2009). It provides an 'algebraic' language, which involves the use of numbers and variables, with the aim to support students to construct relationships between patterns. The other system is *Casyopée* (Lagrange, 2010). It offers a dynamic geometry window incorporating representations of measures and of their covariation connected to a symbolic environment designed to support students' work on mathematical functions. Both systems offer opportunities for students to understand key actions in the process of modelling a dependency into a functional relation. However, eXpresser uses non-standard 'symbolic' representations while Casyopée's symbolic forms are consistent with current notations at secondary level. Next, I adopt the approach formalising functional dependencies to analyse data of eXpresser's and Casyopée's use in two respective studies so as to make sense of their potentialities for functional meaning making.

FUNCTIONAL RELATIONS IN FIGURAL PATTERN TASKS

eXpresser. The microworld affords the creation of coloured patterns in the construction area (Figure 1) by repeating a building block of several tiles ('unit of repeat'). The students can select tiles of different colours to construct the unit of repeat and then to define a pattern by specifying the number of repetitions and the appropriate number of coloured tiles in its property window (e.g., Figure 4). The number of coloured tiles can be represented iconically through expressions involving numbers that appear tied in a grey frame and 'unlocked numbers' – i.e. variables – and appear tied in a pink frame. A variable can be defined through a pop-up menu by 'unlocking' a particular number corresponding to an attribute of a construction (e.g., the number of red tiles, the number of repetitions) and provides a representation of an independent variable and its current value. Variables can be copied, deleted or used in operations (e.g., addition). Thus, through the use of variables, students can create relationships between two patterns of different colours based on dependencies (e.g., between the numbers of tiles of different colours). A pattern is shown dynamically (i.e., animated) by pressing the button Play (Figure 1). Then, the microworld picks random values for every variable and the model is shown dynamically in the construction area. Thus, students have the opportunity to see how their construction would look if the values of the independent variables of their current construction had different values.

It is important to mention that a model is always coloured only if the same independent variable has been used to build appropriate general expressions representing the total number of tiles for each one of the patterns used for the construction of the model. In different cases, the unfolded model/pattern appears to be distorted ('messed-up') and it is not coloured (e.g., see Figure 4b, c). Another feature of eXpresser is that of 'General Model' window (Figure 1): when the students animate a pattern this window shows different instances of the construction for different values of the various parameters in relation to the values assigned by the system in the representation appearing in the construction area. In order to colour their pattern in the 'General Model', the students have to build a general expression (i.e., the *Model Rule*, Figure 1) that always gives the total number of all tiles in the model (i.e., not just any pattern).

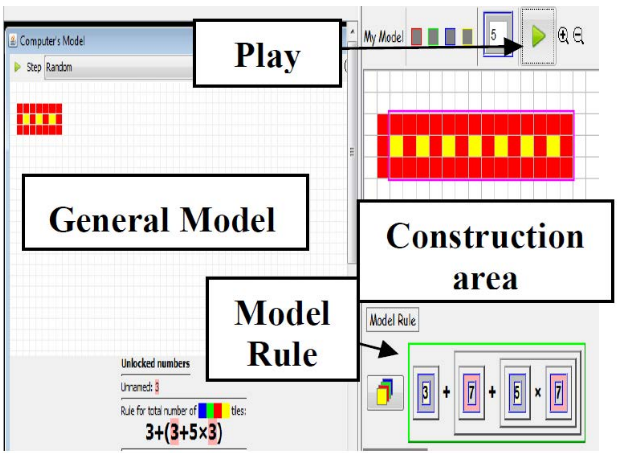

Figure 1: A pattern in eXpresser

The experiment. In the study with eXpresser (Zoupa, 2013), three case study groups of 13-year-old students (6 sessions for each group) were asked to construct and validate patterns through general expressions that underpin them. Since the students had not had any experience with patterns in their school lessons, the aim was to investigate if and how the microworld could help them to understand dependencies and express them using the system's structures and symbolic language. The data consisted of screen capture software files, files of students' work and video recordings. The data was analysed under a data grounded approach. Through the analysis of students' interaction with the available tools, episodes were selected to highlight the evolution of meaning generation for function.

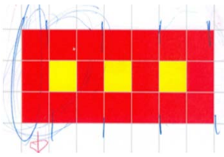

Figure 2

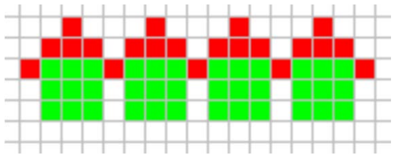

Figure 3

After an initial familiarization with eXpresser, the students were engaged in constructing the patterns shown in Figure 2 and Figure 3 consecutively. They had to allocate the correct number of tiles of each colour that were needed for the construction and then to create appropriate general relationships by using the same independent variable in the task. Next, I describe one group of students' work in four phases and corresponding steps that took place in the second and the third session.

Phase 1: Exploring the role of numbers and variables

Task: Construction of the pattern in Figure 2. (a) Constructing two building blocks (patterns): the first one constituted by the first column (3 red tiles) and the second one constituted by the second and the third column (6 tiles: 5 red and 1 yellow). (b) Considering the first pattern as specific. (c) Constructing the second pattern specifically for three repetitions (Fig 4a). (d) Unlocking the number of repetitions in the second pattern but keeping constant the numbers of red and yellow tiles. Feedback showing the construction was not coloured for different numbers of repetition in the construction area (Figure 4b). (e) Unlocking the number of red and yellow tiles without linking these (new) variables to the variable defined in the previous

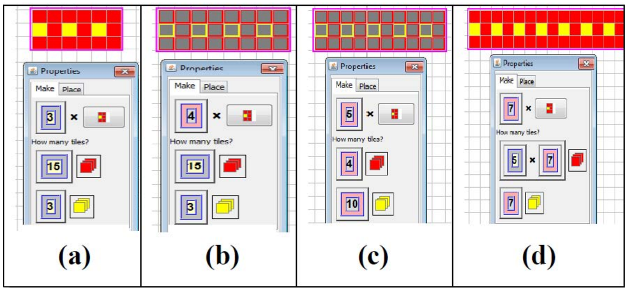

Figure 4: The properties window and the visual outcome (second pattern)

step. Feedback showing that the construction was not coloured in the construction area (Figure 4c).

Phase 2: Building functional expressions within a pattern

Task: Construction of the pattern in Figure 2. (a) Recognising the number of repetitions of the second pattern as an independent variable in the task. (b) Using this variable to express the number or red and yellow tiles (i.e., the number of red tiles is the same as the number of repetitions of the second pattern, while the number of yellow tiles is five times the number of repetitions of the second pattern). Inserting these expressions in the properties window through the choice 'replace' (Figure 4d). (c) Animating the model dynamically in the construction area. Feedback confirming the correct animation of it (Figure 4d).

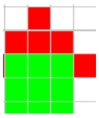

Figure 5a

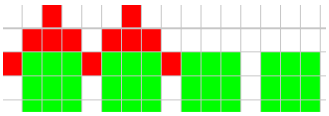

Figure 5b

Phase 3: Building functional expressions between patterns

Task: Construction of the pattern in Figure 3. (a) Constructing three building blocks (patterns): the first one constituted by the one red tile (i.e. the red tile on the left part of the first house), the second one for the roof with 5 red tiles and the third one for the green square with 9 green tiles (Figure 5a). (b) Considering the first pattern as specific and constructing the second and the third ones as general by unlocking the numbers of repetitions and thus creating one independent variable in each one of them. (c) Running the models dynamically. Feedback showing that the construction was 'messed-up' due to fact that the two variables representing the number of repetitions in each pattern changed according to different (randomly chosen) values (Figure 5b). Recognising that the two variables had to take the same value. (d) Linking the two patterns by replacing the one independent variable with the other through dragging and the choice 'replace'. (e) Building appropriate functional expressions for the numbers of green and red tiles in the two patterns.

Phase 4: Expressing the general rule of the total number of tiles in the model

Task: Construction of the pattern in Figure 3. (a) Constructing a general expression giving the total number of all tiles (i.e. not just any pattern) in the Model Rule window through the use of the only independent variable (Figure 6 shows an immediate instantiation of this expression for three repetitions of the model). (b) Expressing the general rule through traditional algebraic notation with paper-and-pencil (i.e., 5x+9x+1).

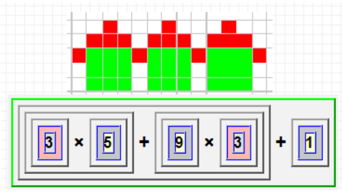

Figure 6

As regards the levels of dependencies, the physical system in eXpresser involves the dynamic reproduction of patterns. At the level of magnitudes, numbers of tiles and numbers of repetitions are involved. These magnitudes are concretized in the system as numbers in grey frames and variables in pink frames showing current instances of their values. I note that the dynamic change of the values (assigned automatically at random) to one variable is shown inside the pink frame of a variable when the corresponding pattern unfolds dynamically in the construction area. Thus, measures are 'encapsulated' within the corresponding magnitudes. As regards the notion of function, the independent variable is the number of repetitions of a building block created by the students while the dependent variable is the total number of tiles (of each colour). In this linear function, the input is the number of repetitions and the output the animated model. In all phases, while exploring the role of numbers and variables and experimenting with building different symbolic forms of general relations, the students considered together the physical system and the dependency between magnitudes. Thus, they worked with dependency and co-variation together at the level of magnitudes and at the level of magnitudes represented through variables.

From a situated abstraction point of view, the domains of students' meaning generation here involve: (a) making sense of the structure of the requested models in terms of specific and general patterns, (b) conceptualising the construction of appropriate building blocks, (c) identifying the independent and the dependent variables, and (d) conceptualising the formulation of functional relations between these variables. Building appropriate functional relations indicated the students' transition to the world of functions as it is embedded in the structures of the system.

As regards students' conceptualisation of covariation and symbolism, the role of feedback was critical. eXpresser provided a dynamic representation of covariation: animating the pattern had the effect of the construction dynamically changing as the values of the respective parameters changed automatically. In this process, 'messing-up' and 'correct colouring' challenged students to create and undertake changes in the symbolic form of the corresponding relations and at the same time to progress in their conceptualisation of the involved covariations as functions.

LINKING GEOMETRICAL DEPENDENCIES AND FUNCTIONS

Casyopée deals with various representations of functions consistent with school mathematics and curriculum. It provides a symbolic window with three registers: numeric, graphic and symbolic (Figure 8). Casyopée also includes a dynamic geometry window linked to the symbolic window. The geometric window allows defining independent magnitudes (related to free points) and also dependent ones (i.e., through the use of the "geometric calculation" functionality, see Figure 7 on the right) involving distances (e.g., lengths), *x*-coordinates or *y*-coordinates. The two windows are interconnected: objects defined in one window can be used in the other. Couples of magnitudes that are in functional dependency can be exported to the symbolic window and the system automatically can define a function. This function can be further treated by the students with all the available tools. This functionality –called "automatic modelling"– is expected to help students in modelling dependencies.

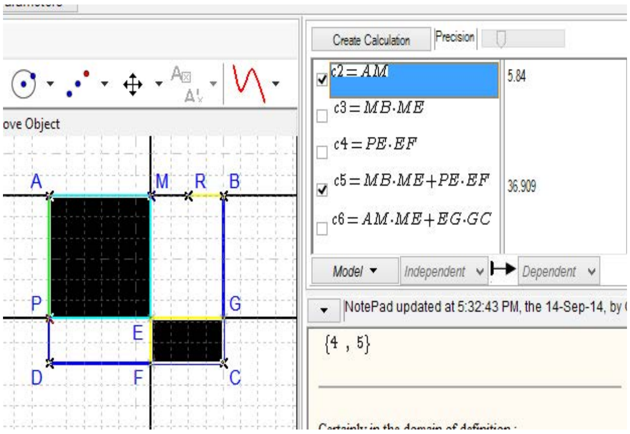

Figure 7

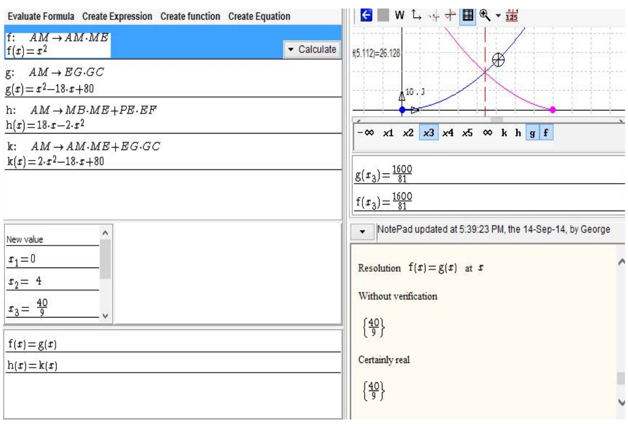
The experiment. In the study with Casyopée (Kafetzopoulos, 2014), three case study groups of 17 year-old students (six sessions for each group) were engaged in solving optimization problems through modelling geometrical dependencies. The aim of the study was to investigate how a computational medium linking CAS and dynamic geometry could help students make sense of function as covariation through: (a) conceptualising dependencies in geometrical situations and (b) modelling them as functions in order to solve the given tasks. Here I will report on students' work in the following task: "The owner of a rectangular estate *ABCD* (*AB*=10m, *AD*=8m) wants to design two gardens and two buildings inside it. In the given geometrical figure (Figure 7), we consider *A*(0;8), *B*(10;8), *C*(10;0), *D*(0;0). *M* is a point on *AR* (*AR*=8m) and *P* a point on *AD* so as *AMEP* to be a square. The figure *EGCF* is a rectangle. The gardens will cover the shaded part of the figure and the two buildings the rest of it. By moving *M* between *A* and *R*, different shapes of the gardens are designed. (1) Is there a position of *M* in *AR* for which the two gardens have the same area? (2) Is there a position of *M* in which the two gardens will have the same area as the two buildings? Justify by: (a) exploring the dynamic figure, (b) using the software to create functions modeling these questions, and (c) using the available tools to find the solutions". Since the main focus of the task was on students' conceptualization of function as covariation, the figure was already prepared for them. The students had to: (a) make sense of *M* as the only free point in the figure, (b) recognize *AM* as an independent variable and use it to define functions of areas, (c) work with different representations of functions. Next, I describe the work of one group of students in four phases and corresponding steps that took place in the last two sessions. The data and method of analysis were similar to the ones described in the experiment with eXpresser.

Phase 1: Exploring dependencies in the geometrical model. (a) Experimenting with the dynamic aspects of the figure by dragging points. (b) Recognising *M* as the only free point in the model. (b) Defining measures for different magnitudes (e.g., the areas of *AMEP* and *EGCF* and their sum) as geometrical calculations (Figure 7, right). (c) Observing covariation at a perceptual level (i.e. how dragging *M* changes the shapes of the shaded parts) and numerically (i.e. through the changes in the values of the corresponding magnitudes). *Phase 2: Identifying independent and dependent variables.* (a) Choosing an independent variable after recognizing dependencies between co-varying magnitudes (e.g., *AM* for the area of *AMEP*). (b) Using the same independent variable for the area of *EGCF* after checking that dragging *M* changes the area *EGCF*. (c) Choosing *AM* as an independent variable for the sum of areas (i.e. *AMEP+EGCF*, *MBGE+PEFD*). *Phase 3: Working with algebraic functions through automatic modelling.* (a) Exporting functions to obtain formulas for four functions (two for question 1 and two for question 2, Figure 8, left) through automatic modeling. (b) Working further on the algebraic functions to solve the problems, i.e. making equal two functions and solve. Identifying the position of M in question 1 (AM=40/9) and question 2 (AM=4 or 5). *Phase 4: Linking different representations of algebraic functions.* (a) Interpreting the answers to questions 1 and 2 given through the equality of functions by coordinating different representations, e.g., linking table, geometry and graphics, focusing on the common point of the two graphs, changing the step in the corresponding tables for more precise values (Figure 9). (b) Conceptualizing the addition of two already defined functions as a new function (e.g., *AM→AM•ME+EG•GC*).

As regards the levels of dependencies, the physical system in Casyopée is the dynamic geometry window which provides the context for modelling the problem in the geometrical setting and opportunities for creating and animating geometrical objects. At the level of magnitudes, the students can use the geometric calculation functionality to construct magnitudes in the form of symbolic objects that can be dependent to the geometrical situation (e.g., expressions of areas). These magnitudes have a dual status in the system since they are concretized symbolically as parameters (*c0*, *c1*, etc.) and numerically as measures whose values can change dynamically (e.g., through dynamic manipulation of the dependent geometrical objects). Thus, the students can be engaged in exploring covariation of pairs of magnitudes, modeling functional dependencies algebraically (through automatic modeling) and working further with mathematical functions. Thus, the combined use of geometric calculation and automatic modeling supports students' transition from the world of measures to the world of mathematical functions through work with magnitudes. This transition is evident in students' activities described above: work in the physical system (phase 1a) was followed by work with magnitudes (e.g., definition of geometric calculations for areas) and observation of covariations (phases 1b, 1c), and then further extended to include identification of independent variable (phase 2), definition of functions through automatic modeling (phase 3) and problem solving by linking different representations of functions (phase 4).

From a situated abstraction perspective, the layers of meanings for function here involve: (a) making



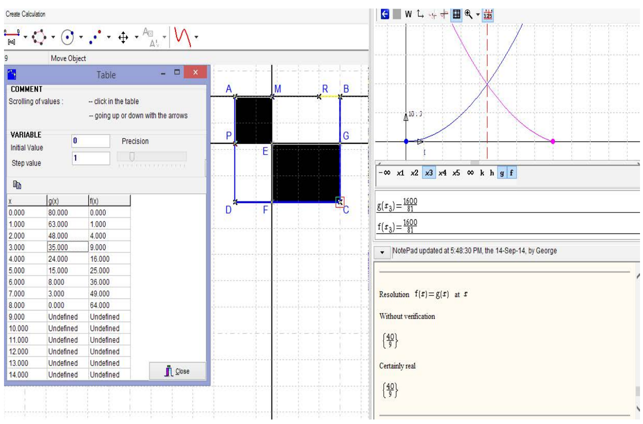


Figure 9

sense of the dependency between *M* and the areas influenced by its move, (b) conceptualizing the creation of relevant geometric calculations, (c) conceptualizing the idea of independent variable representing a geometrical object and using it to express functional dependencies through automatic modelling, (d) abstracting these dependencies at the algebraic level and use the corresponding functions to solve the requested problems.

As regards the symbolic aspect of function, the formulas taken in Casyopée seemed to have legitimized the use of all the available representations of functions by the students. Although the students were able to explain the provided formulas of functions, they chose to work with these formulas at an operational level for solving the given tasks (i.e. through the equality of functions). In doing so, they were engaged in linking different representations of functions.

CONCLUSION

As regards the levels of dependencies, the analysis revealed that eXpresser and Casyopée favour students' work with dependencies at the level of magnitudes as a critical part of their passage to formalisation. In particular, the analysis indicated the importance of working with magnitudes as a bridge between sensual experience of dependencies and symbolic expression of functional relations. In eXpresser, dependencies between magnitudes and visual representation of their covariation (i.e., through dynamic reproduction of patterns for random values) seemed to support the students' articulation of general relations and favour a structural understanding of patterns. Dependencies of this kind in Casyopée seemed to facilitate the students' transition from dynamic geometry and the world of measures to the world of mathematical functions. The analysis of the students' activity according to situated abstraction helped us to capture the progression of their conceptualization of functional dependencies taking into account the role of particular functionalities (e.g., automatic modelling) and feedback (e.g., messing-up). Experiencing covariation through dynamic interplay between symbolic and non-symbolic representations of functions helped the students to make sense of the role of independent variable and symbolism in expressing functional relations and connecting the formalism embedded in the tools to the formalism of school mathematics. This is an indication that the two systems can be used to address well-known and researched difficulties of students with algebra and functions (e.g., recognising independent variable, articulating functional relations and expressing them symbolically) and promote a meaningful transition to algebraic thinking. Thus, the potential of the two systems can be recognised in the direction of enriching representations of functions with new non-symbolic and symbolic ones and of enlarging students' possibilities to construct functional meaning by making connections between these representations.

Developing future mathematics teachers' ability to identify specific skills needed for work in GeoGebra

Jarmila Robová[1] and Naďa Vondrová[2]

1 Charles University in Prague, Faculty of Mathematics and Physics, Prague, Czech Republic, jarmila.robova@mff.cuni.cz

2 Charles University in Prague, Faculty of Education, Prague, Czech Republic, nada.vondrova@pedf.cuni.cz

Our research aims at some aspects of the teachers' TPACK, namely their ability to identify specific skills needed for work in GeoGebra and to develop these skills in their pupils. Future mathematics teachers were acquainted with specific skills via selected tasks to be solved in GeoGebra. The data consist of the pre-service teachers' written solutions and proposals for teaching with GeoGebra and transcripts of discussions. The data were analysed in a qualitative way. Explicit work with the skills is needed for pre-service teachers to realise their importance for pupils' work in GeoGebra. While their technology knowledge was good, their proposals for teaching were mostly static and provided pupils with step by step directions. Implications for educating future teachers to teach effectively with GeoGebra are given.

Keywords: Dynamic geometry, TPACK, pre-service teachers, GeoGebra skills.

INTRODUCTION

In our work as educators of pre-service teachers, we strive to find ways of developing their knowledge and skills so that they use ICT tools in their future practice productively. The programme for future teachers naturally includes mathematical courses (developing their content knowledge), a technology course (developing their technology knowledge or TK) and a general didactics course (developing their pedagogical knowledge). All these strands should meet in a mathematics education course. In this article, we will report on a part of a design experiment (Cobb et al., 2003) aimed at designing a part of a regular mathematics education course focused on ICT. To meet the time constraint within the course, we decided to explore the merits and limitations of one ICT tool only. We chose GeoGebra (or GG) as it mutually connects different representations of mathematical concepts (geometric, algebraic, tabular, graphic) and can assist pre-service teachers during all their mathematical learning. Two areas of mathematics were selected for investigation; geometry (synthetic and analytic) and, thanks to GG's multi-representational nature, functions.

THEORETICAL FRAMEWORK

To work with ICT tools in mathematics, differences between computer and theoretical mathematics must be observed, i.e., issues caused by the representation of mathematical concepts, operations, objects, etc. on the computer screen. For dynamic geometry software, Laborde (1998) points out a necessity to understand differences between theoretical-geometric and computer-graphic worlds (e.g., the necessity to construct such figures whose properties are preserved when the objects are moved – i.e., robust constructions). Robová (2013) presents what she calls *Specific Skills* for work in GG. For the purpose of this article, we chose only those pertinent to functions: I. making functions visible (on the screen), II. changing visual appearance of graphs, III. interpreting points on objects, IV. interpreting numerical results, V. using dynamic features of GG, VI. using graphic styles. Skills I. to IV. are part of technology content knowledge (TCK) while V. is between TCK and technology pedagogical knowledge (TPK) and VI. is part of TPK .

We suggest that the teachers' awareness of the Specific Skills and their ability to design teaching which takes them into account belong to their technological pedagogical content knowledge (or TPACK).

> [TPACK is] the basis of good teaching with technology and requires an understanding of the representation of concepts using technologies; pedagogical techniques that use technologies in constructive ways to teach content; knowledge of what makes concepts difficult or easy to learn and how technology can help redress some of the problems that students face; knowledge of students' prior knowledge and theories of epistemology; and knowledge of how technologies can be used to build on existing knowledge and to develop new epistemologies or strengthen old ones. (Mishra & Koehler, 2006, p. 1029)

There is a growing body of literature on developing TPACK. For example, Balgalmis, Shafer and Cakiroglu (2013) claim that "focusing on the mathematical concept more than technology and using technology when it is really necessary were the basic criteria for effective technology based lesson" (p. 2534). Bowers and Stephens (2011) suggest that rather than elaborate specific types of knowledge for TPACK, the best we can do is to "engage prospective teachers in technology-enhanced mathematical explorations with the explicit goal of discussing the ways in which technology enabled them to describe relationships among objects on the screen that could not have been developed without the tools employed" (p. 291). They describe a course on the Geometer's Sketchpad; they let pre-service teachers explore the software by solving problems and then they discussed the model of TPACK with them. Sfard's (2008) commognitive perspective of learning is of particular importance here: "*Thinking* is an individualized version of (interpersonal) communicating." (p. 81). Thus, "teaching can be seen as the practice of orchestrating mathematical discourses" and "learning can be seen as the ways in which students engage in these discourses" (Bowers & Stephens, 2011, p. 287).

Abbitt (2011) summarises performance-based TPACK measures which are based on the idea that "by examining the design and planning process, it is possible to assess the knowledge of a preservice teacher in the TPACK domains" (p. 292). To achieve this goal, Harris, Grandgenett and Hofer (2010) developed Technology Integration Assessment Rubric for analysing lesson plans. The rubric is to be used with pre-service teachers during a teacher preparation programme and thus it is specifically useful for us. According to the rubric, the plan is assigned 1 to 4 points in four measures: 'Curriculum Goals & Technologies' (curriculum-based technology use), 'Instructional Strategies & Technologies' (using technology in teaching/learning), 'Technology Selection(s)' (compatibility with curriculum goals and instructional strategies), 'Fit' (content, pedagogy and technology together).

Bowers and Stephens (2011) describe a rubric for assessing the quality of pre-service teachers' teaching plans made after 18 lessons of work with the Geometer's Sketchpad. They determined for each plan:

> the degree to which the student demonstrated TK, TCK, TPK, or TPACK with the assumption that these types of knowledge are additive. [...] If a student demonstrated a good use of the technology to examine a particular content area but did not include any particular presentation affordances, such as use of colour or scripting tools, then he or she was characterized as having knowledge at the level of TCK, but not TPACK. (p. 293)

Both rubrics, slightly modified, were used in our research. Finally, we made use of a Tool Competence Model for symbolic calculators suggested by Weigand (2011) which specifically deals with functions: Static Mode (producing static representations), Dynamic Mode (creating dynamic representations), Multiple Mode (using the ICT tool as a multiple representational tool).

METHODOLOGY

The research questions were the following: (1) Are pre-service teachers with good technology knowledge aware of the Specific Skills? (2) How do pre-service teachers connect their content knowledge, pedagogical content knowledge and technology knowledge to prepare proposals for teaching with the help of GG?

By good technology knowledge, we mean that pre-service teachers were able to work in GG, they could orientate themselves in its workspace, they knew where to find required tools and how to use them. In view with literature, rather than presenting them with ideas of effective use of GG, we prepared *worksheets with tasks* in which they had to use Specific Skills which emerge from the differences between computer and theoretical mathematics. It was hoped that by confronting pre-service teachers with such tasks, the

Specific Skills will be brought to their attention and they will realise their importance for their future pupils, too. Two worksheets concerned geometry and two concerned functions. The first set of worksheets on each topic comprised less demanding tasks, while the second set put the pre-service teachers' in pupils' role (the tasks were mathematically more demanding). There was a space after each task in which any skills needed for its solution in GG should be written.

The *first (pilot) stage* of the design experiment took place in spring 2013 (see Robová & Vondrová, 2014) with 19 future lower and upper secondary mathematics teachers, within their second mathematics education course. One of the results was that pre-service teachers should meet more tasks in which technology fails as they are "forced" to reason mathematically then. If the task leads them towards using technology (the solution via software seems to be obvious), they might forget to check the appropriateness of the solution by mathematical means. Thus, we modified worksheets accordingly. It also transpired that we underestimated the importance of discussing the emerging issues. Thus, two discussion periods were to be organised in the second stage in order to make the Specific Skills more visible for pre-service teachers with the hope that they will use them in their teaching proposals. Finally, the quality of the pre-service teachers' proposals for teaching was not very high. Bowers and Stephens' study (2011) suggests that such proposals should be subject to class discussion and the basis for bringing out pre-service teachers' own metacognitive processes (e.g., by asking them to speak about the development of the proposals). Thus, a written peer review was to be included in the next stage.

Main study

Twenty three future lower and upper secondary mathematics teachers participated in the study. It took place during a mathematics education course taught by the second author (Table 1). In the two discussions, the course teacher asked general questions first "what knowledge was needed in order to solve the tasks" and then chose questions on the basis of the pre-service teachers' reactions. The audiotaped discussions focused on specific skills and on merits and drawbacks of GG. The pre-service teachers' written work was collected. Seven pre-service teachers' work on the screen was captured by Camtasia and saved as a videorecording.

After completing 4 worksheets, the students were to prepare a *Project*, that is, a proposal for teaching with the support of GG. The project was to include tasks which would lead to pupils' autonomous investigation of a topic in GG, solutions to the tasks, GG figures, the goal(s) of activities, pupils' prior mathematics and technology knowledge, their expected problems and a suggestion of their remedy, etc. The pre-service teachers submitted their Projects via a Moodle module Workshop. Afterwards, they were randomly assigned their peers' Projects to evaluate.

This paper only focuses on the part of the study dealing with functions. Worksheet 1 on functions comprised tasks on determining the domain and range of functions, their monotony, zero points and x and y-intercepts. They were quite easy to solve as the aim was to make the pre-service teachers aware of the Specific Skills without having to concentrate on the mathematical aspect too much. Worksheet 2 tasks also referred to the Specific Skills but they were mathematically more demanding. Examples of tasks are given in (Robová & Vondrová, 2014).

Analysis of data

In the analysis of the solutions to worksheet tasks, it was followed (research question 1): the pre-service teachers' TK, content knowledge, the Specific Skills. When in doubt, Camtasia recordings were used to get more information. For the analysis of the pre-service teachers' Projects (research question 2), the modified Harris, Grandgenett and Hofer's (2010) and Bowers and Stephens' (2011) rubrics were used as well as

Weigand's Tool Competence Model. As the tasks were to lead to pupils' autonomous work, we also used the measure of hypothetical pupils' role in gaining new knowledge (from A1 – pupils are given step by step instructions, to A4 – it is up to pupils to decide how they will solve the tasks). The two authors coded the projects independently and discussed their coding until 100% agreement was reached.

Two of Harris, Grandgenett and Hofer's (2010) measures were not used in our coding: 'Curriculum Goals & Technologies' (as all the Projects were aligned with the curriculum) and 'Technology Selection(s)' (GG was prescribed). Instead, we used 'Types of Goals' measure which concern explicitly stated goals: Content Goals (related to specific mathematical topics), Skill Goals (related to the development of some skill), General Competence Goals (outside of mathematics). The two remaining measures were used: 'Instructional strategies and technologies' was coded from I1 (technology use *does not support* instructional strategies) to I4 (*optimally supports*); 'Fit' was coded from F1 (content, instructional strategies and technology *do not fit together* with the instructional plan) to F4 (*fit together strongly*).

While Bowers and Stephens' (2011) pre-service teachers' projects consisted of one sketch, our pre-service teachers proposed several tasks for more than one lesson. Thus, we had to assess what feature prevailed in the Projects. Moreover, we did not fully embrace the authors' assertion that the elements of TPACK are additive (they coded pre-service teachers' projects either TK, or TCK, or TPK, or TPACK), thus introducing a kind of hierarchy which, in our opinion, is not in the original model of TPACK. Unfortunately, the authors do not explain what kinds of projects were coded as TPK and we had to use our own modification. Instead of TPK and TPACK codes, we used TPACK1 and TPACK2. The former means that the pre-service teacher demonstrates an understanding of using technology for more informative, quick and effective teaching of mathematics. Tasks proposed make understanding easier but do not lead to argumentation. The latter means that the pre-service teacher realises the potential of the software for developing mathematical reasoning up to the level of argumentation and proof; it goes beyond what can be observed on the screen. This is, we believe, Bowers and Stephens' code TPACK.

Each Project was peer reviewed in writing by 1 to 3 pre-service teachers. In their analysis, we followed to what extent they commented on the phenomena which we identified as important for TPACK (and used for the analysis of Projects): E1 – a shallow evaluation, a pre-service teacher does not comment on obvious deficiencies or merits of the Project, his/her comments are general; E2 – he/she comments on some aspect only, such as the content; E3 – he/she comments on both positive and negative features, uses most measures (Tables 2 and 3); E4 – expert evaluation.

RESULTS

Research question 1 (pre-service teachers' solutions to worksheet tasks)

All pre-service teachers demonstrated good TK. Some, though, did not connect technology and content knowledge sufficiently. For example, when they did not get a result via predefined tools in GG or when no direct tool is available, they did not use other tools of GG to solve the task but made paper calculations. On the other hand, in some cases TCK was evident; e.g., as for f: $y = \sqrt{3x - x^3}$, GG does not find x-intercepts and some pre-service teachers used a function with the same zero points instead to solve the task: g: $y = 3x - x^3$. In terms of pupils' required skills, the pre-service teachers mostly recorded content knowledge, and some TCK (such as "to input an equation of a function", "to determine intercepts", etc.). They least *commented* on the fact that GG rounds off numbers and thus its numerical results must be critically evaluated (for irrational or periodic numbers).

In terms of the Specific Skills, nearly all participants demonstrated the use of skills I., III. and V. Ten of them failed in skill II. *Input a bounded domain.* The most problematic was skill IV. *Interpret numerical results;* seven pre-service teachers did not record 1,7320 as $\sqrt{3}$, thirteen left 0,33333 instead of 1/3 and sixteen did not recognise $\sqrt{2}/2$ in its decimal expansion (or did not use their mathematical knowledge to solve the task without the help of GG to see the result in the exact form).

The group discussion confirmed the above results. The pre-service teachers were able to solve the tasks and commented on many of the differences between computer and theoretical mathematics as they manifested themselves in the tasks (e.g., the point of discontinuity for f: $y = \frac{x^2 + x - 2}{x - 1}$ is not depicted in the graph). The necessity to recognise decimal expansions of common real numbers was not mentioned and when it was brought out by the teacher in the discussion, it transpired that some pre-service teachers did not use this skill for evaluating results GG produced for them, leaving them in decimal expansions. This corroborates our above analysis.

Research question 2 (pre-service teachers' Projects)

Table 2 shows what Specific Skills the pre-service teachers mentioned (or not) in their Projects. Unsurprisingly, the skill to input the equation of the function was the most frequent one. However, the opposite relation, i.e., the fact that GG can display an equation of the function for a given graph (and when the graph is moved, the equation changes), was only given once and once used but not mentioned. Most pre-service teachers used dynamic features and noted a necessity to work with a slider.

Consistently with the above results, the skill to interpret numerical results was only mentioned once and most alarmingly, in five pre-service teachers' Projects the skill was needed but not demonstrated. Almost half of the pre-service teachers used such functions in their Project where this skill was not needed at all and we cannot say whether it was a chance or intention – they might have realised a possible problem and wanted their pupils to avoid it rather than confront it.

Table 3 shows that the quality of Projects varied. It was not our intention to rank them but to assess as many features as possible. But still, differences between pre-service teachers can be seen. On the one hand, student F3 reached very good evaluations in all measures, her Project was of a high quality. On the other hand, student M4's project was quite poor, he only demonstrated TK and did not make any use of the potential of GG. Let us now look at individual measures.

If a pre-service teacher provided some goals for their Projects, they were only about content, that is, what mathematical knowledge they want to develop. No competence outside of mathematics was mentioned nor a skill such as "to experiment", "to make hypotheses based on the observation of what is happening on the screen", etc. It is quite important as skills like that are stressed in Czech curricular documents. The instructional strategy as proposed in Projects was mostly supported by technology. It concerned pupils' individual work with the teacher helping them. The marks for the measure to which 'content, instructional strategies and GG fit together within the instructional plans' were mostly average. The same can be seen from the sixth column: only a minority of Projects included dynamic features of GG (mostly using sliders for functions – "observe what happens on the screen – how the graph changes – when the slider

Table 2: Specific Skills for tasks in Projects on functions (n = 11)

is moved"). In other words, the proposed tasks could be solved without the software and GG only made their solutions more illustrative and quicker.

Student M4's Project was coded as TK only, he does not seem to grasp the ways technology can support the development of mathematical knowledge. Most of the Projects were rated as TCK which means that the pre-service teachers could use GG productively for developing their own mathematical knowledge but did not concentrate on the ways tools of GeoGebra can support their pupils' learning. No Project included tasks which would lead pupils towards the level of argumentation and proof. Just to compare: in Bowers and Stephens' study (2011) 3 out of 21 pre-service teachers were coded as TPACK and 9 pre-service teachers as TK only.

Even though the pre-service teachers were asked to devise teaching in which pupils will work autonomously, the Projects of about half of them were too instructive. They gave pupils tasks which lead them step by step towards the desired goal and provided them with explicit instructions what they should notice and how to continue work.

The pre-service teachers' peer reviews of the Projects were mostly quite superficial and did not comment on even very obvious drawbacks. In the vast majority, the pre-service teachers evaluated the mathematical content only. Their comments were often general ("the project will contribute to pupils' understanding", "the tasks are well chosen", "the use of GeoGebra is effective"). The Projects of students F3 and M2 were evaluated by us as the best ones in most measures. This was confirmed by the analysis of their reviews of their peers' Projects. They wrote detailed and specific evaluations and commented on most of the measures as given in Tables 2 and 3.

DISCUSSION AND CONCLUSIONS

As in the pilot study stage, we conclude that it is far from straightforward that the pre-service teachers will connect their technology, content and pedagogical knowledge without deliberate support from the educator. The presented study remedied some of the deficiencies of the pilot study. We organised more discussion about the TCK and TPACK aspects and included a peer evaluation process. Still, the quality of the pre-service teachers' Projects did not meet our expectation. A good example is the skill to interpret numerical results produced by GeoGebra. The pre-service teachers solved many problems which required this skill, the skill was emphasised in the whole group discussions and still, some of them did not use this skill when it was required and many did not seem to realise its importance for their future pupils. Some of them might not have good understanding of real numbers and do not see that a decimal number with an infinite expansion can sometimes be written in a precise way as a fraction or square root. More content knowledge is needed.

Table 3: Overview of measures used for analysing Projects (n = 11)

One of the implications of our study is that a good choice of tasks must be accompanied by a more explicit discussion about the features of GG use in teaching (represented, e.g., by the measures in Tables 2 and 3). It can "guide students' own metacognitive processes as they reflect on their learning and development efforts" (Bowers & Stephens, 2011, p. 301). This discussion, however, should be in person. In Bowers and Stephens' (2011) study the worst results were reached by pre-service teachers who chose the completely online version of the course: "This could suggest that these students did learn how to use the program, but did not engage in the discursive practices of using technology to probe either their own, or their future students' thinking in the conceptual ways that were discussed during in-person sessions." (p. 294) Students in the blended course had better results and the best were reached by students in the "in person" course. Thus, the discussion should be organised during and after the work on the worksheets and after writing the Projects, commenting on the peers' Projects and seeing the feedback from the peers. The instructions for the peer evaluation must be specific in order to provide pre-service teachers with more guidance by drawing their attention to measures from Tables 2 and 3. We see the peer review as an important part of the development of TPACK.

Due to the number of participants, the results cannot be generalised. The geometry part of the study awaits the analysis and its results together with the presented results will inform the next round of the design experiment in spring 2015.

Knowledge for teaching mathematics with technology and the search for a suitable viewing window to represent functions

Helena Rocha

Universidade Nova de Lisboa, Faculdade de Ciências e Tecnologia, Lisbon, Portugal, hcr@fct.unl.pt

The usual difficulties of students regarding the choice of an appropriate window when using the graphing calculator in the study of functions and the importance of the teachers' knowledge to overcoming them, led to this study. The main goal was to characterize the way teachers address the viewing window in the classroom, trying to infer aspects of the Knowledge for Teaching Mathematics with Technology that can justify that practice. The conclusions reached point to the importance of a set of specific knowledge where I highlight the knowledge of the students' difficulties, the knowledge of mathematical content necessary to understand the impact of the viewing window on the graphic, and the knowledge of teaching strategies that address both the students' difficulties and the relevant mathematical knowledge.

Keywords: Teacher knowledge, technology, functions, viewing window.

INTRODUCTION

Nowadays it is widely recognized the potential of technology for the teaching and learning of mathematics (Goos & Bennison, 2008). However, some studies point to difficulties on the integration of the technology, suggesting that teacher's knowledge is central in classroom use (Doerr & Zangor, 2000; Hoyles & Lagrange, 2010). One of these difficulties is related to the choice of a suitable viewing window to represent the graphic of a function (Cavanagh, 2006).

This study focuses on the teacher's use of graphing calculators during the study of functions at 10th grade and intends to characterize the teacher's practice in what concerns to the use of the viewing window and to infer from that characterization aspects of the teacher's knowledge that can justify that practice.

KNOWLEDGE FOR TEACHING MATHEMATICS WITH TECHNOLOGY

Shulman's work (1986) constituted a starting point for a whole set of investigations that have sought to characterize the teacher's professional knowledge. In recent years many authors dedicated themselves to this theme, trying to clarify concepts, to propose new characterizations and, in some cases, to give a special attention to technology. A look at those characterizations allows the identification of a set of domains that, with greater or lesser emphasis, appear to be consensual: Mathematics, Teaching and Learning, Technology, and Curriculum. These are the base domains of Knowledge for Teaching Mathematics with Technology (KTMT). Curriculum is however a domain that differs from the others in the sense that it is conceptualized in a transversal way, and therefore influential over all the others.

In addition to knowledge base domains, this model particularly values knowledge developed at the confluence of more than one domain. This importance given to a knowledge that goes beyond a particular domain is somehow recognized by Hill and Ball (2009), which consider in their model, for instance, knowledge such as Knowledge of Content and Students. Mishra and Koehler (2006) adopt a similar view in their TPACK model, considering also knowledge domains which consist of the mutual influence among other domains. But the first author who actually considers more than some influence among domains of knowledge, understanding this "influence" as a new domain of knowledge that is added to the initial ones, is Shulman (1986). Here I adopt a similar perspective. I consider two sets of knowledge, that I call inter-domain knowledge: the Mathematics and Technology Knowledge (MTK), and the Teaching and

Learning and Technology Knowledge (TLTK). In both cases the curriculum is considered to be a transversal influence, always present. MTK focuses on how technology influences mathematics, enhancing or constraining certain aspects, and TLTK focuses on how technology affects the teaching and learning process, enhancing or constraining certain approaches. One of the differences between KTMT and TPACK is that the inter-domains knowledge require some knowledge on the base domains but do not develop straightforward from that knowledge. However, the main difference between these two models is the way how KTMT intends to integrate in a single model the research developed on teachers' knowledge and on the integration of technology in teachers' practice. This is why MTK includes knowledge of technology's mathematics fidelity, knowledge of new emphasis that technology puts on mathematical content, knowledge of new sequences of content, and representational fluency; and TLTK includes knowledge of new issues that technology requires students to deal, knowledge of mathematical concordance of the proposed tasks, and knowledge of the potential of technology to the teaching and learning of mathematics. Finally, the KTMT includes Integrated Knowledge (IK). This is a knowledge held by the teacher that articulates simultaneously the knowledge of each of the base domains and the two sets of inter-domain knowledge. It is a knowledge that develops from the interactions between all domains and is characterized by its global and comprehensive nature but, at the same time, by its particularity, in the sense that it is that knowledge that maximizes the specific potential of technology to provide better mathematics learning. It is this knowledge that is the true essence of KTMT (Rocha, 2013).

DEFINING A SUITABLE VIEWING WINDOW

In the literature there are many references to issues related to the choice of the graphing calculator viewing window. Cavanagh (2006) mentions the students' difficulty in understanding the impact on the graph of adopting different values for each axis. Hodges and Kissane (1994) refer to the lack of awareness of students regarding the impact that any change in the viewing window has on the observed graph. Rocha (2002) emphasizes the role of the teacher to minimize the students difficulties related to the definition of a suitable viewing window. This author, as well as Cavanagh and Mitchelmore (2003), highlights the need for the teacher to be aware of these difficulties. And she also stresses the importance of allowing the students the opportunity to face these difficulties in a way that allows them to develop an understanding of the impact of the window over the graph displayed on the calculator's screen. However, Cavanagh (2006) is cautious about the best moment to confront students with these difficulties, stating that it should not occur to soon.

According to Doerr and Zangor (2000) and Kastberg and Leatham (2005), teachers' knowledge is determinant in how technology is integrated in their practice, and in how the teachers highlight the link between knowledge from different sources (such as algebraic and graphic) and the development of critical thinking. And at this level, Cavanagh and Mitchelmore (2003) believe that teachers must do more than simply inform students about the limitations of the calculator and about how this machine can present information in a misleading manner. It is necessary that the teachers strengthen the connections between different representations, continually drawing attention to discrepancies between, for example, the expected graph and the one that is displayed by the graphing calculator. It is also essential, with regard to the aspects concerning the choice of the viewing window, that the teachers appeal to the meaning of the values represented, so that they make sense for students (Rocha, 2002).

However, much of what has been done in research in this area is focused in telling the teachers what the integration of the graphing calculator should involve, and not on analyzing and understanding their practice (Kissane, 2003). And a better understanding of teachers' practice is fundamental if we want to promote teachers' professional development in a relevant way.

METHODOLOGY

Given the nature of the problem under study and in line with the ideas advocated by Yin (2003), the study adopts a qualitative and interpretative methodological approach, undertaking one teacher case study (in the part of the study presented here). Data were collected by semi-structured interviews, class observation, and documental data gathering. The teacher's classes reported here were followed for one school year while she taught functions using the graphing calculator. It was performed an interview before each class, with the purpose of knowing the intentions of the teacher and the underlying reasons. This interview was also used to decide which classes would be observed. During the study, fourteen classes of 90 minutes at 10th grade (age 16) were observed. After each of the observed classes, it was performed an interview with the intention of knowing the analysis that the teacher did of the events. These interviews were based on data from the classes and discuss some episodes selected by the researcher. Data analysis was mainly descriptive and interpretive in nature, considering the problem under study. The process started with the identification of the episodes where the viewing window has been addressed, and then the KTMT model and the respective domains of knowledge (which encompasses the research results around the issue of the viewing window) were used to structure the analysis of the episodes. All interviews and observed classes were audio-taped and later transcribed.

THE TASKS AND THEIR IMPLEMENTATION

Throughout the study of functions, the teacher offers students a wide range of tasks. In this section, I briefly present some of these tasks and their implementation, paying a special attention to the emphasis given to the viewing window.

In parabola's axis

In this task, students should start by marking two points at opposite sides of the axis of symmetry of $y = x^2$ and find the slope of the straight line that goes through them (Figure 1). After trying some examples, they should formulate a conjecture for the slope of the line that passes through any two points in the same conditions. And afterwards they must demonstrate the veracity of their conjecture.

The viewing window is one of the aspects considered by the teacher when she planned the lesson. Given that the experience of the students with the graphing calculator is still not much and that there are already several other aspects that they will have to face on the calculator (mark points on the graph, draw the line, calculate its slope, etc.), she decides to include information about a suitable viewing window on the task:

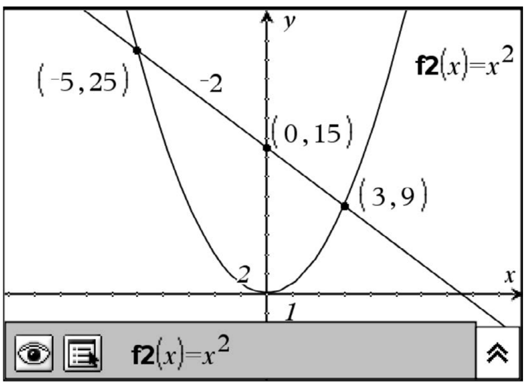

Figure 1: In parabola's

Teacher: You cannot do everything at once. We are just starting to work with the calculator. The students aren't used to it and on this task they already have to be able to do several things with the machine. We have to focus. And in this task the focus is not on the window. So I think it is better to give the window information. This way you avoid wasting time. (pre-lesson 2)

Still, in class the teacher values the importance of the viewing window. She takes the opportunity to introduce the expression 'viewing window' and to point to students two different ways to represent it:

Teacher: To make your job easier, I give you the viewing window. (...) But what is the viewing window?... When I draw a graph, it has no reading if I don't include the scale. I have always insisted on this. A value on the x-axis and a value on the y-axis... for us to realize the scale. (...) When I'm looking at a graph on a calculator (...), I see it in a particular window. We know that the graph will continue. In this case we know the shape of the graph outside this window. In some other cases we don't know. Now, this window has x ranging from -10 to 10 and y ranging from -6.65 to 6.67. So, rather than include the scale on the graph, or together with that, I can write it in two ways: $[-10, 10] \times [-6.65, 6.67]$ or $x \in [-10, 10]$ and $y \in [-6.65, 6.67]$. (class 2)

The box

The goal of this task is to find the length of the side of the square that should be cut out of a cardboard of 1.2 m × 80 cm, to build a box with maximum volume (Figure 2). Working in groups, the students should analyze the problem and come to the conclusion that the volume of the box will be given by $V(x) = 4x^3 - 4x^2 + 0.96x$. Afterwards they are expected to use the graphing calculator to draw the graph of the function and find the value of x that maximizes V.

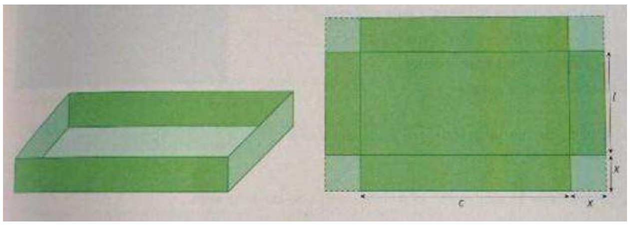

Figure 2: The box

This is a task where finding an acceptable viewing window requires some work. And the teacher seeks to support her students, trying to help them making sense of the values to consider:

Teacher: So let's change the window to get a better view. (...) Let's think a little bit further. What values can x take?
Student: (...) Between 0 and 1.
Teacher: No. What's the size of the cardboard? This is a cardboard.
Student: 80.
Teacher: 80. How far can you cut? You cut at one side and at the other side. How much can you cut?
Student: Ah! 40.
Teacher: Ok, it can change between 0 and 40. So the x can go from 0 up to... instead of 1 I can choose?...
Student: 0.4.
Teacher: 0.4. (...) Let's have a look. Notice I already have the function in the part that interests me. (...) Here it is so low, so low. So what can I do? I can put here a negative value and cut a little bit here (points to the top of the screen) (...) So, let's go, window... You're starting at 0, I'll put -0.5, right? (...) yMin -0.5. And what about yMax? You have 1. 1 is up there, so it has to be a smaller value. What value do you want to try? (...) Try it! (class 7)

But the teacher has also in mind that the calculator provides several ways to change the viewing window. Thus, throughout the lesson she points to her students different possibilities. And, by the end of the lesson, when she addresses the problem with the whole class, she begins by discussing suitable values for x and then she uses successive zoom box until she gets a suitable viewing window:

Teacher: Well, most people did this and got a graphic like this. (...) And now we can't forget that we are in the context of a problem. (...) This means that I could adjust the calculator window according to the values involved on the problem. And one of the possibilities (...) was to go to the window settings and put 0 for xMin, or a little bit less, and for xMax... how much?
Student: 0.4.
Teacher: 0.4. Ok. If I did this, what happened? Then I see almost nothing, but I can notice that the curve is here, but it's so close to the x-axis that is not possible to see. Now I have two choices. I can try to estimate the values assumed by y or I can use (...) the zoom box. Because what I want is to get a better view in this area here, around here. (class 7)

But it is not only the diversity of forms available to change the viewing window and its explanation to the students that are valued by the teacher. More than knowing the commands of the calculator, the teacher wants the students to understand what was done and why it was done, so that in future they are able to deal with a similar situation by themselves. In this sense, the teacher addresses the search for a good viewing window as a process. The viewing window is successively changed taking into account the problem and using the features provided by the calculator. And this is a conscious option of the teacher:

Teacher: I think that if I just do it right, at the next time they are going to face difficulties again. Don´t you think?
Researcher: So, it's a way of showing them the process. Is that so?
Teacher: It is a way. (...) There may be situations where I realize what the optimum window is, but if I don't, I need to have knowledge of some ways to look for it. And that was what I tried to do. (...) Because if not, if I go there and just do it right, they don't even realize that there is some difficulty. They fail to do it, but that's the right window and that's it. (post-class 7)

Folding the corner of the sheet

In this task the students should fold a sheet of paper so that the upper left corner touch the bottom side

(Figure 3) and then find the triangle of largest area that appears in the lower left corner of the sheet of paper. Students work in pairs and begin by doing several folds and taking some measurements. This way they get a set of data that allows them to find a function that fits the data and then find a solution to the problem.

During the task the students are confronted with a set of data that suggests a quadratic function, when the

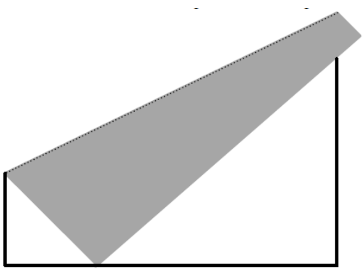

Figure 3: Folding the corner of the sheet

corresponding function is actually a cubic. Students realize that the quadratic function does not fit perfectly to the data but, when they think of alternative functions, they are guided by data visualization and think on a quartic function:

Student: Here we tried a quadratic (...) because the points are like... in parable form, but this is not quite...

Teacher: Yes, it doesn't go through all the points.

Student: It can be like that?

Teacher: (...) We are working with experimental data, so either you weren't very accurate in measurements (and there is always an error in the measurements we make), or that's not the function that best fits your data. Did you try another function?

Student: Yes, we tried this one, the quartic.

Teacher: The quartic. And what happened?

Student: It's better here at the beginning, but then it also doesn't go through the points.

Teacher: Right. And did you try other functions?

Student: No, we just tried these (...) the points are like this... (the student points to the U-shaped distribution of points), so these functions will be the best ones. Unless is grade 6... is it? (class 12)

Most students sought for the function that best fitted the data between polynomial functions of the 2nd and 4th degree. Only the students who tried all kinds of functions provided by the calculator (using regression), considered a polynomial function of 3rd degree:

Teacher: What about you? What conclusion did you reach?

Student: We think it's this one.

Teacher: A cubic. And why did you choose it?

Student: Well, we started by the quadratic because we thought it was. But it doesn't go through all the points. And then we decided to try all that appear here in the calculator and this is the best one... (class 12)

The discussion of the task, performed in the following lesson, is based on the students work. The functions chosen by some students and their graphical representation in conjunction with the data collected are presented. The discussion starts with presentations of 2nd and 4th degree polynomial functions, since these are the dominant responses in the class. The teacher has to insist, asking for something different, in order to get someone presenting a 3rd degree function. Given the obviously better way how this function fits the data, the teacher takes the opportunity to highlight some aspects of the viewing window and the cases where it does not show a global picture of the graph:

Teacher: Most of you looked at these points, and thought it was a quadratic function, but you can't conclude like that. You have to keep in mind that you are only seeing the graphic in a window and what you see doesn't tell you anything about what you don't see. (...) When I introduce a polynomial function of the 2nd degree in the calculator and ask for the graph, I know it will be a parable because I know these functions, because my knowledge

> about Mathematics allows me to know it. (...) But when I see a graphic looking like a U, without more information I can't conclude that this function is a quadratic... because the graph can reverse the concavity outside my window... I don't know... (class 13)

Thus, the teacher analyzes the importance of the viewing window and how a partial view of the graph can easily lead to wrong conclusions.

DATA ANALYSIS

The practice of this teacher seems to be characterized by three different stages in what concerns to the viewing window. At an initial stage, the teacher avoids situations where the students need to look for a suitable viewing window. However, she does not give up of implementing what she believes to be a valuable task, just because the required window is not trivial. Whenever the standard window is not suitable for a full exploration of the task, she informs students about the values they should use on the viewing window. At an intermediate stage, the teacher already proposes to students tasks where they actually need to find a suitable viewing window. At this point the teacher discusses with the students how to find a suitable window, trying to make them develop an understanding over the searching process. At an advance stage, the teacher confront students with misleading situations, where the students need to understand the impact of the viewing window in order to avoid an uncritical acceptance of the graphic displayed on the calculator's screen. All over these stages, the teacher highlights the importance of some kind of written record that gives information about the viewing window being used. This option turns the window into a noticeable and important aspect of drawing graphs on the graphing calculator since the first moment.

The teacher's practice is certainly a consequence of her professional knowledge. So it makes sense to analyze the teacher's practice trying to infer which domain of the KTMT model seems to be involved.

The teacher participant in this study recognizes students' difficulties in finding an appropriate viewing window. As such, initially she avoids complex situations, providing students with explicit information about a suitable viewing window (TLTK). She is also aware of the difference between plotting a graph with and without technology. Namely, she recognizes the importance of recording the scale/viewing window along with the graph obtained on the calculator (MTK). As so, the teacher highlights to the students the relevance of the chosen viewing window. With this purpose in mind, she selects tasks that allow her to emphasize the importance of mathematical knowledge for proper reading and interpretation of graphs, focusing on the usual difficulties of students in a phased manner (IK). Besides that, the teacher is concerned about explaining the different options available to find a suitable viewing window (includes TK), presenting the demand for a suitable viewing window as a process (IK). Thus, the analysis of the teacher's practice emphasizes the relevance of knowledge in the domains of KTMT involving technology: KT, TLTK, MTK and IK.

CONCLUSION

The conclusions of this study point to an approach to the viewing window which takes into account the degree of difficulty involved. Starting from a practice that ensures that the students are aware of the viewing window, but where any change is based on available information, it evolves to a practice where the students are expected to actually find a suitable window, and afterwards it evolves again to include misleading situations. This practice of the teacher is aligned with the perspective of authors such as Cavanagh (2006), who emphasize the importance of a phased contact of the students with situations where finding a suitable viewing window is more complex, recognizing the difficulties usually faced by the students.

The analysis of the teacher's practice also suggests that the way the demand for a suitable viewing window is addressed in the classroom is influenced by the teacher knowledge regarding KT, TLTK, MTK and IK. Namely, it seems to be highly relevant the teacher's knowledge in what concerns to:

— the students' difficulties in finding a suitable viewing window;

— the new emphases that technology puts on certain mathematical knowledge during the search for a viewing window;

— the teaching strategies that allow the teacher to address mathematical knowledge relevant to guide the search for a suitable viewing window, while focusing on the usual difficulties of students in a phased manner;

— and the different options available to find a suitable viewing window, as well as the importance of explaining this options to the students.

In the future, it would be particularly interesting to investigate the impact, on the teachers' approach to the viewing window, of an education program (pre-service or in-service) that emphasizes this set of knowledge. After all, more than being a characterization of the teacher's knowledge, the KTMT model intends to help identify aspects of the professional knowledge that, when included in training programs, can contribute to the professional development of those enrolled.

Designing a didactical situation with mobile and web technologies

Håkan Sollervall[1,2] and Didac Gil de la Iglesia[2]

1 Malmö University, Malmö, Sweden, hakan.sollervall@mah.se

2 Linnaeus University, Kalmar, Sweden

We have designed, implemented and evaluated a didactical situation where 27 students in grade 4 created large triangular constructions in an outdoor environment by involving a customised GPS-based mobile application. The students' strategies for construction were reflected upon during a teacher-led discussion involving web technologies and aiming at the formulation of principles for construction. The effective communication of underpinning theories and possible learning objectives, in combination with user-friendly mobile and web technologies, served to scaffold the teacher's successful orchestration of a logos-oriented mathematical discourse.

Keywords: Didactical situation, mobile technologies, web technologies, design.

INTRODUCTION

Many tasks in mathematics textbooks relate to contexts in the real world that are beyond the student's reach and sight in the classroom. Such tasks are commonly treated in micro-space (Brousseau, 1986) on the student's desk. Students seldom get the opportunity to experience mathematics in large, full-sized space, which is crucial for considering spatial ideas and not only visual ideas as represented in models and in drawings on paper (Bishop, 1980). However, doing mathematics in meso-space, outside the classroom, calls for the teacher to provide and orchestrate meaningful teaching activities. Further didactical challenges include how to connect such activities with mathematically meaningful follow-up activities in the classroom.

Recent developments in the field of technology-enhanced learning show promising attempts to design outdoor teaching activities involving the use of mobile and web technologies (e.g., Sollervall & Milrad, 2012). While mobile technologies can support the design and orchestration of outdoor teaching activities, they pose technological challenges regarding stability (Gil, Andersson, Milrad, & Sollervall, 2012) and pedagogical challenges regarding usability and instrumental genesis (Verillon & Rabardel, 1995).

Beyond these pedagogical and technological challenges, we have to consider how to connect the activities with the regular mathematics curriculum and how to implement complete didactical situations (Brousseau, 1997) in specific schools with specific groups of children, preferably with limited resources for the purpose of scaling up.

For these reasons, we have adopted a co-design methodology (Penuel, Roschelle, & Shechtman, 2007) where researchers in mathematics education and media technology work together with schoolteachers to design and implement didactical situations with innovative technologies such as augmented reality (Nilsson, Sollervall, & Spikol, 2010) and customised mobile applications (Sollervall & Milrad, 2012).

The inherent complexity of the designed activities has on several occasions led to the researchers controlling the implementation of the outdoor activities and neglecting the follow-up indoor activities. Although our ambition is to design didactical situations where the teacher has full agency of the implementation, our conclusion – based on the outcomes of several similar projects – is that a first design cycle should prioritize the functionality of the technologies and the didactical flow of the situation. During the first cycle, we are satisfied if the technologies perform acceptably and the students experience a sequence of meaningful and enjoyable mathematical activities. To support the achievement of such outcomes, the researchers have

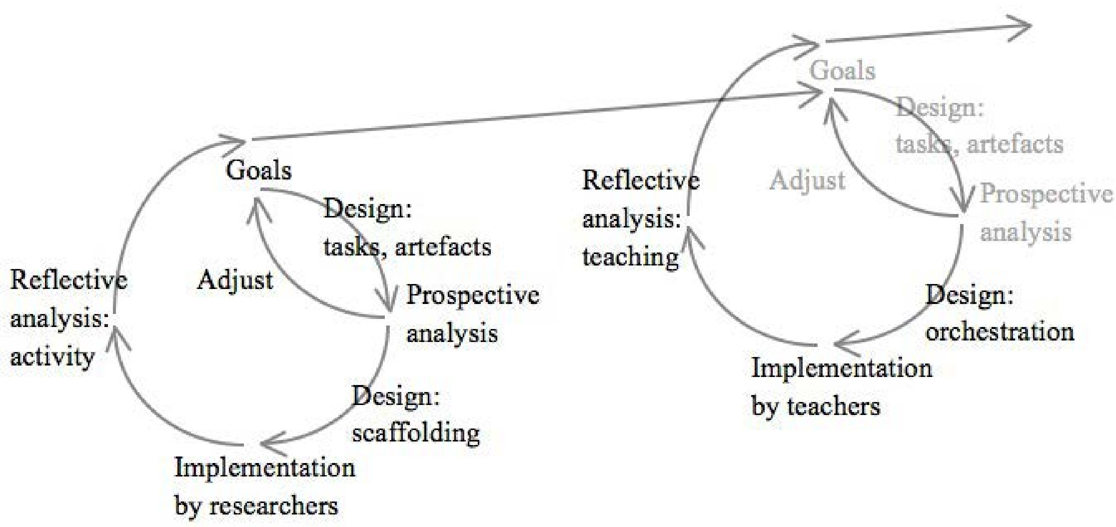

Figure 1: First and second design cycle, as implemented in the current project

been actively involved in implementing the activities (Figure 1).

During the second design cycle, the researchers provide support for new teachers to orchestrate and adapt the didactical situation by enhancing the customised technologies, communicating learning objectives, and indicating how these objectives may be achieved by unfolding didactical affordances of the situation. The teacher is fully responsible for pedagogical design and implementation (Figure 1), but is not involved in the initial phase where the activity, including its tasks and artefacts, is modified by the researchers who also prepare guidelines for orchestration. These guidelines are communicated to the teacher during a short preparatory session, directed at enabling the teacher to interpret and unfold the learning opportunities that are embedded in the didactical situation.

In this paper, we report on the second cycle implementation of a complete didactical situation and characterize the possible learning opportunities in terms of dimensions within a mathematical praxeology (Rodríguez, Bosch, & Gascón, 2008).

Our research question addresses the evaluation of an implemented didactical situation, specifically designed to promote a logos-oriented mathematical discourse:

> How do the scaffolds provided support logos-orientation in a teacher's orchestration of a didactical situation that is specifically designed with mobile and web technologies to provide opportunities for a logos-oriented discourse?

THEORETICAL AND METHODOLOGICAL CONSIDERATIONS

A teacher's design cycle includes the analysis of a teaching activity both before and after it is implemented with students. Such prospective and reflective analyses are central features of design-based research (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). In our prospective analyses, we put focus on students' hypothetical action trajectories, analysed from a socio-cultural perspective. In the reflective analyses, and particularly when advanced technologies are involved, we shift our focus of attention between the cycles. In the first cycle, we simply evaluate the activity flow. In the second cycle we evaluate the teaching outcomes, and in the third cycle we analyse the learning effects. The current paper reports on a second cycle and will put focus on evaluating teaching outcomes, for the purpose of informing future implementations of the activity by modifying and improving the guidelines for orchestration. This approach is underpinned by an ambition to find a reasonable distribution of ownership between researchers and teachers.

In the process of designing teaching activities with advanced technologies, we have noticed that fundamental didactical principles may become neglected when the research efforts favour enhancing the performance of the technologies themselves. For example, involving technologies that provide extensive feedback may remove didactical challenges that are actually needed to promote students' learning processes. For this reason, we have adopted the theory of didactical situations (Brousseau, 1997) as a design model. The fundamental structure of a didactical situ-

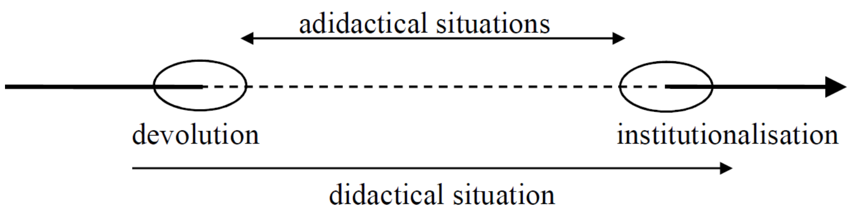

Figure 2: Structure of a didactical situation

ation – devolution, adidactical situations, institutionalisation (Figure 2; adapted from Balacheff, 2013) – fits particularly well when designing with mobile technologies across physical contexts.

The three phases within a didactical situation become naturally separated if adidacticity is promoted by giving the students full responsibility for the technology-supported exploration of mathematical tasks by retroacting only with the milieu and not the teacher, as indicated in Figure 3 (left pane, adapted from Bessot, 2003, p. 7).

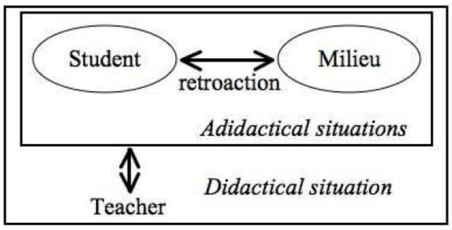
While the theory of didactical situations provides a structure for a teaching activity, with focus on achieving mathematical learning objectives, we utilize the notion of praxeologies to capture qualitative differences of the learning opportunities that are offered to the students during a didactical situation. In our analysis, we will charac-terise such teaching outcomes in terms of praxeological elements (Figure 3, right pane).

While praxis, that is, tasks and techniques, naturally dominates within the adidactical situations, the logos dimension may emerge in the phase of institutionalisation where the students are invited to reflect on their experiences by engaging in technological and theoretical discussions about how and why the techniques work. A technology-oriented discourse may include describing techniques, explaining how they work and when they work, while a theory-oriented discourse aims at justifying the techniques and the technological claims (Rodríguez et al., 2008).

In previous projects (e.g., Perez, 2014) we have observed situations dominated by praxis-oriented activities where the teacher has not unfolded the logos-oriented affordances that were embedded in the situations. In the current study, we chose to make explicit the notion of praxeologies for the teacher and discussed a variety of affordances for a logos-oriented discourse during the institutionalisation phase, based on the students' experiences from exploring tasks in the outdoor environment.

DESIGN CONSIDERATIONS

In the first cycle, a teaching activity in an outdoor environment was designed for the purpose of investigating spatial orientation ability (Peng & Sollervall, 2014). The teaching activity involved ten similar tasks that each called for the coordination of two given distances with respect to two given reference points. Each such task can be interpreted as the construction of a triangle with three given sides, a construction that is treated in Euclid's Elements (Heath, 1908, p. 292; Figure 4).



Praxis	Logos
Tasks	Technology
Techniques	Theory

Figure 3: A didactical situation (left pane) and elements of a praxeology (right pane)

Book I Proposition 22

Out of three straight lines, which are equal to three given straight lines, to construct a triangle: thus it is necessary that two of the straight lines taken together in any manner should be greater than the remaining one.

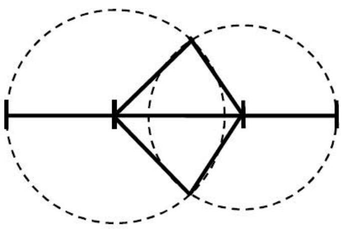


Figure 4: Euclidean construction of a triangle with three given sides

During the second cycle, the purpose was to stimulate a logos-oriented discourse during the phase of institutionalisation, involving technology as well as theory:

— technology: identifying and comparing strategies for construction, distinguishing between possible and impossible constructions;

— theory: justifying the strategies particularly the circle strategy, formulating criteria and arguing why some constructions are possible and others are not.

Based on their experiences from the first design cycle, the researchers designed a complete didactical situation encompassing devolution, an outdoor activity, and institutionalisation. The outdoor activity involved ten tasks, that each called for the coordination of two given distances with respect to two given reference points. Seven of the tasks involved possible constructions while three were impossible, such as "10 15" when the distance between the reference points was 35 meters. The impossible constructions were included for the purpose of stimulating a technology-oriented discourse during the institutionalisation phase.

The researchers' ambition was that the students should work with their ten tasks in small groups, simultaneously and independently, in the schoolyard. To achieve variation of tasks between the groups, it was decided to place six different reference points in the schoolyard (Figure 5) and to vary the order of the tasks. For example, Group 7 had their first task "20 30" against the house and the tree (Figure 6, right pane) while Group 5 had "20 30" as their eight task against the bicycle and the car.

The didactical situation was designed for up to 14 groups and targeting students in grades 4–6. The 14 sets of tasks were deployed on mobile phones (androids) supporting a customised technological application (Figure 6, left pane).

Although Euclidean constructions are not in the grade 4 mathematics curriculum in Sweden, the presented didactical situation connects well with mathematical content such as distances, measurements, and circles. Moreover, the institutionalisation phase involved mathematical communication and reasoning, as competencies that are strongly emphasised in the steering documents for mathematics education in Sweden.

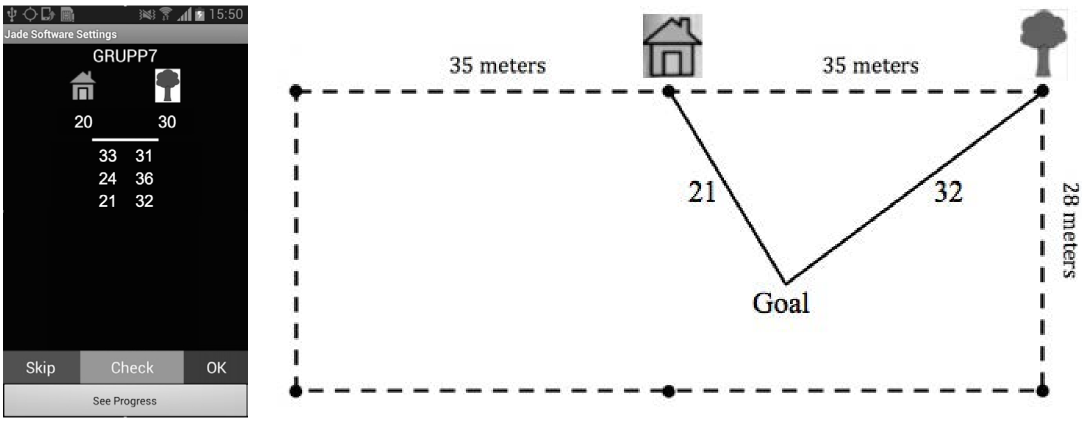

Figure 5: The presented Google Map (left pane) and the actual field (right pane)

Figure 6: The display (left pane) and an illustration of the solved task (right pane)

SCENARIO FOR THE DIDACTICAL SITUATION

Two days before the activity was implemented, with 27 students in grade 4, the researchers met the teacher at her school. After a short outdoor session where the mobile technologies were tested hands-on, she was informed about the researchers' desire to promote a logos-oriented discourse. The schematic structures of a didactical situation and a praxeology (Figure 2 and 3), the Euclidean circle strategy (Figure 4), together with possible logos-oriented learning objectives, were presented on a single sheet of paper and was briefly discussed. A sample set of 10 tasks was also presented and discussed. Furthermore, the teacher was informed about the possibility to show the students' results on a Google Map. It was made clear that these ideas should serve only to inspire her and that she was completely free to orchestrate the activity according to what she believed would be best for her students, not for the researchers.

The entire activity including devolution, the outdoor activity, and institutionalisation, was video-taped and lasted 1 hour 45 minutes (8.00–9.45 on a Friday morning).

Scenario for devolution

The 27 students arrived to the regular classroom at 8 o'clock in the morning. They had been told in advance that they would engage in an outdoor activity and use mobile phones. Before the students arrived, the teacher had divided them into 12 groups that were displayed with on the whiteboard. The three visiting researchers introduced themselves and the teacher informed the students that they were going to work with mobile phones to solve mathematical tasks outdoors on a field where the researchers had placed six coloured markers (cat, house, tree, bicycle, car, horse).

The field and the markers were displayed on a Google Map (Figure 5, left pane). When the teacher asked the students if they recognised the field in the picture they immediately answered yes. The teacher informed the students that they were going to look for "magic points" that were located specific distances from two of the markers, and that they were going to use the mobile phones to check the distances. The teacher asked the students what they would do if they were not satisfied with the measurements and they readily answered that they would try again. Each group received a phone from the teacher and got them started after a few instructions.

When all students had opened their first tasks that were all different (an example is shown in Figure 6, left pane) the teacher told them to go to the field (Figure 5, right pane) and try to solve the tasks. The time was now 8.15. The researchers noticed that the teacher had not informed the students about the inherent inaccuracy in the GPS values that may cause a measurement error of a few meters.

Scenario for the outdoor activity

As mentioned earlier, the researchers had prepared 14 sets of 10 tasks. The 10 tasks were identical with respect to distances but were presented to the groups in different order and with respect to different markers. Each task referred to distances to two of the six markers. For example, for Group 7 the distances "20 30" were shown on the display of their mobile phone directly under pictures of "house" and "tree" (Figure 6, left pane). The objective was to find the point on the field that was located 20 meters and 30 meters from the markers, respectively (Figure 6, right pane). The response "21 32" could be considered as acceptable. On a few occasions, the teacher negotiated this issue of non-exact measurements with the students directly on the field.

The students showed no signs of confusion either regarding how to handle the mobile phones, how to interpret the tasks, and even accepted the somewhat inaccurate measurements. They were enthusiastic and engaged fully in the tasks, although some phones did not give correct measurements due to thick clouds that caused large errors in some of the GPS-values. After half an hour some students complained that it was cold outside and the teacher decided at 8.50 to ask them to go back to the classroom.

Scenario for institutionalisation

At 8.56, everyone was back in the classroom. After a short discussion about some incorrect values and asking if the students liked the activity (which they did) the teacher asked the groups to present their strategies for finding the "magic points". Most of the groups were eager to present and the teacher promised that they would all get to do it. The first group gave their mobile phone to one of the researchers who downloaded its log file to a computer that was connected to the classroom projector. Their tasks and their attempts

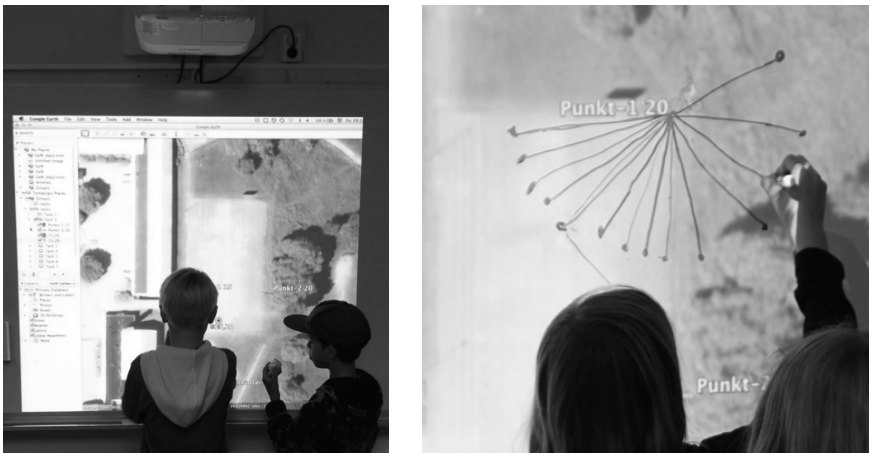

Figure 7: One group presenting (left pane) and the whole class contributing (right pane)

became visible (numerically) on the board (a regular whiteboard, not interactive) to the left of the Google Earth (Figure 7, left pane). They chose the task they wanted to present and what attempts they wanted to be shown with "pins" on the Google map visualisation.

For several of the groups, the teacher had to tell the students to describe the task before they started talking about how they worked with it. During the presentations, she repeatedly asked technology-oriented questions like "How did you think when you did that?", "Why did you do walk like that?", and "How did you get those values?". Several of our previously identified strategies were confirmed (Peng and Sollervall, 2014) but the targeted circle strategy did not appear in the presentations.

However, when all the groups had presented, the teacher continued the discussion, focusing on the last group's presentation. They had marked a point located 20 meters away from the bicycle marker (upper right corner in Figure 7, right pane) and had drawn a line segment from the point to the marker. The teacher asked the class if somebody could mark another point that was also located 20 meters away from the bicycle. Several students tried, but failed. They seemed confused about what to do but were eager to contribute. The teacher commented on their attempts, for example "Oh that is more than 20 meters", "That point is too close", "That is too far away". She tried to guide the students by asking questions: "If you stand there and it is 20 meters, how can you walk to keep 20 meters?", "Where else can you find 20 meters?". Finally, one student managed to mark a point that seemed to be the same distance from the marker. The teacher confirmed the attempt by saying: "Yes! You found it!" and then "How did you know how to do it?". The student responded: "I just thought it out". The teacher continued with "Now I want each of you to mark a new point, that is also located 20 meters away from the bicycle", and "Don't worry, there are infinitely many such points and each of you will get a chance to mark one". Most of the students caught on to the idea about keeping the distance 20 meters but changing directions, and occasional mistakes were quickly corrected. When about ten points had been marked, all located on the field, the teacher commented: "Oh, nobody is being brave today". One student understood what she referred to and readily marked a point in the bushy area behind the field (Figure 7, right pane). A few more points were marked outside the field. A crucial scaffolding question was asked.

Teacher: Do you begin to see a pattern? You can walk in any direction.
Student 1: Oh it is a circle!
Student 2: A spider web!
Teacher: Yes! A circle! Can you all see that?

The teacher drew a circle through the points.

Teacher: Now I have 20 here and how can I find 30 down there?

The students were invited to mark points that were initially not connected with the first circle. These points were corrected after comments from the teacher, who wrapped up the discussion at 9.45 by saying "If you can find the point where the two circles meet then you have found the magic point". Although enforced by the teacher, the concluding theory-oriented comment completed a didactical situation addressing all the four dimensions of an emerging point praxeology.

CONCLUDING DISCUSSION

The institutionalising discourse may be characterised as teacher-driven but student-centred. The teacher was informed about the researchers' desire to promote logos-oriented discussions and was prepared for orchestrating the session towards issues relating to technology and theory. Knowing about possible strategies for construction guided her to ask logos-oriented questions aiming particularly at the circle strategy. She patiently awaited the students to catch on to the mathematical ideas that were embedded in the didactical situation. She amplified the students' presentations by adding interpretations that led them to unfold ideas that were shared among all the students by involving them in making new constructions.

The teacher's orchestration was influenced by the preparatory session two days before the trial, particularly regarding the logos-orientation and the circle strategy. The customised mobile applications inspired the students to engage in the outdoor activity, while the web technologies served to underpin the presentations and connect their obtained measurements with their field experiences. All students could readily relate to what the presenting students were referring to on the Google map application. These technical design features scaffold effective communication in the classroom and enabled the teacher to put focus on asking logos-oriented questions.

A few incidents occurred during the implemented outdoor activity. The inaccurate and sometimes failing GPS-values (due to cloudy weather) caused confusion among some of the students. However, the teacher swiftly handled all such incidents.

It may be noted that the teacher did not address the issue of possible and impossible constructions. This may be considered as a natural decision due to the fact that the students were quite young (grade 4) and possibly not yet ready to engage in conditional reasoning. Instead, the teacher engaged the students in interpreting their triangular constructions in terms of circles, as one of several suggested discourses.

The mobile-assisted outdoor activity offered opportunities for the participating 27 students to simultaneously engage in similar coordination tasks, involving the same pairs of distances but with respect to different markers. Being informed about possible logos-oriented discourses and having observed the students acting in the outdoor environment, the teacher cleverly managed to institutionalise their common experience with respect to the circle strategy. The customised mobile and web technologies inspired the students to engage in the activities and supported transitions between outdoor and indoor contexts. These supporting technologies enabled the teacher to put focus on pursuing mathematically meaningful institutionalising activities, thus successfully finalizing a complete and complex didactical situation.

Theory of semiotic mediation in teaching and learning linear algebra: In search of a viewpoint in the use of ICT

Melih Turgut

Eskisehir Osmangazi University, Eskişehir, Turkey, mturgut@ogu.edu.tr

Utrecht University, Freudenthal Institute, Utrecht, The Netherlands, M.Turgut@uu.nl

This paper presents a research project on the description of a linear algebra course within the perspective of the Theory of Semiotic Mediation (TSM), in order to construct mathematical meanings prioritizing artefact–sign (i.e., ICT tools) and social context relationships. I will first describe the project and, following a theoretical framework of the TSM, discuss a priori epistemological analysis of GeoGebra's potentiality to be used as an artefact to bring out key linear algebra concepts in future didactic interventions. I also present the results of a pilot study elaborating the potentiality of GeoGebra for students' construction of the mathematical meaning of free variables. Future steps of the project are also outlined.

Keywords: Theory of semiotic mediation, teaching and learning linear algebra, ICT.

LEARNING LINEAR ALGEBRA: EPISTEMOLOGICAL ISSUES

Because of the strength of generalization, linear algebra is a powerful theory used to frame problems belonging to quite different contexts, but at the same time, it may be difficult to construct in itself. From a didactic point of view, merely taking a theoretical approach, i.e., introducing *vector space* concept to students, that is, only giving axioms, means asking students to enter a meaningless game of symbols, because the historical genesis of linear algebra indicates numerous lengthy steps to form an evolution of the idea of vector spaces. The notion of a *vector* begins with Aristotle who represented 'force' in geometric terms (Chong, 1985). However, after approximately 2000 years, mathematical representations of vectors were used as points and directed line segments by Gauss and Hamilton in terms of Cartesian geometry. Researchers used *matrices* to represent these geometrical ideas, as well as linear equations, and, by practical discernment, they obtained certain extensions to elimination techniques, n-tuples, determinants and transformations. However, all these developments were operational, sometimes having different theoretical elements, and so used different mathematical languages. There was, however, a missing *unified*-general approach covering and connecting all of them. In 1888, Giuseppe Peano defined the vector space concept with an axiomatic system, as *a set* satisfying certain axioms (Dorier, 2000). This was a formal definition, and opened a door to non-geometric vector spaces, such as polynomials and square matrices. Since we, as linear algebra lecturers, use all of these concepts together, one can conclude that the use of different notations, depictions and axiomatic language is essential for the teaching of linear algebra. From a didactical point of linear algebra education, the axiomatic-formal system of the course reveals a learning obstacle in teachers' hands; the *obstacle of formalism* (Dorier, Robert, Robinet, & Rogalski, 2000). This obstacle is associated with the specific *terminology* of linear algebra and appears when students are faced with the mathematical *symbol language* triangle, composed of equations, matrices and vectors. Students waver 'under an avalanche of new words, symbols, definitions and theorems' and therefore, for many students, 'linear algebra is no more than a catalogue of very abstract notions' (ibid. p. 95). In summary, the formalism obstacle can be considered as students' failure to grasp linear algebra's symbols and their associated-corresponding *mathematical meanings*. From the viewpoint of *semiotic registers* (Duval, 2006) of such mathematical meanings, learning linear algebra needs *conversion* between different registers; 'graphical', 'tabular' and 'symbolic languages' of linear algebra or, in other words, students should have 'cognitive flexibility' to overcome the obstacle of formalism (Dorier & Artigue, 2001, p. 270).

The construction of mathematical meanings cannot be easily achieved through a direct use of ICT, needing a careful *didactic design* of tasks to exploit the use of *artefacts* (Mariotti, 2012). I will try to overcome the obstacle of formalism using such didactic designs enriched with ICT tools, in particular GeoGebra (5.0 version) (its potentiality will be presented in detail), for students' construction of mathematical meanings of linear algebra concepts. Taking a semiotic approach, I will focus on the *Theory of Semiotic Mediation* (TSM) (Bartolini Bussi & Mariotti, 2008); both the design of the tasks and analyses of the processes.

RESEARCH QUESTIONS AND THEORETICAL FRAMEWORK

This study is a one-year, post-doctoral research project, planned to start in February 2015, focusing on the following research questions:

— *How should a linear algebra course be designed within a didactic-semiotic perspective?*

— *Does this approach overcome the formalism obstacle of linear algebra students?*

Taking into account the TSM, I intend to address both research questions. This is because the TSM is a Vygotskian-rooted approach in math education proposed by Bartolini Bussi and Mariotti (2008). It relates to the *semiosis* feature of math, which bases the teacher's actions in a *social context* and on the hypothesis that the *production of signs* can be elaborated on when the teacher intentionally uses an artefact to accomplish a math task within a communication-oriented process. By use of specific artefacts in the mediation process, the TSM aims to construct math meanings in students' mental schemes; in other words, to transform *personal meanings* into *math meanings,* while they solve the proposed tasks as *mediator*. In this process, the main focus is on the *emergence of signs* that foster students' possible math learning. Within this aim, the TSM is constructed on two key elements: *the notion of the semiotic potential of an artefact* and *the notion of a didactic cycle*. The semiotic potential of an artefact is associated with its '... *evocative power*, stressing the distinction between meanings emerging from the activity with the artefact and the math meanings evoked by such activity' (Mariotti, 2013, p. 442). In other words, it is related to the potential for math meanings to emerge whilst students solve a mathematical task. The notion of a *didactic cycle* is about the design of the teaching-learning process, especially describing semiotic processes: (i) *activities with artefact* (students work in pairs or in small groups), (ii) *individual production of signs* and (iii) *collective production of signs* (Bartolini Bussi & Mariotti, 2008, pp. 754–755). Iteration of such didactic-semiotic (environment) processes aims to foster the evolution of personal signs-meanings to (desired) math signs-meanings. This is because the (desired) evolution of the signs is 'artefact signs', 'pivot (hinge) signs' and culturally accepted 'mathematical signs' (ibid, pp. 756–757). Therefore, as an important component of this polysemy of the artefact, the teacher has a central role; she should orchestrate mediation with specific social activities to exploit the semiotic potential of the artefact (Mariotti, 2013), i.e., her role should be surrounded by an interacting triangle of, *use of artefact, personal meanings*, and *math meanings* in a socially-communicative environment.

Why I select TSM in this project to overcome obstacle of formalism

Harel (2000) proposes three teaching principles for learning linear algebra (p. 180):

— the *concreteness principle* associated with results stemming from the use of the *axiomatic language* of linear algebra and students' pedagogical needs, in particular, the transition from geometric to abstract features. For instance, the concept of a polynomial as a vector is not concrete for students if they cannot comprehend the mathematical notion of linear independency.

— the *necessity principle* that refers to instructional activities which should form *a problematic environment* for the construction of mathematical concepts, with students seeing an 'intellectual need' (ibid, p. 185).

— the *generalization principle* that reflects students' generalization of driven concepts after the problem-solving process; in particular, with the help of the *intellectual need* character of the proposed learning environment.

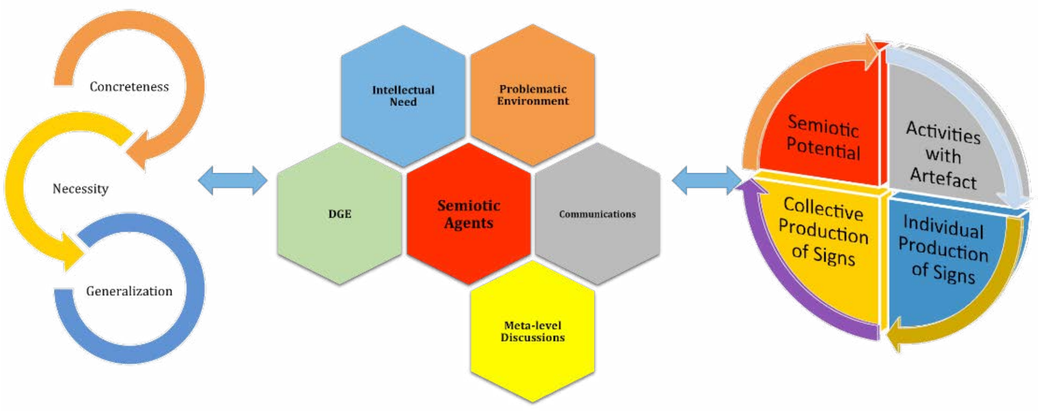

Figure 1: Key epistemological concepts in relation to the TSM

In summary, one can conclude that construction of math meanings of the geometric features of linear algebra through ICT tools can provide dialectic relationships among abstract features. The use of ICT didactic designs should provide a problematic environment (necessity) (Turgut, 2013); preparatory insights (concreteness) for non-geometric linear algebra (Harel, 2000), and math discussions for comprehending abstract concepts. In other words, as Dorier and Artigue (2001) emphasize, the lecturer should create an environment for students, which provides an opportunity to reflect on '*meta-level discussions*' of problems, referring to the generalization principle. This can also be an opportunity to *unify* linear algebraic concepts (p. 271).

Several attempts have been done within the semiotic perspective to analyse and construct math meanings of linear algebra with ICT tools. Sierpinska, Trgalová, Hillel and Dreyfus (1999) designed a research program with Cabri–geometry II of a geometric model of vector space in order to overcome the obstacle of formalism. Lengthy teaching experiments (within different conceptual perspectives) reveal that students are able to grasp math meanings, in particular specific concepts, such as linear combination (ibid, p. 129). Hillel and Dreyfus (2005) investigate how the conditions of *communication* influence the construction of math meanings, whilst students are attempting to solve tasks regarding the projection of vectors and an approximation with Maple CAS. Episodes were constructed on different semiotic systems, in particular *agents* for communication; the students themselves, an observer, the computer and Maple, classroom teacher, classroom notes and text. At the end of the sessions, the agents (communicative semiotic environment) were able to contribute to students' construction of new meanings of linear algebra concepts. The researchers also emphasize the Maple role as a 'silent mediator' that stems from students' wait for-know-decide-use process of the commands. In summary, this was a glimpse of the use of dynamic geometry environments (DGE) as an artefact in the teaching/ learning linear algebra.

To sum up, all these together imply a puzzle including several keywords. I postulate and summarize the following key concepts to overcome the obstacle of formalism that, all together, fit with the TSM (Figure 1).

The keywords in Figure 1 have dialectic relationships with the TSM's core elements. For instance, intellectual need and problematic environment are related, but the dialectic relationship between them also implies the notion of the semiotic potential of the artefact and task designs. Consequently, the TSM underpins this process, because the TSM is a powerful framework for both the design of didactic cycles and analysis of the signs. Another fact is that the communication-meta level discussions process corresponds to Individual and Collective Productions of Signs and so on.

Within the framework of Figure 1, I hypothesize that GeoGebra may be a powerful artefact to use in task designs because one main potentiality of the use of GeoGebra is its involvement of a 3D interface, and hypothetically, this might help students to *unify* the different representations of linear algebra. However, it needs a grain analysis to describe the key points that we want to emerge from its use.

Semiotic potential of some tools of GeoGebra: A priori analysis

The following *priori* epistemological analysis of GeoGebra will describe our goals and answer the following questions; what key linear algebra concept can

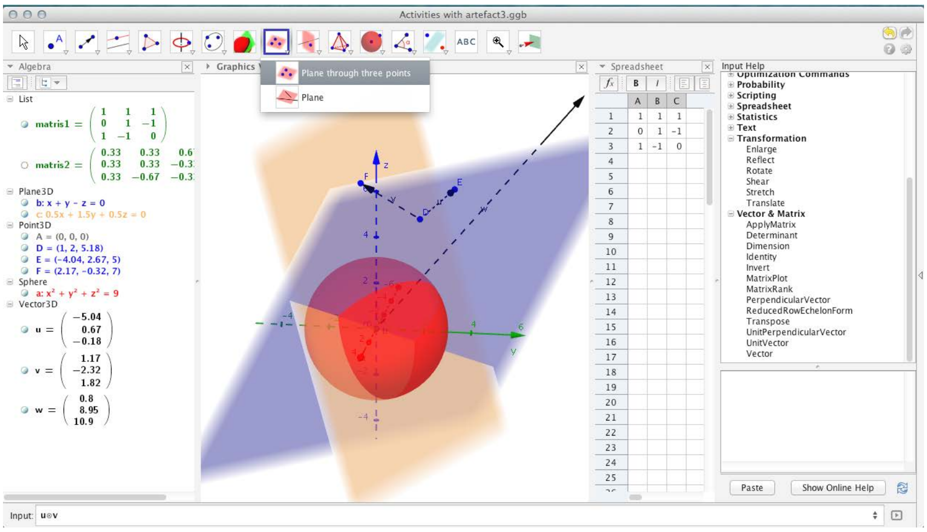

Figure 2: GeoGebra interface with different windows

emerge from the artefact, and what can we do with GeoGebra? As a consequence, this process leads us to discuss the *semiotic potential of the artefact* that is the core element of the TSM. The analyses of semiotic potential has a *dialectic* relationship between explication of goals and attempting to see what happens when we present the designed tasks to students, and then see which of their *utilization schemes* are useful to transform into mathematical meanings. To sum up, the process of outlining the semiotic potential of an artefact needs a deep analysis encompassing an epistemological and didactic-cognitive perspective that will give us a framework to assist in the design of the second phase of the TSM. Let us first describe this artefact's tools in relation to linear algebra.

In the GeoGebra interface (Figure 2), all the windows can be viewed together; the CAS, Graphics, 3D Graphics, Spreadsheet and Algebra. Using a spreadsheet table, such as Excel, one can form matrices with any rows or columns. They immediately appear in the Algebra window. With the help of the Input Help column (right side), other forms can also be accessed. The key element, a vector, can be composed by the Input line or in the Spreadsheet window in the form of co-ordinates and vectors (also with manipulations, cross product or forming a line) that appear simultaneously in the Graphics window. The Graphics window enables the plotting of a 3D view of the lines, planes and surfaces. At the same time, the tools of this window provide certain 3D applications, but the important one is the plane through three points. In addition, the Transformation part in the Input Help window provides a matrix transformations application in the plane, but not in 3D. As a limitation, one can see several tools in the windows, but the tools may be limited for the purpose of the tasks to prevent possible cognitive loads on the students. The viewing of these windows all together can create an environment for the possible *conversions* of different semiotic registers by students that may help them unify linear algebraic concepts. Therefore, I decided to consider the following four different semiotic registers (in sense of Duval, 2006): *algebraic register* (AR), 2D *graphics register* (2DGR), 3D *graphics register* (3DGR), and *spreadsheet register* (SR). Conversion of these registers might help students to shift different representations of linear algebraic concepts. Besides this powerful feature of the artefact, 2DGR has a *slider* component that forms an environment as a *dynamic variation*. This process is also applicable in other registers by *moving*, or the controlled movement of the mouse. These may be important in enabling students to evolve meanings of particular notions, because *variation* in 2DGR and 3DGR, provided by the slider and AR, may be key elements in the construction of associated meanings in the design of cycles for our future didactic interventions. I limit myself to the emergence of 'free variables in R^3' in the system of linear equations and associated geometric invariants with the following pilot study, which aforementioned registers can evoke students' learning.

PILOT STUDY AS A TEACHING EXPERIMENT

In this part, I attempt to elaborate the semiotic potential of GeoGebra, in particular, the use of AR, 2DGR (slider tool) and 3DGR, in the construction of a link between the system of linear equations, augmented matrices and intersection of planes. In other words, I focus on the question, 'will the use of those semiotic registers evoke construction of mathematical meaning of free variables?' For this purpose, I designed a task involving manipulation on different registers (inspired by the problem in Anton, 1981, p. 54). The educational goals of the experiment are:

— conversions among 2DGR (slider), 3DGR and AR,

— evolution of personal meanings to mathematical meanings of a free variable,

— fostering construction of the mathematical link among the concepts.

Using three registers, I prepared a task, as described in Figure 3. The participants of the experiment were two sophomore level undergraduate mathematics education students, and the experiment was implemented at the beginning of a linear algebra course, following the topic of solving the system of linear equations. A number of students volunteered to participate, but only two were selected according to their mathematical background and communication skills. They had performed moderately on former courses, and had taken only three mathematical courses; general mathematics, abstract mathematics and geometry. The fact is that they knew the equations of a plane, and the augmented matrices corresponding to the system of linear equations. The students were unable to use GeoGebra since, prior to the experiment, I had introduced the main tools of the software by removing any unnecessary tools, i.e., the only tools in the 3DGR were *move* and *rotate*. Thereafter, they practised dragging and shifting in the windows.

The expected situations in this experiment were; (i) the students' analyses using two sliders for a and b (2DGR), (ii) at the same time analysing the variations of the equations in AR, (iii) and the positions and manipulations of the plane in the 3DGR. Overall, the task was prepared to analyse the system of linear equations in terms of the variations of a and b, (for instance when a=0, b=2, the planes coincide). I estimated that, after they analysed such variations, they would focus on the system in AR, and thereafter, they would build an augmented matrix in order to attempt to solve the system. As a next step, they would compare their results within dynamic variations in 2DGR and 3DGR, also associated with the *intellectual needs* of the task. In the end, they would first construct a mathematical meaning of *two free variables*, as well as its corresponding meanings on the planes' movements and intersections (c, d, e in AR, with yellow, red and purple planes in 3DGR).

Procedure and data analysis

The experiment was implemented as a teacher-researcher, involving Buse and Deniz (pseudonyms), working as a pair on a computer screen. The data consisted of video-recorded interviews, screen recorder software and students' productions, with the teaching episode ending after 40 minutes. Within a semiotic lens, the data was analysed with respect to the TSM's frame of categories of signs (Bartolini Bussi & Mariotti, p. 756); emergence of *artefact signs*, *pivot-hinge signs* and *math signs*. Artefact signs are a production driven as a result of an immediate use of the artefact characterizing the proposed task; math signs refer to math meanings, such as definitions, a proposition or a math proof. Pivot signs refer to hy-

Task: Move the sliders a and b, and explore and explain what is happening in the GeoGebra interface systematically.

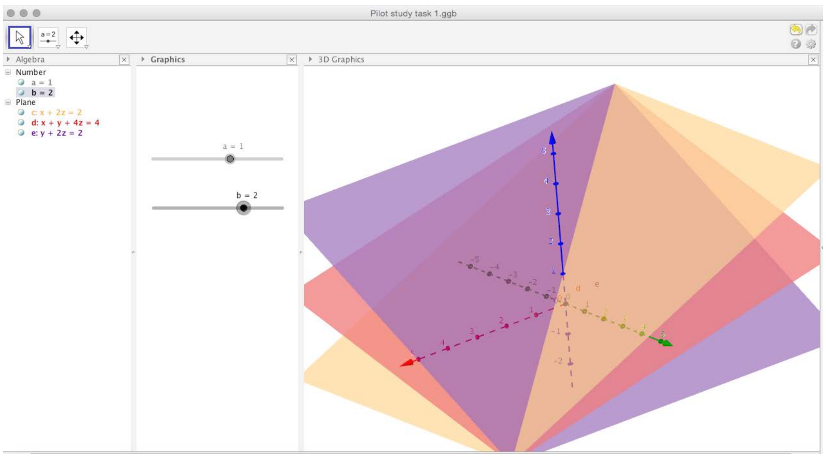

Figure 3: GeoGebra interface of the proposed task

brid terms in natural language, such as 'object' or 'thing', associated with math terminology (ibid.).

Summary of the results

After the teacher had introduced the task, the students tried to make certain interpretations by moving the sliders and analyzing the different registers together, and, thereafter, they focused on the equations in the AR. In this way, they comprehended what was differentiating in the plane equations whilst they dragged the sliders, since they realized that a system of linear equations existed with the key values being a=0 and b=2. They also formed the planes' equations with respect to a and b, and Buse pointed out that the solution of the system must be related to these values. In this process, the teacher was orienting the students to focus on the relationship between the a and b values as well as the solution of the system of linear equations. The following excerpt is drawn from the discussion from which the signs evolved: from artefact type to mathematical signs.

45 Teacher: You said at the moment, values of a=0 and b=2 must be in relation to a solution of this [indicating the system on the paper sheet] system, how you are sure about that?

46 Buse: Because changing the values here [indicating the 2DGR], shows us different type intersections here [indicating 3DGR], in fact, sliders are affecting the equations [meaning the AR]. These intersections must be similar to the position of the lines that we discussed.

47 Deniz: Exactly, look [moving the sliders] if a=0 and b=2, all the planes coincide. Oh yes, it is already obvious here [referring AR], in all the equations z=1, as in the case of coinciding lines, therefore, I think, the solution must be infinite here.

Thereafter, the students also explain other cases using their knowledge, stemming from an analysis of the system of linear equations in R^2: when $a \neq 0$, $b \neq 2$, the intersection of the planes is 'single point', 'exact solution' and 'consistent system'. Similarly, if a = 0, $b \neq 2$, they mention 'parallel planes', 'no solution', and 'inconsistent system'. Thereafter, the teacher asks how to find the relationship between the augmented matrix and the interpretations expressed by the students. They use the Gauss-Jordan elimination method. The following excerpt is drawn from this discussion.

71 Buse: Look [showing the solution her pair], I put a=0 and b=2 to see what will happen, I could only calculate z=1. I can not find x or y.

72 Deniz: We can not find, look, the second and third rows are completely zero.

73 Teacher: What does it mean? How can you relate this fact with your initial interpretation?

74 Deniz: Any real number can satisfy this system if we put it instead of x or y. They are independent from the plane equations, since, this is consistent with the picture here [indicating 3DGR], where there are two variables that we cannot find, but the solution, I mean, the intersection is a plane: a two-dimensional thing. But I am not sure whether this hypothesis is valid for other cases.

75 Teacher: Let's analyse other cases then.

76 Deniz: [She is moving the sliders, checking her hypothesis] If we take a=1 and b=2, there is again an infinite solution, [looking at the matrix form] and we can not find y either x, but x=y, since we have one free variable, the intersection is a line; a one dimensional thing.

As a consequence, Buse points out the exact solution, 'no free variable', and therefore, 'single point and 0-dimensional thing'. To sum up, I observed a semiotic chain (Bartolini Bussi & Mariotti, 2008) in the use of different semiotic registers, from artefact signs to math signs of *free variables* such as: 'chancing value' (item 46); 'intersection of the planes' (item 46); 'solution types' (item 47); 'independence from equation' (item 74); 'variable' (item 74); 'dimension' (items 74–75); and 'free variable' (item 76).

CONCLUSIONS

Even if linear algebra does not consist of only geometrical features, as Harel (2000) states, it can be a powerful 'corridor to the more abstract algebraic concepts' (p. 185). In this project, I aim to construct math meanings of geometrical features in linear algebra concepts within the semiotic potential of an artefact; with GeoGebra, and particularly in this work, I focus on the notion of a free variable. Through this experiment, I conclude that the emergence of the notion of a free variable has a strong link with student recognition of geometry and to relating geometric objects' invariants with their infinitive characteristics, such as variables. The use of different registers helped students to articulate the different cases. In the experiment, I realized that the main feature was the students' use of the software. Because they did not know how to use it as an instrument, they were not able to master the use of the sliders when they changed windows. The project will continue with underpinning teaching experiments and case studies to analyze the semiotic potential of the mentioned software in terms of, 'what key linear algebra concepts can emerge' through its use, and I will also point out students' utilization schemes in sense of Rabardel (1995). The description of such utilization schemes may also be a basis for describing possible meanings that may emerge during the designed activities.

ACKNOWLEDGEMENT

I would like to thank Maria Alessandra Mariotti and Paul Drijvers for their kind and endless contributions during the preparation of this paper. This project is supported by *The Scientific and Technological Research Council of Turkey* (TÜBİTAK BİDEB) under 2219–International Postdoctoral Research Fellowship Programme.

Using spreadsheets in learning equations

Osman Bagdat

Anadolu University in Eskisehir, Faculty of Education, Eskişehir, Turkey, osmanbagdat@anadolu.edu.tr

Spreadsheets as a very functional tool has been used in many studies to facilitate transition process from arithmetic to algebra. In this study, we describe middle-grade students' experiences about using spreadsheets in learning equations. For this purpose, ten 7th grade students who had been taken an elective mathematics course participated in a spreadsheet activity about exploring equations with two unknowns. As a result, working on the problem arithmetically with spreadsheets helped students to conceive the spreadsheet cells as variables and it facilitate the students' formulization of arithmetic generalisations.

Keywords: Spreadsheets, arithmetic, algebra.

INTRODUCTION

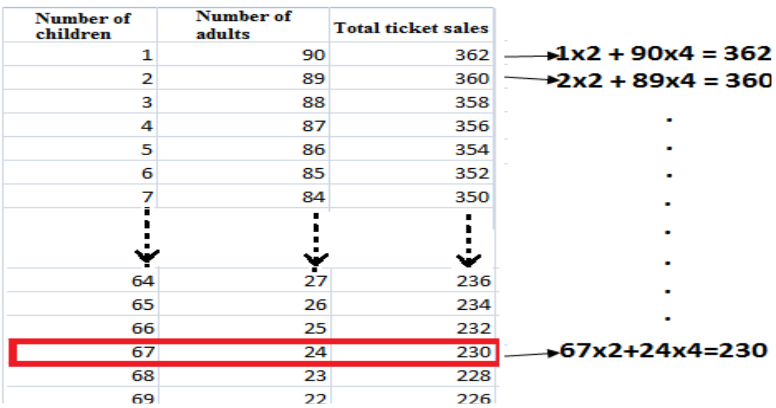
Transition from arithmetic to algebra is considered as one of the crucial point of mathematics. Many studies indicate that majority of students have difficulties in this process. In recent years, using technological tools have been seen as an alternative approach to overcome these difficulties. Since spreadsheet activities provide instant feedback in an interactive environment, it appeared as an important learning tool for students. Lots of studies have been done in math education about spreadsheets, many of which in algebra. Spreadsheets, in particular, provide students with a learning environment in which students can explore equations (Lagrange & Erdogan, 2008), and make pattern generalizations which are one of the crucial components of algebraic reasoning. Students can provide variety of solutions and have chance to see relationships among the variables as numbers change (Edwards & Bitter, 1989).

Although the importance of using spreadsheets in teaching algebra, we do not encounter many examples in actual Turkish classroom settings. This study contributes the efforts of utilizing technology in learning and teaching mathematics through a real example from a middle school classroom setting.

METHODOLOGY

This study was conducted with ten 7th grade students in a public middle school in Eskisehir, Turkey. Data were collected through a word problem (see below) which can be solved both arithmetically and algebraically. Students worked in pairs throughout the classroom period. The whole problem solving process was recorded on all computers through using the software, Camtasia Studio 7.

> *The problem*: "On Tuesday a total of 91 people visited the local zoo. Entrance fees: 4 TL (Turkish Liras) for adults and 2 TL for children. At the end



Number of children	Number of adults	Total ticket sales

68	23	228
69	22	226

Figure 1: Sample student solution

of the day the total ticket sales were 230 TL. So how many children visited the zoo?"

FINDINGS AND DISCUSSION

Initially, students used the "trial and error" strategy to find the total number of children visiting the zoo. The teacher provided a table drawn on a paper for each group for draft solutions and asked students to think about the possible numbers of children and adults visiting the zoo. In this moment, students used only calculators. After a few trials, the teacher asked students to continue working on the problem using pre-designed spreadsheets. While some groups randomly entered numbers for children and adults and tried to find the total ticket cost (i.e., 230 TL), others used a more systematic way (see Figure 1).

Later the teacher asked students to solve the problem algebraically. Specifically, the teacher asked students to create algebraic representations for the total number of people visited the zoo, and the total ticket sale. Following algebraic equations were provided from a teacher-led group discussion:

Teacher: What does x+y=91 represent?
Student A: It is the total number of people visited the zoo. While "x" is the number of students, "y" is the number of adults. The total number of people who visited the zoo is 91.
Teacher: Okay. How about 2x+4y=230
Student B: Since children pay 2 TL for each ticket, I wrote "2x" for the total amount of money they pay for entrance to zoo. Then I did the same thing for adults (4y). The total ticket sales should be 230 TL. So I wrote "2x+4y=230."

Working on the problem arithmetically with spreadsheets helped students to conceive the spreadsheet cells as variables. Thus, it facilitated making sense of variable and helped students make a smooth transition from arithmetic to algebra.

Influence of dominant cognitive structure on the way of students' thinking during problem solving

Edyta Juskowiak

Adam Mickiewicz University, Poznań, Poland, edyta@amu.edu.pl

In this contribution, I present a part of a research project, whose goal is to study and describe the ways in which 14-year-old students and students of the Department of Mathematics and Computer Science at Adam Mickiewicz University in Poznań, Poland, use respectively the graphic calculator and Geogebra for solving particular tasks. During this study, I attempted to answer the following question: what is the influence of dominant cognitive structure, predicative or functional, on the way of thinking of students during specific problem solving?

Keywords: Dominant cognitive structure, problem solving with technology, mathematical thinking, GeoGebra, graphic calculator.

INTRODUCTION

The appearance of graphing calculators and GeoGebra computer software in Polish schools has raised the interest of the research community in the students' learning process with the use of those tools, aiming at recognizing both their advantages and disadvantages as well as their role and place in the process of learning and teaching mathematics. In this context, it is important to know the differences concerning the ways in which people work on the same task with or without the use of technology (Demana & Waits, 2000).

THEORETICAL FRAMEWORK

For this study, I have used Schwank's theory of functional and predicative thinking (Schwank, 1995, 2001). Schwank's study shows that in every human being we can observe a relatively stable tendency to exhibit a way of thinking characteristic of one of the two cognitive structures: either the predicative or the functional one.

QUESTIONS

How do pupils and students of mathematics (future teachers) solve mathematics problems using the graphing calculator and GeoGebra in relation to their dominant cognitive structure, be it functional or predicative? Does the analysis of solution of the problem allow determining the dominant cognitive structure of each student? Is this structure the same during the student's work on a task with or without technology?

METHOD

This research study involved first grade junior high school students and students of Math and Computer Science Department of Poznań Adam Mickiewicz University, specializing in teaching. The work of the high school students was observed in the context of an examination requiring solving non-standard tasks with a graphic calculator; the work of the university students was observed in the context of a research project focusing on the ways of working on non-standard tasks with or without the use of new technologies. The data gathered consisted of the records of the students' work on the task with technology, the records and notes of a discussion with the students after the activities with technology, and the students' worksheet (Juskowiak, 2014).

RESEARCH RESULTS AND IMPLICATIONS

The attempt to define the way of thinking of the examined junior high school students and university students, based on their solutions, has turned out not to be an easy task. It required a specific methodology, which entailed a precise monitoring of the students' work on the task through the use of tools for recording the students' activity with technology. Such methodology allowed observing the problem solving process in a very precise and detailed way, so helping to define the students' way of thinking. Though this is a preliminary small-scale study, it seems to show that on the basis of tasks solution one can draw conclusions about the students' dominant thinking structure. The same dominant cognitive structure manifested both in working with technology and without its use. Only in one case, this did not occur: a student with a dominant predicative cognitive structure solved the math problem with technology showing a functional cognitive structure. This confirms the fact, which had already been observed by Schwank, that the tendency to a specific way of thinking does not exclude thinking in other ways (Schwank, 1995, 2001).

Integrating technology into primary and secondary school teaching to enhance mathematics education in Hungary

Zsolt Lavicza[1], Istvan Juhos[2], Balazs Koren[3], Kristof Fenyvesi[4], Csaba Csapodi[2], Marta Kis[2] and Jose-Diego Mantecón[5]

Keywords: Technology, teaching traditions, design experiments.

During the past decades, technology has been becoming an integral part of everyday life and slowly shaping mathematics and science teaching and learning (e.g., Heid & Blume). Although there has been enormous investment on educational technologies in many countries, technology has yet to make a sizable impact on education (e.g., Drijvers et al., 2010). On the one hand, students are becoming increasingly proficient users of technology while, on the other hand, opportunities offered by technologies have still little been utilized. Nevertheless, technologies are becoming more integrated into education providing new opportunities for pedagogical approaches and classroom organisation. For example, mathematicians stated that they use technology because in this way they can more easily treat students as mathematicians and nurture their knowledge through discovery and experimentation (Lavicza, 2010). To utilise the opportunities technology offers we developed a large-scale project, GEOMATECH (http://geomatech.hu), in Hungary integrating teaching traditions of the country as well as good practices from around the world.

Many Hungarian mathematicians, scientist and mathematics educators have a world-wide respect. In addition, mathematics education theorists and practitioners, George Pólya, Zoltán Dienes, Imre Lakatos, Tamás Varga among others, are often quoted as great innovators and founders of modern theories and practices in mathematics education. In the GEOMATECH project, we are developing new approaches for technology integration into Hungarian schools utilising Hungarian teaching traditions, successful international examples, and experiences of Hungarian teachers. The research team of the project is closely working with 45 teachers (25 mathematics, 20 science) and their students (1200 mathematics, 800 science) for 8 months utilising Design Experiment and the Community of Practice frameworks (Cobb et al., 2003; Jaworski, 2006) to develop teaching materials and employing theories of inquiry-based education (Artigue & Blomhoj, 2013). The research team offers continuous feedback to the material development, teacher training and software development teams to extend this work to other Hungarian schools. The GEOMATECH project (owing to the generous 8million Euro EU Funding, TÁMOP-3.1.12) will develop high-quality teaching and learning materials for all grades in primary and secondary schools in Hungary. These materials (1200+ Mathematics, 600+ Science) will be embedded into an on-line communication and collaboration environment that can be used as an electronic textbook, a homework system, and a virtual classroom environment. In addition to material development, we will offer 60-hour professional development courses for more than 2400 teachers in 800 schools in Hungary. Furthermore, we will organize a wide-range of teacher and student activities including competitions, mathematics and science fairs, and develop a network of schools for the long-term sustainability of the GEOMATECH project. The technology background of the project is offered by GeoGebra (http://geogebra.org), which an open-source, dynamic mathematics software widely used around the world.

All activities in GEOMATECH will be evaluated by the research team and questionnaires to measure students' various beliefs and conceptions will utilise the modified instruments of Andrews and Mantecón (2015). Currently, we are in the initial phase of the project starting the Design Experimental phase and preparing the project team (almost 200 people) for further tasks in the project. In our poster, we will outlined the theoretical frameworks, the different stages of the project and highlighted initial results from the Design Experimental phase.

On the usage of media when solving exercises – the activity theory viewpoint

Hannes Stoppel

Westfälische Wilhelms-University Münster, Institute of Education of Mathematics and Computer Science, Münster, Germany, hannes.stoppel@uni-muenster.de

A lot of digital media are used in mathematics lessons. Students take recourse in them when difficulties arrive while solving exercises, but other difficulties often appear when choosing an inappropriate method to solve an exercise under usage of digital media. Students need to know whether, when, and in which way (wwww) to use digital media for procedures. Wwww differs for the same procedures in dependence on the digital media used. Activity Theory (AT) will be helpful to understand procedures used in solving exercises as described with examples of Computer Algebra Systems (CAS).

Keywords: Activity, method, object, digital media, CAS.

INTRODUCTION

In accordance with earlier findings (Stoppel, 2012), solving exercises include the development or the choice of *methods* like algorithms and their application to *objects* like equations or geometric figures. The analysis of students' solutions from two universities and several grammar schools showed that solving exercises depends on the ability of students to choose or develop an appropriate method to design or select any useful object for the solution of the exercise afterwards.

Based on these results, some exercises from calculus and probability theory were solved with different CAS. The analysis of solutions showed that different syntax of CAS leads to differences in the choice or the development of methods and activities for solving the exercises.

THEORETICAL BACKGROUND

Several possibilities for usage of CAS in different phases of a solving process are shown in Zehavi and Mann (2005). Examples of the applicability of CAS are described in Pointon and Sangwin (2001). We used Activity Theory to observe connections between the syntax of operations of media and the solution processes. Studies concerning activities when using digital media already exist (e.g., Kaptelinin & Nardi, 2006). In contrast hereto we draw on the concept of activity system by Leontiev (1978) to study the methods used inside of solutions, and representations of the activity system of Engeström (1987) to investigate artefacts regarding the usage of media and their interconnections to methods.

Wwww lead to two questions: *1. In what situations are students unable to find methods or connections of methods to objects? 2. What might be helpful for students to find legitimacy methods and connections?* An analysis of several correct and wrong solutions in the abovementioned study shows that AT is helpful to understand the phases of the solving processes.

RESULTS

On the way to the application of a method, the learners need to decide whether to choose an already familiar method or to construct a method by themselves. Independent of being useful for solving a given exercise, the hierarchy of the approaches to solutions, the types of solutions and the way through solutions play a big role for students. When using different digital media, students might need to solve parts of exercises employing different command syntax. The command syntax could lead to methods that differ from usual methods of solutions without digital media, so that, with digital media, students might be distracted or even unable to recognize the solution at the end.

To find answers to question 2, we need to take a look at the usage of media by students in mathematics lessons.

While solving exercises, activities are important for the development of methods. Their complexities are visible in Engeström's (1987) activity system while the inclusion of methods into solutions is shown by Leontiev's (1978) concept.

With help of the systems the importance of various aspects and the interrelationships between them for a successful solution of an exercise becomes evident. Teachers need to consider them to support their students and to decide on wwww to use digital media.

Students learning mathematics with resources and technology

Introduction to the papers of TWG16: Students learning mathematics with resources and technology

Matija Lokar[1], Ornella Robutti[2], Nathalie Sinclair[3] and Hans-Georg Weigand[4]

1 University of Ljubljana, Ljubljana, Slovenia, Matija.Lokar@fmf.uni-lj.si
2 University of Torino, Torino, Italy, ornella.robutti@unito.it
3 Simon Fraser University, Burnaby, Canada, nathsinc@sfu.ca
4 University of Würzburg, Würzburg, Germany, weigand@dmuw.de

SCOPE AND FOCUS OF THE WORKING GROUP

Recent discussions within the CERME technology group have confirmed the relevance of introducing information and communication technology (ICT) in mathematics education with a range of various resources, such as software, hand-held devices and online classroom activities. The scope of the working group at CERME9 was to address the opportunities and possibilities, as well as the challenges and limitations that resources and technology present for student learning. Due to the large number of participants in the technology group at the last CERME conferences, the group was divided into two strands. TWG15 concentrated on "teaching with resources and technology", while the focus of TWG16 was on "students learning with the help of resources and technologies".

In TWG16, we were interested in empirical results obtained in the course of the last few years and decades concerning, for example, the introduction of new learning methods and concepts, the improvement of learning within the frame of old concepts or new forms of exercises in the whole range of mathematics education. Moreover, we wanted to set the scope towards the future, to think about general conclusions for mathematics education, and the research required as well as the implications for the classroom.

A range of different issues was covered, including:

— The design and/or use of the current software and technologies concerning students' formal and informal learning, at school and out of school;

— The design of teaching experiments with software and technologies concerning student learning;

— The influence of computers, notebooks, tablets or handheld-technology on the learning of mathematical concepts and the construction of learning environments;

— The results of empirical studies and investigations, especially those concerning long-term learning with ICT, massive courses, national programmes relating to the teachers' professional development;

— The possibilities of present and up-coming mobile communication and representation tools like tablets, smartphones;

— The possibilities of different methods of assessment using ICT;

— The influence of web-resources and online courses on the learning of mathematics;

— The examples of "best practice" in the classroom;

— The examples of the use of technologies designed for the support of students with disabilities.

RESULTS OF TWG16

In TWG16 we received 23 papers and 3 posters from 15 different countries. In the following sections, the topics are classified as *old questions* and *up-coming* *topics* strongly represented in TWG16, which are discussed first, and finally the topics referred to as *missing topics* are discussed.

"Old question" strongly represented in TWG16

Starting with the Dynamic Geometrical Systems *Cabri-Geomètre* and *The Geometer's Sketchpad* in the late 1980s, dynamic mathematics has always been a strong argument for the use of new or digital technologies. Nowadays, there are numerous simulations in mathematical and environmental settings, which use dynamism in connection with *touch screen technology*. An example is the "place value chart" (Figure 1), which visualizes the changes while moving the tokens from one column to the other (see the article of Behrens). See also the papers by Brunström and Fahlgren and Bray, Oldham and Tangney.

Multi-linked representations are another often mentioned argument for using digital technologies in the learning process. Figure 2 shows the symbolical, numerical and graphical representations of a quadratic function, which enable, for example, identifying structural analogies in the different representations (see the articles of Pinkernell and Swidan).

There are many more topics that are important and will stay important in the following years:

- ICT and problem solving and/or guided inquiry learning (see for example the paper by Schumacher and Roth)
- The relationship between hands-on materials and ICT
- The transition from activities to mathematical thinking
- The transition between ICT-tools and paper-and-pencil activities
- The benefits of ICT for the learning of content, e. g., calculus
- Programming and its connection to mathematics (see the paper by Misfeldt and Ejsing-Duun)

Up-coming topics

a) Touch Screens and Human-Computer Interaction

Touch screen working with tablets is already a frequently discussed topic in present classrooms. Gestures will become more important – for example, while zooming into a graph or diminishing an interval – to help visualizing and, hopefully, understanding mathematical concepts. The complexity of simultaneously changing more than one variable (by moving the fingers) should by no means be underestimated. But the empirical basis concerning these new features is still quite small. See the paper by Bairral and Arzarello.

b) Internet resources – Social media or networks

Although Internet resources such as Facebook, etc. are not constructed for doing mathematics, social media or networks open new possibilities, for example, "peer learning". There might be automatic help systems available, but there will also be the possibility to get personal help from experts, tutors, students or other Internet users. See the article of Puga and Aguilar.

c) Automatic Testing – Automatic Feedback

Intelligent tutoring systems have been developed and tested in mathematics classrooms for many years (see the article of Borba, Azevedo and Barreto). Nowadays, there seems to be a new approach possible in forma-

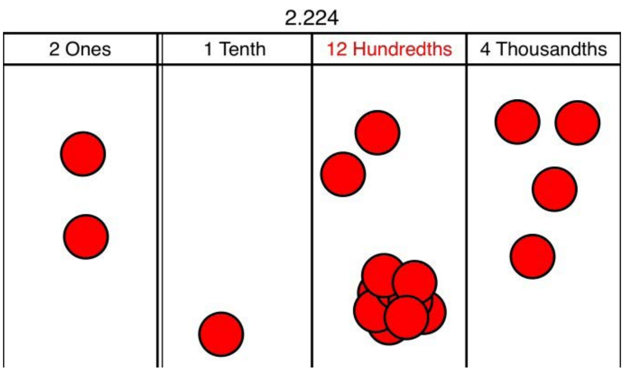

Figure 1: Changing the number's representation within the place value chart by moving tokens

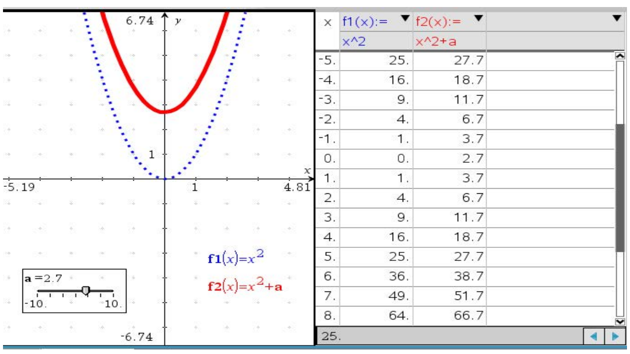

Figure 2: Dynamic multiple representation environment for exploring the effects of a on the representations of $f(x)=x^2+a$

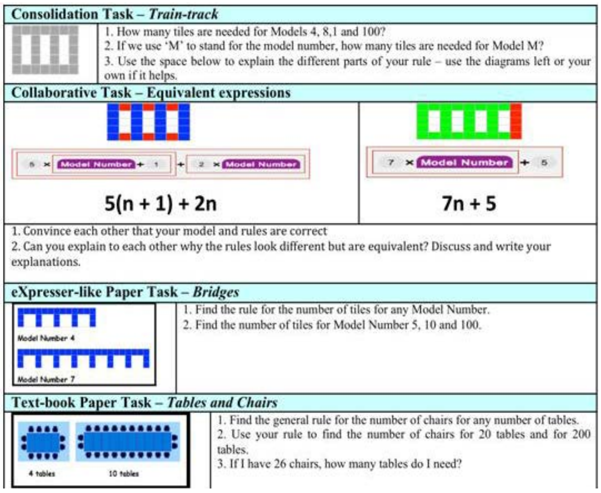

Consolidation Task – *Train-track*

1. How many tiles are needed for Models 4, 8,1 and 100?
2. If we use 'M' to stand for the model number, how many tiles are needed for Model M?
3. Use the space below to explain the different parts of your rule – use the diagrams left or your own if it helps.

Collaborative Task – Equivalent expressions

5 × Model Number + 1 + 2 × Model Number

5(n + 1) + 2n

7 × Model Number + 5

7n + 5

1. Convince each other that your model and rules are correct
2. Can you explain to each other why the rules look different but are equivalent? Discuss and write your explanations.

eXpresser-like Paper Task – *Bridges*

Model Number 4

Model Number 7

1. Find the rule for the number of tiles for any Model Number.
2. Find the number of tiles for Model Number 5, 10 and 100.

Text-book Paper Task – *Tables and Chairs*

4 tables

10 tables

1. Find the general rule for the number of chairs for any number of tables.
2. Use your rule to find the number of chairs for 20 tables and for 200 tables.
3. If I have 26 chairs, how many tables do I need?

Figure 3: Transition from arithmetic to (formal) algebra (Geraniou & Mavrikis)

tive assessment within the frame of automatic testing and automatic feedback, especially in arithmetic and algebra.

The system described in the paper by Geraniou and Mavrikis supports the transition from arithmetic to algebra by visualizing the variables in different representations. The article of Mackrell shows how real-world problems will be solved in a CABRI environment through the provision of effective feedback. There are a lot of didactical problems in the construction of systems like these: the problem of the right feedback in problem solving activities, the possibility of different kinds of feedback and feedback as step-wise help, feedback on task level or/and process level, and so on. Haddif and Yerushalmy focus their research on e-assessment of challenging calculus construction e-tasks designed to function as a dynamic interactive environment of multiple linked representations (MLR) that provide feedback to the learner (Figure 4).

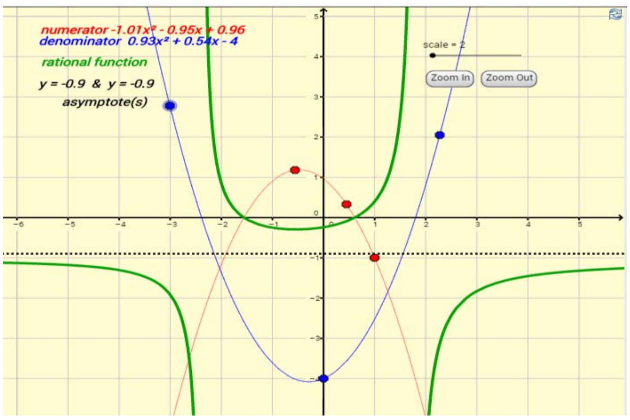

Figure 4: Construction of rational functions by given "dots" of the graph of the function

d) The significance of "games" for mathematics learning

Young students often play games on their tablets and smartphones, which raises the possibility of integrating mathematical games into the environment that is already present. Soldano, Arzarello and Robutti want the users to improve their proving abilities in a geometric environment, while Avraamidou wants the users to build houses, while adjusting the budget in relation to some variables such as the size of the building, the cost of the furniture and the mood meter.

e) ICT-support and special needs students

We only received one contribution referring to the learning style of a special needs student. Particularly students with physical disabilities might benefit from the possibilities of digital technologies. However, empirical research is still quite rare and the results are quite individual anyway, and generalizations almost impossible because of the great variety of special needs.

Missing topics

In TWG16 we have "only" received 26 papers and posters and, of course, these contributions represent a relatively small array of all possible topics. This just might be an indication of the waning importance of some topics, which were quite intensively discussed only a few years ago.

— The new possibilities of ICT concerning creating videos, doing screen recording, gathering and analysing big data … were not discussed in TWG16.

— Digital technologies allow more individuality, for example, the creation of portfolios and personalized e-textbooks.

— Communication is the norm and the goal in the NCTM standards (2000) and nowadays in many curricula all over the world. DT might support cooperation between communities and enable the "opening" of the classrooms.

— Completely new and emerging technologies have not been discussed in our group: sensor devices, augmented reality, mobile technology …

— Symbolic calculators are not discussed in any paper. They seem to be disappearing because they cannot compete with laptops, tablets and smartphones. But there are still strict regulations (in some countries, for example in Germany), and these tools are not allowed during examinations.

There are also some topics that might be called traditional and will be an ongoing problem in mathematics education, not only in relation to the use of digital technologies:

— We need more long-standing quantitative empirical investigations;

— We – as researchers – have to use proper research methods, which are informed by contemporary theories, and base our work on the existing and growing research in mathematics education;

— We have to get some more information about the actual use of digital technologies in real classrooms.

Research papers

Children's perception of the affordances of the mathematical tools

Yasmine Abtahi

University of Ottawa, Ottawa, Canada

Vygotsky's theory proposes a sign/tool-mediated view of learning. Tools and signs are inseparable parts of teaching and learning of Mathematics. Vygotsky's theory provokes questions: how are tools perceived, how are signs tied to the use of tools and consequently how are tools being used in the mathematics classroom. In this paper, I look at Vygotsky's perspectives on the perception of the tools, through the lens of Gibson's view of affordances. I analyse three children's interactions with the mathematical tools, as they gradually begin to tie signs to them, while working on addition of fractions problems.

Keywords: Perception, affordances, tools, fractions, meaning.

INTRODUCTION

Fractions are one of the most challenging concepts to teach and learn in elementary-school mathematics (Steffe & Olive, 2010). Lamon (2007) noted that fractions are one of the topics in elementary-school mathematics that are among 'the most difficult to teach, the most mathematically complex, the most cognitively challenging, and the most essential to success in higher mathematics and science' (p. 23). One way to assist children in learning fractions is to employ different mathematical tools in the classroom (Cramer & Henry, 2002; Misquitta, 2011; Mendiburo, 2011; DeCastro, 2008; Mills, 2011; Cramer, Post, & del Mas, 2002). Extending Swan and Marshall's (2010) definition, mathematical tools are any *tool-like* objects that can be handled by an individual during which mathematical thinking is fostered. Objects – any foci of attention (Engestrom, 2009) – are inseparable parts of any mathematics classroom. They include tools such as an abacus, symbols such as x^2, and graphs. The use of *tool-like* objects refers to Marx's view of the use of *working tools*; where man uses the physical and mechanical properties of objects to reach his goals. Hence, an abacus is a tool-like object and x^2 is not, because children are able to use the physical and mechanical properties of an abacus to achieve a mathematical goal.

Although the use of mathematical tools is conceptualised as being useful in the learning of fractions, children encounter difficulties in grasping the relationship between mathematical tools and the mathematical meanings that they are intended to represent (Norman, 1993; McNeil & Uttal, 2009; Rabardel & Samurçay, 2001). The process within which the child grasps the interrelationship between mathematical tools and the meaning of a mathematical concept is a highly complex one.

McNeil and Uttal (1997) explained that any mathematical tool "can be thought of in two different ways: (a) as an object in its own right and (b) as a representation of something else" (p. 43). For example, if the relationship between the sizes of the pieces in fraction circles and the concept of the additions of fractions is not clear to a child, then he/she needs to learn not only the mathematical concept, but also the functionality of the fraction circles as a system and its relationship with the mathematical concept; in other words, he/she needs to learn two separate systems and the relationship between them.

In this paper, I look at the interrelationship between mathematical tools and the mathematical meanings represented by the tools, in the context of fractions learning. Within the mathematics education research, the relationship between the mathematical tools and the mathematical concepts has been studied under different theoretical framework, in particular Cultural Historical Activity Theory (CHAT) and Actor-Network Theory (ANT). CHAT providing a detailed theoretical lens to analyse the mediated actions of a subject, investigates the subjects activity in relation to a particular goal (Engestrom, 1999). ANT, on the other hand examines the association of human and non-human entities as nodes of a network (Fenwick & Edwards, 2010) nodes of the network. Both these theories, even though seemingly relevant, have limitations in the particular context of my study. My focus in this study is on how children, with their own perceptions, utilise the physical properties of tools to construct meaning for the mathematical concept, through solving a mathematical task. Neither CHAT nor ANT provides me with a lens to thoroughly examine the role of the physical properties of the tools in children's understanding of fractions. Therefore, to look at the physical properties of mathematical tools – as objects in their own right – I used Gibson's notion of *affordances*. And to look into children's mathematical perception as they interact with the tools (i.e., the interrelationship between the tools and mathematical meanings). I introduce the concept of *perception*, as viewed by Vygotsky in the *object/meaning* ratio.

GIBSON'S VIEW OF AFFORDANCES

Concerned with how the environment supports cognitive activity, Gibson (1977) contended, "in any interaction involving an agent with some other system, conditions that enable that interaction include some properties of the agent along with some properties of the other system" (Gibson, 1977, p. 72). Gibson's notion of *affordance* focuses on the contribution of the physical system to the cognitive activity. The term affordance refers to whatever it is about the environment that contributes to the kind of interaction that occurs. In relation to the learning of mathematics, the term affordances refer to whatever it is about a mathematical tool that contributes to the interaction of the child with these tools in the process of solving a mathematical task. I consequently refer to the term *perception* as whatever it is about the child's thinking that contributes to the interaction with the tools.

In a child's interaction with the tools, it is crucial to highlight where to locate the reference of the term affordance. For example, is the affordance that fraction circles provide for making half a unit or 1/2, a property of the fraction circles, a property of the child interacting with it, or properties of both? Fraction circles are a set of nine circles of different colours. Each circle is broken into different equal fractional parts, which use the same size as a whole. Gibson argued "affordance is a property of whatever the person interacts with, but to be in the category of properties, we call affordances, it has to be a property that interacts with a property of an agent in such a way that an activity can be supported" (p. 341). Hence, for the properties of a mathematical tool to be called its affordances, they need to be perceived by the child in such a way that a mathematical activity can be supported. For example, the physical properties of fraction circles that might assist a child to grasp a fractional concept are called their affordances *only* if the child perceives the interrelationship between the physical components of the fraction circles and the mathematical task, e.g., to solve 1/3 + 1/2. The physical properties of fraction circles might also be perceived as useful to build a bridge; these properties are called affordances if the task at hand is bridge making.

The above argument implies that interacting with an environment that provides an affordance for some activity does not entail that the activity will happen; the occurrence of the activity is intertwined with: the activity of the agent in that situation – that is his/her perception – and the task at hand. Assuming the task at hand is a particular mathematical task to be solved by the child, it is then the perception of the child that needs in-depth analysis; that is how the child perceives the tool and its affordances, in accordance with the mathematical task. Vygotsky's notion of Object/Meaning ratio offers a systematic approach to look at the gradual yet complex process of change in the child's perception as she/he interacts with the mathematical tools to make meanings for the tool as well as the mathematical concept.

VYGOTSKY'S VIEW OF PERCEPTION

A special feature of human perception is the perception of real objects (Vygotsky, 1976). The perception of the real objects involves the perception of not only colours and shapes but also of meaning; we do not see a round object with two hands, we see a 'clock'. The attachment of meaning to an object is a process that develops through the use of signs in interactions with tools (Vygotsky, 1978). Signs, such as language, drawings and the various systems of counting, are 'means of internal activity aimed at mastering oneself' (Vygotsky, 1978, p. 55). To better explain the process of attaching signs to the use of tool-like objects, I use Vygotsky's object/meaning ratios.

Vygotsky argued that at first the perception of a human being could be expressed figuratively as a ratio in which the numerator is the object and the meaning is denominator – object/meaning. This means that for a young child the object is dominant and the meaning of the object is subordinate. At this stage, the physical properties of things play an important role in a child's interaction with them. For instance, a stick can be a horse in child's play but a box of matches cannot be a horse. It is only later, when the child can make use of signs and symbols in her/his interaction with the objects, that the meaning becomes the central point and objects are moved from being dominant to being subordinate, thus giving rise to the meaning/object ratio. At this stage Vygotsky noted that, for example, to show a location of a horse on a map a child could put a box of matches down and say, 'This is a horse'. The perception of the child can now be expressed as a meaning/object. This figure of perception in which the meaning dominates is the result of tying signs to the tools; the box of matches is a symbol (sign) to represent the horse.

Vygotsky's object/meaning view has a two-fold theoretical implication for the study of children's perceptions as they interact with the mathematical tools to solve a task. On the one hand, it provides a base for analysing the gradual changes of the child's perception of the affordances of the tools as the child interact the tools to work on a mathematical activity. On the other hand, it provides a base for analysing the gradual changes of the child's perception of the interrelationship between the tools and the mathematical meaning they are intending to represent.

Provided that the child is interacting with a mathematical tool to solve a mathematical task, at the initial stage of the child's encounter with the mathematical tool, the child's perception can be presented by the object/meaning. This figure of perception applies to how the child perceives the affordances of the tool (i.e., the meaning of the tools as an object in relation to the task at hand) as well as how the child perceives the mathematical concept represented by the tool (i.e., the mathematical meaning). At this stage, the tool is dominant and its meaning(s) – as an object or its mathematical meaning – is subordinate. Hence, this is the stage that the physical properties of the mathematical tool play an important role in the child's interaction with them, both to perceive the affordances provided by the tool and to perceive the mathematical concept presented by the tool. For example, in fraction circles, the relationship between sizes and colours of the pieces plays an important role in how the child perceives the affordances of the fraction circles and the fractional concepts they are presenting.

In order to invert this ratio, that is, in order for a tool to be used as a symbol (a sign) for a mathematical concept, the child needs to increasingly tie signs to their use of the tool. Children do this by talking about what they do, talking about the tasks, drawing, and using mathematical symbols. It is in the gradual process of inverting the object/meaning ratio to a meaning/object ratio that children grasp the interrelationship between the affordances of mathematical tools and the meaning of the mathematical concepts that they are intending to represent.

In the following sections, I illustrate these ideas with two examples of children's interactions with mathematical tools as they attempted to solve addition of fractions problems. In the first example, N and J used their perception of the addition of fractions to make meaning of the affordances of a newly designed mathematical tool (i.e. the fraction board) in relation to the task. During the interviews, N and J used different mathematical tools, such as fraction strips and Cuisenaire Rods to solve different addition of fractions problems. My rationale to report their interaction with the fraction board is that this tool was designed by me, hence children had no previous encounters with the tools. Children's first interaction with the tools gave me an opportunity to examine how they used the mathematical perception of the addition of fractions to perceive the affordances of the fraction board. In the second example, Teresa used the affordances provided by a mathematical tool to make meaning of the addition of fractions. In both cases, however, the children's perception, both of the mathematical concept and of the tool, changed gradually and through tying signs to their interactions with the tools as they worked on the specific mathematical tasks. The reason for selecting these two pieces of data is to implicitly illustrate how the children's perceptual change of the affordance of the mathematical tools goes through similar gradual and complex process as children's gradual changes in perception of the mathematical meanings presented by the tool.

THE CASE OF J AND N: WORKING WITH THE FRACTION BOARD

J and N, in grade 5, participated in a small-scale research study in which they were asked to use a mathematical tool called the fraction board to solve 1/6 + 2/5. The fraction board is designed to help students with the addition of fractions. It contains fraction strips of half, third, fourth, fifth and sixth, a board which frames a fraction chart from one to 1/30, and a wooden roller which holds the fraction strips and moved up and down the board (Figure 1).

Both N and J has previously demonstrated an understanding of the addition of fractions through other tasks, but neither of them had had previous encounters with the fraction board. Hence, they initiated the task by attempting to grasp the mathematical affordances of the fraction board, as an object on its own right. With the initial help of the researcher (Y), N and J started to perceive the general physical properties of the tool, not in any particular relation to the task at hand. For example when Y began to introduce the physical components of the board both N and J quickly perceived the affordances of the strips by assigning a fractional amount to them:

Y. Okay I just very quickly tell you that this is a fraction board. These are called fraction strips and we have different kinds
J. This is 1/2 and this is 1/4 [*pointing to different fraction strips*]

At this stage, the physical properties of the tool played an important role in N and J's perception of the tool. For example, the ways in which different fraction strips are partitioned into different equal sized parts, assisted N and J to perceive their affordances.

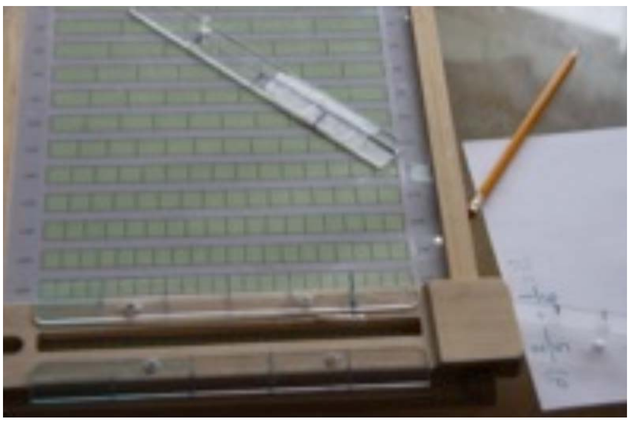

Figure 1

Through the gradual increase of the use of signs in their interaction with the tool, N and J's perception of the affordances of the strips gradually changed. This time in relation to the particular task at hand (i.e., to solve 1/6 + 2/5), they picked the strips of 6ths and 5ths as stated:

J. that is the 1/6 so I need one of that
N. yes and for that you need two (*pointing to the 1/5 fraction strips*).
[J colours the strips, one part on the 6ths and 2 parts on 5ths]

It was only later, that N and J were able to tie signs related to the mathematical meaning of the addition of fractions to their use of fraction board, perceive other affordances of the tool, and solve the mathematical task at hand. After selecting the two useful fraction strips of (6ths and 5ths). N and J started to perceive the "adding" affordances of the tool: "N. and I ...I...I guess they would go in here (pointing to the roller)". After loading the strips on the roller, N and J did not immediately perceived the affordance that the tool provided for finding the common denominator. So they used their perception of the mathematical concept of the need of a common denominator to perceive the affordances of the tool. They knew that to add 1/6 + 2/5, they needed to "turn the 5 and 6 into something". So they started to randomly moving the roller down the fraction board to see what number on the chart fit in both 1/6ths and 1/5ths. They unsuccessfully tried 12ths, 9ths and 18ths:

J. we can turn this (6ths) into two twelve's. *[they stopped at the 12ths line, noting 5ths did not fit]*
N. Lets try the nines
J. nop...
N. No definitely not
L. try 18 ... 18 going to 18?

After a few trial and errors they again used their perception of the concept of addition of fraction to conclude that the number that fits in both 5ths and 6ths is the thirtieths.

J. Oh... I get it, I can do it.
[...]
J. 1, 2, 3, 4, 5
N. five... five thirtieth
J. so we can trade this into five thirtieths

N. and then counting on the sixths... (*counting from the top of the roller...*), so 1, 2, 3, 4,5, 6,7 ,8, 9, 10, 11, 12... twelve thirtieth

J. so we can trade this (*pointing to the one sixth strip on the fraction board*) with 12/30. So we can change it into 17/30.

N and J's interaction with the fraction board is an example of how perceiving the mathematical affordances of a mathematical tool is a gradual process, which is intertwined with the mathematical task. Moreover, this example shows how N and J's object/meaning ratio (where they interacted with physical properties the fraction strips and the board to perceive the affordances of the fraction board) was inverted to a meaning/object ratio (where they used the affordances of the fraction board to solve the task).

THE CASE OF TERESA: WORKING WITH FRACTION KITS

This example is borrowed from Pirie and Kieren's (1989) study, in which Teresa used fraction kits to solve an addition of fraction problem. The reason for including this episode is that Pirie and Kieren's (1989) study was conducted over a period of time, which made it possible to look at Teresa's gradual changes in perception over a longer time span. Fraction Kits were designed by Tom Kieren; they contain rectangles, based on a common standard sheet as a unit, representing halves, thirds, fourths, sixths, eighths, twelfths, and twenty-fourths.

Teresa began the task of adding two fractions, not knowing what to do. She said 'I don't know' and 'I think you just add the tops and the bottoms' (Pirie & Kieren, 1989, p. 163). She was then given the fractions kits and a series of tasks. By perceiving the affordances provided by the fraction kit, 'she noticed that one fourth, three eights, and two sixteenths together exactly cover three fourths' (Pirie & Kieren, 1989, p. 163). Later, Teresa could 'add' 1/3 + 1/6 + 6/12 using the affordances of the kit. This is the stage in which the physical properties of the fraction kit, for example, the relationship between the sizes and colours of the pieces, played an important role in Teresa's interaction with the kit.

After a while, with a gradual change in her perception of the mathematical concept of the addition of fractions, she was able to tie signs to her interaction with the tool: 'You can do 2/3 + 5/6 because twelfths fit on both' (Pirie & Kieren, 1989, p. 167). Later, when asked 'What is 1/2 + 3/4 + 2/5 + 7/10?', Teresa, without using the kit, she said:

> Twentieths will fit on all of them. Two times ten makes twenty, so one times ten or ten twentieths. Four times five makes twenty so three times five is fifteen twentieths... (p. 169).

Teresa's gradual perceptual development for the addition of fractions, through the use of the fraction kit, made it possible for her to make statements like:

> Addition is easy. You can make up the right kind of fractions just by multiplying the denominators and then just get the right numerators by multiplying by the right amounts (p. 169).

This example shows how in the process of Teresa's interaction with the mathematical tool her object/meaning perception (where she used the fraction kit to solve the task) was inverted to become a meaning/object ratio (where she used signs and symbols to solve the task). In this process, Teresa increasingly used signs, while interacting with the fraction kits.

DISCUSSION

In this paper, I have employed Gibson's concept of affordances and Vygotsky's notion of object/meaning ratio to analyse children's interactions with two different mathematical tools. Teresa's case demonstrated a gradual perceptual change in the mathematical concept of the addition of fractions as she used a fraction kit to solve the addition of fractions tasks. J and N's case, by contrast, showed a gradual perceptual change in the affordances of the mathematical tool (i.e., the fraction board). These two examples show how children's perception of a mathematical tool and their perception of the mathematical meanings presented by the tool go through similar gradual and complex processes. Moreover, in both cases the children perceptions, of the tools and of the mathematical meanings, are highly intertwined with the children's attempt to solve the mathematical task. For example, in J and N's case, they would have perceived different affordances provided by the fraction board, had the task been to find the equivalent fractions of a particular fraction.

Perceiving the affordances of a mathematical tool is highly intertwined with perceiving the mathematical concepts there are intended to represent and with the task at hand. However, the main reason for contrasting the case of Teresa (implicit focus on changes in perception of mathematical meaning) with the case of N and J (implicit focus on changes in perception on the affordance of the tool) in this paper, is to illustrate significance of combining the Gibson's view of affordances and Vygotsky's view of perceptual changes.

Based on Gibson's view, the affordance of an object only become apparent in the ways in which the object is being used in a particular task. Based on this perspective the meaning of the object is interrelated with not only what the child is doing with the object, in relation to the task at hand, but also the mathematical meanings that may or may not be apparent to the child using the tool. Consequently, the Gibson's view of an object makes Vygotsky's notion perception in the object/meaning ratio more dynamic.

Moreover, the combination of Gibson's view of affordances with Vygotsky's perspective of object/meaning ratio may shed some light on how the children use the physical properties of the mathematical tools to perceive their affordance and their relationships to the mathematical task.

Further research is required to examine how the physical properties of mathematical tools play a role in children's interaction with them.

Gaming the system: An opportunity to analyse difficulties in arithmetical problem solving

David Arnau[1], José Antonio González-Calero[2] and Miguel Arevalillo-Herráez[3]

1 University of Valencia, Department of Didactics of Mathematics, Spain, david.arnau@uv.es

2 University of Castilla-La Mancha, Department of Mathematics, Spain

3 University of Valencia, Department of Computer Science, Spain

Gaming the system is a behaviour that must be avoided when interactive learning environments are designed. However, from the point of view of the research in mathematics education, the observation of this behaviour may bring to light the students' knowledge. In this paper, we provide results of a study in which primary education students (10–11 years old), grouped in pairs, solved problems in an arithmetical way using an intelligent tutoring system. We analyse cases in which the students were able to refine a fuzzy idea of how to calculate a quantity based on the belief that they necessarily had to use certain quantities, operations or conceptual schemes. We also provide examples of how sometimes such students' certainties can become obstacles.

Keywords: Word problems, intelligent tutoring systems, gaming, primary education, arithmetic.

INTRODUCTION AND AIMS

One-to-one tutoring (one teacher for one student) produces better results than instruction in ordinary groups (Bloom, 1984). However, the high cost of this kind of teaching prevents a widespread use. One way to circumvent these difficulties is to use intelligent tutoring systems (ITSs) that reproduce some of the actions that are carried out by a human tutor. The learning of arithmetical word problem solving has been a field where the design of new ITSs has abounded. Some examples would be AnimalWatch (Beal, Arroyo, Cohen, & Woolf, 2010); HERON (Reusser, 1993); or MathCal (Chang, Sung, & Lin, 2006).

Gaming the system is an unwanted behaviour when ITSs are used in teaching situations. We use the definition of gaming provided by Baker and colleagues (2009): "attempting to succeed in an interactive learning environment by exploiting properties of the system rather than by learning the material (by systematically guessing or abusing hints)" (p. 475). To avoid this behaviour, some control elements should be introduced during the ITSs design. However, from the point of view of the research in mathematics education, the observation of systematic guessing in a computer environment can provide us with information about students' prior knowledge when they make a mistake and the degree of certainty associated with this knowledge (see examples about the importance of analysing these performances in Mavrikis, 2010; Shih, Koedinger, & Scheines, 2008).

In this report we briefly describe the operation of the ITS called Hypergraph Based Problem Solver (HBPS) when it is used to solve word problems in an arithmetical way. We put forward an analysis of the performances of primary education students (10–11 years old) when they solve problems arithmetically using HBPS. It is an exploratory study that is the first step of an ongoing research about the effect of gaming when teaching to solve word problems with an ITS. In particular, in this paper, our analysis focuses on the moments in which the students resort to gaming the system to advance into the resolution process when a verbal cue acts as a source of confusion. The aim of this report is to show that the analysis of this behaviour provides relevant information about students' knowledge and misconceptions.

THEORETICAL FRAMEWORK

The arithmetical solving of word problems implies the repeated execution of analytical-synthetic processes (Bogolyubov, 1972). During the analytical process, solvers try to link the unknown quantities with the known ones through conceptual schemes that typically arise from the described situations in the statement (Riley, Greeno, & Heller, 1983). For example, a problem in which the time spent by a person going from one point to another is mentioned will usually evoke typical conceptual schemes of distance-rate-time (Mayer, 1981) such as the distance covered by a person is obtained through multiplying the speed of this person by the time spent. In an arithmetical solution, conceptual schemes let solvers link one unknown quantity to other known ones, and therefore make possible directly calculating the unknown quantity. Obviously, when students solve word problems, they may find difficulties in matching up the conceptual scheme to the right operation. These difficulties are reflected in the construction of incorrect operations.

On the other hand, when solvers read a problem statement some key words, which act as verbal cues, can lead them to identify not only the conceptual scheme, but also the arithmetical operation necessary for finding the solution: e.g., altogether, lost, gained, etc. However, as Nesher and Teubal (1975) pointed out, these key words also might act as a source of confusion leading the solver to an incorrect mathematical operation. In this way, Lewis and Mayer (1987) called statements such as "Joe runs 6 miles a week. He runs 3 times as many miles a week as Ken does. How many miles does Ken run in 4 weeks?" (p. 366) inconsistent compare problems, because the solution requires division of two numbers but the structure *times as many as* is involved. Several studies have shown that students tend to generate more solution errors in word problems that contain key words that suggest the opposite operation to that which is required in the solution process (Hegarty, Mayer, & Green, 1992; Lewis & Mayer, 1987; Nesher & Teubal, 1975).

MATERIAL AND METHODS

Material

In this study we used the program HBPS (Arnau, Arevalillo-Herráez, Puig, & González-Calero, 2013; Arnau, Arevalillo-Herráez, & González-Calero, 2014; González-Calero, Arnau, Puig, & Arevalillo-Herráez, 2014), which is able to supervise both the arithmetical and algebraic ways of solving word problems [1]. In fact, HBPS was designed around the main actions that an expert human tutor would do when supervising a student at solving an arithmetical problem. In particular, HBPS can infer the line of reasoning that a student is following and provide him/her adapted feedback messages using natural language. In this sense, results from Arnau, Arevalillo-Herráez, and González-Calero (2014) back the idea that HBPS is able to provide conceptual support as human experts do. These capabilities enable the system to offer a human-like personalized tutoring. This feature may be especially relevant taken into account that one of the potentials of ITSs is to make individualized tutoring widely and inexpensively available (Woolf, 2009). For this study we employed a version of HBPS, in which *help on demand* were deactivated and error messages were reduced to a simple notification. To illustrate the operation of HBPS we use the problem *The plans*, whose statement and a brief analysis is offered below.

The plans: Ann and Mike earned 36,000 € for designing a bridge. Since they did not work the same amount of time it should be distributed so that Ann will receive five parts of what they earned and Mike, seven parts. How much money did Mike earn?

The problem may be reduced to the known quantities (total of money, M (36000); number of parts that corresponds to Ann, Pa (5); and number of parts that corresponds to Mike, Pm (7)) and to the unknown ones (total of number of parts, P; money that corresponds to one part, Mp; and money that Mike receives, Mm). These quantities can be linked by the relations: $P = Pm + Pa$, $Mp = M/P$ and $Mm = Mp \cdot Pm$ [2]. If a solver follows this solution path, the last operation, which is used to calculate the part of money that corresponds to Mike, would be multiplication. When students are introduced to the solving of proportional sharing problems, this may cause difficulties due to the fact that in equal sharing problems the determination of these quantities usually implies dividing. In addition, in these problems it is common to find the key word *part*, which is usually associated with the mathematical operation division.

In the version of HBPS used in this study, the students can see the statement of the problem and find the name of the quantities that must be employed in a drop-down menu. When they select a name of a known quantity, they must assign the appropriate numerical value to it (see screenshot on the left in Figure 1). When they select a name of an unknown quantity they must assign an arithmetic operation that HBPS calculates automatically. To assign this operation, the expressions are introduced by using a calculator-like component. It is composed of a button

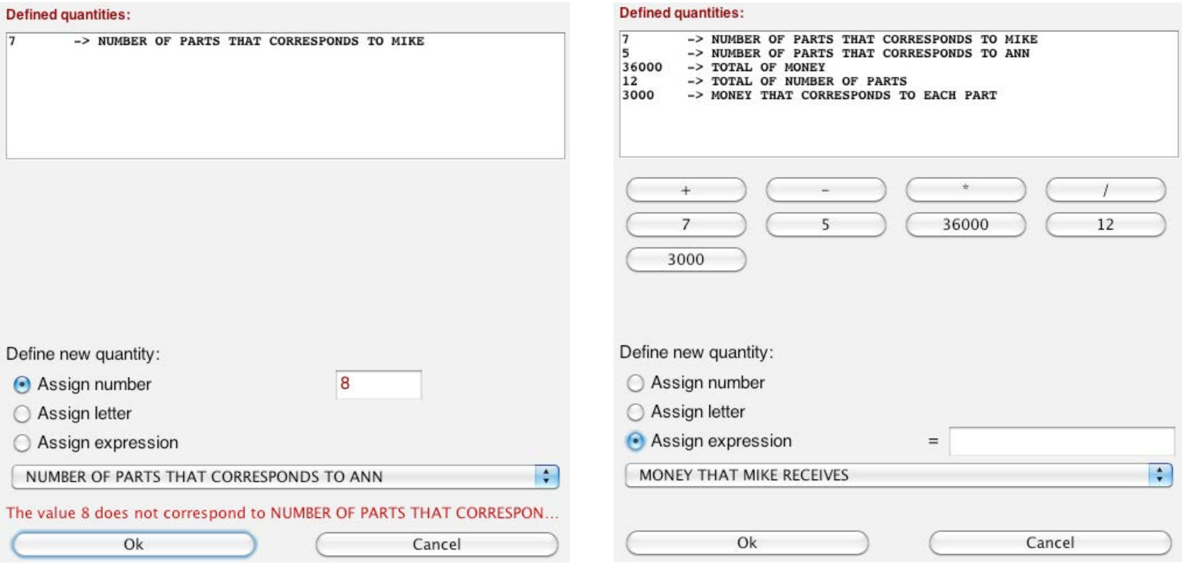

Figure 1: Error message (left) and construction of an arithmetical expression (right)

for each arithmetic operation, and another button for each different quantity that has been introduced into the system by the student (see screenshot on the right in Figure 1). In case of incorrect assignment of value or operation, this version of HBPS generates a simple error message by which the user is reported that last action is not correct but no additional information is offered (see screenshot on the left in Figure 1).

Empirical study design

The empirical study was carried out in a natural group of primary education composed by 20 students between 10 and 11 years old. As part of a wider study aimed at analysing how HBPS influences the students' proficiency in arithmetic word problem solving and that is not described in this report, the students had used HBPS to solve word problems in the classroom. Then, six students were chosen and they were grouped in pairs. The criterion adopted to select the students pursued to pair students who had shown difficulties in the same problems during the former phase of the study. Each pair was offered the problems that both members had previously failed to solve when they had been working individually in paper and pencil at the end of the instructional phase with HBPS. One of the problems the three pairs had to solve was *The plans*. They were asked to try to solve it using HBPS and they were encouraged to verbalise their actions. The sessions were video-recorded and afterwards the performances were transcribed to written language. As our investigation aimed to observe the process of problem solving, the researcher had a very low degree of intervention (Schoenfeld, 1985). The researcher just provided the sequence of problems and helped with technical problems that could appear. The analysis of these transcriptions makes possible to identify at each moment what relationship among quantities was established by the pairs and which mathematical operation was employed to link quantities in order to evaluate how students translate information from the statement into the mathematical language over the resolution process.

RESULTS

Next, we describe episodes of systematic guessing produced when the three pairs were solving *The plans* problem. All cases start from a situation in which the unknown quantities "total of number of parts" (12) and "money that corresponds to each part" (3000) have been already determined and the only remaining quantity to be determined is "money that Mike receives". At this point the determination of this quantity requires the use of the conceptual scheme "total money = money per part × number of parts". First we offer the sequence of operations that each pair introduced from that moment onwards in order to calculate the only unknown quantity.

Lola-Juan: (1) 36000 – 3000; (2) 36000/3000; (3) 36000/12; (4) 3000/12; (5) 3000·12; (6) 3000/7; (7) 3000 – 7; (8) 3000 – 12; (9) 3000·7.

Julia-Roberto: (1) 36000/7; (2) 3000/12; (3) 3000/7; (4) 3000/12; (5) 3000/7; (6) 3000/7; (7) 36000/12; (8) 3000/12.

Pablo-Helena: (1) 36000/3000; (2) 36000/7; (3) 3000/7; (4) 36000 – 3000; (5) 3000/12; (6) 3000·7.

The pair Lola-Juan

The pair Lola-Juan starts the sequence performing three operations in which the quantity "total of money" is involved. In the dialog that follows, there are evidences that they are initially convinced that that quantity must be employed to calculate "money that Mike receives". After rereading the statement, Juan says that the quantity that must be used is "money that corresponds to each part" (3000) (item 7, Lola-Juan). By contrast, Lola is still convinced of having to use "total of money" (36000) (item 6, Lola-Juan) and, in fact, she introduces 36000/12 (item 10, Lola-Juan).

1 Lola: Then...
2 Juan: 36000 divided by 3...? ... divided by 3000 (he introduces 36000 − 3000 and an error message is shown).
3 Juan: I think it is divided by.
4 Lola: So divide it. (Juan introduces 36000/3000 and an error message is shown.)
5 (It is heard how they reread the statement quietly.)
6 Lola: It certainly has to be 36000 (she introduces 36000).
7 Juan: No, it has to be 3000.
8 Lola: But then...
9 Juan: But then, divided by 12?
10 Lola: 36000 divided by 12 (Lola introduces 36000/12).
11 Juan: You have already done it and you got 3000! (He says so before the error message appears.)

From the fourth attempt on (item 14, Lola-Juan) the quantity "money that corresponds to each part" (3000) appears in all the operations they perform. However, as it is shown in the following dialogue, the erratic sequence of operations seems to point out that they are not so sure about which quantity will be the other one or which operation they will have to use.

12 Lola: Let's see... 3000 divided by 12.
13 Juan: Or 3000 times 12 or minus 12.
14 (Lola introduces 3000/12 and an error message is shown.)

During the rest of the resolution Lola seems to have no doubts about the necessity of using the quantity "number of parts that corresponds to Mike" (7). In actual fact, it seems like she were trying to make use of the scheme money = money by part × number of parts (item 15, Lola-Juan). However, she divides by 7 instead of multiplying by it. This could be a consequence of associating sharing with division. After introducing 3000/7, Lola deduces that a multiplication must be done, whereas Juan carries on trying operations with the only criterion that "money that corresponds to each part" (3000) must appear.

15 Lola: Wait. If he receives 7 parts: 3000 divided by 7.
16 (Juan introduces 3000/7 and an error message is shown.)
17 Lola: Or multiplying, it will be multiplying.
18 (Juan introduces 3000 − 7 and an error message is shown.)
19 (Juan introduces 3000 − 12 and an error message is shown.)
20 Lola: 3000 times 7 (she says so before Juan introduces the last expression).
21 Juan: That's true, minus 7 or minus 12 (Juan introduces 3000 − 12 and an error message is shown).
22 Lola: 3000 multiplied by 7.
23 Juan: Yes (he introduces 3000·7 and it is shown the message of problem solved correctly).

The pair Julia-Roberto

This pair opted to use division in all the attempts. This fact suggests that the pair erroneously considers a certainty, beyond any doubt, that the money an individual receives must be calculated using the mathematical operation division. Maybe the pair thinks that, given the fact that "the money Mike receives" is a part of "the total of money" and that there is a quantity "number of parts that corresponds to Mike", the problem could be interpreted as a partition division one. As it shown in the following excerpt, the solving process is conditioned by this belief, which causes the pair not to manage to solve the problem. The dialogue starts when they introduce the first expression of their sequence.

1 (Julia introduces 36000/7 and an error message is shown.)
2 Roberto: So then, that number (he points out 3000 on the screen) must be there for some reason.
3 Julia: Yes. This one divided by 12 (while she is saying this, she writes 3000/12).

4 Roberto: 3000 divided by 12?
5 Julia: I don't know (she introduces 3000/12 and an error message is shown).
6 Roberto: Divided by 7, I think so.
7 Julia: Yes.
8 Roberto: And if it isn't like that, nothing.
9 (Julia introduces 3000/7 and an error message is shown.)
10 (They seem to read the name of the quantities inaudibly.)
11 Julia: It is divided by 7.
[...]
12 Roberto: It would be money divided by the parts that Mike receives and it doesn't come to anything (while he is speaking, he introduces 3000/7 and an error message is shown).

The pair Pablo-Helena

After performing, at the request of Helena, the operation 3000/7 (third in their sequence) and obtaining an error message, they decide to read, in the window *Defined quantities* (see screenshot on the right in Figure 1), the name of the quantities and their values. Then, the following dialogue started in which it is evidenced how the Pablo's suggestion of performing a multiplication was the trigger for solving the problem (item 9, Pablo-Helena). Indeed, Helena immediately reacts to this idea by identifying the correct operation (item 10, Pablo-Helena). It should be underlined that when Pablo mentions the operation multiplication to Helena she straightaway turns her attention to the quantity "number of parts that corresponds to Mike".

1 Pablo: Ah, I think it is (he introduces 36000−3000 and an error message is shown)...!
2 Helena: There is nothing else, only this one (she says this while Pablo is opening the drop-down menu where the name of the only non-defined quantity appears).
3 Pablo: So we have to find it out, because we have already done a lot.
4 Helena: Let's see.
5 Pablo: And can't it be 3000 divided by 5?
6 Helena: And 3000 divided by 12?
7 Pablo: It may be.
8 (Pablo introduces 3000/12 and an error message is shown.)
9 Pablo: It may be multiplying.
10 Helena: By 7!!
11 Pablo: I'll try it then (he introduces 3000·7 and a message of problem solved correctly is shown).

DISCUSSION

All the three cases can be classified as gaming the system performances. However, this does not mean that all the students' actions correspond to trial and error efforts without any trace of reflection. In fact, what is observed is a repeated analytical-synthetic process by which students try to establish the relation that the quantity "money that Mike receives" has with the rest of quantities already determined. The process makes visible the students' conceptions about what quantities should be used to solve the problem. Additionally the protocols reveal how the pairs' certainties evolve. In particular, the three pairs turn their attention to the quantity "money that corresponds to each part" (3000) after having been working with the quantity "total of money" (36000) (for example, at first Lola stated that this quantity had to be used).

The pairs that solved the problem correctly posed a multiplication just after having proposed a division. However, the trigger for writing the correct operation wasn't the same. In the case of the pair Lola-Juan, Lola proposes multiplying after the system had reported an error when introducing the operation 3000/7, which had been proposed by her. This may be attributed to Lola's capacity of synthesising the correct operation once she had identified the conceptual structure that linked the quantities. In the case of the pair Pablo-Helena, Pablo merely suggested using a multiplication and it was Helena who proposed to multiply by "number of parts that corresponds to Mike" (7). Perhaps, Pablo's suggestion acted as a hint for Helena, since, up to that moment, she had seemed to be sure about the need of performing a division.

The pair that did not solve the problem correctly insisted that it was necessary to divide by "number of parts that corresponds to Mike" (7). In fact, they posed the operation 3000/7 up to three times. This suggests that they had identified part of the conceptual scheme that linked the quantities, but they were not able to make a synthesis correctly. Possibly, the fact that a share of the total money had to be done could induce them to consider that a division had to be performed.

In this case, the pair's certainty that a division was mandatory could become an insurmountable obstacle.

This report illustrates how students' conceptions play an important role in gaming the system behaviours. The analysed cases are far from being irrational trial and error sequences in which the pairs abuse of the system's capabilities without engaging with the problem. Although, even in the case of the pairs that finally solve the problem, more evidences apart from the excerpts are needed to state that learning took place, these pairs seems to have gain insight into the conceptual structure of the problem either by refining their previous certainties or by completing them. It should be recognised that the fact that some pairs managed to solve the problem can be favoured by the setting of the study in which the students worked collaboratively in pairs. However, according to the purpose of our work, we opted to use this setting because two-person protocols are appropriate for analysing decision-making behaviour instead of using one-person protocols that could give rise to the purest students' cognitions (Schoenfeld, 1985). Besides these considerations, the reported cases demonstrate that gaming behaviours can be an important source of information about students' knowledge and the difficulties associated with some problems. Often, this kind of performances is classified as mere trial and error attempts and little attention is paid to it. However, intelligent tutoring systems are now capable of logging and processing all the user's actions when he/she is solving a problem. In this context, future studies may address how this massive information could be employed in intelligent learning environments in order to scaffold students' learning.

ENDNOTES

1. We consider that a solving process will be arithmetical when the solver calculates all unknown quantities going from the known to the unknown quantities. On the other hand, a solution will be algebraic when the solver uses one or more letters to represent unknown quantities, which will result in one or more equations.

2. Although relations have been represented by using algebraic language, we are not asserting that the relations are represented in this way on the mental level. We have just offered a schematic representation of the net of quantities and relations that can be taken from the statement. To do so we have represented the relations by algebraic language although this does not mean anything about the algebraic or arithmetical character of the solving process.

Instances of mathematical thinking through collaborative gameplay

Antri Avraamidou

University of Leeds, School of Education, Leeds, UK, antri.av@gmail.com

This paper examines the computer gameplay of two 12 year old children. In the analysis of gameplay in building a house without budget constraints and then a second house with budget constraints within "The Sims 3" video game in out-of-school settings, four variables appeared: Budget; Size of the House; Cost of furniture/devices; and Sims mood meter. This paper argues that those four variables influenced the mathematical relationships in building the two houses and the ways players' used the game's artefacts in line with their everyday and mathematical prior understandings affected their gameplay and therefore the exploration of mathematical relationships that form instances of players' mathematical thinking.

Keywords: Gameplay, mathematical thinking, out-of-school settings.

INTRODUCTION

The aim of this paper is to present instances of mathematical thinking as it occurred during the gameplay of a group of two 12-year old children who were, collaboratively, building two houses in "The Sims 3" video game, in out-of-school settings. The building of the first house had no budget constraints and thus the gameplay was less constrained than it was in the building of the second house with budget constraints. Much of this paper argues that four variables that occurred during gameplay, influenced the mathematical relationships in building those 2 houses. These variables were *Budget*, *Size of house*, *Cost of furniture/devices* and *Sims mood meter*. The paper is structured as follows: an integrated review of literature and presentation of the theoretical framework; the setting and methodology of the study; results pertinent to the focus of this paper; a discussion of issues arising.

LITERATURE REVIEW AND THEORETICAL FRAMEWORK

Everyday experience and daily interaction with the world are perceived as starting points of mathematics (Bonotto, 2005). European Commission recommends mathematical competence as one of the eight key competences a citizen should develop for lifelong learning by being able to "develop and apply mathematical thinking in order to solve a range of problems in everyday situations" (European Commission, 2007, p. 6). Mathematical thinking is often described as a process and Stylianides (2009, p. 258), for example, refers to mathematical thinking as a process that includes: "exploring mathematical relationships to identify and arrange significant facts into meaningful patterns" that can be later used in order to make conjectures. Hoyles (2003, p. 4) posits that these mathematical relationships may be captured within the tools of an environment "but these relationships lie dormant until they are mobilised, and it is in their mobilisation that meanings are created". Several researchers have explored the mathematics used in everyday situations: workplace settings (Magajna & Monaghan, 2003); in the streets (Nunes, Schliemann, & Carraher, 1993; Saxe, 1991); and in supermarket shopping (Lave, 1988). They argue that the mathematics used in these settings is not formal mathematics but, rather, 'street mathematics', 'supermarket mathematics', and so on. Given that a quite common activity that children do in their everyday life is playing video games (ESA, 2012), the question arises: What sort of mathematics (if any) might emerge, is developed and is applied during gameplay?

Devlin (2011, p. ix) argues that "well-designed video games are going to play a major role in school mathematics education in the future". However, Bragg (2006, p. 233) argues that "assumptions that students will see the usefulness of mathematics games in classroom are problematic" and Bourgonjon, Valcke, Soetaert and Schellens (2010) argued that not all students appreciate the use of games, for educational purposes, in the classroom. That might be because, in most 'computer off the shelf (COTS) games' context and gameplay are inextricably linked, whereas in most educational games, the educational content and context often demote the gameplay (Reiber, 1996). During the past decade, several researchers have turned their interest to the way COTS games might enhance players' learning. For example, Squire (2006) illustrated the way the game *Civilization* helped students learn history in afternoon activities at school. Additionally, Gee and Hayes (2010), after exploring the Sims series video game, argued that building in such virtual worlds requires geometry knowledge and skills. The educational potentials of COTS video games exist, but how does mathematics enter gameplay in out-of-school settings?

Players' actions are central to the construction of their meanings and computers can provide a window making players' meanings visible (Noss & Hoyles, 1996). Within such actions, the construction of new knowledge is linked to the negotiation and consolidation of previous knowledge as in constructionism (Papert, 1993). In this research, actions are considered to be directed by players' goals as they are playing the game (Leont'ev, 1978). 'Goals' are mainly interpreted in two ways in literature related to mathematics' research; as the goal that directs an action of an individual which is part of an object-oriented activity (i.e., Leont'ev, 1978) and as 'emergent goals', essential 'deeds' that need to be done and are emerged during the activity (i.e., Saxe, 1991). During an activity, an individual consciously performs goal-directed actions (Leont'ev, 1978). However, in practice-related situations, there are instances where plans need to be changed and other goals emerge. These emergent goals are very important for understanding the activity because they emerge as a result of the interaction of individuals with their material world, through practice (Saxe, 1991).

In his research regarding candy sellers' real-life activities in Brazil, Saxe (1991) developed a research framework, consisting of three components in order to investigate the strategies and techniques that children used in the practice of selling candies in the streets. Within such a framework, one is able to analyze the interplay of culture and individuals' goals (and cognitive process) as it occurs within a practice (Saxe, 1991). Saxe's (1991) emergent goals component consists of four parameters: *social interaction, activity structures, prior understandings* and *conventions/artefacts*. This model suggests that candy sellers' goals that emerge during their activities in their situated practice, are shaped and affected by their *social interaction* with each other or with other individuals involved in the practice (i.e., buyers), by their *prior understandings* that they bring in the practice (i.e., existing knowledge), by *conventions and artefacts* related to the activity (such as money and currency conventions) and lastly, by the whole *activity structure*. A previous study that examined the gameplay of an 11-year old boy, who was building houses in "The Sims 2" video game (the precursor of "The Sims 3") using Saxe's model to analyze the goals that emerged during gameplay, argues that the creation and use of an artefact-strategy that the player had developed during gameplay was a mathematical abstraction (Avraamidou, Monaghan, & Walker, 2012).

WHAT IS "THE SIMS 3"?

"The Sims" series (http://www.thesims3.com/) are popular real life simulation games that allow players to control the lives and relationships of game characters and create houses for them, in an open-ended basis. Unlike many popular games, "The Sims" series do not have an explicit goal/objective that the players need to accomplish and players do not 'typically' compete with each other (or with a computer) in order to win. In fact, players can decide on the way they want to play the game. There are three game modes when playing The Sims (initial game): the Live Mode; the Buy Mode; and the Build Mode. While playing the Live Mode of the Sims, players can control the Sims characters during their virtual living in the Sims houses and observe their lives, maintaining (or not!) a balance between each Sims character's mood meter by fulfilling their desires or making their fears come true, while the Sims virtual time passes by. Players can pause the virtual time of the game and edit and/or delete constructions of the Sims virtual houses and neighbourhoods and also, build from scratch virtual houses for the Sims in the Build Mode. Lastly, players can decorate and furnish their Sims' houses while in the Buy Mode of the game, by selecting items that appear in the menu. All items in the Build and Buy mode have prices in the game's currency 'Simolins' indicated with the letter 's'. An important aspect of the Sims series is the budget. The Sims families have specific budgets and when players need to build, edit, delete and/or buy items for a family, they need to do so within the budget of that specific family. When the budget is exceeded, players need to 'sell' or delete items so as to increase the amount. When playing the Live Mode of the game, players can increase the family's budget by finding jobs for unemployed Sims or making sure that employed Sims go to work and earn money.

RESEARCH DESIGN

This paper reports on an exploratory case study (Yin, 2003) of the gameplay of two 12-year olds, Marios and Christina (M & C), who were selected on the following criteria: a. they were friends that usually met to play together; b. they had not played "The Sims" series before; c. both wanted to play the specific game; and d. both participants and their parents gave their consent to the research. The researcher approached the parents of one participant, informed them and when both parents and participant gave their consents, the participant was asked to name one of his/her friend that they wanted to play the game with. Then participant's friend and friend's parents were also informed and gave their consent. Participants were informed that they were being recorded for research's purposes but were not informed that the research was related to mathematics. M & C played the game in Christina's bedroom, using the researcher's laptop. They collaboratively built three houses: a. built a house without budget constraints, b. built a house for a Sims family with a specific budget and c. reshaped an existing house of the game following a scenario given by the researcher. Participants' talk and on-screen activity were recorded using screen recording software (Ambrosia) with audio recording, in order to ensure a rich data collection of approximately 5 hours of recorded gameplay. The researcher was present during their gameplay and acted as observer participant but her role was restricted to only assist them with any technical difficulties. Overall, three meetings took place, where M & C built and edited the three houses but only the first two houses will be used for the purposes of this paper.

Data were transcribed in Greek (both talk and descriptions of their actions) data analysis was conducted in three stages. The first stage produced open codes *a la* Strauss and Corbin (1998), describing participants' actions during gameplay that were later grouped into categories. During the second stage of analysis, players' actions and goals that directed those actions were identified. Whilst conducting the second stage of analysis, a pattern was observed: there were goals that emerged whilst actions were performed in order to achieve a previous goal. Thus, a third stage of analysis was conducted, where emergent goals were identified and players' actions were grouped into episodes consisting of related goals and emergent goals.

RESULTS

The selected results that follow are structured in a way to support the discussion section and the focus of this paper regarding the way the four variables (Budget, Size of the house, Cost of furniture/devices and Sims mood meter) influenced the mathematical relationships in building the two houses.

The four variables were initially identified through the first stage of analysis that produced 13 categories that are illustrated in Table 1 below. The four variables arose from the analysis as overlapping sets whose elements are the categories.

Overall, 206 goals were identified in the second and third stages of analysis (144 in House 1 and 62 in House

Variable	Related categories
V1: Budget	tensions/disagreements, feelings when referring to budget issues, ways to spend less / save money, interaction with the game's features (errors), experiencing the reality of the game
V2: Size of the house	tensions/disagreements, referring to previous house, experiencing the reality of the game, appearance considerations, ways to spend less / save money
V3: Cost of furniture	tensions/disagreements, feelings when referring to budget issues, ways to spend less / save money, referring to previous house, appearance considerations, ways to spend less / save money
V4: Sims Mood meter	tensions/disagreements, experiencing the reality of the game

Table 1: Related categories of first stage of analysis and the four variables

House 1 ground floor – kitchen, living room, bathroom

House 2 – kitchen, living room, bedroom, bathroom

Figure 1: House 1 and House 2 (almost) final versions

2) of which a total of 60 were emergent goals. Four of those emergent goals are illustrated next in the four variables-related results.

During the construction of House 1 there were in fact only two variables enabled; Cost and Size. Budget and Sims Mood meter variables were not affecting players' actions because there was no family and therefore no budget restrictions. As soon as players selected a family to build House 2, the Budget and Sims Mood meter variables were enabled. This affected the other two variables, Size and Cost. The relationship of the four variables will be discussed in the Discussion section. First, a description of the variables is needed.

Variable 1: The budget

The 1st house that M & C built (House 1), was a house without any budget constraints. They created a two-storey house that was valued by the game as 224.023s including furniture and devices. When M & C selected the Williams family (husband, wife and a baby) to build a house for (House 2) the family's available budget of 17.491s appeared on the gameplay screen and as soon as they added or deleted something the available budget increased or decreased respectively. When the available budget was almost used, the game excluded the unavailable options of the Buy mode menu that the family could not afford with a red colour. When M & C wanted to furnish the bathroom (Goal: *To furnish the bathroom*), they saw that they only had money (127s) to buy a baby's toilet seat because it was the only available option in the menu.

Christina: It's red! Everything is red! (non-affordable)
Marios: Where are they going to go when they will want to go to the toilet?

A new, emergent goal then occurred: *To increase the available budget.* They needed to achieve this emergent goal in order to be able to achieve the initial goal of furnishing the bathroom. They decided to move the bedroom furniture in the living room and delete the parents' and baby's bedrooms. The family's available budget increased to 5.009s and they created a smaller room which they decided to be a room for the parents and the baby. They then furnished the bathroom and the rest of the house.

Variable 2: The size of the house

House 1 was a relatively large house that cost 86.388s unfurnished (including foundations, walls, tiles, windows, doors and lights). When they started building House 2 with a budget that was ≈1/10th of the first house's total value, they stated that they would do and maintain a smaller house by saying *"We will do one floor, because it is a small family, that's OK"*. Indeed, they did eventually create a smaller-sized house, having only a ground floor instead of two which cost 15.508s, unfurnished (see Figure 1).

M & C reshaped House 2 several times by deleting rooms in order to make the house smaller and increase the budget as described earlier. Category 'space-size-arrangement issues' showed that they had issues with the size of House 1 as well. While furnishing the kitchen of House 1, Christina stated *"What are we going to do with all this space?"*. The initial table they added was the largest table in the menu but they said that it was too small for their kitchen. Then another goal emerged: *To reduce 'all that' space of the kitchen.* They talked about reducing the size of the kitchen but preferred to add two more tables and ten chairs around them to make the table look bigger instead.

Variable 3: The cost of the house including furniture/devices

The total cost of House 1 was 224.023s in which 137.635s was the cost of furniture and devices, whereas in House 2 it was 17.491s including a cost of 1.983s for the furniture and devices. Indeed, House 1 was filled with a, sometimes unreasonable, number of luxurious items that were mostly chosen according to appearance criteria (see Figure 1). In fact, the category 'appearance considerations' most frequently appeared in House 1. In contrary, House 2 was equipped with essential furniture and devices bearing in mind the family's budget. The Cost variable was noted by the players when they started adding furniture in House 2 and more specifically when the budget was decreased significantly. Table 2 below illustrates selected quotes of players' talk during the building process of House 1 and House 2. Each row maps quotes of talk while performing similar actions in each House.

M & C's talk changed when adding the same items in House 2, as it included expressions showing that they compared the cost of the items and chose the ones that were not expensive bearing in mind the budget.

Variable 4: The Sims mood meter

M & C stated that they were done with House 2 and they were happy leaving the family with a budget of 861s. They then switched to the Live mode of the game to play with the family. While exploring the mood meter of their Sims they noticed that their Sims did not have a device to cook (emergent goal: *To provide food for the family*) and they added an oven/hob in the kitchen. They then noticed that they were not happy with an "unfinished" room looking at the mood meter. Thus a new goal was emerged: *To make the Sims happier*. They added the cheapest available wallpaper that they saw (they did not notice that there were free wallpapers in the menu) and added the missing tiles in the kitchen in order to get their Sims mood meter higher and thus, their Sims happier, reducing the budget to only 9s.

DISCUSSION

In this section, I look at the relationships of the four variables Size, Cost, Budget and Sims mood meter and the way they influenced mathematical relationships in the two houses, with particular regard to literature on mathematical thinking and Saxe's emergent goals model.

Going back to Stylianides' (2009) description of mathematical thinking as a process of exploring relationships, M & C recognized that there were relationships between the four variables. They figured out that increasing either the Size or the Cost of the House resulted in decreasing the available budget. Furthermore, they recognized that in order to increase the available Budget, they needed to decrease either the Size or the Cost of the House. For example, when M & C needed to increase the budget of the family in House 2 in order to continue building the house, they either decreased the Size of the house or selected furniture with low Cost or did both. It is not claimed here that M & C were fully aware of the exact interrelation of those four variables. However, stating that they would do *"a smaller house because it is a small family"*, reducing the size of the house to increase the budget and selecting the cheapest available options indicate that they recognized the way each variable affected the other.

The mathematical relationships that were influenced by the four variables were 'invisible' as they were *"lying dormant"* (Hoyles, 2003, p. 4) within the artefacts of The Sims 3 game. However, those relationships became 'visible' during the gameplay, through the way M & C used the game's artefacts. For example, the Sims

House 1	House 2
"Add more windows here to make the room brighter"	"No, we will not add any more windows, look (pointing at the budget).
"This wallpaper looks nice, add this one (worth 10s per column)"	"No, that's 10 (wallpaper worth 10s per column), that's expensive. That's 4, that's good".
"No, choose this one or this one" (the two most expensive available TVs)	"Not that one (the more expensive TV), that one (the cheapest), it doesn't need to be nice-looking"
"It was 100.000s before and now we added so many expensive things and is now only 200.000s? That's fine" (third meeting)	"No no, that's expensive. We can't"

Table 2: Players' talk while building House 1 and House 2

mood meter and the Budget are two important artefacts of the game. When M & C chose to play with the family in the Live mode, the meter was enabled. When M & C needed to increase the mother's Mood meter, by adding devices in House 2, they realised that in order to do so, they had to spend more money from the family's available Budget and therefore increase the Cost of House 2 so as to increase the level of the meter by providing the family with a device to eat. Even though their initial plan was to leave the family with an available Budget of 861s, they chose to spend that budget, in order to make their Sims happier.

The interpretation of the Budget, the Sims Mood meter and the Sims' needs in House 2 was in fact shaped by M & C's everyday knowledge of a house's structure and content and also of real life needs. For example, Marios' statement: *Where are they going to go when they will want to go to the toilet?* was enough for them to start deleting parts of House 2 and rearrange the furniture and rooms. It is important in real life to have a bathroom/toilet in a house and within the Sims game, they recognized that deleting items resulted in getting a refund and therefore increasing the Budget. Going back to Saxe's (1991) emergent goal model, the goal of *'increasing the budget'* emerged and was achieved as a result of M & C's prior everyday and mathematical understandings during their interaction with the game's artefacts. Examining the other three emergent goals that were presented earlier (i. to reduce 'all that' space of the kitchen, ii. to provide food for the family and iii. to make the Sims happier), the way M & C used the artefacts of the game's features, including the available Budget, the Sims Mood meter and artefacts, in line with their prior understandings in order to achieve those emergent goals, influenced their gameplay. In addition, the four variables that occurred during gameplay, influenced the mathematical relationships that were hidden within those artefacts. In fact, this constrained gameplay of M & C, was an "activity with relationships" (Noss & Hoyles, 1996, p. 124) that M & C explored during their gameplay.

This paper argued that there were instances of players' mathematical thinking during their collaborative gameplay of The Sims 3 video game in out-of-school settings. Those instances are not school-alike formal mathematical processes. Rather, the mathematical thinking occurred informally but meaningfully for the players in order to achieve their goals during gameplay. These instances were captured by players' exploration of the mathematical relationships, hidden within the artefacts of the game. Those relationships were influenced by the four variables that emerged during the gameplay. The use of those artefacts, which was highly affected and shaped by players' everyday and mathematical prior understandings, was crucial for the gameplay.

The use of hands and manipulation touchscreen in high school geometry classes

Marcelo Bairral[1] and Ferdinando Arzarello[2]

1 UFRRJ, Seropédica Brazil, mbairral@ufrrj.br
2 Università di Torino, Torino, Italy, ferdinando.arzarello@unito.it

Touchscreen dynamic environments user interfaces employ a specialized interaction model on screen. In this paper, we analyse students' manipulation to explore and justify their geometrical reasoning on a free online touch device: the Geometric Constructer (GC) software. We discuss data from a teaching experiment with Italian High School students. The experiment was videotaped. Based on this we observe two domains (constructive and relational) regarding the development of geometrical thinking on GC. Students' manipulation on constructive domain is basically done to make construction and it contributes to exploration and to arise conjecturing. Indeed, manipulation in relational domain can suitably support and improve students' justifying and proving performances.

Keywords: Touchscreen device, GC software, constructive domain, relational domain, dragging to approach.

INTRODUCTION

The emergence of multi-touch devices - such as iPods, iPhones and iPads - will promote new impact and challenges in learning and instruction in general, and in mathematics in particular. Although in Mathematics Education some touch devices have been developed (for instance, Geometer Sketchpad Explorer, Geometric Constructer, GeoGebra app, Sketchometry and Math Tappers apps) research is still scarce concerning mathematical learning through touchscreen manipulation.

In our current research project[1] we are interested in the way of manipulation of tablet resources as iPad. Particularly, how ways of touchscreen manipulation can improve students' geometrical thinking. In this paper we are addressing issues regarding the question: during the process of solving geometric problems using the software GC which domain (constructive or relational) of manipulation touchscreen could be fruitful to improve student's strategies for justifying and proving? We assume (i) that manipulation on tablet is different from a mouse click and (ii) that mathematics used by students to solve a geometrical task in a paper-and-pencil environment is different from what they use in a touchscreen device.

Gesture and touchscreen manipulation

The role of gesture, particularly the touchscreen, in supporting mathematical reasoning in technological context is an emerging field of research in mathematics education (Arzarello et al., 2013; Nicholas, 2013). Regarding their usage, environment mobile touchscreen user interfaces employ a specialized interaction model.

Interaction through current mobile touchscreens basically occurs with the computer recognizing and tracking the location of the user's input within the display area. In other words, interactivity occurs in response to two dimensions of the input action (Yook, 2009; Park, 2011). This enables six basic finger actions for input: tap, double tap, long tap (hold), drag, flick, and multi-touch (rotate). According to Sinclair and Pimm (2014), these types of manipulations "describe specific configurations and actions of the finger(s) on the screen and they are different from those discussed in the mathematics education literature in two ways: they involve contact with a screen and they perform an action" (p. 210).

Even though we are not looking only for ways of touch that represent mathematical concepts (for instance, rotation) we agree with Boncoddo and colleagues (2013) that a particular way of manipulation may

1 In Brazil, the research project is granted by Capes (Ministry of Education).

serve as an important function of grounding mathematical ideas in bodily form and they may also communicate spatial and relational concepts. Specifically for geometrical thinking, inspired in (Hostetter & Alibali, 2008), we consider important to stress that, in touchscreen devices, manipulations are based on visuospatial images, linguistic factors influence gestures and ways of touchscreen are communicatively intended.

Adopting an embodied cognition perspective in our research we highlight reciprocal connections between ways of touchscreen and cognition. Contrary to what happens in clicking, manipulating touchscreen interface implies a continuity of action, the spatiality of the screen, the movement simultaneousness and movement combination and, depending on the resource device, the feedback speed. On the following Figure, we observe one student trying to explain one of the properties of the isosceles trapezoid. He uses hands to represent the sides that are not parallel.

Touchscreen manipulation in dynamic geometric devices

Inspired in (Tang et al., 2010) we assume that touchscreen manipulation is not the same as mouse clicks (Arzarello et al., 2014; Bairral et al., 2015). There are differences if we use a usual PC, where dragging is produced with the help of a mouse, or we use a touchscreen of a tablet, where we can use our fingers to move the figures, and there are differences if we can use more than one finger (as in multi-touch environments) or only one finger.

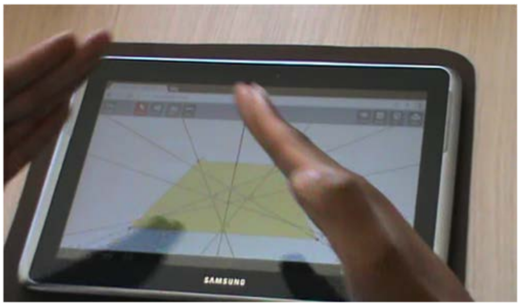

Figure 1: Student construction on GC

As we have had a first shift and improving passing from paper and pencil environments to DGS with drag and drop activities (e.g., Cabri Géomètre, Sketchpad, etc.), now we have a further shift and improvement with the transition to multi-touch environments (e.g., Geometric Constructor, SketchPad Explorer, Sketchometry) and to the variety of simultaneous fingers' actions they allow.

When we manipulate the screens in our device with touchscreen interface, we perform a set of movements. Some manipulations we perform have specific mathematics cognition, like when we want to enlarge (or reduce the size of) a picture in some image editor (Paintbrush), or when we perform this through a touchscreen manipulation.

On such occasions we "pull" the image diagonally, upwards or downwards, or we "click" on one of its vertices, so both dimensions (width and height) are reduced or enlarged proportionately. If we do not perform this type of movement, i.e., if we manipulate only one dimension, the image will come out deformed.

Nevertheless, although all these manipulations are based on one mathematical concept (method of the diagonal as a way to generate similar figures), they are not necessarily the same in cognitive terms (the action of enlarging without deforming), epistemological (the simultaneous changing in different parts of the shape) and spatiality (work and manipulating area on the screen). By the way, we still have to go further on these singularities.

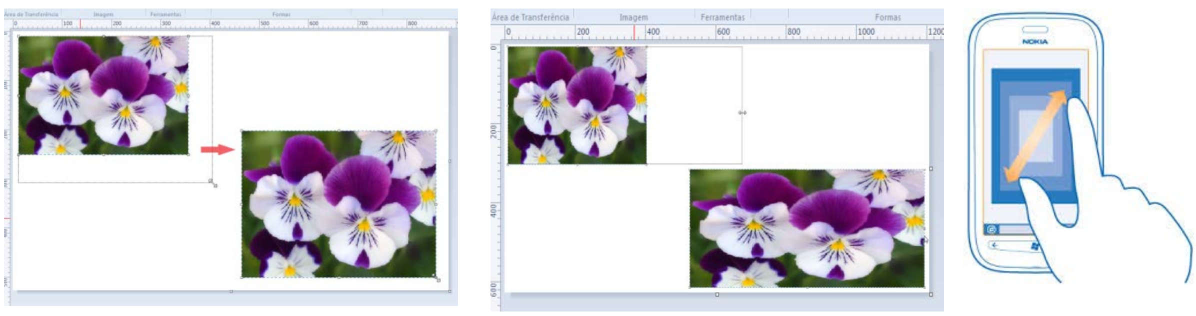

Figure 2: (a) Illustration of an enlargement in a drawing program; (b) distortion in a drawing program; (c) enlargement through sliding on the screen (Bairral et al., 2015)

Domains of manipulation and geometric learning in dynamic touchscreen devices

Touchscreen dynamic environments user interfaces employ a specialized interaction model on screen. In agreement with Arzarello and colleagues (2002), within this type of environment the interaction also concerns deeply perceptual aspects, which involve not only the objects (e.g., drawings) but also the physical perceptions of students, their motions, gestures, languages, etc. and the artefacts that they use as mediating instruments. Perceptual aspects which must be analysed concern many components, i.e. visual phenomena, motion, kinaesthesia, inner time(s); on the other hand, the most typical theoretical features are the structured mathematical objects, their invariant properties, conjectures, theorems, proofs.

Even though in the relational domain students also construct geometric objects we observed (Arzarello et al., 2014) that it is in this particular domain where they show more interacting and reflecting about the construction.

According to Arzarello and colleagues (2014), a cognitive process within a GC device could be seen in two interrelated domains of manipulation: the construction domain, where students basically refer either to tap and hold, which are the basic actions, or to isolated ways of constructing geometric objects (point, line, circle, shape, etc.) with a touch interface. What we call relational domain is a combination of this constructional and the performed touchscreen actions, which include drag, flick, free or rotate.

While in a construction domain student act as discrete observation (focused on some specific construction or constructed object or even doing some touch on the screen) in the relational domain their manipulation seemed more focused on their questioning, conceptual understanding and other emergent demands concerning their manipulation as a whole construction.

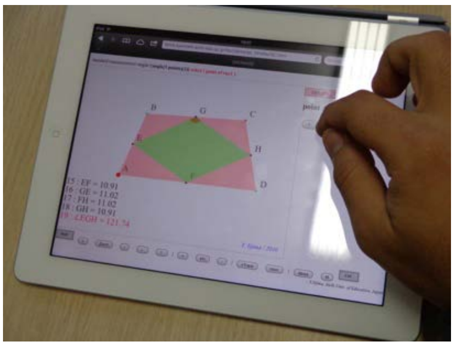

Figure 3: Student construction on GC

METHODOLOGICAL ASPECTS OF THE STUDY

We are conducting teaching experiments (TE) with High School (Brazilian and Italian) students and Brazilian prospective mathematics teachers. In this paper, we discuss data from one TE: five High School students (16–17 years old) at Liceo Volta (Turin, Italy) working on software Geometric Constructer (GC). All of them had previous experience with dynamic geometric environments (DGE). Each session took about two hours long and it was videotaped. In each session the students worked out on proposed tasks.

Geometric constructer features

The choice of GC software is because, as far as we know, it is the only software which incorporates all the potentialities of usual DGE in a fully touch-screen device. By 'potentialities' we mean two main facts (Arzarello et al., 2014): (i) the possibilities of using more than one digit (multi-touch) on the screen to interact with the software and (ii) the possibility of making constructions and not only explorations. As far as we know, at the moment there are very few types of mathematical software that satisfy both these features.

Some of the haptic devices on the market (for instance, GeoGebra app and FreeGeo) satisfy (ii) but not (i): in fact, they allow users to move only one point each time, which makes them very similar to environments where dragging is done with the mouse. A very few, for example Sketch-explorer, satisfy (i) but not (ii). GC satisfies both[2]. Using GC we may construct basic geometrical objects (points, segments, lines, circles), measure them, drag and make traces of geometrical objects and so on. The Student using different colors to edit the construction and measuring internal angles from the quadrilateral EGHF for the Varignon theorem task[3].

2 It has been designed by Professor Iijima Yasuyuki (Aichi University of Education, Japan2) and we used its version in English.

3 The Varignon Theorem proposed task: In quadrilateral *ABCD*, the middle points (*E*, *F*, *G* and *H*) on each side have been drawn, forming quadrilateral *EFGH*. What characteristics does *EFGH* have? What happens if *ABCD* is a rectangle? What if it is a square? What if it is any quadrilateral? Demonstrate.

The proposed and analyzed task: Constructing square[4]

Build a quadrilateral ABCD. On every one of its sides build a square external to the quadrilateral with one side coinciding with the side of the quadrilateral. Consider the centers of the squares that have been built: R, S, T, U. Consider the quadrilateral RSTU: what can you observe? What commands do you use in order to verify your conjecture?

Data analysis

Due to continuity of motion and spatiality on the screen we consider that with touchscreen devices analysis should be about paths of interaction rather than points of interaction. Further, it would be mathematically inappropriate (in most cases) to reduce data of a trace to a single point, as we observe in device without touch action. The analytical process was done in two main steps: (1) identification of each type of manipulation (Arzarello et al., 2014; Park et al., 2011; Yook, 2009) and (2) construction of timeline to gain information of the global cognitive movement throughout interaction on GC software. Based on videotaping the timeline illustrates the ways of touchscreen and shows geometric aspects from students' interaction on the GC software (Arzarello et al., 2014, p. 47). For the first step we adopted Yooks' (2009) framework as summarized in the following Chart 1.

RESULTS

In the following two Charts (2a and 2b), we show part of a timeline elaborated by students' solving the task with the software GC performing four types of basic actions[5] (tap single, scale, hold single and hold multi).

Although in order to make a construction (point, line, angle, circle etc.) the user has to use the software icons, we observed all the manipulation on the screen. We didn't consider touch on the icon as an example, for instance, of the tap or hold touchscreen. Rather, in some interval of time we could observe more than

Action		Type	Motion
Basic	Refers to tap and hold which are the basic ways of interacting with a touch interface.	Tap (single) Tap (double) Hold (single) Hold (multi)	Closed
Active[1]	It is a combination of the basic action and the performed finger action, which includes drag, flick, free, or rotate.	Drag Flick Free Rotate	Open

Chart 1: Yook framework quoted by Park (2011, p. 23)

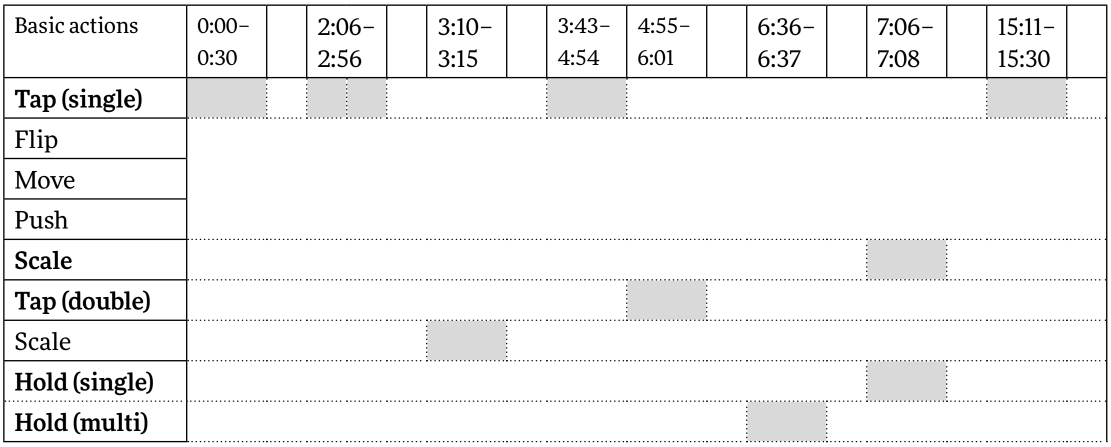

Chart 2a: Part of the timeline illustrating basic actions

4 This activity was thought as a task to introduce curiosity among students for the next task (Napoleon Theorem).

5 To fix the timeline on the CERME template, we cut down some time interval.

Active actions	0:00–0:30	0:30–0:50	1:28	1:46–1:54		3:15–3:20		6:05–6:09		8:31 / ... / 15:02		15:35–16:55
Drag free												
Drag approach												
Flick												

Chart 2b: Part of the timeline illustrating active actions

one way of touch, but we selected some in which the exemplified type has predominance.

Due to the nature of the task (with open construction and exploration) we identified the predominance of touchscreen types on the relational domain and basically touch such drag (free or approach) and flick. The rotate didn't occur in this task. As we can see on the Chart 2b the usage of drag to approach was dominant.

As we observed in a previous analysis (Arzarello et al. 2014) the dragging to approach works as a refreshing, a quite stabilizing and reflecting area for deep understanding of the geometric properties that emerge from the manipulation on drag free or other way of touchscreen. This type of manipulation seems to be an appropriated moment to improve justification and proving.

According to Arzarello and colleagues (2014), manipulation in the constructive domain seemed to be focused on only predetermined motion, whereas motion through relational manipulations is open in the sense that it can generate more unpredictable processes. We still have to research further on the issue of open motion.

Manipulation on construction domain seems focused on only predetermined motion although motion through relational manipulations provides motion open in a sense that they can generate more unpredictable processes. By the way, we still have to go further on the issue of open motion and on the issue of the two domains of manipulation on GC software.

To summarize the reflection above, we illustrate on Chart 3 how we are relating the two domains of touchscreen with geometrical thinking and the motion through touchscreen. Although students dealt naturally with the device, their manipulation apparently was related with the software constraints (or advantages) or with the proposal task.

FINAL REMARKS

As simultaneous touchscreen manipulation of spots on the screen brings about implications of an epistemological order, it also adds complexity to our cognitive structures. This particular feature was observed by one of the students in our research. According to him, "*in a very complex figure, moving several elements at the same time can become a bit difficult*". Besides this cognitive implication, the use of touchscreen devices in the teaching of mathematics brings about transformations in didactic and epistemological realms, and educational research is still lacking.

Another relevant issue to consider is the way using a multi-touch-screen allows changing the task design in a substantial way. More precisely, multi-touch screen devices allow designing geometrical problems in a different way from the usual one, which would be very difficult within non-multi-touch screens environments. For example, within multi touch screens it is possible to ask two students, who use the same screen, to play mathematical games, where each of them pursues antagonist aims: exploiting the strategy they use to win they can so enter into the mathematical property upon which the game has been built (Arzarello et al., to appear).

We identified the touch "to approach" as a predominant way in this type of environment. This sort of touchscreen should be seen as a cognitive tool to empower learners conjecturing and exploring for argumentation during the process of solving the task. This allows us to ascertain that the drag-approach allowed by the multi-touch environment can suitably support and improve students' justifying (exploring) and proving (conjecturing) performances.

We think that manipulation that promotes open motion (relational ways of touching) can be appropriate to provide new epistemological challenges regarding geometric knowledge and different ways of proving. Since the drag to approach is a relational action, it

Video time	Screen example	Students geometrical thinking on GC			
		Type of touch-screen manipulation	Geometric strategy by touchscreen	Nature of motion	Domain of manipulation
2:30–2:40		Tap (single or double)	Student constructing square tapping with one finger and making the construction point by point	Closed motion, predetermined (specific goal, basically construction)	Discrete construction and isolated observation (perception). Usually students make constructions for exploration.
6:30		Hold (single)	Student making a zoom at one point		
0:03		Drag free	After having constructed the last square on each side of the quadrilateral ABCD, a student drags freely point P to see what happen with the shapes	Open motion, but focused on emergent conceptual demand of the task	Related construction and global observation for analyze conjectures and geometric properties and shapes. In this domain manipulation on screen is predominant.
5:35–5:45		Drag-approach	Student approaching MNOP to a rectangle to analyze how the shapes become constructed on the side		
			Student using 4 fingers (2 from each hand) for dragging 4 points simultaneously and shaping them as a square		
5:18–5:28		Free	Student moving freely point C		

Chart 3: Students' geometrical thinking on GC device

seems to be an appropriated moment to improve justification and proving within mathematics classrooms using touchscreen devices. But we would say that, depending on the aim of the teacher, the nature of the task is important and the teacher may let students work freely on the task, using naturally their own way of touch.

A new organization of lessons and of the nature of proposed mathematical tasks (didactic), a view on the touchscreen manipulation that is different from mouse dragging (cognitive), and attention to the changes in mathematics when simultaneously moving different points in a figure (epistemological) are examples of changes and will be an object for reflection on our results in CERME9 (TWG16).

How a digital place value chart could foster substantial understanding of the decimal place value system

Daniela Behrens

University of Bremen, Bremen, Germany, daniela.behrens@uni-bremen.de

When using digital technology in the mathematics classroom, teachers should always consider whether the tool supports the students' learning process in a way "traditional tools" do not allow. In this sense, the aim of this paper is to discuss theoretically how an interactive place value chart could foster substantial understanding of the decimal place value system in the context of decimal fractions, by analysing the artefact's potential for learning. Here, special attention is dedicated to the mathematical, structural aspects of the place value system included in the software. This theoretical discussion builds the foundation for future empirical investigation that will be outlined at the end of the paper.

Keywords: Decimal fractions, place value system, interactive technology, semiotic resources.

INTRODUCTION

Different studies emphasize that students build several misconceptions concerning decimal notation (e.g., Heckmann, 2006; Steinle & Stacey, 2004). The majority of these misconceptions indicate a lack of understanding of the decimal place value system which is fundamental to understand our decimal notation of numbers and which therefore plays an important role in learning mathematics.

Besides practical learning approaches based on activities with concrete material (e.g., Montessori) also research on human cognition and especially on mathematical thinking emphasizes that knowledge formation does not evolve only in human mind, but rather through activities concerning the body, the interaction with an artefact and linguistic and symbolic resources (Radford, 2005, p. 111).

In this sense a digital, interactive place value chart (designed by Kortenkamp) offers special opportunities to actively explore the place value system for a substantial understanding of our decimal number notation in a way traditional tools (e.g., paper-pencil place value charts, base-ten-blocks) do not allow.

To discuss this theory, I will first show how the mathematical structure of the place value system is build up and how this is included in the digital tool, so that a first analysis of the mathematical content within the tool is given in this paper. Based on this I will furthermore reason why especially this tool could support students' understanding of the place value system in comparison to other materials. As a last part I will present my research approach to investigate empirically how this tool might support students' understanding of the place value system regarding decimals. This project, called DeciPlace, is a cooperative project between Ulrich Kortenkamp (University of Potsdam) and Angelika Bikner-Ahsbahs (University of Bremen).

AN INTERACTIVE PLACE VALUE CHART TO FOSTER THE CONCEPT OF PLACE VALUE CONCERNING DECIMAL FRACTIONS

The expansion of the number system from natural to rational numbers often gives rise to difficulties in the learning process in relation to fractions but also concerning decimals.

Different research projects emphasize that students build several misconceptions on decimal notation (e.g., Heckmann, 2006; Steinle & Stacey, 2004). These misconceptions often lead to inadequate strategies, for example to order decimals by size like "longer-is-larger" or "shorter-is-larger" (Steinle & Stacey, 2004). Heckmann (2006) considers transmissions from natural numbers and fractions (especially if fractions are taught before decimals) as the main causes for misconceptions (ibid, pp. 77–89). This suggests the assumption that some students have a non-viable understanding of our decimal place value system or do not use it, so that they are not able to arrange decimals according to size correctly (ibid, p. 51).

That is why it is recommended to focus explicitly on the place value system while learning the concept of decimals (Heckmann, 2006, pp. 52, 562ff.; Padberg, 2009, p. 166; Steinle & Stacey, 2004, p. 548).

Place value

The decimal place value system is based on four properties that are important to understand (Ross, 1989, p. 47):

1) Positional property. The quantities represented by the individual digits are determined by the position they hold in the whole numeral.

2) Base-ten property. The values of the positions increase in powers of ten from right to left.

3) Multiplicative property. The value of an individual digit is found by multiplying the face value of the digit by the value assigned to its position.

4) Additive property. The quantity represented by the whole numeral is the sum of the values represented by the individual digits.

Within the mathematical structure of the place value system defined by these properties, the decimal fraction is a particular structure that is determined by a fixed value represented by a number in decimal notation. In order to preserve the decimal fraction and its structure, only transformations like bundling and de-bundling are allowed in the place value system.

Although learners already know the decimal place value system and its properties, at least unconsciously, while ordering natural numbers and calculating with them, they normally do not pursue this concept in relation to decimals. Furthermore the extension of the place value system from natural numbers to decimal numbers is not self-explanatory (Padberg, 2009, p. 167), since there are not only analogies but serious differences between both (ibid, p. 170). Therefore the emerging extensions and general properties of the place value system should be addressed adequately when teaching decimals to avoid inappropriate transfers from natural numbers and to foster a suitable understanding of our decimal place value system related to decimals.

The interactive place value chart by Kortenkamp and its benefits

One of the main reasons for difficulties in mathematics learning is the fact that mathematical objects and structures are not directly accessible through our sensory organs. Nevertheless we can represent mathematical objects and structures through symbols as well as through visuals and we can gather experience engaging in mathematical activities on concrete material to get access to mathematical concepts (Gersten et al., 2009; Schipper, 2003).

That is why it is recommended to use visuals and concrete activities to develop an adequate understanding of place value (e.g., Heckmann, 2006, p. 577).

A digital, interactive place value chart (designed by Kortenkamp, see Ladel & Kortenkamp, 2013) allows the combination of concrete acting and iconic and symbolic representation of numbers. The following a priori analysis of the artefact examines the possible functions of the interactive place value chart and their corresponding mathematical meanings within the place value system. The main functionalities of the interactive place value chart are the representation of a number by tokens in a place value chart and the variation of the number's representation by changing the quantity within place values moving tokens, while keeping the number invariant.

At the upper row of the place value chart the symbolic representation is described through the particular place values (Tens, Ones, Tenths, Hundredths, etc.), structured in columns. Additionally, the represented number can be displayed in standard notation. The bottom row as the main part shows tokens representing the quantity of each place value within the whole number (see Figure 1).

A number can be created by adding tokens in the given place value columns by tapping the screen. Mathematically, this signifies an increase of the quantity in a particular place value by the quantity of added tokens. Here, the relation between particular place values and the number in standard notation can be explored addressing indirectly the *positional*

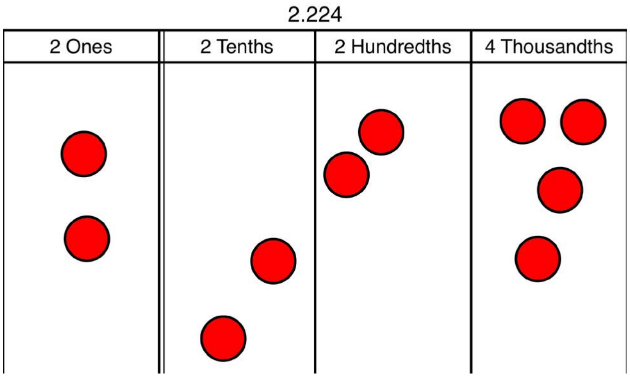

Figure 1: The digital place value chart

and the additive property of the place value system. Additionally, the function of the decimal zero is illustrated by a blank column of tokens.

The fundamental characteristic of this interactive place value chart concerns the invariance of the number, while varying its representation within the particular place values. Specifically, the user can slide tokens directly on the touchscreen, either within the same column or to other columns. Here, the former action can be done to structure the token's arrangement, e.g. to facilitate counting the tokens within a column. For the latter activity of moving a token to another column there are three different possibilities of the artefact's reaction, which are guided by the mathematical structure of the decimal place value system:

a) When the user slides one token to one column rightwards, the token multiplies into ten tokens within the new column. If the user moves for example one token of tenths to the hundredths, in the hundredths-column there will emerge 10 tokens (see Figure 2).

   Here, the artefact represents the transformation of the representation through de-bundling according to the *base-ten-property* of the decimal place value system. The artefact furthermore follows the *multiplicative property* of the place value system, which implies that the quantity in each place value has to be multiplied with the according place value that decreases in powers of ten from left to right, so that the quantity in place values has to increase in powers of ten while de-bundling from left to right.

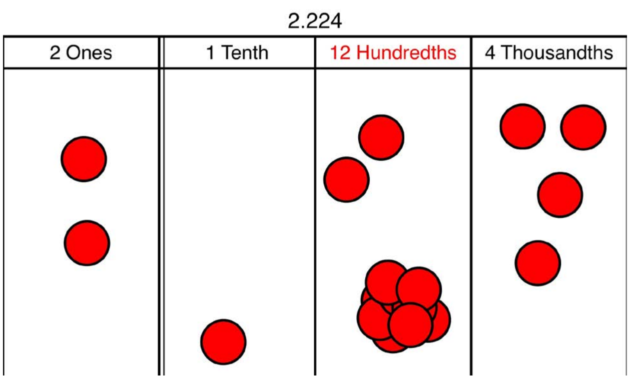

Figure 2: Changing the number's representation within the place value chart by moving tokens

b) When the user slides one token to one column leftwards, there are two cases:

   i) If there are at least ten tokens in the initial column, nine tokens go along with the slid token and the ten tokens merge to one token in the new column. Here, the artefact automatically bundles according to the *multiplicative* structure and the *base-ten-property* of decimal place value.

   ii) If there are less than ten tokens in the initial column, the token slides back to its initial position, because the condition for bundling only groups of ten is not given.

To sum up, the analysis of the relation between artefact signs and the underlying mathematical meaning shows that the interactive place value chart follows the particular structure and corresponding properties of the decimal place value system by performing and illustrating bundling and de-bundling activities.

As an additional functionality, the number of place values as well as the basis of place values can be changed, so that the chart can address further number systems (basis 2–16) and can be used on different levels of learning.

How this interactive place value chart might support substantial learning activities related to decimal place value in comparison to other learning materials for place value systems will be the focus of the following passage.

The interactive place value chart in comparison to other materials

To explore the structure of decimal fractions and the allowed rules within the decimal place value system, students need a tool that follows the rules keeping the structure invariant. In contrast to "traditional" place value charts (paper-pencil or with real tokens), the interactive place value chart allows and even performs bundling and de-bundling activities (see above). Ladel and Kortenkamp (2013) emphasize that this allows to "operate with the tokens *while keeping the represented number unchanged*" (p. 191, italic in the original), whereas in traditional place value charts the manipulation of tokens means a change of the number and therefore a change of the underlying structure. In this sense the "modern approach emphasizes the human activity and is ruled by the object (i.e. the numbers), not the artefact" (ibid). That means that the use of traditional place value charts requires to reflect and understand the artefact, so that the artefact and its function become additional issues to understanding. In contrast, the interactive place value chart follows and even illustrates the structure and the rules of the place value system, so that it could be helpful especially for low-performing learners.

Compared to the base-ten-blocks as well as linear-arithmetic-blocks materials, the interactive place value chart does not illustrate particular place values by different sizes and aspects, but by its position within the chart. Therefore the positional property of the place value system is emphasized. This can be seen as a preparation for the symbolic notation through digits, because the digits of a number equally do not differ in aspect, instead their position within the number is essential (positional property). This preparation is important for disconnecting from concrete activities on the tool to understand and symbolise decimal numbers (Scherer & Moser-Opitz, 2010, p. 85; Schipper, 2003, p. 223). Hasemann (1995, p. 13) points out that exactly this transition from the concrete situation to formalising and symbolising is the main difficulty of understanding mathematics for many students.

Another chart that is used to illustrate the structure of our decimal number system is the Gattegno Chart (see Figure 3), where "each column has a *digit name* associated with it (*one, two, three,..., nine)* and each row has a *value name* associated with it (*thousand, hundred, -ty, [nothing])*. Thus, a number name can be thought of as made up from *digit names* and *value names*" (Hewitt, 2005, p. 45, italic in the original). With respect to this structure the Gattegno Chart aims to "[help] students to learn to say and write number names" (ibid, p. 44) as well as it is meant to "[provide] a basis for work on place value, decimals, addition and subtraction, multiplication in powers of 10 and standard form" (ibid). Various tasks are suggested for exploring the chart's structure to invent calculating methods (see, e.g., Hewitt, 2005). However, these calculating methods are rather based on the chart's structure than on conceptual understanding of the decimal place value system. The properties of our decimal place value system could be addressed by specific tasks within this chart, but in contrast to the interactive place value chart they are not illustrated directly within the table. Moreover the Gattegno Chart is focused on the symbolic representation of numbers in contrast to the interactive place value chart, where the iconic representation includes in particular the illustration of the multiplicative and base-ten property.

OUTLOOK INTO THE EMPRICIAL RESEARCH TO BE CONDUCTED

With this analysis of the mathematical structure of the place value system included in the interactive place value chart and the theoretical considerations on its benefits, the basis for an empirical investigation of the artefact's impact on students' learning is provided. On this basis my research approach will be to investigate empirically how students interact with the digital place value chart in the process of conceptualising the place value system as a main factor for constructing a fruitful concept of decimals.

In learning processes and their profound analysis, the use of artefacts seems to play a crucial role, especially while investigating the interactive place value chart, because the culturally construed structure of the place value system is already included in this artefact. Recognising this structure "may occurs [sic] for the

0.01	0.02	0.03	0.04	0.05	0.06	0.07	0.08	0.09
0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9
1	2	3	4	5	6	7	8	9
10	20	30	40	50	60	70	80	90
100	200	300	400	500	600	700	800	900

Figure 3: An example of the Gattegno Chart

expert automatically and unconsciously" (Mariotti, 2012, p. 28), but students firstly have to explore and get to know this structure within the place value chart through the use of the tool (ibid.). That is why Radford emphasizes that artefacts in the mathematics classroom "are not merely devices that provide stimuli for cognitive development" (Radford, 2014, p. 360), but "they are part of cognition, which we see simultaneously as ideational and material" (ibid).

With the neuropsychological model "gestures as simulated action" from Hostetter and Alibali (2008) we can moreover understand why also the dynamics and relations between different semiotic resources (gestures, inscriptions, language, etc.) might be important in the analysis of learning processes. Hostetter and Alibali (2008) state that "gestures emerge from the perceptual and motor simulations that underlie embodied language and mental imagery" (p. 502). That is why this approach leads to suppose that for example not only gestures and language, but also gestures and activities on artefacts in a learning situation are intertwined with each other and so both have to be considered in the analysis also concerning their relationship.

Recent studies about the role of gestures in mathematics learning revealed that especially high-performing learners use gestures while "generalising" a mathematical concept, so that it seems as if they bridge the transfer from concrete acting to mathematical thinking through gestures (e.g., Goldin-Meadow & Beilock, 2010).

Regarding the interactive place value chart we can note that the sliding-actions needed to operate with the tokens originate in concrete sliding-actions of real tokens, but as well they are gesture-based because of the chart's touchpad-surface. Furthermore the place value chart emphasizes the spatial property of the place value system within the chart, which also can be experienced by the sliding-actions on the touchpad. The virtuality of the digital place value chart, its gestural basis of sliding-actions and the spatial property seem to be suitable to transfer the chart and the sliding-actions into the gesture space as a virtual and dynamic representation, that can similarly be used to reason (verbally) about the place value system and its properties in relation to decimals.

Equally it would be possible that students transfer the virtual place value chart into an inscription, where the sliding-action and therefore the bundling- and de-bundling-activities of place value can only be represented statically and fixed in contrast to gestures.

In summary, all semiotic resources, the mathematical concept of the place value system and its impact on the artefact should be part of the analysis of learning processes. Thus the focus of investigation will be on the role of bodily and artefact-mediated action and perception together with linguistic and symbolic activity, so that the following research questions are traced:

— How do students construct decimals with the interactive place value chart? What conditions foster or hinder this process?

— How do students use semiotic resources interacting with and disconnecting from the interactive place value chart, and what functions do these resources accomplish within the process of learning?

To examine the mentioned research questions video-recorded interviews with student-pairs in grade 5 will be conducted before these students are formally introduced to decimal fractions. The students will be on different levels of their mathematical development and come from an inclusive setting within a comprehensive school (Oberschule) in Bremen. Within these interviews the students receive tasks dealing with the properties of the place value system in relation to decimal fractions, where they can use the interactive place value chart.

The final goal of my research project will be to develop further the tool of the interactive place value chart and to design a learning environment that fosters substantial understanding of the place value system regarding decimal fractions taking into account different semiotic resources. Therefore, the tasks as well as the design of the tool will be developed further during the process of data collection based on the emerging results of analysis. That is why the realisation and the analysis of the single interviews will be organised in an alternating way.

Concerning the design of the tasks it is important to allow a non-predetermined use of different semiotic resources besides the tool (gestures, inscriptions, language, etc.), so that it will be possible to investigate the impact and function of different, spontaneously used resources on the students' process of understanding. Here, the semiotic bundle (Arzarello, 2006, p. 267) as a refined notion of semiotic system provides a suitable framework for the analysis of semiotic resources. This framework of semiotics combines the enlarged notion of semiotic system stated by Ernest (2006) and the Vygotskian approach of psychological processes (Arzarello, 2006, pp. 278f.). This means that besides the classic semiotic resources like words and inscriptions also gestures and artefacts are included in this modern notion of semiotic system (Radford, 2002, footnote 7). Thereby the Vygotskian approach allows "a deeper understanding of its [the semiotic system's] dynamics" (Arzarello, 2006, p. 279). That this enlarged semiotic approach of semiotic bundle could be fruitful in the analysis of learning processes has already been shown in particular studies. Different research projects on the role of gestures in mathematical learning processes (e.g., Behrens, Krause, & Bikner-Ahsbahs, 2014; Krause, 2015 in preparation; Sabena, 2007) revealed for example that within the whole semiotic activity, gestures play an important role in the students' process of generalisation. In this sense Radford describes the role of gestures by supplying "the unperceivable general with something concrete" (Radford, 2005, p. 115).

Peer learning in mathematics forum on Facebook: A case study

Yaniv Biton[1,2], Sara Hershkovitz[1,2] and Maureen Hoch[2]

1 Shaanan College, Haifa, Izrael, yanivb@cet.ac.il, Sarah@cet.ac.il

2 Center for Educational Technology, Tel Aviv, Israel, MaureenH@cet.ac.il

To help students prepare for the resit exam of the mathematics Bagrut (Israeli matriculation) of 2013, the Center for Educational Technology established a virtual review session using Facebook, for four days before the exam. 614 students and 16 teachers participated. We examined three central questions, each about using Facebook to prepare for the mathematics Bagrut: What opportunities for learning were created? What are the students' opinions? What are the teachers' opinions? Analysis of the posts on Facebook revealed five types of situations with potential for learning. Answers to on-line questionnaires show that both students and teachers hold positive opinions towards the solution for learning provided by Facebook. We recommend researching opportunities for learning afforded by the social networks.

Keywords: Facebook, learning opportunities, student interactions.

INTRODUCTION

Online social networking sites such as Facebook have developed in recent years and have become the most popular meeting places for youth and adults (Boyd, 2010). Many studies have investigated the potential of using these networks to promote learning (e.g., Forkosh-Baruch & Hershkovitz, 2013; Neman, Lev, & Amit, 2013). In some of these studies of teacher-student interactions the student has the status of the teacher's friend (Madge et al., 2009) and hierarchies are formed as a result of this friendship status (Steinfield, Ellison, & Lampe, 2008). Asterhan and colleagues (2013) discuss whether and how teachers may use Facebook for innovative, collaborative forms of online learning that extend beyond the traditional classroom, and whether this is at all recommendable or feasible.

Recently many researches have studied the Facebook option of creating a group where teacher and students belong but do not need to be "friends". Students perceived learning in this environment as very intensive and collaborative in nature (Meishar-Tal, Kurtz, & Pieterse, 2012). In the learning of mathematics, social network sites have been found to invite student collaboration and encourage learning (Baya'a & Daher, 2013).

In this present research the learners were members of a group on Facebook opened specially for preparation for the mathematics Bagrut (Israeli matriculation) exam. We investigated what opportunities for learning were created as a result of the interactions that formed within the group and examined the viewpoints of students and teachers who took part in the study group. We present the results of a pilot study, in preparation for a wider research on this subject. In this pilot we chose the medium of Facebook as being familiar and convenient. In a larger study we recommend investigating other possible platforms and comparing the influence of different platforms.

Our research questions were:

1) What opportunities for learning could be identified as a result of interactions on the Facebook forum?

2) What were students' and teachers' attitudes towards these interactions on the Facebook forum?

OUTLINE OF THE RESEARCH

Eight groups – four in Hebrew and four in Arabic – were opened on Facebook for four days, twelve hours a day, before the resit of the mathematics Bagrut exam. Teachers were on call to respond to students (three shifts of four hours). The Hebrew speakers' group comprised 513 students, and the Arabic group 101 students. The groups were divided according to the questionnaires in the Bagrut exams at intermediate and advanced levels. The teachers were trained in on-line teaching, in the principles of a forum, and in the Facebook tools, and were given technical instructions on how to provide responses in the forum.

During the activity the students raised questions in whatever subject they wished. The questions were uploaded to the forum as photographs or as details of book, page, and exercise number (the teachers were provided with all the relevant textbooks). On receipt of a question the teacher sent a reply, "I will upload an answer soon" and after several minutes (on average 10 minutes) he uploaded a response to the forum as a photo of the page on which he wrote the solution, or hints on how to reach it. At the end of the study session online questionnaires were sent to the students and teachers who took part in the forums. 105 students and 15 teachers completed the questionnaires.

RESEARCH METHODS AND TOOLS

We used a mixed methods research model (Johnston & Onwuegbuzie, 2004) which combines qualitative and quantitative data analysis. The research tools were two online questionnaires, one for students and one for teachers, comprising open and closed questions. The open questions for the student included those on his background, which exam paper he was taking, how he heard about the study group, and his suggestions for what he would like to preserve in the study group and what he would like to improve. The open questions for the teacher included those on his seniority, his online teaching experience and the classes he usually teaches. Teachers were also asked to write down their feelings about teaching through Facebook, to describe interactions they remember favourably, etc. The closed questions in both questionnaires comprised statements on a Likert scale from 1 (disagree) to 4 (strongly agree). These statements included issues such as the use of technology, peer learning, motivation to continue learning/teaching in a similar manner in the future, interactions with students, etc.

The participants answered the questionnaire at the end of the Facebook review session. The answers to the open questions were analysed by three mathematics education experts to improve validity reliability by triangulation (Denzin & Lincoln, 2000). The analysis was carried out in four stages: first the answers were collected; in the second stage all the answers were divided into short sentences; subsequently each sentence was classified according to general subject matter; and finally the sentences in the same subject matter group were collected together and arranged according to categories. After much discussion 100% agreement was achieved between the judges about the categorisation of the data.

In order to learn what opportunities for learning were created as a result of revising for the Bagrut exam in mathematics through the medium of Facebook an analysis was made of the content appearing in Facebook throughout the review session. First we divided up all the content into analysis units according to the participants in the interactions: teacher-student and student-student. In the second stage we analysed all the interactions and learning opportunities that arose. The analysis consisted of identifying and characterizing the students' questions and the correctness of their explanations. Each analysis unit was examined with the aim of pinpointing the development of mathematical knowledge during the interaction. From this analysis we identified learning opportunities which can be seen in Figure 2. In order to preserve the privacy of the participants care was taken to ensure anonymity.

FINDINGS

Figure 1 shows the number of students in each group according to the levels of the exam papers (804 and 805 – intermediate, 806 and 807 – advanced) and the number of questions or discussions raised (the posts).

Figure 2 presents a map of the opportunities for learning observed throughout the review session.

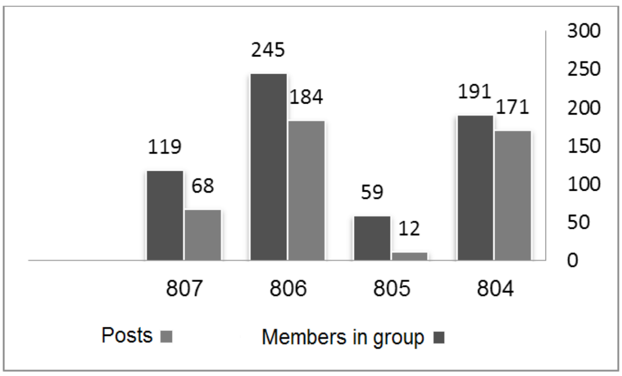

Figure 1: Number of participants and number of posts in each study group

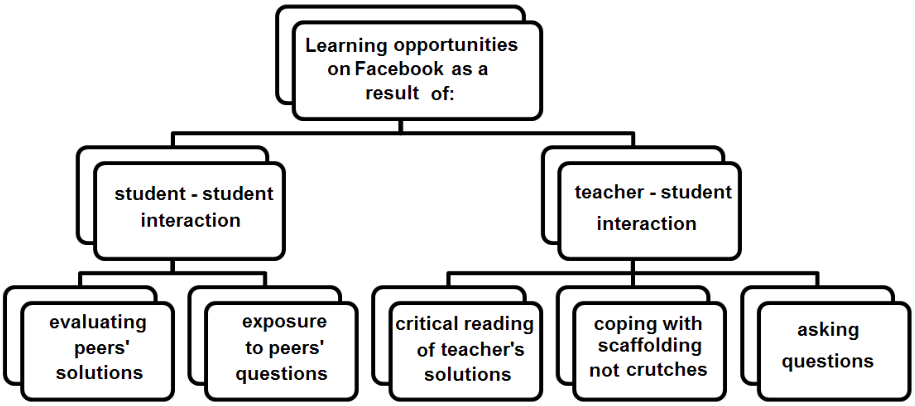

Figure 2: Learning opportunities on Facebook resulting from teacher-student interactions and student-student interactions

We now provide a short description of each opportunity and some episodes from the forum.

Evaluating peers' solutions

During the review session students asked for help in pinpointing the mistakes they had apparently made in their solution, intending that the teacher would evaluate their work and find the mistake. We observed that during the time that passed between a student uploading his solution and receiving a reply from the teacher (perceived as the source of authority in the forum) other students responded and tried by themselves to pinpoint the source of their peer's error. The students' attempts created a cognitive appeal to the correctness or incorrectness of the evaluation and thus started a chain of responses until a final response was given by the teacher. Similarly we noticed that throughout the review session students had considerable success in taking the teacher's role by attempting to provide explanations through the forum. This finding is strengthened by the students' answers to the questionnaire at the end of the review session. 72% (N=104) stated that they learned from responses given by other students.

We now provide an episode from the forum. Here we give an example of a student-student interaction in which a student uploads his solution to a problem and requests help to find his mistake. Sagi refers to the following problem (of which only the relevant sections are replicated here).

> A sequence of 2n+1 numbers satisfies the following conditions: $a_1 = 10, a_{n+1} = 5a_n$.
>
> a. Express in terms of n the sum of the terms in the even-numbered places.
>
> b. The last term in the sequence is 3,906,250. Calculate:
>
> 1) the sum of the terms in the even-numbered places
>
> 2) the sum of the terms in the odd-numbered places
>
> 3) the term in the middle of the sequence.

Sagi posts the following:

> I need help with general understanding of this problem. It's clear to me that the sequence is geometric and that the q is 5.... The general term, according to the given information, should be $a_n = 10 \cdot 5^{2n+1-1}$. And so a_2 is 6,250. It's clear that's incorrect because it should be 50 but I would be happy for an explanation of what I am not understanding here, and for the solution. Thanks.

Sagi attempts to phrase his difficulty in his own words. We can see that he recognizes that the sequence is geometric and knows the formula for the general term in a geometric sequence $a_n = a_1 \cdot q^{n-1}$. However he substitutes 2n+1 for n in the formula thus finding the last term instead of the general term. Avichay replies to Sagi and the following dialogue takes place:

Avichay: The general term in a geometric sequence is $a_n = a_1 \cdot q_{n-1}$ and so $a_2 = 10 \cdot 5^1 = 50$.

Sagi: Right, but here the last term is in place 2n+1.

Avichay: That doesn't change anything buddy.

Sagi: I'm pretty sure it does because in section b you have to use the general term $a_n = 10 \cdot 5^{2n}$.

Avichay: That formula is for every geometric sequence. The number of terms doesn't matter for this formula, only for the sum formula.

Sagi: I'm pretty sure you're wrong. Let's wait for one of the tutors to answer.

Avichay: Okay, but there you're looking at the sum of terms. You asked what's a_2?

Sagi: Let's wait for an answer. I want to be sure. But really, thanks pal.

Avichay: I think I understand what your problem is...... The n-1 in the power of q isn't according to the number of terms in the sequence but the place of the term in the sequence.

Avichay: And if you want to find the value of a_2 you need to do $q^{(2-1)}$.

Avichay is determined to help Sagi and tries to fine-tune the mathematical language he uses in his explanation. Sagi appears doubtful but is grateful for Avichay's efforts. The improvement in Avichay's language throughout the episode is evident. At the end of the discussion between Avichay and Sagi, Achinoam joins in as follows:

Achinoam: In my opinion if you substitute 2 in the first formula given $a_{n+1} = 5a_n$ you get $a_2 = a_1 \cdot 5$, that is $10 \cdot 5 = 50$.

Sagi: Right, that's clear, but I'm trying to understand why the formula for the general term, and it's correct, doesn't give me $a_2 =50$.

Achinoam: Why not? It works out terrific...If I understood you correctly you meant the formula for the general term $a_n = a_1 \cdot q^{n-1}$ where you substitute 2n + 1 for n?

Achinoam: If so, I can help.

Sagi: Yes.

Sagi: That's what I meant.

Achinoam: Terrific so: $a_{2n+1} = a_1 \cdot q^{2n+1-1}$ and that's in fact equal to $a_{2n+1} = a_1 \cdot q^{2n}$ and then if you want a_2 your n will have to be 1/2 and then $a_2= a_1 \cdot q^{2*1/2}$ and that works out $a_2= a_1 \cdot q^1$ and that's exactly right if you substitute the givens and you do get $a_2=$ 50.

Achinoam: I hope you understand me.

Sagi: Wow thanks a lot!! Simply all the time I read my general term to be a_n instead of a_{2n+1}. Really thank-you. I was getting stressed out.

Achinoam: Hey – my pleasure. Just glad I was able to help.

Achinoam has shown Sagi how he could have got the correct answer using his method. Sagi says he now understands and clarifies his mistake in his own words. Ironically Achinoam's convincing argument is mathematically flawed. Here the intervention of the teacher is required to make sure that Sagi and Achinoam will understand that n cannot take the value 1/2.

From an analysis of the present dialogue we can learn about learning opportunities that occurred among the students: exposure to different solution methods, improvement in mathematical language through giving explanations and asking questions, perseverance and motivation on the part of Sagi to find his mistake on the one hand and the desire of his peers (Avichay and Achinoam) to help him on the other.

Exposure to peers' questions

Throughout the review session students were exposed to questions raised by other students and tried to answer these questions themselves. This finding is based on the number of observers of each post in the forum, on the students' reports in the questionnaire, and on the responses of the students in the forum itself. Exposure to peers' questions expanded the available pool of exercises and presented the additional challenge of dealing with questions that were difficult for their peers to solve. This finding is supported by the students' questionnaires where 78% reported that they learned from questions raised by other students.

Critical reading of teachers' solutions

The most significant learning opportunities that occurred during the review session were the chance to read, to analyse, and to understand the teachers' solutions on the forum. On some of the posts, after reading the teachers' solution the student returned to his own solution to compare the two methods. In this excerpt we can see the comparison one student made after receiving the teacher's answer to his question. At the end of this post an error was found in the book, thanks to the student's "stubbornness".

> Thanks. But somehow in the answers they put 3/4 instead of 3 root 3 divided by 2. And according to the volume of the prism that you found I got the correct t but the maximum volume is different. Maybe they made a mistake? I'd like you to solve the rest because I didn't get the same answer ...

Coping with scaffolding not crutches

In not a few cases the teacher's response was advice for continuing the solution and the student had to deal with the problem on his own. 87% of the students claimed that the teachers' tips helped them learn. In this excerpt we see a hint given by the teacher and the student's satisfied response that it helped him to solve the problem.

> Teacher: I recommend you to try to finish this by yourself. If not, let me know and I'll post the solution. Tip: the lateral area is the sum of the areas of the rectangular faces without the bases.
>
> Student: Thank you very much for the help. I got it right! ☺

Asking questions

Throughout the review session, in addition to the problems the students posted as photos or text, they asked concrete questions on particular parts of a solution, and expressed doubts that arose during a solution. In contrast to questions asked face to face, here asking questions requires another skill – the ability to formulate the question in writing, with suitable emphasis for the teacher who is supposed to answer.

The following excerpt shows a student's questions after a solution has been posted by the teacher. It includes a search for explanation/proof, indicating critical reading of the solution.

> It's not clear to me why you can deduce from the sketch of the graph alone that there are no maximum or minimum points? Who says there isn't one before the asymptote? And how can you tell without a table if the function is increasing or decreasing from the asymptote? Thanks!!

Instructional interactions on the social network

The answers to the questionnaires were analyzed as described in the section on research methods. In Table 1, we show examples of students' and teachers' remarks in each of the categories: motivation for continued learning, peer learning, technology utilisation, and supportive learning climate.

As can be seen in the table, students' and teachers' responses were mainly positive, and in general the participants' responses indicate great satisfaction with the use of Facebook in preparing for the exam. 75% of the students (N=105) stated that it was easy for them to ask questions and receive replies through Facebook, 79% stated that they would like to use Facebook in this way also for learning other subjects, and 87% stated that they would like to continue learning in a similar

Categories	Student questionnaire	Teacher questionnaire
Motivation for continued learning	I'm glad I got the chance of the Facebook forum. It gave me the option with exercises that I couldn't solve, not to give up like I usually do, but to get the solutions from a teacher – that really helped me.	I really liked the fact that the students asked relevant questions, related to the answers, and didn't give up until they understood.
Peer learning	The forum was a very good idea. We could learn from other students' questions and answers.	A student posted a question after a lesson, and I noticed that students started to help each other in the forum, and succeeded in solving some parts of it.
Technology utilisation	I would recommend improving the method of posting pictures on Facebook.	The idea of photographing the problem or the solution and posting is brilliant and effective in making best use of the time and for presenting the solution.
Supportive learning climate	I would be very happy to get this kind of help throughout the year. It is all over and above what a student can expect for success. Thank you so much for all the help.	The students' appreciation was heart-warming.

Table 1: Students' and teachers' remarks about the integration of Facebook in preparing for the Bagrut exam in mathematics

manner throughout the year. 93% of the teachers (N = 15) stated that the environment encourages meaningful learning and that the project justifies the investment of resources. There was 100% agreement among the teachers on willingness to continue in a similar manner next year. 93% stated that they would be interested in opening similar learning environments for their own students during the year.

A little criticism on the use of technology was heard from both students and teachers, relating to the uploading of pictures that were sometimes not clear, thus making it difficult to understand and respond to the problem. In addition, teachers in charge of forums where there was a lot of activity indicated the need for extra staff to help manage the responses where necessary.

DISCUSSION AND CONCLUSION

In this research we asked what opportunities for learning could be identified as a result of interactions on the Facebook forum. The Facebook forum encouraged different interactions between teachers and students and among the students themselves. These interactions provided the learners with learning opportunities which included: asking questions, peer learning, different methods of problem solving, and critical reading of solutions, and were exposed to questions from different textbooks and to solution methods of different teachers. These learning opportunities carry extra value and are important in the learning process leading up to the Bagrut exam and in general. Individual study without interactions with peers or with a teacher is unlikely to afford any of these opportunities.

We also asked what were students' and teachers' attitudes towards these interactions on the Facebook forum. The findings in this research indicate students' great satisfaction with the opportunity given them to study for the mathematics Bagrut exam through the medium of Facebook. They were motivated to deal with questions their peers found difficult. The findings relating to the students' positive opinions of learning in a Facebook environment strengthen findings of earlier studies about learning on social networks (Meishar-Tal, Kurtz, & Pieterse, 2012). The teachers also expressed great satisfaction with the Facebook environment for learning and declared their intention to adopt a similar environment preparing for Bagrut exams in the following years and for teaching during the school year.

Advantages of this technological platform included the neutralizing of the time factor – the learning could, and did, take place at all hours of the day and night. Weaker students were able to take advantage of the greater abilities of their peers and to learn from them. Students who lack confidence to ask questions in a face to face situation felt freer to express themselves. The activity was open to students from different schools with different backgrounds. These are only some features that are not present in a traditional classroom.

This research was an initial testing of teacher-student and student-student interactions on Facebook in a four-day review session in preparation for the Bagrut mathematics exam. The results encourage continuation and further research into these and other related aspects, on wider groups of teachers and students, and for longer time periods. A wide based research in the subject would be likely to lead to peer learning also among the teachers themselves – on how to characterize students' questions leading up to the exam, and in general. In addition, we recommend that continued research on these issues could provide educational policy makers with an understanding of the value of investing in similar projects in the future.

Combinatorial reasoning is very important in mathematical development, providing students with contact with essential problem solving. One form of symbolic representation of combinatorial situations is a tree diagram. Two experimental studies were designed and implemented, the first with adults in initial schooling and the second with Elementary School children. Comparisons were performed in order to observe the impact that the use of tree diagrams – virtual or built with pencil and paper – had on combinatorial reasoning. From initial poor performance, both children and adults in initial schooling benefitted from instruction by use of tree diagrams that enabled them to perceive how elements can be combined in a systematic manner and helped them develop their combinatorial reasoning.

Keywords: Combinatorial reasoning, tree diagrams, children and adults; initial schooling.

THE ROLE OF SYMBOLIC REPRESENTATIONS ON COMBINATORIAL REASONING

Combinatorial reasoning is a way of thinking very useful in general mathematical learning. According to Batanero, Godino and Pelayo (1996), Combinatorics is a key element of discrete mathematics, being essential for the construction of formal thought. The nature of combinatorial situations – counting techniques of possible groupings of a given set of elements that meet certain conditions, without necessarily having to count them one by one – provides students contact with essential problem solving and may help their development in Mathematics and other subjects.

Diverse forms of symbolic representation may be used in solving combinatorial problems, such as: drawings, lists, tree diagrams, tables, formulas and other forms. These distinct symbolic representations may provide means of systematization and help students understand how to obtain the total number of combinations.

The role of symbolic representations in mathematical development is pointed out by Vergnaud (1997) as a key element in conceptualisation. Considering Combinatorics, Fischbein (1975) emphasizes that the use of tree diagrams can enable advances in the development of combinatorial reasoning because this representation helps systematization by pointing out the necessary steps in choosing elements to compose combinations.

In a longitudinal study, Maher and Yankelewitz (2010) investigated the initial understanding of eight and nine year olds in a problem of *Cartesian product*. The authors defend that it is necessary to invite children to use various representations to express their ideas and ways of thinking, because representations give meaning to the problems and communicate ideas. Thus, children can find patterns, be systematic and generalize results.

Sandoval, Trigueiros and Lozano (2007) proposed the learning of Combinatorics by use of the software *Árbol*. The study was conducted with 25 Mexican children, aged 11 to 13, and the authors observed improvements in student performance, especially regarding the choice of strategies for efficient resolution. Thus, it is emphasized that this software, through tree dia-

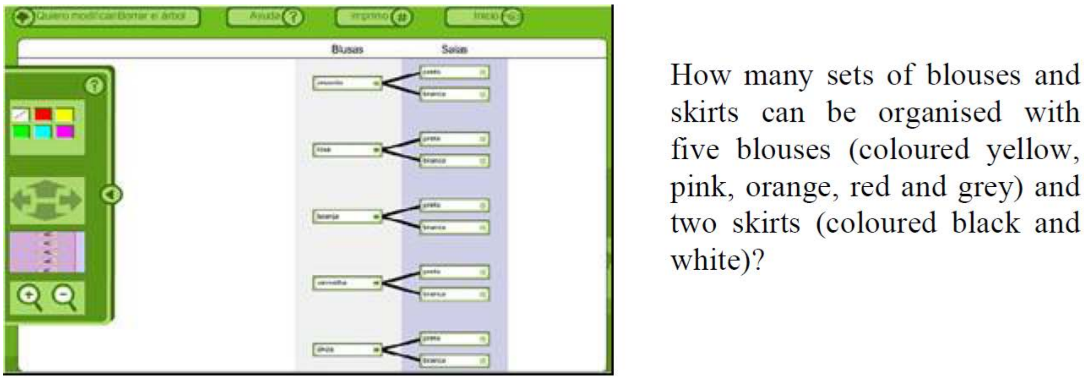

Figure 1: Árbol screen of a Cartesian product problem

grams, favours the use by children at initial level of schooling, because it provides possible combinations in all types of combinatorial problems (*Cartesian products*, *combinations*, *arrangements* and *permutations*). Figure 1 shows a screen of the software *Árbol* of a *Cartesian product* problem in which in it possible to visualise the total number of combinations in a tree diagram.

COMBINATORIAL SITUATIONS

According to Vergnaud (1997), to study and understand how mathematical concepts develop in students' minds through their experience in school and outside school, one needs to consider a concept as a three-uple of three sets: the set of situations (S) that make the concept useful and meaningful; the set of operational invariants (I) that can be used to deal with these situations; and the set of symbolic representations (R) that can be used to represent invariants, situations and procedures. Thus, the immense role played by symbols cannot be ignored in mathematical teaching and learning, as means to articulate invariants – conceptual properties and relations – situations and strategies used in problem solving.

Vergnaud (1997) also points out that combinatorial problems are part of what he calls *multiplicative structures*. In the same direction, Pessoa and Borba (2010) defend that as connected concepts, different types of combinatorial problems should be taught in the classroom and present examples of these distinct situations:

Cartesian product: At the square dance three boys and four girls want to dance. If all the boys dance with all the girls, how many pairs will be formed?

Simple permutation (without repetition): Calculate the number of anagrams that can be formed with the letters of the word LOVE.

Simple arrangement: The semi-finals of the World Cup will be played by: Brazil, France, Germany and Argentina. In how many distinct ways can the three first places be formed?

Simple combination: A school has nine teachers and five of them will represent the school in a congress. How many groups of five teachers can be formed?

TWO STUDIES ON COMBINATORIAL REASONING DEVELOPMENT

With the aim of investigating the role of symbolic representations – in particular the use of tree diagrams – on the development of combinatorial reasoning, we designed and implemented two experimental studies. The first one involved adults in initial schooling and in the second study took part Elementary School students (5th grade, 10 year olds).

Method of the 1st Study: Adults in early schooling using tree diagrams and lists

The adults taking part in the study were 24 students of classes corresponding to the 4th and 5th years of regular Elementary School with no previous systematic instruction on Combinatorics. They were separated into three groups, each group consisting of eight students. After solving an eight item pre-test (two problems of each type), they were taught in groups that varied in terms of symbolic representations used: G1 – lists and tree diagrams; G2 – tree diagrams; and G3 – lists. After the learning session they solved an eight problem post-test.

Method of the 2nd Study: Children using virtual or written tree diagrams

This study was conducted with 40 students from the 5th grade of Elementary School, divided into four groups, that took part in a pre-test (eight Combinatorics problems), followed by different forms of intervention and two post-tests (also with two of the four types of problems), which assessed the progress achieved a few days after the teaching session (immediate post-test) and nine weeks after the intervention (delayed post-test). Just as the adults, the children had no previous systematic instruction on Combinatorics. During the teaching session, the students worked in pairs. The first experimental group (EG1) worked with the software *Árbol* (Aguirre, 2005) in which diagram trees are constructed; the second experimental group (EG2) constructed tree diagrams with pencil and paper; the third group, a control group (CG1), worked, through drawings, multiplicative problems, according to the classification proposed by Nunes and Bryant (1996) (excluding Combinatorics); and the fourth group was an unassisted control group (CG2), that took part only in the pre and the post-tests.

HOW DO TREE DIAGRAMS HELP COMBINATORIAL REASONING?

Results of the 1st Study: Adults progress on combinatorial reasoning

Initially (at pre-test) the adults presented only incorrect answers or partially correct answers with very few correct combinations presented. They preferred to use lists in their answers but, usually, were not systematic in their usages and could not obtain the total correct number of combinations.

After the teaching session, all three groups progressed in their combinatorial reasoning. An Analysis of Variance (ANOVA) showed no significant differences between groups ($F (2, 21) = .78$; $p > .05$). Thus, both forms of symbolic representations helped the adults to understand the combinatorial relations involved in the problems, but tree diagrams more clearly helped them to be systematic in their answers.

Table 1 shows that at post-test the adults presented more correct answers or much more answers very close to the correct ones.

Progress in understanding was, however, sometimes limited. Figure 2 shows two examples of partially correct answers at post-test.

The first example (a *Cartesian product*), asked to indicate possible couples by choosing a man, out of a group of four, and a woman, out of a group of six. The adult that answered in this manner presented only four couples, considering there were only four men available. The second example (a *combination*) asked to form pairs, out of a group of five people. The adult in this case incorrectly considered, for example, Luíza

Problem type	Incorrect Answer		Partially correct answer		Correct answer	
	Pre-test	Post-test	Pre-test	Post-test	Pre-test	Post-test
A	75	14,6	25	81.2	0	4,2
C	47,9	6,2	52,1	83.3	0	10.5
P	91,7	50	8,3	50	0	0
CP	91,7	12.5	8,3	75	0	12.5

A – Arrangements; C – Combinations; P – Permutations; CP: Cartesian products

Table 1: Percentage of types of answers in each problem type, at pre and at post-test

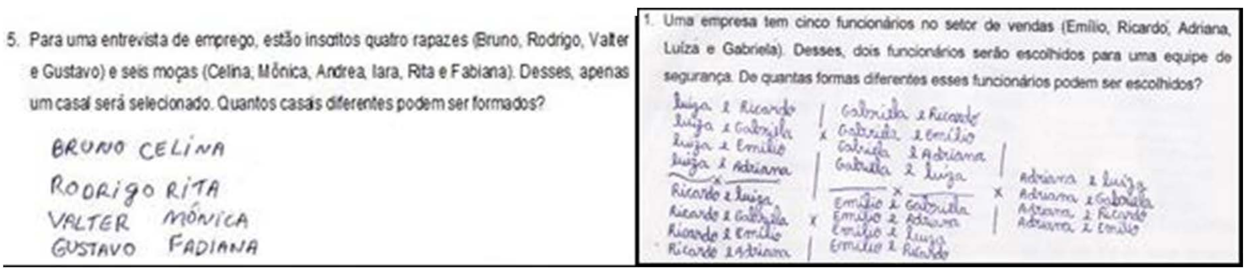

Figure 2: Partially correct answers at post-test

and Ricardo as a different pair from Ricardo and Luíza. In this way, 20 pairs were listed instead of only 10.

In three of the problem types, correct answers were presented at post-test, but difficulties with *permutations* still remained. When using lists, the adults listed some of the *permutations* but not all of them. The lists were sometimes limiting in the understanding that in *permutations* all elements are used in all possible orders.

Some preferred, after the teaching session, to use tree diagrams and those that used this symbolic representation tended to do so in a more systematic manner that led to correct answers. Figure 3 is an example of a correct answer presented at post-test of the problem of *combination* of two elements out of five. In this type of problem, and others, the adults benefitted from use of tree diagrams because this form of representation highlighted the need to be systematic in the combination of elements in distinct combinatorial situations. The adult in this case noticed that if Emília and Ricardo have been already marked as a pair (top left hand side), than the branches started with Ricardo must not include Ricardo and Emília as a distinct pair.

Results of the 2nd Study: Children's advances in combinatorics

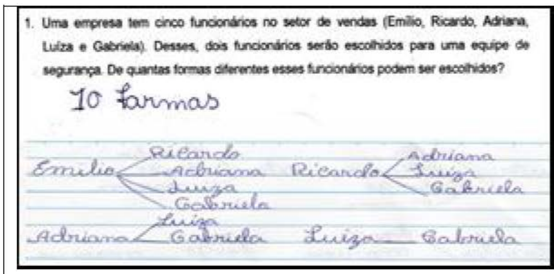
In the study with 5th grade children, each of the eight problems was scored zero to four, depending on how correct the answer was. If no combinatorial relation was observed the answer was scored zero; if only one combination case was presented, the score was one; if a limited number was presented, the score was two; if a larger number was presented, but not the total number of cases, the answer was scored three; and, finally, the score four was given to answers that were completely correct – with the total number of cases asked for. Thus, the total possible score was 32.

Table 2 shows children's performance at pre-test, immediate post-test and delayed post-test. The initial means were very similar because the children were distributed in the groups by pairing their scores and all four groups had very low initial scores.

By use of paired t-tests, significant differences were observed when performance at pre-test and immediate post-test were compared, for both experimental groups (EG1: t (8) = -2.920; p = .0019; EG2: t (8) = -3,447; p = .0009). Thus, the teaching session that used tree diagrams (either virtual or in pencil and paper) was effective in developing children's combinatorial reasoning.

No significant differences were observed between performance at immediate post-test and delayed post-test for the two experimental groups (EG1: t (8) = -0.472; p = .649; EG2: t (8) = -1.541; p =.162). This indicates that learning was retained by children of both experimental groups because, after nine weeks, the children still were able to recognize the distinct combinatorial relations involved in the problems and also were still able to successfully present correct combinations.

The children in the control groups presented no significant differences in performance, neither when



1. Uma empresa tem cinco funcionários no setor de vendas (Emílio, Ricardo, Adriana, Luíza e Gabriela). Desses, dois funcionários serão escolhidos para uma equipe de segurança. De quantas formas diferentes esses funcionários podem ser escolhidos?

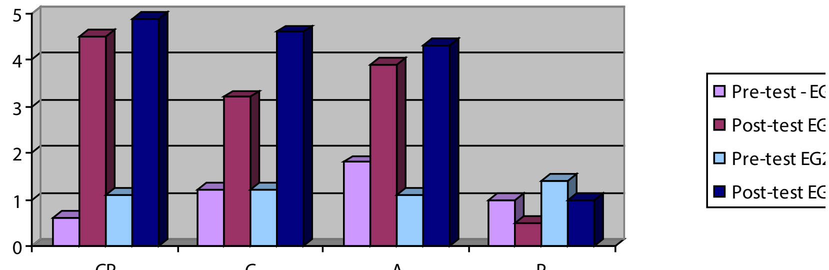
10 formas

Since Ricardo and Adriana have already been marked (top right hand side), than Adriana's branches do not include Ricardo and Luiza's branch only includes Gabriela, since Luiza has already been paired with all the previous persons.

Figure 3: Correct answer at post-test with tree diagram

Groups	Pre-test	Immediate post-test	Delayed post-test
EG1 – Software *Árbol*	4,6	12,1	13,22
EG2 – Pencil and paper	4,8	14,8	16,44
CG1 – Multiplicative problems	4,7	4,1	4,0
CG2 – Unassisted	4,9	2,8	4,2

Table 2: Means of groups at pre-test and two post-tests



CP: Cartesian product; C: Combination; A: Arrangement; P: Permutation

Graph 1: Means of experimental groups at pre-test and immediate post-test according to problem type

pre and immediate post-test were compared (CG1: t (9) = 0.751; p = .472; CG2: t (9) = 0.391; p = .705), nor when immediate and delayed post-test were compared (CG1: t (9) = 0.0750; p = .946; CG2: t (9) = -0.782; p = .454). Thus, only solving other multiplicative problems (not including combinatorial ones) or just taking part in other regular school activities was not sufficient to improve combinatorial reasoning.

Table 2 also indicates a slightly better improvement in EG2 when compared to EG1. This performance somewhat higher may be related to the fact that students in this second group solved the situations using the same representation (writing with pencil and paper) adopted in the pre-test and post-tests, while students in the first experimental group solved the problems aided by the software and at post-tests had to use a pencil and paper representation. In addition, EG2 may have been benefited by having to think about the combinatorial relations concurrently with the construction of the tree diagrams, while EG1 had the tree diagrams built by the software, and it was necessary to think of these relations only when selecting the valid cases constructed. A positive result, observed mainly by the students of the group that learned with the software, was that at post-test the children used different types of strategies – tree diagrams, lists and diagrams – showing that students did not merely learn a procedure but understood the relations involved in distinct types of combinatorial problems.

Taking in consideration problem type, Graph 1 indicates that there were huge improvements at post-test in *Cartesian products*, *combinations* and *arrangements*.

Means in these types of problems were higher than four (considering that there were two problems of each type and that for each problem the maximum score was four, and the total maximum was eight). This indicates that children in the experimental groups tended to obtain correct answers in at least one problem of these types. The graph shows no improvement in *permutations* and, just as what was observed with adults, the children possibly needed more time to better understand the tree diagram construction of this problem type, in which all elements are used in distinct orders.

Figure 4 shows a child, from the first experimental group, solving similar *combination* problems at pre and at immediate post-test. At pre-test the problem involved selecting two pets out of three animals (a dog, a bird and a turtle) and at immediate post-test the problem involved the choice of two teachers out of four (Ricardo, Tânia, Luíza and Sérgio). Initially the child incorrectly answered that there was only one way of choosing two pets out of three animals. At post-test the child used a tree diagram and correctly answered that there were six different ways.

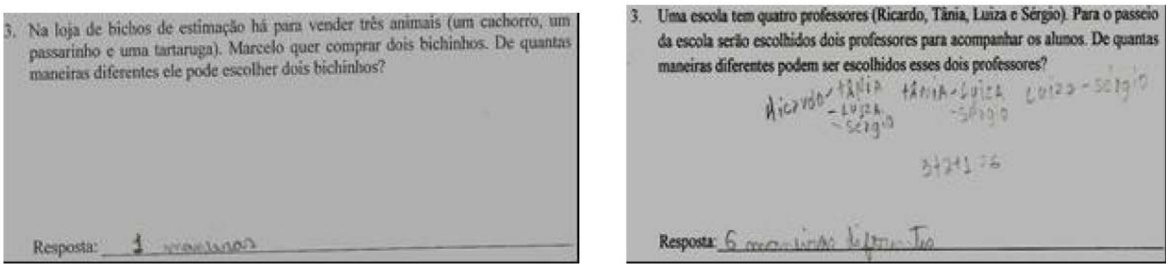


Figure 4: Incorrect answer at pre-test and correct answer at immediate post-test of a child from the first experimental group

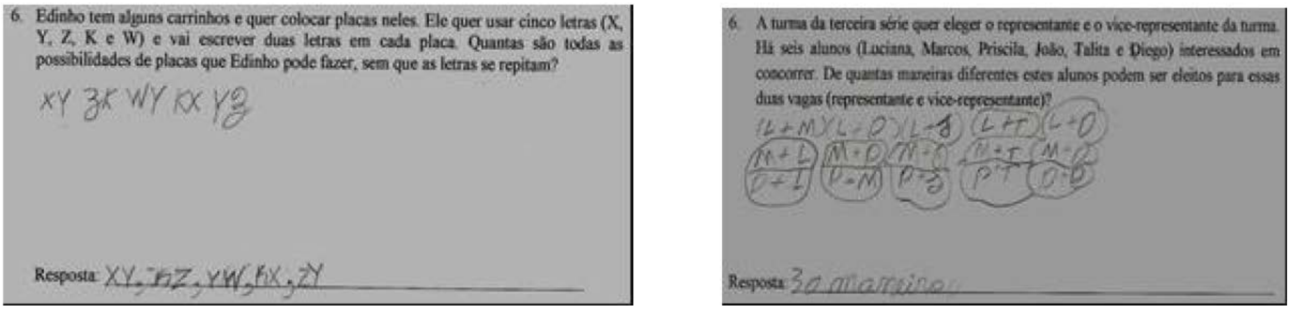


6. Edinho tem alguns carrinhos e quer colocar placas neles. Ele quer usar cinco letras (X, Y, Z, K e W) e vai escrever duas letras em cada placa. Quantas são todas as possibilidades de placas que Edinho pode fazer, sem que as letras se repitam?

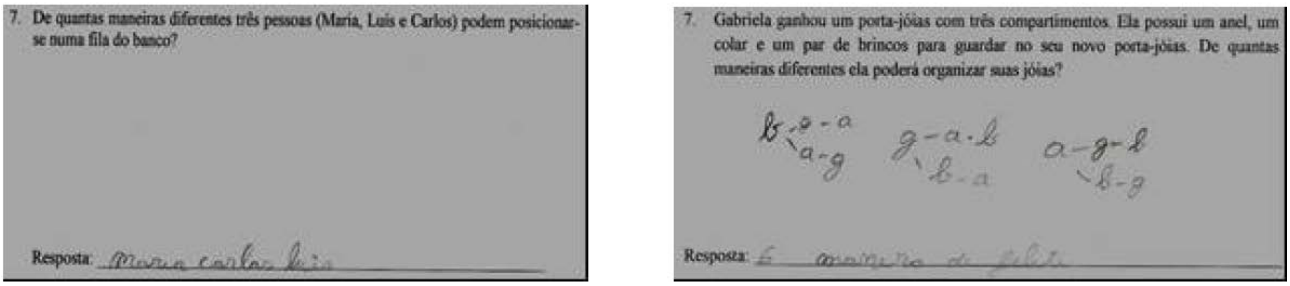
XY ZK WY KX YZ

Resposta: XY, KZ, YW, KX, ZY

6. A turma da terceira série quer eleger o representante e o vice-representante da turma. Há seis alunos (Luciana, Marcos, Priscila, João, Talita e Diego) interessados em concorrer. De quantas maneiras diferentes estes alunos podem ser eleitos para essas duas vagas (representante e vice-representante)?

Resposta: 30 maneiras

Figure 5: Incorrect answer at pre-test and correct answer at immediate post-test of a child from the second experimental group



7. De quantas maneiras diferentes três pessoas (Maria, Luís e Carlos) podem posicionar-se numa fila do banco?

Resposta: Maria carlos luis

7. Gabriela ganhou um porta-jóias com três compartimentos. Ela possui um anel, um colar e um par de brincos para guardar no seu novo porta-jóias. De quantas maneiras diferentes ela poderá organizar suas jóias?

Resposta: 6 maneira de colocar

Figure 6: Incorrect answer at pre-test and correct answer at immediate post-test of a child from the second experimental group in a *permutation* problem

Figure 5 shows a child, from the second experimental group, solving similar *arrangements* problems at pre and at immediate post-test.

The pre-test problem involved choosing two out of five letters (X, Y, Z, K and W) for license plates. The child listed only five options out of the 20 possible *arrangements*. The list was not systematic and the child did not consider that the order of choice implied in different options (the licence plate XY is different from the YX one). The immediate post-test problem involved the choice of a representative and vice-representative of a class out of six students (Luciana, Marcos, Priscila, João, Talita and Diego). The child listed 15 *arrangements* and answered that there were 30 in all. The child was very systematic in the listing produced. First all the choices with Luciana (represented by the initial L) as representative were listed, followed by Marcos (represented by the initial M) as representative and Diego as representative (represented by the initial D). The child at this point generalized that for each student as representative there were five options, so with all six children there would be 30 distinct *arrangements*.

Progress was not generally observed in *permutation* problems but Figure 6 shows how a child (from the second experimental group) solved this type of problem at pre and at post-test. The pre-test problem involved ordering three people (Maria, Luís and Carlos) in a line. The child presented only one option.

At post-test, the child used a tree diagram and was successful in doing so. The problem involved putting a ring (anel), a necklace (colar) and a pair of earrings (brincos) on three trays of a jewel box. The child correctly considered all possible branches of the tree and concluded there were six different ways of putting the jewellery in the box.

One interesting aspect is that many children from the experimental groups preferred to use listings at post-tests, despite having had the experience – by use of software or pencil and paper – of using tree diagrams. What was observed was that learning with tree diagrams enabled systematic listing, not present at pre-test. Figure 7 is an example of a child, of the second experimental group, that at post-test correctly listed the 24 possible couples, chosen from a group of six boys (Gabriel, Thiago, Matheus, Rebato, Otávio and Felipe) and four girls (Taciana, Eduarda, Letícia and Rayssa).

This was also observed amongst adults – the preference of use of listing was maintained but the child or adult used systematic lists, after instruction. This seems to be strong evidence that the child or adult did not simply learn a procedure but understood what relations were involved in distinct combinatorial problems.

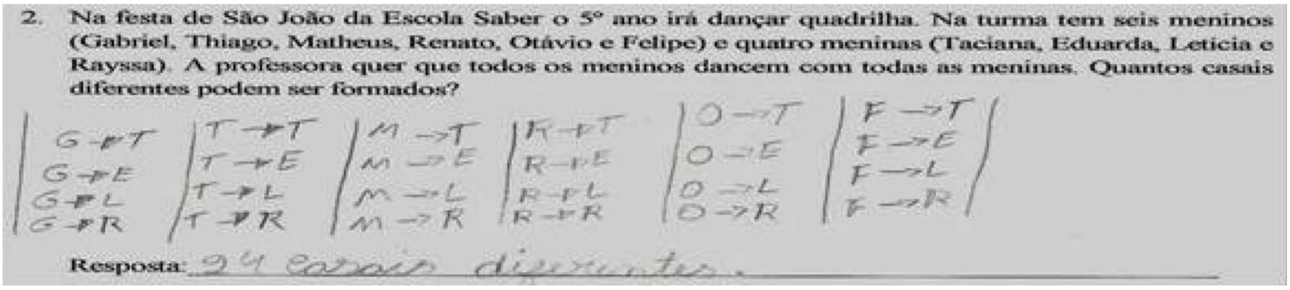


Figure 7: Correct answer at delayed post-test using listing of a child from the first experimental group

USING TREE DIAGRAMS IN INITIAL SCHOOLING

The two studies presented show that despite initially not understanding combinatorial problems, children and adults in early schooling can develop their combinatorial reasoning by use of robust symbolic representations (Vergnaud, 1997), such as tree diagrams, that aid the systematic enumeration of combinations.

Tree diagrams – built by software use or in writing – may help students' understanding of combinatorial situations, because this form of representation may aid systematic choice of elements to compose combinations, as pointed out by Fischbein (1975), and also attested by Maher and Yankelewitz (2010); and Sandoval, Trigueiros and Lozano (2007). The use of tree diagrams also enabled improvement in listings that at post-test were used in a systematic manner by adults and children. The better use of listings shows that the participants had not merely developed procedural knowledge (how to use tree diagrams), but had developed a better understanding of combinatorial situations.

One aspect that must be pointed out is that the use of the software *Árbol* helped children develop their combinatorial reasoning but it required an extra effort when the students answered the problems by use of pencil and paper. In this case, what had been learnt using the software, had to be *transferred* to pencil and paper solutions. This aspect must be considered in teaching situations and future studies may look into how the use of technology may enable the use of varied forms of symbolic representation in solving combinatorial problems.

Care is required in using tree diagrams in *combinations* and *permutations*. In *combinations* care is needed in not considering twice equivalent cases and in *permutations* the tree may have many steps of choice that must all be considered.

Combinatorial reasoning is a very relevant aspect in mathematical development and schooling is an important factor in this progress. How Combinatorics is taught can aid combinatorial reasoning development and tree diagrams may be used as tools that effectively represent combinatorial situations and the relations involved. This symbolic representation is especially useful at initial schooling by its visual aspect that enables both children and adults to perceive how elements can be combined in a systematic manner and help them develop their combinatorial reasoning.

Technology-mediated realistic mathematics education and the bridge21 model: A teaching experiment

Aibhín Bray, Elizabeth Oldham and Brendan Tangney

Trinity College Dublin, Dublin, Ireland, braya@tcd.ie

Many recent curriculum reforms aim to address shortfalls with regard to student engagement with mathematics by harnessing the affordances of technology, social constructivist pedagogies, contextual scenarios, and/or approaches aligned with Realistic Mathematics Education (RME). However, these may not sit well within a conventional classroom setting; a 21st Century (21C) learning model may be more appropriate. This paper describes a teaching experiment in Ireland, supporting an ongoing curriculum reform; it used technology-mediated activities consonant with social constructivism, RME, and 21C learning. The study involved twenty students (aged 15–17) over a two-day period. Results suggest that the approach has the potential to increase student engagement with and confidence in mathematics.

Keywords: RME, contextualised learning, twenty-first century learning, technology-mediated, post-primary education.

INTRODUCTION

Debate regarding the quality of mathematics education at post-primary level is ongoing in many countries. Recent curriculum reforms have typically focused on developing students' conceptual understanding, problem-solving ability and productive disposition (National Research Council, 2001), with the intention that students would be able to apply their mathematics confidently in real-life and other contexts. However, on leaving school, many students' views of the subject are still fragmented and de-contextualised (Gross, Hudson, & Price, 2009), resulting in low levels of mathematical confidence and engagement. Research indicates that factors contributing to these attitudes include a formal, abstract and assessment-driven approach that reinforces behaviourist and didactic tendencies in teaching and learning, with content and procedure prized over literacy and understanding (Conway & Sloane, 2005; Ozdamli, Karabey, & Nizamoglu, 2013). Mathematical creativity is generally not encouraged, leading to a perception of mathematics as involving memorisation and execution of set procedures that lead to unique, correct answers (Dede, 2010; Ernest, 1997), and a belief that mathematics is "hard, right or wrong, routinized and boring" (Noss & Hoyles, 1996, p. 223).

It has been suggested that, within an appropriate pedagogical framework, the use of technology in the classroom can make mathematics more meaningful, practical, and engaging (Drijvers, Mariotti, Olive, & Sacristán, 2010; Olive et al., 2010). Social constructivist educational theories have been shown to align particularly well with the affordances of technology (Bray & Tangney, 2013; Patten, Arnedillo Sánchez, & Tangney, 2006). Another approach seen as addressing limitations in traditional mathematics education is that of Realistic Mathematics Education (RME) (Gravemeijer, 1994; van den Heuvel-Panhuizen, 2002), which also sits well with social constructivist pedagogy. However, activities combining a technology-mediated, social constructivist and RME approach to mathematics learning do not fit easily into the conventional classroom with its didactic teaching and short class periods (Wijers, Jonker, & Kerstens, 2008). So-called 21st Century (21C) learning models – emphasising a student-centred, active approach and key skills such as collaboration, communication, creativity and problem-solving, as well as content – may be more appropriate (Dede, 2010; Voogt & Roblin, 2012).

In Ireland, a reformed post-primary mathematics curriculum is being introduced (Cosgrove, Perkins, Shiel, Fish, & McGuinness, 2012). The reform initiative, known as ‘Project Maths’, aims to increase students’ understanding, problem-solving ability and engagement, particularly with regard to problems set in context; it recommends a focus on constructivist learning and an emphasis on the meaningful use of technology. Research is being undertaken, not only to evaluate the effectiveness of the project on a national scale (Jeffes et al., 2013), but also to examine specific teaching experiments. In particular, Jeffes and colleagues (2013) refer to the problem that “teachers are currently emphasising the content of the revised syllabuses rather than the processes promoted within it”, and that “students need to be regularly given high quality tasks that require them to engage with the processes promoted by the revised syllabuses” (p. 5). Within this context, we aim to investigate whether the combination of a technology-mediated approach, RME and a particular model – Bridge21 (Lawlor, Marshall, & Tangney, 2015) – of 21C learning facilitates the development of mathematics learning activities that increase student engagement and confidence. To provide a framework, the key features of RME and of the Bridge21 model are described and different levels of technology usage are discussed. The combination of the three elements is then illustrated through the description of a two-day experiment in a school setting. Preliminary results are discussed and tentative conclusions drawn.

FRAMEWORK

In this section, the three elements of the framework are outlined briefly.

Realistic Mathematics Education (RME)

RME is an approach to mathematics education that involves students developing their understanding by exploring and solving problems set in contexts that engage their interest, with teachers scaffolding their reinvention of the mathematics that they encounter (Freudenthal, 1991). Five characteristics of RME are identified: (i) the importance of problems set in contexts that are real to the students; (ii) the attention paid to the development of models; (iii) the contributions of the students by means of their own productions and constructions; (iv) the interactive character of the learning process; and (v) the intertwinement of learning strands. It should be noted that the contexts do not have to be drawn from the real world; the important aspect is that the students find them meaningful (van den Heuvel-Panhuizen, 2002).

The five characteristics guide a process called ‘progressive mathematisation’ (Gravemeijer, 1994). This involves: starting from a problem set in a context; identifying the relevant mathematical concepts involved; gradually refining the problem so that it becomes a mathematical one representing the original situation; solving that problem; and interpreting the solution in terms of the original situation. Mathematisation has two components, designated as ‘horizontal’ and ‘vertical’. They are described by Dickinson, Hough, Searle, and Barmby in terms of modelling: “The process of using a model to solve a particular problem is known as ‘horizontal mathematisation’, while that of using the model to make generalisations, formalisations etc. is known as ‘vertical mathematisation’” (2011, p. 48). As the students engage in progressive mathematisation, they encounter the concepts first informally, then ‘pre-formally’, and only eventually at a formal level. The mathematisation and formalisation processes are illustrated in the teaching experiment described below.

The Bridge21 Model of 21C Learning

Bridge21 is a particular model of 21C learning developed in the authors’ institution (Lawlor, Conneely, & Tangney, 2010). It was originally used in an out-of-school outreach programme, and in recent years has been adapted for use in Irish post-primary schools. Currently it is being trialled in a number of schools as part of a systemic reform process in Irish education (Johnston, Conneely, Murchan, & Tangney, 2014). In this team-based pedagogical model, adults act as guides and mentors, scaffolding and orchestrating the learning experience. The model is innovative in that it offers a structured approach to the implementation of a 21C Learning activity, providing a set of steps to facilitate a successful intervention. The steps typically include: team formation; a divergent-thinking, ‘warm-up’ activity; investigation of the problem/challenge; planning; an iterative phase of task execution/problem solving/artefact creation; presentation; and reflection. Strict deadlines are enforced to encourage planning and ensure the teams stay on-task. The physical learning space is configured to support a collaborative, project-based, cross-curricular and technology-mediated approach, with an emphasis on individual and group reflection.

Technology usage (enhancement and transformation)

Use of digital technologies in mathematics education has the capacity to open up diverse pathways for students to construct and engage with mathematical knowledge, embedding the subject in authentic contexts and returning the agency to create meaning to the students. It can facilitate an emphasis on practical applications of mathematics, through modelling, visualisation, manipulation and more complex scenarios (Olive et al., 2010). However, Olive and colleagues (2010) also note that "it is not the technology itself that facilitates new knowledge and practice, but technology's affordances for development of tasks and processes that forge new pathways" (p. 154). The SAMR Hierarchy (Puentedura, 2006) offers a useful tool for describing different levels of technology integration in activities (Figure 1). The Bridge21 approach focuses on the creation of activities that fall within the Transformation space on the hierarchy. However, within the field of mathematics education, the use of technology to augment traditional approaches – outsourcing the calculation, increasing speed and accuracy, and thus permitting more focus on underlying concepts – is also seen as important. In the activities developed in this project, technology is incorporated in such a way as to create and support tasks that are meaningful and realistic for the students; it is not used merely to re-instantiate aspects of traditional mathematics teaching.

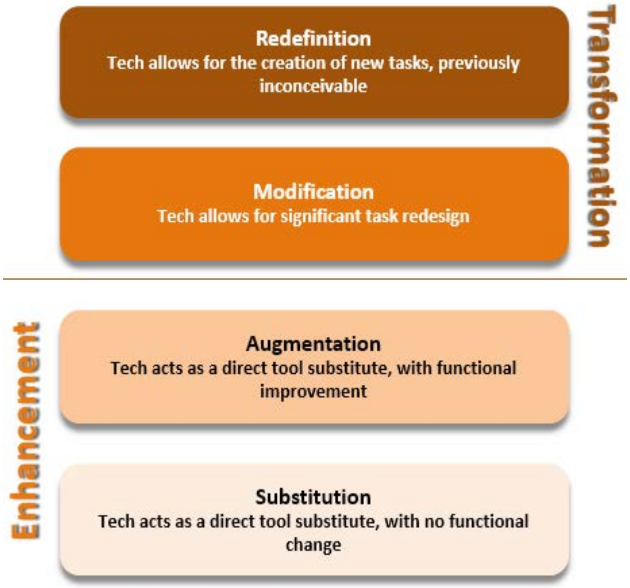

Figure 1: SAMR Hierarchy (Puentadura, 2006)

RESEARCH METHODS

The experiment discussed in this paper makes up one embedded unit within an overarching explanatory case study (Yin, 2014). To date, three such experiments have taken place within school settings and initial results are currently being analysed. A mixed methods approach to data collection and analysis has been taken, with considerable emphasis placed on qualitative data (Creswell, 2003; Yin, 2014). Qualitative analysis uses a directed content approach, and a pre-experimental design is used to analyse the quantitative data.

The Mathematics and Technologies Attitudes Scale (MTAS) (Pierce, Stacey, & Barkatsas, 2007) was utilised to gather quantitative data. MTAS is a 20-item questionnaire with a Likert-type scoring system. It has five subscales:

1) Behavioural Engagement: how students behave when learning mathematics

2) Affective Engagement: how students feel about the subject

3) Mathematical Confidence: students' conceptions of their ability to do well in the subject and to handle difficulties

4) Confidence with Technology: students' confidence in their ability to master technological procedures required of them and resolve difficulties

5) Attitude to using Technology in Mathematics: the degree to which students feel that technology provides relevance, aids their learning, and contributes to their achievement in mathematics.

The instrument was administered to students before and after the interventions, and paired t-tests were used to analyse the data (Creswell, 2003). While it is ambitious to expect meaningful data about such large and important issues from a 20-item questionnaire, the descriptors of the MTAS subcategories have been very useful to guide the qualitative analysis, permitting a more in-depth investigation of the themes.

Qualitative data came from focus-group interviews conducted 2 to 4 weeks after each intervention. The MTAS subscales were used as a-priori codes to direct content analysis of the interviews using NVivo10. Use was also made of codes drawn from a set of design principles for mathematics learning activities that fit within the technology-mediated, Bridge21/RME paradigm; their development is described by Bray, Oldham, and Tangney (2013). Some of the elements used as codes include: task design that is realistic, practical, and open-ended; teamwork; and transformative and computational use of technology. Matrix coding was used to identify associations between elements of the design principles and subscales of MTAS.

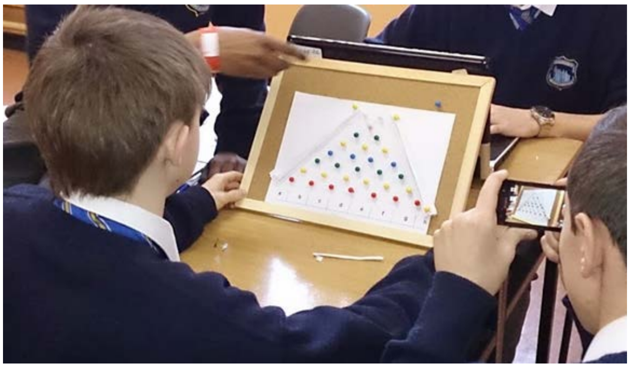

Figure 2: Plinko and probability

THE TEACHING EXPERIMENT

The students involved were from year 10 (age 15/16), which in the Irish system is known as Transition Year. This is a one-year school programme in which the focus is on personal, social, vocational and educational development, providing opportunities for students to experience diverse educational inputs in a year that is free from formal examinations (Department of Education and Science, 2004). Timetabling is more flexible than is the case for other school years, facilitating teaching experiments that are not constrained by short class periods. The first author had access to students for two days, from 10 am to 4 pm. During this period, she acted as the main teacher, or facilitator, with one classroom assistant. The class consisted of 20 male students of mixed ability, assigned by the class teacher to 5 groups of 4 students each, in such a way as to balance abilities. The environment was a large room with movable desks; each team was allocated a workstation, where they could work together. Laptops (two per team, to enhance collaboration), smartphones and other resources were provided.

Each of the two days followed the same general structure, based on the Bridge21 learning model of warm-up, investigation, planning and implementation. Throughout the day the facilitators interacted with the students, scaffolding their exploration of the mathematics and the technology. Based on the activity, the final section of the day was dedicated to a 'sales pitch' on day 1 and a competition on day 2; in each case this was followed by group presentations, in which the students discussed what they had accomplished and the mathematics they had understood. A whole-group discussion concluded the sessions.

The first day's activity was 'Plinko and Probability', which encourages students to develop a deep conceptual understanding of patterns, Pascal's triangle, probability and bias. Plinko is a game of chance based on a Galton board: a board with evenly spaced pegs arranged in staggered order, to form a triangle (Figure 2). Balls should be funnelled onto the board from directly above the top peg. If the pegs are symmetrically placed, the marbles have equal probability of bouncing left or right. A number of evenly placed slots form the base of the board, into which the marbles fall.

The students were informed that they were going to be developing a game for a casino and would have to devise the rules and scoring system in such a way that the game would be appealing to players, but that the casino owners would win overall. They were provided with a Plinko board template, a cork-board and some pins and marbles, smartphones, and laptops with open-source spreadsheet software and the free video analysis tool, Kinovea[1] (Figure 2). They were also given a sheet of exploratory questions relating to the possible paths on a Galton/Plinko board.

The aim of the activity was to encourage the students to make sense of what appears to be random behaviour. In particular, they were encouraged to identify that the number of routes to the pegs in the grid (starting from the top) forms Pascal's Triangle, and also to understand the probability of a marble landing in a particular bin if the board were perfect. In addition, they analysed their own boards, using the spreadsheet to tabulate and visualise 100 rolls. They were thus able to see how well their game conformed to a digitally generated one,[2] introducing the notions of bias and fairness. They used video tracking to see if any of the marbles they rolled followed the same path to any one bin, developing a practical understanding of the concept of probability.

Tasks that involve odds and chance are familiar to Irish students. In order to engage the students further, and add to the realistic aspect of the activity, they were required to decorate their boards, and develop the rules and scoring for their game, with the purpose of making a sales pitch to the facilitators ('casino owners') and to the year 12 (aged 17/18) students of the school ('players'). The successful team would be the one that was able to persuade both groups of the validity and attractiveness of their model. This aspect of the activity led to much heated discussion regarding the best way to organise the game, for example: "The stats are here!", "We get more money if we do it my way!", and "Just think about it, we make more money!"

In terms of the process of mathematisation, the first part of the activity, in which the students developed a physical board, and from that a mathematical model of the probabilities of their board, exemplifies horizontal mathematisation. Vertical mathematisation is evident in their generalisation of these probabilities into the set of rules for their games; in particular, some teams advanced beyond the basics and began to use the AND/OR rules of probability – beyond the curriculum for this year group – to set up more general models. Progress from informal through pre-formal and on to formal conceptualisation was facilitated by the tools available to the students, with the formal language introduced as the concepts were developed. In particular, the development and exploration of the boards encouraged the identification of the pattern of Pascal's Triangle, and the use of video-analysis and spreadsheet technology supported the development of formal mathematical models.

The work on day two involved collection, representation and analysis of data, line of best fit, correlation, causality, and extrapolation. It used the Barbie Bungee activity described by Bray and Tangney (2014) and Tangney, Bray, and Oldham (2015).

RESULTS OF THE TWO-DAY EXPERIMENT

Quantitative data

The sampling distributions were normally distributed according to the Shapiro-Wilk test. Paired *t*-tests identified gains in all MTAS subscale scores; the differences were significant ($p<0.5$) for all subscales except Mathematical Confidence.

Qualitative data

Coding matrices generated by NVivo facilitated comparison between MTAS and the design principles, in order to generate conjectures as to the primary factors that caused the gains in student engagement and confidence indicated by the MTAS scores.

The coding process is in its early stages. However, initial results suggest that the aspects of the design principles most associated with Affective Engagement were the realistic (in the RME sense), cross-curricular and guided discovery aspects of the task design; the Bridge21 activity structure; and the transformative use of technology, which facilitated the realistic nature of the tasks. Behavioural Engagement was also positively associated with the realistic, practical and guided discovery aspects of the task design, the activity structure and the transformative use of technology, but the impact of working in a team also appeared to have a positive effect. Mathematical Confidence was positively associated with the real, guided, and practical tasks, with the use of technology also appearing influential. The use of technology, both transformative and computational, was most significantly related to Confidence using Technology, with the variety of technology noted as adding to flexibility and adaptability. The transformative and computational use of technology, in conjunction with the task design, appeared to have the most influence on students' Attitude to using Technology in Mathematics.

DISCUSSION AND CONCLUSIONS

There is evidence from the results that technology-mediated interventions using the Bridge21 model and embodying an RME-style task design can have a positive impact on student experience in the classroom. The qualitative results in particular, indicate a encouraging increase in student engagement with and confidence in mathematics. The quantitative results also showed gains on all the MTAS subscales, although it should be noted that the gain for Mathematical Confidence did not reach significance.

It is worth noting, however, that the students taking part in the experiment described here appeared particularly favourably disposed to the approach – one student went so far as to say "... it changed the way I look at maths... it was a life-changing experience!" (Groups in other schools were positive but not quite so ebulliently so.) Also worth noting is that, while the impact of the collaborative, team-based approach was primarily positive, this is the one area in which some misgivings were expressed; one negative association was recorded between it and both Behavioural and Affective Engagement: "The groups [...] in our class, we all like, know each other, and people just like got pushed aside and lost motivation to do anything and were just a bit bored."

Ongoing data analysis is using an inductive approach, looking for emergent themes, not directly related to MTAS or the design principles. One of the most interesting themes to emerge thus far is the students' positive sense of ownership of their learning, which they are associating with mathematical confidence, reasoning that "because you can have your own idea, even if the teacher is explaining it wrong, or ... in a different way, it's like you have your own idea about it and you can add to what they are telling you to do".

This study set out to identify whether activities designed within a technology-mediated, socially constructivist, RME setting could increase student engagement with and confidence in mathematics, in line with some of the aims of the Project Maths syllabus. While initial results are promising, the relative novelty of the approach may be a contributing factor, and although the experiment took place in a school, it did so in a year in the Irish school system that allows for flexible approaches to curriculum and timetabling. If however, the findings can be replicated – both for repeated use with similar students, and for classes following syllabi leading to state examinations – it would augur well for addressing some of the shortcomings identified in the implementation of Project Maths to date.

Crossing the bridge: From a constructionist learning environment to formal algebra

Eirini Geraniou and Manolis Mavrikis

Institute of Education, University College London, UK, e.geraniou@ioe.ac.uk, m.mavrikis@ioe.ac.uk

In the digital era, it is crucial to explore how digital technologies can be successfully integrated in the mathematics classroom and what their potential impact on learning is. This paper presents some reflections based on data gathered as part of the MiGen project (www.migen.org[1]) from studies aimed to investigate ways to support the transition to formal Algebra, through the use of a constructionist learning environment and carefully designed 'bridging' activities that consolidate, support and sustain students' algebraic ways of thinking. Our claim is that explicit links need to be made to Algebra through those specially designed activities so that such a digital tool can support students' learning of formal Algebra in order to be successfully integrated in the mathematics classroom.

Keywords: Generalisation, microworlds, transition, algebra.

INTRODUCTION

In the last few decades, the number of appearances of digital technologies designed for mathematics learning keeps growing. Relevant research (e.g., EACEA Eurydice Report, 2011), though, has shown that these technologies are not always used to their full or intended potential and also, students rarely use ideas, concepts or strategies they seem to have acquired through their interactions with such technologies. For example, Gurtner (1992), referring to the Logo environment, demonstrated that the tool's features which are designed to support students when faced with complex mathematical problems may impede them from making connections between their work in Logo and any mathematical or geometrical ideas they are already familiar with and use when problems seem less complex. Also, the lack of information on why and how to build bridges to formal mathematics, which were not often made in standard Logo situations, led to the lack of connections to formal mathematics (Gurtner, 1992). In this paper, we discuss our approach to support students' transition of moving back and forth from paper-and-pencil to interacting with digital tools and therefore consider ways of facilitating the integration of digital technologies in mathematics classrooms. In particular, our focus is on the transition to formal Algebra and how students 'transfer' their knowledge from their interactions with a digital tool, namely eXpresser, specially designed to support and address students' difficulties with learning algebra, to paper-and-pencil (PaP) activities.

There is a lot of research on the issue of 'transfer' (e.g., DiSessa & Wagner, 2005). Our interpretation is closely aligned with Beach (2003) who has argued that the metaphor should be viewed as transition instead of transfer. Crossing boundaries from one location to another is in fact a process of transition and therefore people are the ones who move and not knowledge or learning. In the case of Logo, Gurtner (1992) considered "the type of connections generally expected, and very seldom observed, between Logo practice and mathematics" (p. 247) as *transfer* and suggested that there is a need for a long period of practicing in Logo, especially one which is rich in reflection, so that some transfer to mathematics can happen.

Going back to our focus on Algebra, the transition to formal Algebra has been investigated by various authors (e.g., Radford, 2014) and the literature is replete with examples of student difficulties (e.g., Stacey & MacGregor, 2002). Students struggle to understand the idea behind using letters to represent *any* value (Duke & Graham, 2007) and are inexperienced with

1 The MiGen project was funded by the ESRC/EPSRC Technology Enhanced Learning Programme (RES-139-25-0381 2007–2011). Part of the research reported here was in the context of an ESRC 'Follow-on' project (ES/J02077X/1) and the M C Squared project, which was co-funded by the EU, under FP7 Strategic Objective ICT-2013.8.1 "Technologies and scientific foundations in the field of creativity" (Project No. 610467).

mathematical vocabulary. Even students capable of expressing a general rule through the use of words, like 'always' or 'every', struggle to use letters and symbols and form algebraic expressions.

Similarly to Radford (2014), who claimed that there is a need for specially designed classroom activity to support students' developmental path to formal Algebra, and to Gurtner (1992), who suggested presenting structured tasks, using appropriate microworlds and making explicit interventions during students' interactions, we claim that a digital tool specially designed to support the development of algebraic ways of thinking (AWOT) together with carefully designed bridging activities should 'smoothen' the transition to formal algebra without rendering it impossible for students to reach the mathematical 'bank of algebra'. Besides 'learning' the tool and developing expertise in using it, students should make the connections to mathematics. The issue is to find out ways for supporting students to make such connections.

EXPRESSER AND THE TRANSITION TO ALGEBRA

The MiGen system is a pedagogical and technical environment that improves 11–14 year-old students' learning of algebraic generalisation. Its core component consists of a microworld, eXpresser, which has been specially designed to help students develop AWOT through a series of generalisation tasks (Noss et al., 2012). In eXpresser, students construct figural patterns by expressing their structure through repeated building blocks of square tiles, and articulating the rules that underpin the calculation of the number of tiles in the patterns. A typical activity in eXpresser asks students to reproduce a dynamic model (or part of it) presented in a window that appears on the side of the activity screen.

Figure 1 shows a model where a row of red tiles is surrounded by grey tiles. Students are asked to construct a model that works for *any number* of red tiles, and find a rule for the total number of tiles surrounding the red tiles. They can test generality by *animating the model:* that is, by letting the computer change the number of red tiles at random. The design of eXpresser capitalises on animated feedback and on the simultaneous representation of a *specific* and *general* model ('My Model' and 'Computer's Model' in Figure 2), built by combining patterns and on the close alignment of the symbolic expression, the *Model Rule* and the structure of the model. All numbers in eXpresser are *constants* by default, referred to as 'locked' numbers. When the user 'unlocks a number', it is possible to change its value; it becomes a *variable*. In the *Computer's Model*, a value of the variable ('Num of Red Tiles' in this example) is chosen automatically at random (it is '10' in Figure 2) which will generally be different from that in the specific model ('6' in Figure 2). So the *Computer's Model* indicates to students whether their constructions are *structurally* correct for the different values of the variable(s). Students also construct a *model rule* for the total number of tiles, and validation of its correctness is made evident by colouring: tilings are *only* coloured if the rule for the number required is correct.

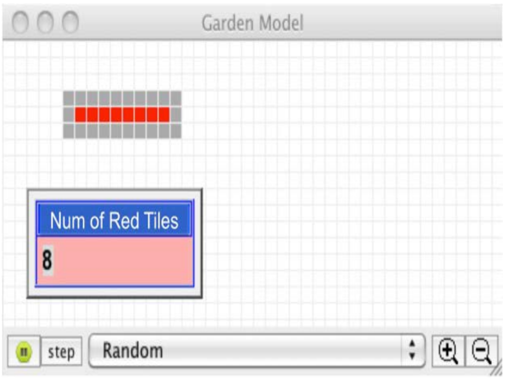

Figure 1: A model for 8 red tiles surrounded by grey tiles. Students must construct a general model and find the general rule

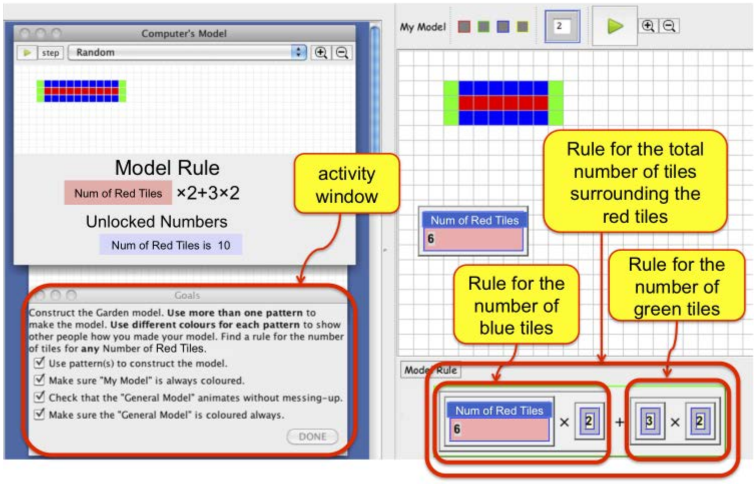

Figure 2: The eXpresser screen showing the general and specific models (Computer's Model on the left, and My Model on the right), and a correct rule for the total number of surrounding tiles. The task goals are shown in the "Activity window" (lower left-hand corner)

To make connections to formal Algebra feasible and support the transition from interactions with the eXpresser tool to PaP Algebra, we had to consider what characterizes formal Algebra and more specifically AWOT. Algebra involves a number of mathematical concepts, from numbers, to variables, from numerical expressions to expressions that involve the use of 'unknown' numbers and functions. Various authors have characterised algebra as 'generalised arithmetic' (e.g., Kieran & Chalouh, 1993). For example, Sfard and Linchevksi (1994) distinguished between the operational phase, where "the focus is on numerical processes and there is no hint of abstract objects rather than numbers" (p. 197) and the structural phase, which involves processes of manipulations of symbols. They argued, therefore, that there are "two crucial transitions: from the purely operational algebra to the structural algebra 'of a fixed value' (of an unknown) and then from here to the functional algebra (of a variable)" (p. 191). Leading on from these distinctions, Radford (2014) considered three conditions that characterise algebraic thinking: (i) *indeterminacy*, which is about recognising the use of 'unknown' values in the form of variables, parameters, etc.; (ii) *denotation*, involving the symbolisation of the undetermined values of the problem in question that can include the use of natural language, gestures, signs, as well as a mixture of these or symbols and (iii) *analyticity*, involving the skill of manipulating the indeterminate quantities like known values.

In the case of the eXpresser tool in our previous work (Mavrikis et al., 2013), we have identified two AWOT. The first one is:(i) *Perceiving structure and exploiting its power*, which is about noticing what stays the same and what is repeated in a figural sequence so as to understand how the sequence is 'structured', supporting therefore "the development of structural reasoning" and the habits of "breaking things into parts" by identifying "the building blocks of a structure" (Cuoco, Goldenberg, & Mark, 1996, p. 69). This AWOT, especially as it is operationalized in eXpresser that encourages students to construct what they perceive and manipulate the various properties of their constructions, could relate to Radford's (2014) indeterminacy and analyticity conditions, but also to the initial transition from the operational to the structural algebra of a fixed value of an unknown as described by Sfard and Linchevski (1994) above. The second AWOT is: (ii) *Recognising and articulating generalisations, including expressing them symbolically*, which is the process of translating the observed structure in an algebraic expression, using formal algebraic notation to write general rules for numerical sequences. This AWOT can be linked to Radford's (2014) denotation condition as well as the second transition from the structural algebra to the more functional algebra of a variable (Sfard & Linchevski, 1994), as its focus is on the production of formal algebraic expressions.

BRIDGING ACTIVITIES

We designed a sequence of activities both to help students become familiar with the tool but also to facilitate the transition to algebra. The sequence starts with introductory and practice tasks that ask students to construct figural models. It continues with individual activities, such as the one described above (see Figure 1). Students were asked to construct the task model in eXpresser using different patterns and combinations of patterns, depending on their perceptions of the task model's structure and derive a general rule for the number of square tiles needed for any Model Number. In our initial studies, students were presented with off-computer tasks, immediately after the final eXpresser task in an effort to reveal their strategies on solving similar tasks on paper and whether eXpresser had an impact on those strategies or not. In later studies, though, and after close collaboration with teachers, we recognised the need of activities, which promote students' reflections upon mathematical concepts and problem-solving strategies they used *throughout* their interactions with eXpresser and not just at the end. These we referred to as consolidation tasks. So, throughout their interactions with eXpresser and immediately afterwards, students were presented with four types of bridging activities (examples are given in Figure 3), which are designed to support their transition to paper-and-pencil tasks: (i) *Consolidation tasks*, which are usually short tasks that are used to intervene and encourage students to reflect on their interactions with eXpresser throughout a sequence of eXpresser tasks, (ii) *Collaborative tasks*, which are presented at the end of an eXpresser task and focus on students' justification strategies regarding rule equivalence, (iii) *eXpresser-like paper tasks*, which are figural pattern generalisation tasks on paper, and (iv) *text-book or exam like tasks*, which are the traditional generalisation tasks given to students on paper.

STUDENT DATA

Over the past 7 years, we have carried out studies in 6 different schools in London, worked with 11 mathe-

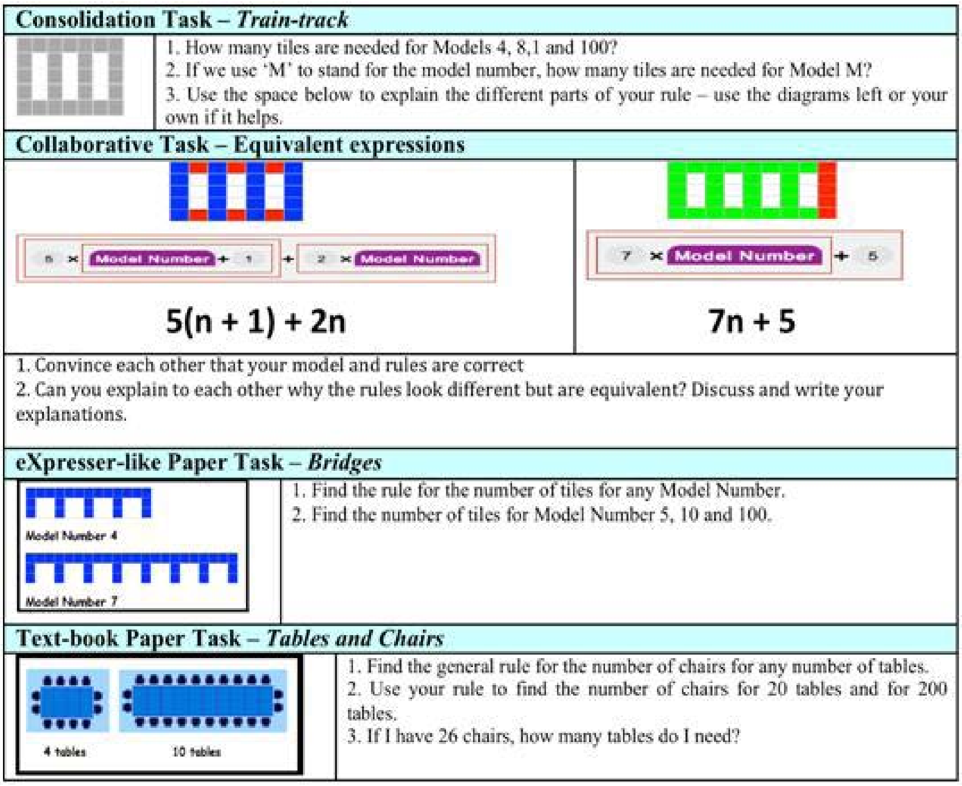

Figure 3: Examples of Bridging Activities

matics teachers and collected data from 553 students aged 11–14 years old. Each study was carried out over the course of four consecutive lessons, during which students became familiarised with the tool through some simple tasks, worked on one or two main activities and then were given bridging activities. A sample of students was interviewed at the end of their interactions with eXpresser. All students had been introduced to Algebra at school before their interactions with eXpresser, but of course their experience varied based on their age. Our data comprise one-to-one and small groups of students' and teachers' interviews and transcripts, video and audio files from interviews, one-to-one, small groups and classroom observations, detailed logs from students' interactions in the form of a database and bridging activities. Results from our studies are presented in a number of papers (e.g., Mavrikis et al., 2013; Noss et al., 2012; Geraniou et al., 2011). In this paper, we focus on the data collected from the bridging activities students worked on independently (or in pairs/groups of 3 for the collaborative tasks) during, but mostly after their final interaction with eXpresser. Using the two AWOT described in Mavrikis and colleagues (2013), as an analytical framework for interpreting students' strategies, we present our initial results under those two headings.

(i) Perceiving structure and exploiting its power. For the consolidation tasks, which were used with 175 students as their necessity was identified later in our studies, most of the 175 students demonstrated on the model figures presented on paper how they visualised the structure of the given model. In Figures 4, 5, 6 and 7, we present some examples of students' answers on the four bridging activities presented in Figure 3. Students clearly marked the different parts that would remain the same in any instance of the pattern and the parts, which, repeated every time, create the different instances of the pattern. Especially for the collaborative task, students verbally identified their building blocks in their models and rules and compared them to conclude about their equivalence. An example of two students' collaboration and its outcome is presented in Figure 5. Students demonstrated a variety of ways to visualise the task patterns and it was evident how influenced they were by the eXpresser's features as they were using the eXpresser terminology, e.g., number of building blocks or models. For example, in Figure 6 [F], [G] and [H], students drew the 2 building blocks that they could use if they were solving this task in eXpresser, that of a column of 3 square tiles and that of an 'L'- shaped one of 5 tiles. For example, Janet named her independent variable as "number of red BBs" (BBs stands for Building Blocks), and even though

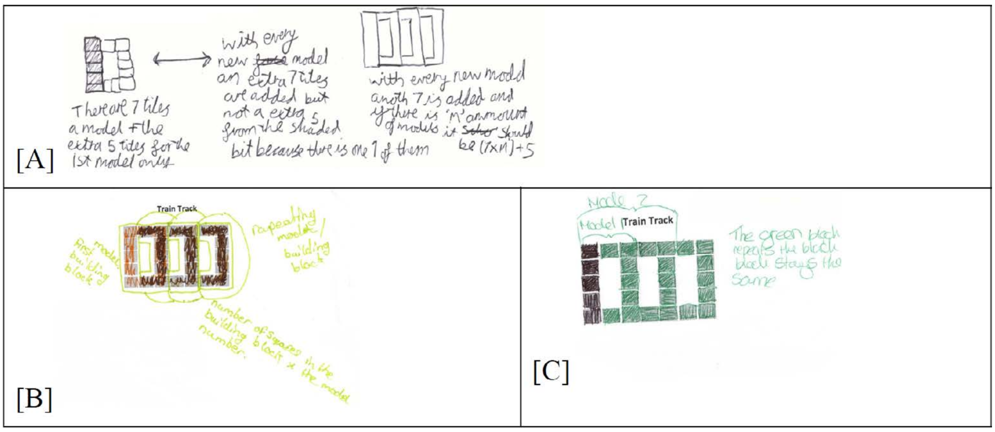

Figure 4: 13 year-old students' answers on the Train-track consolidation activity

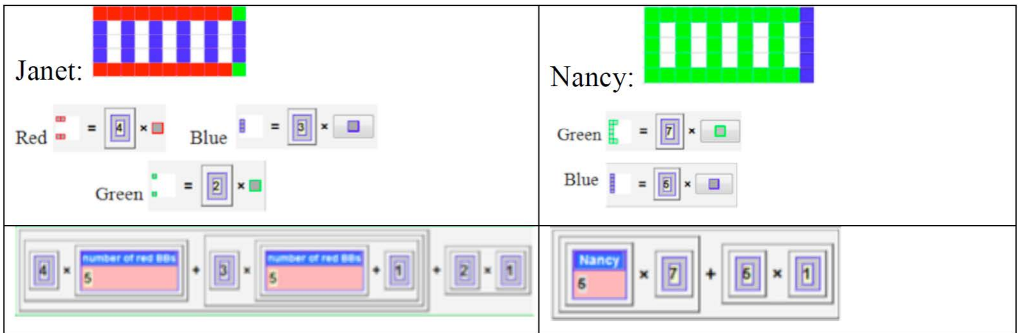
Nancy, named hers as 'Nancy', she used eXpresser's terminology in her discussions with Janet.

(ii) *Recognising and articulating generalisations, expressing them symbolically*. Students seemed to rely on the structure of the given task model in order to articulate a general rule. Most of them provided clear explanations to justify their derived rules.

Their work revealed some fluency in using the formal algebraic language. They identified what stayed the same and translated that into a constant in their rule. For example, in Figure 6 [H], the student annotated their rule (5xM)+3 and showed that the coefficient 5 is the number of repeated building blocks in their second building block. The constant 3 is the number of tiles in their first building block, which is not repeated. Similarly, the student in Figure 6 [G] successfully identified 2 building blocks, that produce the task model, and indicated which building block stays the same and which is repeated.

Students' answers revealed their ability to articulate general statements, such as "with every new model, another 7 is added and if there's 'M' amount of models, it should be (7xM)+5" (Figure 4[A]) or "there is always 2 chairs to the ends of the single tables, then 2 chairs on the end of all tables put together" (Figure 7[I]). But the crucial step was their ability to translate that generalisation in parallel to their visualised structures into general rules and argue about similarities (or differences) between their models and derived general rules, when discussing rule equivalence (e.g., Figure 5). Most students used the eXpresser language and terms such as 'model number' to represent the variable in their rule (e.g., "5xwhatever model number n is+3", Figure 6[D]), as an intermediate step before expressing their derived rules in a formal algebraic expression (e.g., "(5xM)+3", Figure 6[H]). During collaboration, most students seemed to reach similar conclusions. Janet and Nancy for example recognized that the simplified general rule for their models is 7n+5



4n + 3(n+1) + 2x1	7n + 5x1

Nancy:	Yeah it's one red building block plus one blue building block so that would actually kind of make the…
Janet:	yeah, it would make the same shape...
Nancy:	because one red building block added to one blue building block…
Janet:	and that's the same as one of my green building blocks.

Figure 5: 12 year-old students' discussion on the Collaborative bridging activity

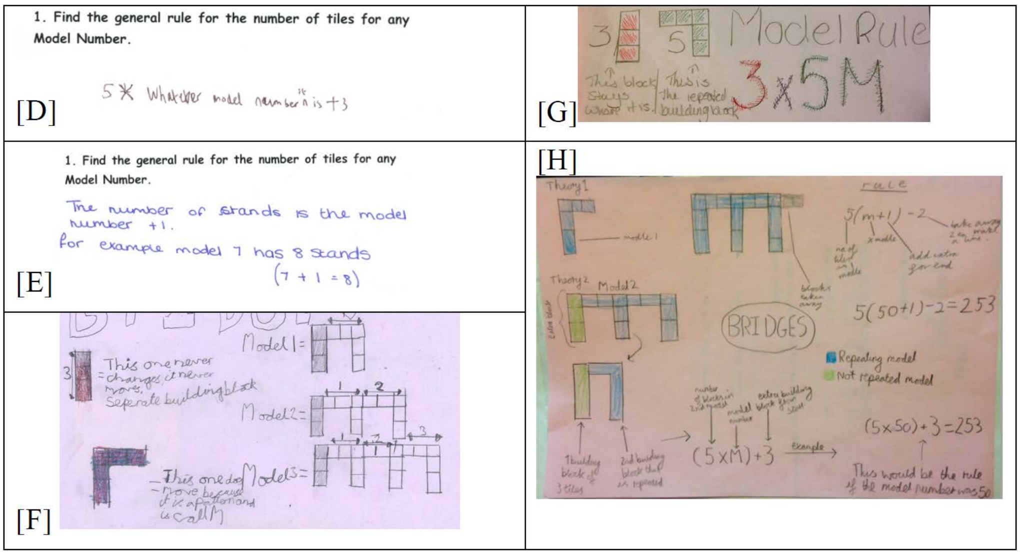


Figure 6: 12 year-old students' work on the eXpresser-like Bridges bridging activity

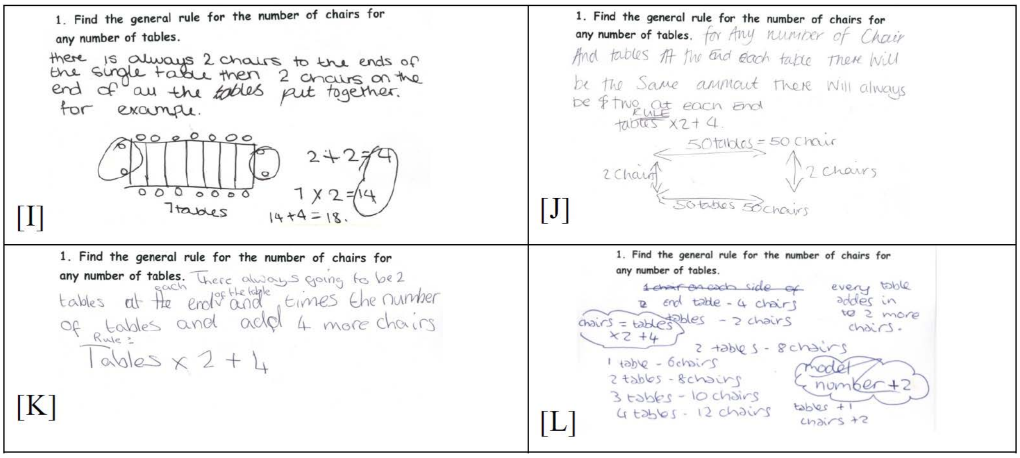

Figure 7: 12 year-old students' work on Tables and Chairs textbook-like activity

and that 'n' represents any model number. eXpresser seems to have played a crucial role in this outcome, as it encourages students to name their variables ('unlocked' numbers) based on what their values represent and therefore allows students to give meaning to that variable, thus easing students' transition to formal algebraic language.

Even though the bridging activities have been carefully designed to prevent students from looking for the term-to-term rule in a sequence, there were some students, especially in the text-book like bridging activities, who reverted to their past experiences and worked out the answers for each consecutive term in a sequence. For example, in Figure 7 [L], the student calculates the number of chairs when having 1 table, 2 tables, 3 tables, etc. Despite, their focus on the term-to-term rule, they spotted the correct general rule and wrote "Chairs=tablesx2+4". Such an outcome though may be ephemeral and more work is needed to support the sustainability and longevity of any AWOT formed soon after interacting with eXpresser.

CONCLUSION

When solving problems, mathematicians do not need to stop and think, but instead get into a "mechanical mode" (Sfard & Linchevski, 1994). Similarly, students who become experts in a digital tool may learn how to interact with it procedurally and provide right answers, but not necessarily reflect on and consolidate their knowledge during their interactions. Consequently, they may fail in developing a robust understanding of the mathematical concepts (and procedures) the tool was designed to help them with and may not be able to offer mathematically valid justifications for their actions. Such an outcome can discourage teachers from using digital tools in their mathematics lessons, as they are not convinced of their value.

In the case of eXpresser, the examples presented above reveal how students seem to successfully cross the 'bridge' from eXpresser algebra to formal algebra. Students demonstrated a conceptual understanding behind the development of general rules and generalised and adopted AWOT when solving PaP generalisation tasks. eXpresser, through the use of its language, supported students in their transition from numbers to 'unknown' numbers and variables and made the transition to symbolic thinking successful. In our experience, for such transitions to be successful, there is a need for bridging activities making the connections to algebra explicit. Their need and value have been mentioned by Gurtner (1992) too, who argued that 'the do-math-without-noticing-it' philosophy of Logo can be abandoned in favour of techniques that *explicitly* present looking for connections" (p. 253). We also recognised, similarly to Gurtner's (1992) research that "In contrast to the more classical transfer model [...] useful bridges can be built from the beginning, as soon as work has started in both domains" (p. 265). This was addressed by the consolidation tasks. There also seems to be the need for a long period of practice with eXpresser, rich in reflection and consolidation, before transfer to mathematics can be possible.

We have investigated the initial transition from a constructionist learning environment to the PaP algebraic generalisation tasks, and we have only started looking at the further transition to tasks that focus on abstract algebra, as described by Sfard and Linchevski (1994). The main concern is to identify and make more explicit the residual knowledge that gets noticed particularly by the interaction with constructionist learning environments. A successful integration in our view involves the successful transition from interacting with a digital tool to the awareness of the knowledge that can potentially be transferred to PaP activities and identifying ways to encourage the sustainability of such knowledge. Our aim remains to investigate further the issues of 'Transfer' and 'Bridging' and support the implementation of digital tools in the classroom through carefully designed and innovative bridging activities that consolidate and sustain students' mathematical ways of thinking.

Digital interactive assessment in mathematics: The case of construction e-tasks

Galit Nagari Haddif[1] and Michal Yerushalmy[2]

University of Haifa, Faculty of Education, Haifa, Israel, gnagarih@campus.haifa.ac.il, myerushalmy@univ.haifa.ac.il

Our research focuses on the e-assessment of challenging calculus construction e-tasks designed to function as a dynamic interactive environment of multiple linked representations (MLR) that provide feedback to the learner. A construction e-task requires students to use technological affordances to construct examples that satisfy specific conditions. The e-task is checked automatically and intermediate actions and submitted answers are reported. We present here an example of a construction e-task and report on a pilot experiment designed to elucidate the role of the dynamic MLR environment in solving and assessing construction e-tasks. Specifically, we examine the student's submitted solutions and analyse whether it helps reflect the reasoning behind the answer.

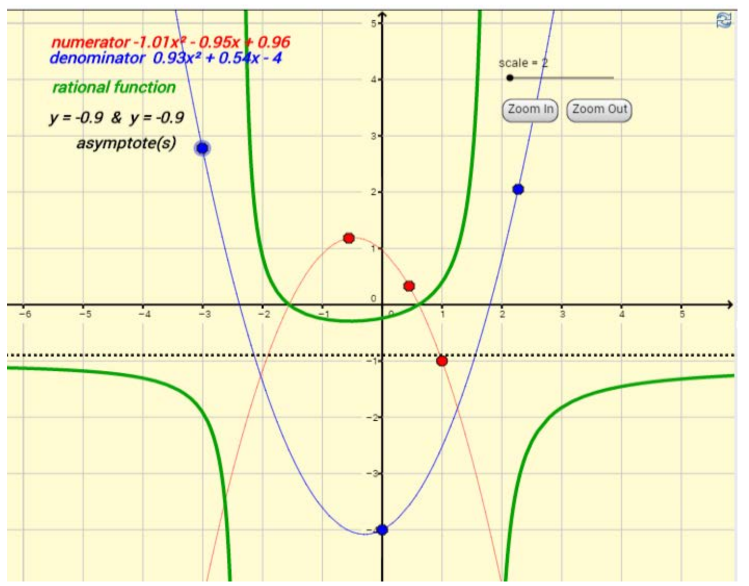
Keywords: Calculus, assessment, representations, technology, examples.

THRORETICAL BACKGROUND

The Joint Information Systems Committee (JISC)[1] defines e-assessment as the end-to-end electronic assessment process that uses information and communications technology (ICT) to present the assessment activity and to record the responses. By the term e-assessment we refer to forms of assessment that are created to be delivered, answered, managed, and marked mostly automatically, using ICT. We are especially interested in e-assessment of conceptual understanding of the content of calculus by high school students. In the present study we define an e-task as a technology-aided mathematical activity that engages students in seeing and doing mathematics. Scalise and Gifford (2006) introduced a categorization of innovative item types that may be useful in e-assessment. These types are based on categories of ordering involving successively decreasing response constraints, from fully selected responses (as in conventional multiple-choice questions) to fully constructed one (as in the traditional essay). The latter can be a challenge for computers to analyze meaningfully, even using sophisticated tools. According to the authors' review, technology makes a limited contribution to tasks that attempt to assess higher-order mathematical skills. Our research focuses on designing and studying challenging e-tasks in a dynamic MLR environment that provides reflecting feedback through e-assessment. We are particularly interested in high-school level e-tasks, which until recently have been limited mostly to closed multiple-choice questions.

The dynamic linkage of MLRs has been used as a design strategy that attracts attention to the relation between different representations. Yerushalmy (1997) and Yerushalmy and Schwartz (1999) have incorporated these strategies in the design of e-tasks in the areas of functions and calculus. The ability of digital tools to translate instantaneously across representations enable students to exhibit and evaluate actions in more than one representation system. Cognitive and pedagogical research suggests that appreciating the manner in which multiple representations are related is not automatic (e.g., Tall, 1991). Using multiple representations supports and requires tasks that involve decision-making and other problem-solving skills, such as estimation, selecting a representation, and mapping the changes across representations. E-tasks involving MLRs provide feedback to students that reflects the process of inquiry during the examination (reflecting feedback).

In computer-based instruction, feedback is any message or display that follows the learner's action or response. Vasilyeva and colleagues (2007) provided an overview of feedback studies and classified feedback into several types. For more than two decades, Yerushalmy and colleagues have explored the main differences between reflecting and judgmental feedback. Reflecting feedback provides immediate feedback to students about



(a) Construct a rational function: define the numerator and the denominator functions by dragging the dots marked on the functions.
(b) Fit the appropriate asymptote(s) to the rational function you have determined.
(c) Alternatively, choose a set of asymptotes and try to find a rational function with those asymptotes.
You can use this environment to explore the behavior of rational functions formed by dividing a constant, linear, or quadratic function by a linear or quadratic function.

Figure 1: Dynamic MLR learning object: rational functions and asymptotic behavior, http://tube.geogebra.org/student/m97472

their actions in multiple linked representations, and offers students the opportunity to judge and reflect upon the action taken. By contrast, judgmental feedback provides a short right/wrong answer, without other representations or explanations. Yerushalmy (1991) compared three groups of students performing symbol manipulations in algebra: one group received a reflecting graph feedback, the second judgmental feedback without a graph, and the third group used a symbolic manipulation aid. Yerushalmy found that judgmental feedback had a positive effect on the process, but that the students still lacked the motivation or ability to complete the tasks correctly. The effect of feedback was more significant on the first and third groups than on the second one (the manipulator aid motivated the students to obtain a correct product, and the graph feedback motivated them to make algebraic investigations).

Examples may be used for assessment in several ways. One obvious use is in refuting conjectures, either by citing standard counter-examples or by constructing new ones. Higher-level skills are needed when constructing instances of mathematical objects that satisfy certain properties, because typically there are many correct solutions but no general method by which such a solution can be constructed (Sangwin, 2003). When students are asked to create their own examples, they experience the discovery, construction, or assembly of objects and of their relationships (Liz, Dreyfus, Mason, Tsamir, Watson, & Zaslavsky, 2006). Occasionally, students create an example based on a ready-made example, which helps them reach the correct answer. A major affordance of technology is that it allows the easy creation of many different examples.

Figure 1 shows the GeoGebra applet, a challenging dynamic MLR learning object (http://tube.geogebra.org/student/m97472). To support inquiry learning of rational functions and of their asymptotic behavior, this object provides graphic and symbolic representations of the numerator and denominator (linear and quadratic functions of a single variable) and of their quotient. Users create instances of the rational function (Figures 1 and 2), explore and discover which functions have specific types of asymptotes, how many, and what are the reasons for it. During

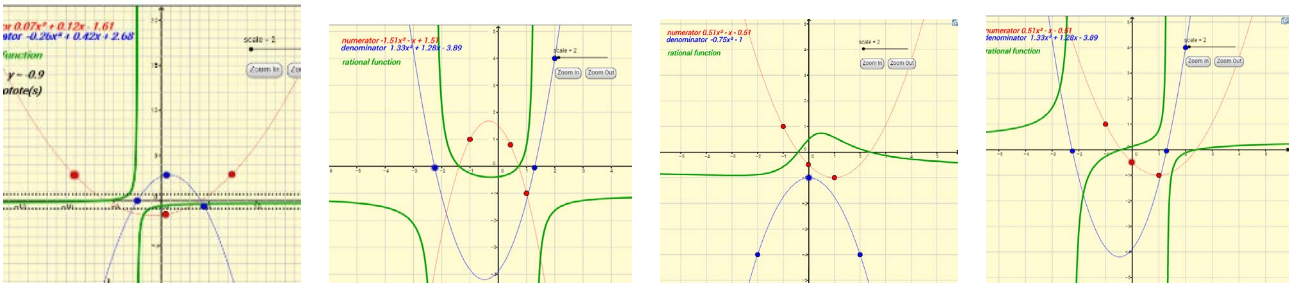


Figure 2: Examples/instances of rational functions of two quadratic functions

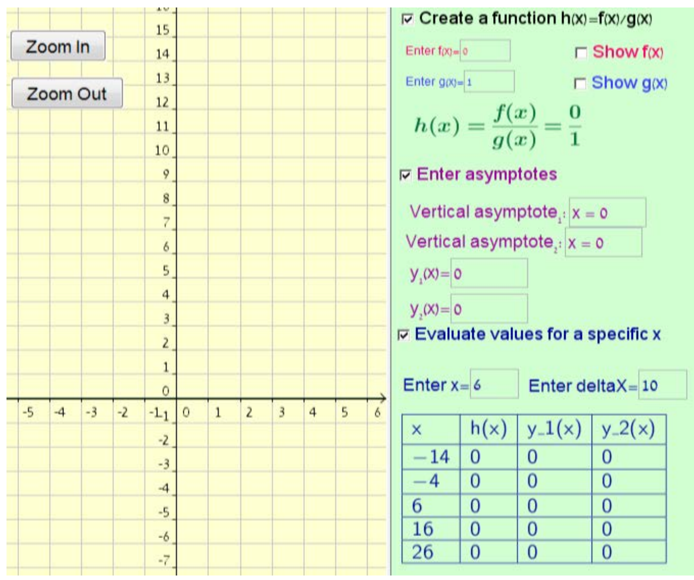
the exploration, the GeoGebra applet provides many instances of the same object (Figure 2), and students can evaluate their actions, reflect upon the feedback they receive, and change their conjectures accordingly (Santos-Trigo & Camacho-Machín, 2013).

GOALS AND FRAMEWORK

The current research is part of the Digital Interactive Assessment project at the University of Haifa (http://assess.gigaclass.com). A main challenge for the developers is to design e-tasks that on one hand invite opportunities for active personal learning and on the other set limits that pertain either to pedagogy or content (Watson & Mason, 2006). Our research arises from the challenge to design e-tasks that faithfully assess future learning and teaching. We are also seeking to create e-tasks that check automatically not only the correctness of the answer but also its justification, without the need for human check of written explanations. Because examples play an important role in justifying answers (e.g., Buchbinder & Zaslavsky, 2013) and can be checked automatically, we decided to include them in the present study. In this paper, we focus on construction tasks requiring students to construct examples that satisfy specific conditions. These e-tasks can be used to generate examples and provide tools for exploration. The tools are interactive MLR artefacts designed for mathematical experimentation, and may be part of the GeoGebra applet (the words tools and artefacts are used without any theoretical connotation; the tools in the e-task shown in Figure 3 are the value table, the coordinate system, and the symbolic input line). Each designed e-task appears as multimodal text. The designed tools are suitable for experimentation, and the answers submitted are checked automatically, almost without human intervention. The answers appear as live screenshots of the relevant representations within the tools, for example symbolic expressions, tables of values, and graphs. Therefore, they can be checked automatically. Figures 3 and 4 contain an example of a construction e-task (http://tube.geogebra.org/student/m440111) created by the authors. The e-task, which was inspired by the applet shown in Figure 1, also deals with vertical and horizontal asymptotes and has three representations: numeric (the value table), graphic (coordinate system), and symbolic (input line for the algebraic expression of the function). Students are asked to construct the requested function by typing an appropriate symbolic expression. Before the exercise, students receive instruction about using the numeric table (by typing x and deltaX as shown in Figures 3, 4), dragging points to create different instances of functions, using sliders (Figures 1, 2) using the zoom in and zoom out buttons (Figures 1, 3, 4), and about other technical issues. At this initial stage of the study, we intend to follow the students' reasoning mainly by asking them to submit their answers and to highlight the relevant component that justifies the answer. To make this possible, the task must provide multiple tools or operations for sending the answer. Moreover, students must be able to choose an appropriate numeric interval or a point in the table, or indicate on the graph the relevant segment. The value table in the e-task shown in Figure 3 is initially empty. Students



In each of the above parts you are required to submit a screenshot that supports your answer. You may write further explanations, if necessary. The diagram allows construction of the function in the form: $h(x) = \frac{f(x)}{g(x)}$. Define the numerator function f(x), the denominator function g(x), and the asymptotes by entering their expressions. You may use the value table and change x, deltaX.

Construct a function $h(x) = \frac{f(x)}{g(x)}$:

1) With one vertical asymptote $x = 4$ and one horizontal asymptote $y = 2$
2) With two vertical asymptotes $x = 4$, $x = 2$
3) With two vertical asymptotes $x = 4$, $x = 2$ and one horizontal asymptote $y = 2$
4) With two horizontal asymptotes $y = 2$, $y = -2$.

Figure 3: Example of construction e-tasks

The task:	Possible correct solution: $h(x) = \frac{2x}{x-4}$
Construct a function in the form: $h(x) = \frac{f(x)}{g(x)}$ with one vertical asymptote, $x = 4$, and one horizontal asymptote, $y = 2$.	
Figure 4: A possible correct submission for a construction e-task

may enter an infinite number of values of x and its surroundings (deltaX). To support their construction, students must choose the appropriate values of x and its surroundings. Figure 4 shows a possible correct solution (the relevant components are surrounded by rectangles): the student constructs the function $h(x) = \frac{2x}{x-4}$ and builds the value table around $x = 4$, with $\Delta x = 10000$ to support the argument that $\lim_{x\to\pm\infty} h(x) = 2$. The second value table around $x = 4$, with $\Delta x = 0.0001$ supports the arguments that $\lim_{x\to 4^+} h(x) = \infty$, $\lim_{x\to 4^-} h(x) = -\infty$. Both tables support the student's construction and demonstrate that $y = 2$ is a horizontal asymptote and $x = 4$ is a vertical asymptote of the function $h(x) = \frac{2x}{x-4}$.

The automated checking system is under construction, therefore we can report only on a pilot experiment. The submission and checking of the answers were conducted manually rather than automatically. Our research question is: What is the role of the dynamic MLR environment in completing construction e-tasks. Specifically, we explore how students use the environment to solve the task and what is the added value of marking certain parts on the screenshot they submit as the solution in reflecting reasoning behind the answer. To obtain initial answers to the above questions, we conducted a pilot experiment.

PILOT STUDY

We report a few excerpts from the experiment we conducted with two pairs of 11th grade high school students: Iddo and Ilay, and Shira and Ayala. Each pair studied with the same teacher but in different schools. They studied the standard curriculum of functions and calculus in a regular classroom, without special emphasis on technology, and they successfully passed the Israeli matriculation exams.3 Each pair worked on eight calculus e-tasks created with the GeoGebra software (each e-task had up to four parts). Most of the e-tasks in the pilot experiment were construction e-tasks related to calculus, not necessarily asymptotes. In each e-task students were asked to mark certain parts on the submitted screenshot that reflect additional reasoning on their part regarding the answer. One of these e-tasks is shown in Figures 3 and 4. At the beginning of the experiment, the first author demonstrated all the functions of the applet. She was present during the experiment and answered technical questions (for example, how to enter the square root function into the input bar). The experiment was videotaped to capture the complete sound track and everything that happened on the computer screen. All subject matters included in the e-tasks are from the standard curriculum, and the participants were already tested on these topics at their matriculation exams. The students were asked to say out loud whatever they were looking at, thinking about, doing, and feeling as they went through their task. This enabled us to see the process of task completion as it was taking place, rather than only its final product, and to listen in on the problem-solving process. Figures 5 and 6 present different trials of the two pairs, including their conversation, as they were working on the e-task that appears in Figure 3. Both pairs were asked to construct a function in the form $h(x) = \frac{f(x)}{g(x)}$ with two horizontal asymptotes, $y = 2$, $y = -2$.

First pair: Ilay and Iddo

Ilay: It is difficult... It (the result) has to be square of something.

(Writing in their papers for several minutes.)

Iddo: Aaah! When you have $\sqrt{x^2}$, you have plus and minus. Try to do $4x^2$ divided by... no... it'll be reduced.

One minute later:

Iddo: Let's try $\frac{2x}{\sqrt{x^2}}$, then think that you divide the numerator in x and it equals 2, and then you divide the denominator in x and you put it into the $\sqrt{x^2}$ so that it equals 1. But there is another option of -1.

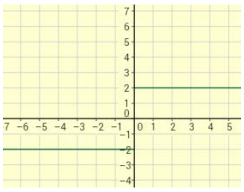
(Iddo refers to: $h(x) = \frac{2x}{\sqrt{x^2}} = \frac{2x}{\sqrt{x^2}} : \frac{x}{x} = \frac{2}{\frac{\sqrt{x^2}}{x}} \Rightarrow \frac{2}{\pm\sqrt{\frac{x^2}{x}}} = \frac{2}{\pm 1} = \pm 2$)

(First try on the screen.)

Iddo: Yes, right,

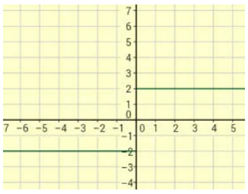
Ilay: It's all from our yellow book...

Iddo: Let's see what's wrong here.



On the screen:
$h(x) = \frac{2x}{\sqrt{x^2}}$
$y = 2, y = -2$

Iddo: These are not the asymptotes.

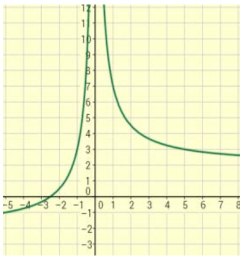


On the screen: $h(x) = \frac{2x}{\sqrt{x^2}}$
They remove the horizontal lines $y = 2, y = -2$

Two minutes later:

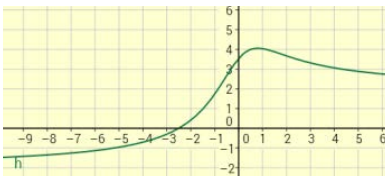
Iddo: Add 5 to the numerator. No, no... actually yes, it has to work, I think.

Iddo: Oh, add 2 to the denominator, because then if you have a negative value for x, then $x^2 + 2$ is positive.



On the screen:
$h(x) = \frac{2x+5}{\sqrt{x^2}}$

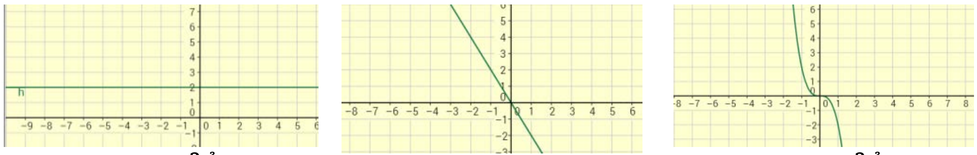
Ilay: Great!



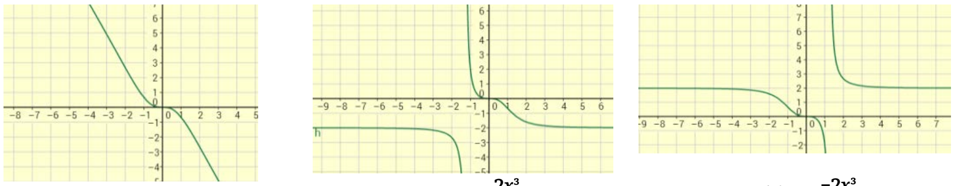
$h(x) = \frac{2x+5}{\sqrt{x^2+2}}$

Figure 5: First pair's conversation and attempts at construction

Second pair: Ayala and Shira

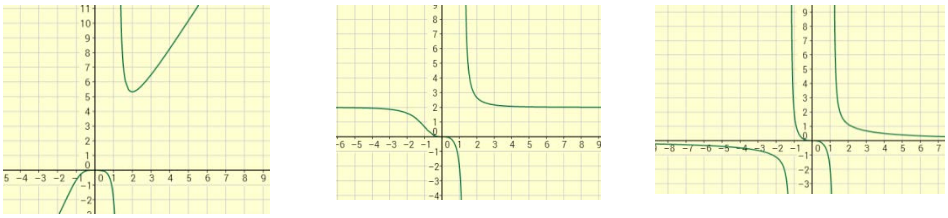


1. $h(x) = \frac{2x^3}{-x^3}$ 2. $h(x) = \frac{2x^3}{-x^2}$ 3. $h(x) = \frac{2x^3}{1}$



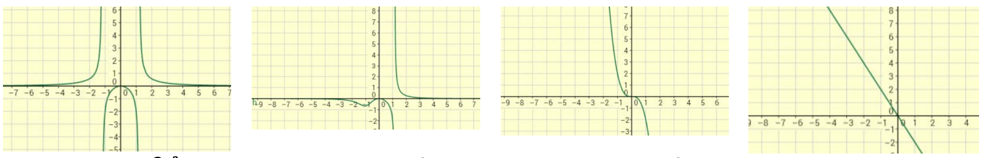
4. $h(x) = \frac{2x^3}{-x^3+2}$ 5. $h(x) = \frac{2x^3}{x^3+2}$ 6. $h(x) = \frac{-2x^3}{-x^3+2}$

Ayala: Do you remember that Felix (the teacher) read us from the book about horizontal asymptotes? The asymptote is the relation between the highest position, here and here (numerator and denominator)?
Shira: You know what? We can cheat a little.

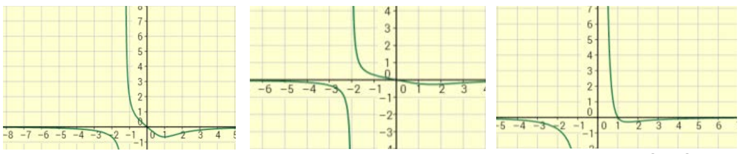


7. $h(x) = \frac{2x^4}{-x^3+2}$ 8. $h(x) = \frac{-2x^3}{-x^3+2}$ 9. $h(x) = \frac{-2x^3}{-x^4+2}$

Ayala: Now there is a horizontal asymptote y=0. Think about it mathematically, not graphically. If you divide this and this in x^4, it is cancelled.



10. $h(x) = \frac{2x^2}{-x^4+2}$ 11. $h(x) = \frac{2x^2}{-x^5+2}$ 12. $h(x) = \frac{-2x^3}{1}$ 13. $h(x) = \frac{-2x}{1}$



14. $h(x) = \frac{-2x}{x^3+2}$ 15. $h(x) = \frac{-2x}{x^3+8}$ 16. $h(x) = \frac{-2x+2}{x^3}$

Shira: I'm sure that if we had more time we would have found the answer.

Figure 6: Second pair's conversation and attempts at construction

DISSCUSSION AND CONCLUSIONS

Construction e-tasks have a great potential for e-assessment of higher-order mathematical skills. The e-tasks may have an infinite number of possible solutions, which all can be checked automatically. The solution stages (Figure 5) attest to the fact that submitting the correct answer is not accidental. Below we discuss the functionality of the dynamic MLR environment in solving and assessing construction e-tasks.

The first pair had no difficulties constructing the required examples (Figure 5). In each of the three trials they obtained a function with the required horizontal asymptotes, $y = 2$, $y = -2$. They did not submit the first trial because they were not familiar with the Heaviside step function, and did not submit the second trial because it had a vertical asymptote as well. Finally, they decided to submit the third trial. They appear to have started working with a firm conjecture in place regarding the functions with two horizontal asymptotes, and therefore constructed successfully the appropriate functions after a small number of educated trials. They used the dynamic MLR environment merely as a control, to provide feedback about their results. The conversation transcript (Figure 5) shows that their trials were accompanied by correct mathematical explanations. By contrast, the second pair used the MLR as a tool for empty trial and error experimentation. They made 16 trials (Figure 6), all of them involving polynomial or rational functions, which cannot lead to a function with two different horizontal asymptotes. Their conversation transcript (Figure 6) implies that they had no ideas or direction, and guessed without method. Shira suggested cheating the computer, and Ayala tried to recall the rules of her teacher for finding asymptotes. They did not have a ready-made example, which may have helped them reach a correct answer, and the tools were of no help in constructing such an example. They could not meet the challenge and therefore did not submit a function. The dynamic MLR environment provided the second pair with feedback regarding their incorrect answers. We may carefully state that the MLR tools in construction e-tasks can help those who are close to the correct answer, but when the correct answer is too far removed, the tool may encourage trial and error behavior. When the students constructed the correct function, they submitted the screenshot with the appropriate value table, as shown in Figure 4. In this case, other justifications, beyond the construction itself, are redundant. Although we report here only on the asymptote task, the evidence is consistent with other construction e-tasks included in the pilot experiment, but not reported here because of lack of space.

In the pilot experiment we saw repeatedly that the correct construction was accompanied by appropriate value tables, mathematical explanations, and educated trials. We therefore cautiously suggest that a correct final answer, if produced in a compound environment such as the MLR, eliminates the need for manually checking all the solution stages, enabling automatic checking of the solution. Tracking the solution process may be important to assess a partial solution, however, when the submitted construction is partially correct. The experimental setting would allow triangulation of human checks of scanned paper submissions, tracks of intermediate stages and simultaneous computerized video records.

A framework for describing techno-mathematical fluency in beyond-school problem solving

Hélia Jacinto[1] and Susana Carreira[1,2]

1 University of Lisbon, Research Unit of the Institute of Education, Lisbon, Portugal, helia_jacinto@hotmail.com

2 University of Algarve, Faro, Portugal

This study seeks to characterize the mathematical problem solving activity with digital tools that emerges from students' participation in an online mathematics competition. Using a qualitative approach, we elected the case of a 13-year-old participant aiming to understand the ways in which she interweaves her mathematical competence and her technological fluency for solving problems, using GeoGebra. Main results expose the role of the digital tool that permeates every stage of the problem solving process, since the tool is used for solving and for expressing the solution. We further propose a framework for describing the processes that may capture the interplay between mathematical knowledge and technological fluency in solving problems, termed techno-mathematical fluency.

Keywords: Beyond school mathematics, digital literacy, mathematical competitions, problem solving, techno-mathematical fluency.

INTRODUCTION

The constant immersion in a technologically pervaded world is changing the "kind of mathematical abilities that are needed for success beyond schools" (Lesh, 2000, p. 177), especially since the new and powerful tools made available are introducing "new kinds of problem-solving situations in which mathematics is useful, (...) and they radically expand the kinds of mathematical understanding and abilities that contribute to success in these situations" (p. 178). Whilst the kinds of mathematical thinking needed beyond school are shifting, the types of problem solving situations that demand some form of mathematical thinking are also changing. Furthermore, little is still known about the problem solving that occurs beyond the classroom and additional research is needed specially to understand the role of digital technologies in such activity (English & Sriraman, 2010; Santos-Trigo & Barrera-Mora, 2007).

A glimpse on the context: The mathematical competition SUB14

SUB14® is a web-based mathematical problem solving competition organised by the University of Algarve. Addressing 12-13-year-old students, it is supported by a website where the problems are published. The Qualifying consists of ten problems, each one published every two weeks. Participants may solve the problems using their favourite methods or tools, but they are explicitly required to report on their solving process offering a complete and detailed explanation of their reasoning. At this stage, the rules allow and encourage help seeking from relevant others. Participants who answer correctly to eight or more problems may attend the Final stage, which consists of a one-day tournament at the University of Algarve (see Carreira, 2012).

Our goal is to investigate mathematical problem solving with digital tools in this beyond-school competition, where participants may use their favourite digital tools but, at the same time, are required to use a mathematical stance. We report our progress on analysing how they combine their mathematical knowledge and their technological fluency in solving the competition's problems.

THEORETICAL BACKGROUND

This study is supported by a conception of inseparability between the subject and the digital tool in the development of mathematical thinking. Thus, we consider *humans-with-media* (Borba & Villarreal, 2005) as a central unit in understanding problem solving activity with technology. This metaphor brings forth the idea that mathematical thinking is an outcome of this symbiosis between people and the digital tools they use.

Mathematical problem solving – the mainstream view

The competition poses non-routine problems, whose context is fully and clearly expressed in the statement, which allow different techniques, procedures or tools. As these problems are not aligned with the mathematics curriculum and a diversity of approaches and tools is encouraged, this problem solving activity can be seen as the development of a productive way of thinking about a challenging situation (Lesh & Zawojewski, 2007). Current frameworks consider a mathematical literate person as someone who is an *active problem solver*, in other words, who has the "capacity to formulate, employ, and interpret mathematics in a variety of contexts. It includes reasoning mathematically and using mathematical concepts, procedures, facts and tools to describe, explain and predict phenomena" (OECD, 2013, p. 5).

Looking for a way of explaining student's and expert's problem solving performance, Schoenfeld (1985) proposed a model comprised of four dimensions: basic resources, heuristics, control, and belief systems. The processes followed by the solvers were organized into five stages: *read* – time spent "ingesting the problems conditions" (p. 297); *analysis* – attempt to fully understand the problem "sticking rather closely to the conditions or goals" (p. 298) that may include a selection of ways of approaching the solution; *exploration* – a "search for relevant information" (p. 298) that moves away from the context of the problem; *planning and implementation* – defining a sequence of actions and carrying them out orderly; *verification* – the solver reviews and assesses the solution. While paper and pencil were the predominant tools used in Schoenfeld's studies, today's wide dissemination of powerful technological tools is raising new queries, namely if and to what extent these frameworks still account for the mathematical problem solving proficiency in the presence of digital tools (Santos-Trigo, 2007, Santos-Trigo & Camacho-Machín, 2013).

Bringing together mathematical and technological literacies

In reporting studies that sought to identify the mathematical competencies needed in several workplaces, Hoyles, Noss, Kent and Bakker (2010) highlight an interrelationship of the technology use and the mathematical skills of the workers, proposing the notion of *Techno-mathematical Literacies* as encapsulating both the technological and the mathematical skills needed within those specific work contexts.

Debates concerning the digital skills needed in our daily activities are undergoing. The European project

Process	Problem or Digital Task
Statement	State clearly the problem to be solved or task to be achieved and the actions required.
Identification	Identify the digital resources required to solve a problem or complete a task.
Accession	Locate and obtain the required digital resources.
Evaluation	Assess the objectivity, accuracy, reliability and relevance of digital resources.
Interpretation	Understand the meaning conveyed by a digital resource.
Organisation	Organise and set out digital resources in a way that will enable the solution of the problem or achievement of the task.
Integration	Bring digital resources together in combinations relevant to the problem or task.
Analysis	Examine digital resources using concepts and models which will enable solution of the problem or achievement of the task.
Synthesis	Recombine digital resources in new ways which will enable the solution of the problem or achievement of the task.
Creation	Create new knowledge objects, units of information, media products or other digital outputs which will contribute to the solution of the problem or achievement of the task.
Communication	Interact with relevant others whilst dealing with the problem or task.
Dissemination	Present the solutions or outputs to relevant others.
Reflection	Consider the success of the problem-solving or task-achievement process, and reflect upon one's own development as a digitally literate person.

Table 1: Processes of digital literacy (Martin & Grudziecki, 2006)

DigEuLit developed a theoretical framework addressing the meaning and operationalization of "digital literacy" by describing the activity of a digital literate person when dealing with a digital task (Martin & Grudziecki, 2006). Those processes (Table 1) can be summarized as actions required before solving the problem (stating, identifying, accessing, evaluating, interpreting, organizing), while producing the solution (integrating, analysing, synthesising, creating, communicating), and actions that occur afterwards (disseminating and reflecting).

To some extent, this list of processes resembles the problem solving stages proposed by Schoenfeld (1985). Due to the rules of the competition, a mathematical problem may be considered as a digital task that requires a number of technological skills, so we conjecture that these two frameworks can provide the necessary level of detail for describing problem-solving-with-technologies. We, therefore, ponder an association of the *stages* and processes: *read* – statement (i.e., appropriation of the situation and the conditions in the problem); *analyse* – identification, accession, evaluation, interpretation (i.e., initial attempt to comprehend what is at stake, namely the mathematics that may be relevant and the tools that may be necessary); *explore* – organization, integration, analysis (i.e., the quest for a combination of mathematical and technological tools within a plausible strategy); *plan and implement* – synthesis, creation, communication (i.e., carrying out the outlined strategy); and *verify* could be complemented by dissemination and reflection since, at this point, there isn't an overlap between the two frameworks. Thus, the notion of *techno-mathematical fluency* stresses the need to be fluent in a language that entails mathematical and technological knowledge, promoting the skilful use of digital tools, and the efficient interpretation and communication of the mathematical solution produced.

Dynamic Geometry Software in problem solving

Constructing figures and investigating their properties are two of the most commonly known affordances of Dynamic Geometry Software (DGS). In particular, one of the features of DGS is that it "visually make[s] explicit the implicit dynamism of thinking about mathematical geometrical concepts" (Leung, 2008, p. 135) embedded in a challenging task. However, such dynamic environments are not only helpful in visualizing geometric concepts and understanding rules, but also in producing conjectures and generalizations, and finding connections amongst concepts (Baccaglini-Frank & Mariotti, 2010; Jones, 2000). When tackling model eliciting problems, students often perceive and make use of the affordances of the software in order to develop a conceptual model of the situation. They undertake a construction, revealing how they are interpreting the problem and depicting the mathematics concealed; they explore and investigate properties (Iranzo & Fortuny, 2011).

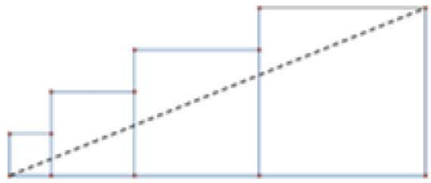
Carreira, Jones, Amado, Jacinto and Nobre (to appear) have identified six general affordances of GeoGebra for solving geometrical problems within the competition SUB14: immediate constructions, measurement, referential constructions, setting properties, constructions using parameters or variables, and drag and explore. Claiming that the perception of the affordances of GeoGebra is crucial to this problem solving activity, the researchers observed how several students tackling the same problem with GeoGebra produce different digital solutions that comprise qualitatively different conceptual models. We now argue that such differences may be explained by the solvers' latent techno-mathematical skills, regardless of where the mathematical and technological knowledge were learnt or developed.

RESEARCH METHODS

Our main goal is to develop a deep understanding of the interplay among mathematical knowledge and technological fluency during the development of the solving process within SUB14. Thus, we developed an interpretative study where the research methods were steered by qualitative techniques for gathering, organizing and analysing empirical data (Quivy & Campenhoudt, 2008).

We report the case of Jessica (fictitious name), a participant whose productions stood out due to the sophisticated use of technology, namely GeoGebra, for solving these problems (Jacinto & Carreira, 2013). Data include the solutions sent by Jessica in two editions of SUB14; an in-depth interview with Jessica, audio and video recorded, focusing her problem solving activity in the classroom and at SUB14, and asking her to remember and retrace solutions submitted to the competition; and two specific solutions, where she used GeoGebra, were also selected for a deeper analysis. Whilst the data from the interview provide a view of Jessica as a

Consider a sequence of squares of sides 1, 2, 3, 4,… cm, arranged so that they are connected to each other, as illustrated on the right. Once together, cut up all the squares by a line drawn from the bottom left corner of the smaller square to the upper right corner of the larger square. What is the area above the cut line, if the sequence has 8 squares?



Don't forget to explain your resolution process!

Figure 1: The problem "United and Cropped"

student, a problem solver and a technology user, the GeoGebra's construction protocols and the written explanations shed light upon the interplay between mathematical knowledge and technological fluency. As the rules of the competition explicitly require to document the solving processes, we assume that the final versions of the constructions performed with GeoGebra account for the interplay between Jessica's technological and mathematical knowledge to solve the problems and express her reasoning.

The several types of data were organized using NVivo®, where audio and video data were transcribed. The analysis followed an interpretative perspective providing a holistic description of the case, by combining Jessica's perception of her own problem solving activity (interview), with the analysis of the participant's productions (GeoGebra file), enlightened by the theoretical ideas discussed above.

THE CASE OF JESSICA

Jessica is a 13 years-old girl who engaged in SUB14 during her 7th and 8th grades. Her answers to the problems are always on time, she describes and properly justifies her processes in a clear language. She developed a particular interest on GeoGebra that stemmed out from her school experience, since her teacher used it often as a way to present geometrical contents. Despite being teacher-centred, it has driven Jessica to download, install and explore GeoGebra at home, independently.

Jessica: As I said, we use technology a lot. We have a board… a white board, and we also have an interactive board. We used GeoGebra very often when we were studying geometry and geometric transformations.

Researcher: When you say "we used", you mean the teacher?

Jessica: Precisely. And we watched it.

When asked to recall and retrace her solution to the problem "United and Cropped" (Figure 1), she claimed to enjoy solving geometry problems because of the possibility of improving the solutions' graphical display, afforded by GeoGebra.

Jessica: I think I went straight to GeoGebra. I knew it had something to do with geometry. I realise it was a triangle (…) and that by rearranging it in a simpler manner all I had to do was calculate the whole area and then subtracting the area of this triangle, which is easy: base times height divided by two. And then I thought… Oh, great! Geometry! I'm getting it neat!

Jessica usually resorts to a notepad, coloured pens, a calculator and the computer. Initially, she thinks that GeoGebra only affords "dressing up" the solution that she finds by using paper-and-pencil but, later, she acknowledges that manipulating the construction also led her to a powerful understanding of the problem.

Jessica: Hum… usually I look for the notepad and a pen, then [go to] Word and then I always… well I always use GeoGebra or some other software to add something to the text, for presenting a more complete work.

Researcher: So… you use it [GeoGebra] only after you solved the problem?

Jessica: Yes, but… it depends. If GeoGebra or some other tools would help me understand the problem, then I'd use it firstly and later I'd move to Word.

The image shows a large square divided into 14 smaller squares, coloured in yellow, of different but integer dimensions, and 1 white rectangle, also of integer dimensions. The white rectangle has an area of 30 464 cm^2.
Which is the area of the larger square?

Don't forget to explain your resolution process!

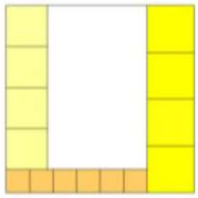


Figure 2: Statement of the problem "A divided square"

Researcher: Ok, so you also use them while you're still looking for the solution...

Jessica: Yes, for instance, in this case [the problem United and Cropped] I started by going to GeoGebra to understand it properly, and then I discovered 'Oh, that is a triangle right there, therefore I have to subtract the area of that triangle'. In that case, I started with GeoGebra for a better understanding.

Her solving activity starts outside the screen but she easily recognizes that digital tools afford powerful approaches to the SUB14's problems. The following section reports Jessica's work with GeoGebra while solving another geometry problem.

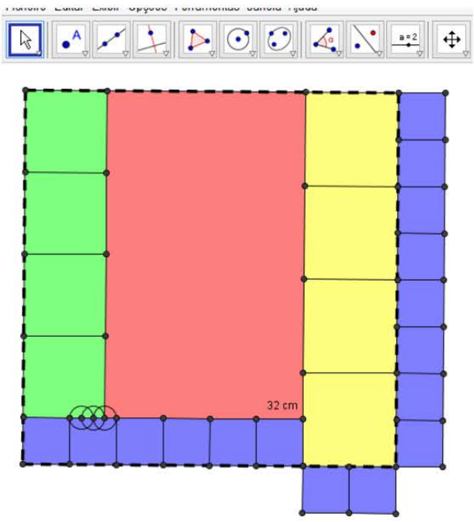
The problem "A divided square"

Jessica's solution (Figure 3) combines the construction of the figure presented in the statement and a written explanation where she presents a 'label' that helps in interpreting the image and her problem solving processes, including finding the area. A closer analysis of the 'construction protocol', which allows tracking steps of the construction, reveals that GeoGebra's role goes beyond 'embellishment'.

Resorting to immediate and referential constructions she represents the larger square that supports the construction: draws two perpendicular lines and a circle centred at their intersection and a radius of length CD. Then, she constructs four squares on the right by finding midpoints, using parallel and perpendicular lines and their intersections. Finally, she builds four squares and colours them in yellow (Figure 4).

As for the lower squares (Figure 5), Jessica marks R as the midpoint of FQ, then uses a central reflection of the point F over R and obtains F'$_1$ which coincides with Q. She marks I' as the central reflection of I over F'$_1$ and, using another central reflection of F over F'$_1$ marks F' and constructs the segment I'F'$_1$. She then marks S as the midpoint of I'F' and proceeds by using circles with given centre and radius, finds intersections and midpoints, and drawing parallel lines to complete the representation of the lower squares. Similarly, she constructs the remaining squares on the left side (Figure 6).

Finally, by setting properties, she colours polygons, adds several squares along the exterior of the initial square and some circumferences whose centres divide the side of a smaller square in four parts (Figure 3). These items emphasise a visual perception of the



The boundaries of the larger square are dashed. I have changed the colours of the smaller squares so I can differentiate them easily. Same colour squares have the same area.
yellow square side = 1/4 larger square side
blue square side = 1/8 larger square side
blue square side = 1/2 yellow square side
green square side = 1,75 the blue square side
Let us assign x to the side of the blue square.
Length of the red rectangle = $4{,}25\,x$
Height of the red rectangle = $7\,x$
Area of the red rectangle = $4{,}25\,x \times 7x = 30\,464 cm^2$
$2975\,x^2$=30464
$x^2 = 30\,464 \div 2975 = 1024$
$x = \sqrt{1024} = 32 =$ length of the side of the blue square
Length of the red rectangle = $32 \times 7 = 224$
Side of the larger square = $32 + 224 = 256cm$
Area of the larger square = $256cm \times 256cm = 65\,536cm^2$
Answer: The area of the smaller square is 65 536 square centimetres.

Figure 3: Solution of the problem "A divided square"

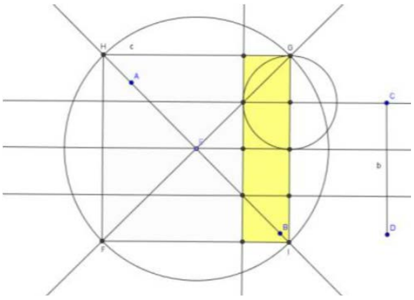


Figure 4: Constructing the initial squares

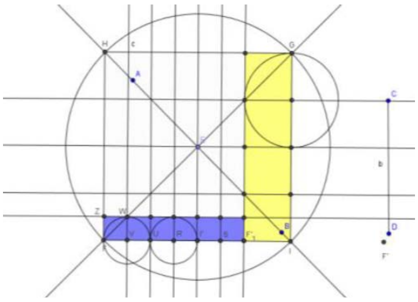

Figure 5: Constructing the lower squares

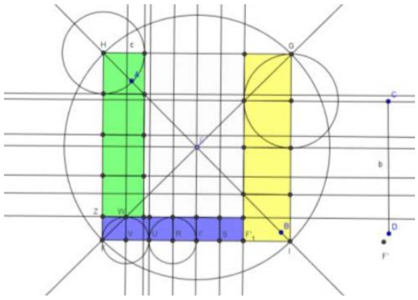

Figure 6: Constructing the left squares

existing relations between several lengths of the geometrical figures. On the right, a label helps interpreting the construction and establishing numerical relations between lengths of the sides of the squares. The unknown is defined as the length of the blue square and, using those relations, she formulates an equation that will provide the measurement that is missing: . With this value she determines the length of the side of the larger square and, then, its area.

This case illustrates how GeoGebra is crucial at several stages of the problem solving activity: it is not only affording the construction but, most importantly, the construction activity is allowing to uncover the relations between the geometrical objects, it is transforming what is invisible and concealed inside the proposed figure, into visible and usable ideas for the development of a way of solving this problem and expressing the solution. In fact, the constructions become part of the reasoning, of the process and the solution itself. This can be interpreted as an instance of the problem solving activity of a student-with-GeoGebra (Borba & Villarreal, 2005).

REFRAMING TECHNO-MATHEMATICAL FLUENCY

Taking the problem solving stages proposed by Schoenfeld (1985) and the processes of the digital literacy framework developed by Martin and Grudziecki (2006) as leverage, we have set an analytical tool to account for the ways a participant deals with digital tools whilst solving a mathematical problem and expressing its solution.

Jessica starts by skimming the mathematical topic enclosed in the problem, such as geometrical notions, rules, procedures, and recognizing GeoGebra as a key digital resource (*Read/statement*). The following stage (*Analyse*) is patent through the *identification* of a mathematical repertoire and a technological repertoire (geometry and GeoGebra's affordances) that are due to her previous knowledge about them and her *access* to them. Moreover, Jessica's choice relies on her *assessment* of the techno-mathematical resources and her *interpretation* of the techno-mathematical outcomes.

She then *Explores* ways of organizing different resources such as notepad, coloured pens, calculator, GeoGebra, text and image editor, e-mail, and several mathematical resources such as properties of parallel and perpendicular lines, circumferences and their representations, areas, algebraic expressions, and combines them in a relevant way to the development of her strategy (*organisation*, *integration*, and *analysis*).

Based on the constructions and their manipulation, she *Plans* and *Implements* her strategy recombining the techno-mathematical resources (*synthesis*) in order to produce new knowledge objects: strategies, representations, conceptual models (*creation*). During these processes, she may ask for the assistance of relevant others (like her teacher) to proceed in finding the solution (*communication*). It is important to note that the activity reported by Jessica and the analysis of the construction protocol suggest that the understanding of the problem and the decision on the actions necessary to solve it are not limited to the initial stage but it develops throughout the analysis and exploration stages and it is deepened during the construction and manipulation of the geometrical figures.

The last stage consists of reviewing the process and the solution (*Verify*) but it also includes presenting the solution to others, in this case, the GeoGebra construction and a detailed explanation of the procedure (*dissemination*). As for the personal *reflexion* on the success accomplished during the problem solving activity, there are no other concrete evidences to support it than the fact that Jessica has decided to present this solution to the judges of the competition.

CONCLUDING REMARKS

The two frameworks selected were meant to characterize the problem solving stages and the processes of digital literacy and, as such, their combination seems to offer powerful tools to approach a description of the latent processes underlying the notion of techno-mathematical fluency. However, some improvements must be pondered. Firstly, the processes of digital literacy are a set of actions that occur in a relatively ordered sequence, unlike the stages of problem solving that, as Schoenfeld (1985) disclosed, are flexible enough to describe failed attempts or new appropriations of the problem. So, the descriptors of the techno-mathematical fluency involved in problem solving within SUB14 must comply with this flexibility. There may also be an overstatement of the digital literacy processes, particularly in the level of detail included in the original framework. Our comprehensive knowledge about the competition and the participants allow us to assume that: i) they often choose the tools they are most familiar with, namely everyday digital tools available in their home environment, hence accession, interpretation and evaluation could result in some benefit if they were agglutinated in a broader process, bringing together knowledge and decisions about the digital resources; ii) the communication process, which relates to possible help seeking, permeates other stages of the problem solving activity, namely in understanding the problem or in devising a path; iii) the verification of the solution is not clearly addressed in the digital literacy processes, but it is a very important metacognitive process for assuring the completeness of the solution; iv) the dissemination process, not considered in Schoenfeld's model, is extremely important given the competitive nature of this activity and the unavoidable fact of having to submit a solution to those who are responsible for their acceptance and from whom a return is expected; v) solving and expressing are inter-related activities that are often inseparable (Jacinto, Nobre, Carreira, & Amado, 2014).

In light of the data and the theory, the notion of techno-mathematical fluency that emerges from the 'problem solving with technologies' activity is a useful way of accounting for the intertwining of mathematical knowledge and technological fluency. Future developments will concentrate on the refinement of the framework descriptors based on further analysis of other participants' problem solving activities, observed within the same informal learning context.

Feedback and formative assessment with Cabri

Kate Mackrell

University College London, Institute of Education, London, UK, katemackrell@me.com

The University of Chicago Number Stories project aims to enhance student engagement in solving real-world problems in a Cabri environment through the provision of effective feedback. The relevant literature concerning feedback and formative assessment in technology situations is hence reviewed in light of the affordances of Cabri, and issues arising in the project, such as providing feedback in open-ended situations, are discussed.

Keywords: Cabri, feedback, formative assessment, real-world problems, technology.

INTRODUCTION

The *Number Stories* (NS) project (University of Chicago, 2014) involves the development of an online database of number stories, which are real-world questions based on real-world contexts supported by factual sources, targeted to individual users (or solvers) including school students at any level, teachers, teacher-educators, home-schoolers, district supervisors, and the general public. Unlike a traditional curriculum project where real-world problems may be used as a means to achieve specific mathematics learning goals, the main aim of the NS project is to promote understanding about how mathematics is used in daily life and to enable solvers to gain in their confidence and ability to apply mathematics in real situations.

Each number story consists of a collection of Cabri files in which the context is established, a question or problem is posed, and a solution is given. There is a wide range in the mathematics required. For example, questions from the "Chain Letters" context, in which one person sends a letter to n people who then send letters to a further n people, may be solved by techniques ranging from dragging representations of letters into mailboxes to using geometric series. Questions may be specific or more open-ended, such as "Who got the better end of the deal when Manhattan was purchased by the Dutch from the Indians in 1626?", which allows a number of approaches and does not have a well-defined solution. Solvers may post their own solutions to the database and explore the solutions posted by others.

A major concern of the project is to make the questions as engaging as possible to solvers through their intrinsic interest, the use of relevant digital manipulatives, and the provision of feedback that will enable solvers to be successful. This paper accordingly reviews research evidence concerning feedback and discusses some of the issues and the ways in which this evidence is being implemented.

The relevant mathematics education literature on feedback comes from classroom contexts where the aim of feedback is to enable the student to meet specific learning goals, not the aim of the NS project. More general learning goals are common, however, as is successful task completion, the difference being that in a classroom context this is taken as evidence that the learning goals incorporated into the task have been met.

DEFINITIONS AND DIFFICULTIES

Feedback may be defined as any information provided to the learner about a response (Wiliam, 2013). Based on Shute (2008), we define formative feedback as feedback given to the learner with the purpose of enabling the learner to modify their thinking or behavior in order to meet the goals of the activity in which they are engaged. Much of the relevant literature on feedback is concerned with formative assessment, which is broader than formative feedback in that learner responses are used more generally to adapt teaching and learning to meet student needs (Sangwin, Cazes, Lee, & Wong, 2010); this might, for instance, involve directing the student to an entirely different activity rather than giving formative feedback on the existing activity.

Digital learning environments such as Cabri provide direct manipulation feedback in which the technology responds to user actions, ranging from displaying text to changing the appearance of a graph or other screen object as its parameters are changed. Such feedback is neutral; any evaluation comes from the student themselves, as they discover which actions enable them to meet their goals.

Formative assessment, in contrast, involves the provision of a more deliberate goal-directed response, ranging from evaluating a student action as correct or incorrect through giving formative feedback such as hints, or changing the task completely by presenting a simpler version or directing the student to external learning resources.

Despite growing awareness of its effectiveness, (academic achievement gains ranging from half to a full course grade have consistently been found (Black & Wiliam, 1998) formative assessment is not widely implemented. Hattie and Timperley (2007) state that there is little feedback at all in classrooms, and that much of this is ineffective. Bellman, Foshay, and Gremillion (2014) identify the implicit, unrealistic expectation that most teachers can immediately adopt the formative assessment model and differentiate instruction. Lee, Feldman, and Beatty (2012) note that teachers find it difficult to gather and respond appropriately to student ideas during whole class discussion. Hence, although technology may offer new opportunities for effective formative assessment (as is currently being explored by projects such as FaSMED (2015)) we cannot assume that implementing effective feedback within Number Stories will be unproblematic.

We will next consider a particular framework for feedback and then explore the affordances and constraints for such feedback in a digital environment.

FRAMEWORK FOR FEEDBACK

Hattie and Timperley (2007) categorize feedback according to its purpose and have developed the following framework for feedback:

a) Feedback at the *task* level (FT) provides information about how well a task is being accomplished in relation to a goal.

b) Feedback at the *process* level (FP) provides information about the processes being used to accomplish a task.

c) Feedback at the *self-regulation* level (FR) provides information to help learners monitor and regulate their own actions towards a goal.

d) Feedback at the *self* level (FS) provides an evaluation of the student as a person.

This framework aligns well with the aims of the NS project, highlighting task completion, but in the context of developing solvers' problem-solving abilities in an environment where solvers are self-directed in their choice of problems to solve.

Hattie and Timperley's review shows that the effects of feedback vary according to level, though there are many mediating factors that still need to be explored. In particular, they argue that FS is least effective, FP and FR are the most effective for deep learning, and FT can be effective when the information in the feedback is "useful for improving strategy processing and enhancing self-regulation" (p. 91).

Feedback at the task level (FT) is the most common type of feedback, but too much feedback at this level may encourage students to focus on the immediate goal and not the strategies to attain the goal. It is more powerful when it results from faulty interpretations rather than a lack of understanding (where it may be better to have elaborations provided through instruction), and enables student to examine erroneous hypotheses and ideas, particularly when the learner has expected the response to be correct), and is most effective when it leads to the development of better strategies for processing and understanding the material. Simple tasks benefit most from FT, and simple FT is the most effective.

Process feedback (FP) is aimed at the process used to create a product or complete a task. FP is more effective than FT for enhancing deeper learning, and is most beneficial when it enables students reject erroneous hypotheses and gives cues to directions for searching and strategizing. Ideally, it moves from the task to the processes necessary to learn the task to regulation about continuing beyond the task to more challenging tasks and goals.

Self-regulation involves the way students monitor, direct and regulate actions towards the learning goal. It includes the capability to self-assess and to seek out feedback. Self-regulation feedback (FR) can lead to further engagement with the task, and enhanced self-efficacy. Bellman, Foshay, and Gremillion (2014) and Sangwin, Cazes, Lee, and Wong (2010) also identify the importance of FR and the way that formative assessment can develop self-regulation capacities.

The most problematic type of feedback is FS. Praise directed at this level bears little relationship to student achievement, and negative FS can undermine self-efficacy.

Some of the implications for NS are straightforward, such as replacing "smiling" and "frowning" faces with more neutral correct/incorrect symbols to avoid FS feedback, and keeping all feedback as simple and goal-focused as possible. Another implication is that feedback may not be enough and that sources of instruction may be needed. Other implications are more problematic: it is clear that, particularly for more open-ended tasks, FP and FR are crucial to sustain engagement, to experience successful task completion and to enhance problem-solving ability.

We next consider the extent to which feedback can be given in a digital environment.

FEEDBACK IN A DIGITAL ENVIRONMENT

The MiGen project (Mavrikis, Noss, Hoyles, & Geraniou, 2013) is a digital environment that has been deliberately designed to incorporate formative feedback and is aimed at supporting children's learning of mathematical generalization. The system includes an open environment in which students can construct and explore the structure within patterns, and an intelligent support system that gives students hints and clues about what to do next. Two major issues have been identified in the development of this intelligent support system which need to be dealt with in any digital environment incorporating feedback.

Interaction bandwidth

The interaction bandwidth of a situation refers to the available modalities and speed of communication that the situation affords (Mavrikis & Gutierrez-Santos, 2010). There are crucial differences between human communication modalities and those that are available to a computer-based system.

> The computer is limited in the amount of information it can obtain from the student, and is also limited in the amount and types of feedback it can provide. These limitations are both technical (c.f., state of the art in natural language processing and generation) and pragmatic (e.g., humans behave differently with computers, i.e. they listen and read with different interest or attention) (Mavrikis & Gutierrez-Santos, 2010, p. 642).

Examples of these limitations include the awkwardness of keyboard input of mathematical expressions and the tendency of students to do written calculations on scrap paper in paper-based mode but to try to work mentally in computer-based assessment (Stacey & Wiliam, 2013).

In contrast, in face-to-face communication in a technology environment, a human facilitator can, for example, speak, point to screen objects, take control of actions, and draw inferences based on facial expressions and gaze direction, far beyond what can be achieved by most computer-based systems. This has an impact on the quality of assessment possible. Sangwin, Cazes, Lee, and Wong (2010, p. 231) note that "The process with which a human teacher engages when assessing work at even this micro-level is both complex and subtle. Both for formative and summative purposes it involves them making many judgments rapidly."

Designing a feedback system involves finding ways to compensate for the reduced interaction bandwidth of a technology environment. This is of particular importance in the NS project; learning may be enhanced by teacher feedback if the materials are used in a classroom, but materials need to be designed to be accessed and used by individuals without teacher support. We next describe some of the possibilities for action, interpretation, and response in a technology environment.

Actions possible

A digital environment may be impoverished compared to a face-to-face environment, but is significantly richer than a paper-and pencil environment. Students may be given dynamic objects to manipulate, such as a 3D object to rotate, or linked representations of equations and graphs (Stacey & Wiliam, 2013), or spreadsheets (Sangwin, Cazes, Lee, & Wong, 2010). Students may also be given tools to construct or operate upon mathematical objects; tools for calculating, graphing, and manipulating algebraic expressions enable student attention to focus on problem-solving strategies, concepts, and structures, rather than mechanical processes. Students may also choose operations which are then performed by the computer (Sangwin et al., 2010).

Non-verbal ways of responding are also possible. Stacey and Wiliam (2013) argue that if a student needs to estimate the height of a tree after reduction by 30%, then dragging a slider to the estimated position provides a better test of estimation than selecting an answer from a list presented on paper. Student choices may also be constrained in ways that are pedagogically useful; given only the choice of "multiply" or "add", solving the equation $3x = 14$ requires the awareness that division by 3 is equivalent to multiplication by 1/3 (Sangwin, Cazes, Lee, & Wong, 2010).

Cabri, incorporating dynamic geometry together with graphs, calculation and the ability to create and evaluate expressions, gives the possibility for a wide range of dynamic objects to manipulate and tools to use, as well as containing more traditional features such as input boxes and multiple choice questions. Importantly, the task designer has control over the availability to students of both objects and tools, enabling a focus that is unusual in a DGS.

Interpretation of actions

The fundamental principle of mathematical assessment with technology is that various mathematical properties of a student's work on a specific mathematical question are established (Sangwin et al., 2010). Technology can also identify other potentially task-related aspects such as the sequence of actions taken, the number of attempts and the response time (Stacey & Wiliam, 2013; Pellegrino, 2010).

Input boxes and multiple-choice questions are easily checked for accuracy. However, feedback based solely on this may not be of particular value to the student, as it may consist of FT alone. These also constrain the type of task that can be given. In particular, geometric constructions and more open-ended questions cannot easily be assessed using these means.

The challenge is to find means to gain more sophisticated evidence on the basis of which FP and FR feedback may be given. This is dependent on both the way the task is modeled (discussed below) and the affordances of the technology. Sangwin, Cazes, Lee, and Wong (2010) note that some DGS (e.g., Cinderella and C.a.R.) allow teachers to set up assignments or exercises that can automatically check student constructions. All DGS can capture information about parameters such as coordinates, lengths, and angles which enables feedback to be given on tasks such as rotating a segment by 90 degrees, or dragging a point to make two segments parallel.

Cabri will soon be able to check constructions, can detect any of the above parameters and also the number of objects inside certain types of other objects. Such objects may also be assigned values that can be the basis of calculations. Cabri also has booleans, which enable sophisticated evaluation of numbers, such as how far the response given is from the correct response, or whether the response is congruent with an earlier estimate. It is also possible to measure response time and number of attempts, and student can make and save a recording of the steps taken.

Response to evidence

There are a number of ways in which the system can engage the student in evaluating their response, and hence enhance the possibility of FR feedback. One is to represent the student response in a different register, or otherwise work out its implications. For example, Sangwin, Cazes, Lee, and Wong (2010) ask students to give an example of a function with certain properties. The function given is then graphed, and the student can evaluate whether or not it has the required properties. Another example is where students are asked to integrate a function. The system finds the derivative of the function provided and asks the student to compare this with the original function. This is designed to encourage the students to differentiate in order to check the result for themselves. Geiger and Redmond (2013) ask students to create a function to model particular data. The system then graphs this function against the data in order to give immediate feedback about the suitability of the model. It is also possible to provide feedback about the immediate correctness of a step, leaving it to the student to evaluate their overall success in achieving the goal. An example here is the Digital Mathematics Environment facility to solve equations step by step, with the program providing feedback on accuracy at each step – but not indicating whether or not the particular steps taken were useful in reaching the goal (Drijvers, Boon, Doorman, Bokhove, & Tacoma, 2013).

In MiGen, responses come from the system, based on the properties of the student evidence (to be discussed below), and may range from variations on "correct" and "incorrect" to feedback that progressively provides more specific help through 'nudge' questions, comments, suggestions, and interventions (Gutierrez-Santos, Mavrikis, & Magoulas, 2010). There is, for example, a suggestion button which students are free to ignore that only lights up if the system observes an action that implies that help is warranted, and drop-down menus that allow students to choose a sentence and ask for help (Mavrikis, Noss, Hoyles, & Geraniou 2013). The advantage of technology here is the immediacy of the feedback, not possible from a teacher (Sangwin, Cazes, Lee, & Wong, 2010).

Apart from the calculus example (due to insufficient CAS) all the specific possibilities above may be implemented using Cabri.

It would hence appear that Cabri enables a rich enough bandwidth to open a number of possibilities for feedback.

Modeling the task to design feedback

The second major issue identified in the MiGEN project is that of modeling the task to design feedback. The importance of such a model is recognized by Pellegrino (2010), who, in describing systems which explicitly make formative interventions and give detailed diagnoses of student understanding, states that such systems are based on an underlying analysis or model of learning and performance in the content domain. Pellegrino recognizes the difficulty in achieving such a system, however, stating that systems with extensive diagnostic assessment capability, while desirable, require considerable research and development efforts. Even for an apparently straightforward task such as the Chain Letter problem in which the solver might be asked to find the number of letters sent after a certain number of iterations all possible solution processes and possible misconceptions would need to be identified.

This is particularly difficult in an open-ended environment. Mavrikis and Gutierrez-Santos (2010) identify a number of difficulties in the MiGen project including eliciting precise, concise, and operationalised knowledge from 'experts' such as teachers and the nature of the microworld:

> the freedom provided to the students to explore such environments makes it difficult to model the task, the learner and the relationship between the target domain and the knowledge which the system affords. (Mavrikis & Gutierrez-Santos, 2010, p. 641)

They found it crucial to involve students at all stages of development, as difficulties were problematic to predict; an in-depth understanding of user behaviour required observing and analyzing situations in their actual context. This modeling was necessary in order to generate the detailed set of messages used as feedback in the intelligent support system.

An implication for NS is that, with its large number of contexts and open-ended questions, the resources in terms of time to create detailed task models and software capability to analyze and appropriately respond (Cabri does not incorporate a programming language) are not currently sufficient to create an intelligent support system of the sophistication of that developed in the MiGen project.

NUMBER STORIES

Starting in July 2014, when feedback consisted simply of "correct" or "incorrect", we have incorporated an increasing range of types of feedback, starting with giving further characteristics of the solver response (such as its distance to the correct answer), but increasingly using techniques such as either on request or after a certain number of incorrect responses representing aspects of the question with further visual manipulatives, or asking solvers to make decisions as to the type of help that they would like.

One particular strategy that we are incorporating is to build in a level of direct manipulation feedback in which the solver can choose to see the consequences of their response, often translating an answer into a visual representation such as a graph or other visual model. For example, distances on the Earth may be shown with a model of the Earth cut with a plane at an appropriate distance from a point. One of the aims of such strategies is to increase the ability of the solver to self-assess.

We are finding that, at least for more straightforward questions, our feedback systems may be elaborated in the process of creating the activities as further possibilities occur, meaning that we do not necessarily need to develop our feedback support system in advance, and will be able to adapt and elaborate it further when the activities are field-tested.

We are looking at ways in which solvers can identify the mathematics that they need to solve a particular problem, particularly in problems that can be solved in a variety of ways. The chain letter context introduced above is an example, where a solution might involve dragging icons, multiplying, or using geometric series. The challenge is to direct the solver to the appropriate solution method while at the same time minimizing the amount of structure imposed. A possibility is to create separate problems, such as a situation involving smaller numbers for less advanced learners rather than attempt to address all possible solution methods in one question.

Some of the challenges we face arise from the scope of the project itself. The lack of specific learning goals, for instance, means that we have the temptation to focus feedback on the FT level, which may lead to merely instrumental problem-solving.

A second issue is that instead of giving any explanation of the mathematics required for learners who lack the necessary understanding to solve a particular NS problem we anticipate directing solvers to other sources. A tension is that such sources will use different contexts and hence may not be seen as immediately relevant. One possibility is to create guided discovery environments using the question contexts.

Another issue is that problems are designed to be independent, rather than follow any particular sequence. This mans that all our feedback needs to be problem-specific, and relatively exhaustive: we cannot refer to other problems which may help the solver with the current problem. It also means that there are a large number of content domains to analyze.

Our main challenge is that many of the most interesting and engaging real-world questions involving mathematics are both open-ended in approach and do not have well-defined answers. An example is the NS about the purchase of Manhattan. It is not possible to create detailed intelligent support systems for each of these questions, in which all solver actions could be responded to appropriately by the digital environment, and we are committed to the use of the materials not being dependent on teacher feedback. One possibility is to structure these questions to give specific choices of direction, or specific sub-questions to solve. However, this is likely to defeat the broader aim of enabling solvers to increase their problem-solving skills, a major part of which needs to be the ability to make appropriate choices. We are considering scaffolding the question around the mathematical modeling process, asking solvers to identify what they need to do to formulate a mathematical representation of the real-world situation, use mathematics to derive results, interpret the results in terms of the given situation, and if necessary revise the model (Geiger & Redmond, 2013, p. 121). Another possibility is to ask solvers to self-evaluate and evaluate others through exploring solutions posted to the database by other solvers. Strategies that enhance FR are hence not just desirable, but necessary, as the most informative feedback possible must come from the solvers themselves.

CONCLUSION

The Hattie and Timperley (2007) feedback framework is a useful fit with the aims of the NS project, involving task completion at the FT level, and, at the FP and FR levels, enhanced ability to engage confidently in the processes of mathematical problem-solving and greater awareness of the use of mathematics in the world. Their findings, together with those of others, give us ideas to incorporate, but also remind us that the best feedback to enable our most obvious goal, successful task completion, will also involve enabling the learner to achieve higher-order learning goals.

Cabri's comparatively rich variety of possibilities for student action, interpretation and response means that we have many possibilities for feedback to explore for structured tasks. However, it is not currently possible to develop a full intelligent support system in which all the processes in which solvers engage can be identified and appropriately responded to by the digital environment. We have hence identified FR feedback as critical and are seeking to develop the ability of solvers to self-assess through strategies such as enhanced direct manipulation feedback and comparison of their work with the work of others.

Field testing will commence in May, 2015, and will enable us to evaluate the success of the strategies that we are currently planning.

Learning mathematics through programming: An instrumental approach to potentials and pitfalls

Morten Misfeldt and Stine Ejsing-Duun

Aalborg University, Research Lab: ICT and Design for Learning, Copenhagen, Denmark, misfeldt@learning.aau.dk

In this paper, we explore the potentials for learning mathematics through programming by a combination of theoretically derived potentials and cases of practical pedagogical work. We propose a model with three interdependent learning potentials as programming which can: (1) help reframe the students as producers of knowledge and artifacts, (2) support abstraction and encapsulation, and (3) promote thinking in algorithms. Programming is a topic that has recently gained interest in primary and lower secondary education levels in various countries, and hence a specific analysis of the potentials in relation to mathematics is paramount. Analyzing two cases, we suggest a number of ways in which didactical attention to epistemic mediation can support learning mathematics.

Keywords: Programming, Constructionism, APOS theory, Algorithmic thinking, instrumental approach.

INTRODUCTION

Programming and mathematics are often thought of as strongly connected activities. Partly because of their shared genes – the first computers were conceptualized and build by mathematicians – but also because programmers attend to logic, procedures, and functions in order to obtain their goals. Over the years a number of projects in mathematics education aimed at utilizing programming to obtain mathematical learning goals with the students. The earliest of these projects tended to collapse in mainstream implementation due a complex combination of lacking technological readiness of the school system, teacher competences, and more principal didactical difficulties with connecting programming activities to accepted mathematical curricular goals.

Recently, several countries have included basic programming in the national curriculum. In some of these countries (such as Estonia and France) programming is placed in direct curricular connection to mathematics, whereas in others (England, and Sweden) programming is related more to a design and engineering agenda. However, in all cases the focus is not on developing general "humanistic" skills with technology, rather it is on thinking in algorithms, writing programs, and developing technology. In other countries such curricular changes are being discussed and tested on a small scale. Hence, it makes sense to take a closer look at the arguments that have previously been proposed for utilising programming in mathematics education. In this paper, we will modestly attempt to describe these arguments, however in order to compare and combine previous thoughts on this topic we will employ the instrumental approach to the use of Information and Communication Technology (ICT) in mathematics education. The instrumental approach was developed in a French didactical tradition to meet the challenge that computer algebra systems posed to mathematics education and it has in the last decade become a European mainstream framework for addressing ICT in mathematics education.

In this paper, we investigate the mathematical learning potentials in programming activities by a combination of literature and empirical observations in classroom settings. Furthermore we explore if the instrumental approach can be activated in order to study these potentials empirically. We will describe some of the main intellectual projects and frameworks in mathematics education that used programming as a means to obtain mathematical learning goals. We suggest classifying these projects in three clusters; (1) *viewing students as producers*, (2) *supporting abstract thinking,* and (3) *developing algorithmic thinking*. Using the instrumental approach as theoretical framework we describe two educational situations utilizing pupils' programming activities in order to learn mathematics.

WAYS OF THINKING ABOUT TEACHING MATHEMATICS WITH PROGRAMMING

Investigation the intersection between mathematics and programming has many aspects. Mathematics and logic gave birth to programming with the pioneering work of Turing and others. Furthermore computing is influencing mathematical work in many areas of society. However the interaction between programming and mathematics that we focus on here, relates to curricular activities in primary and lower secondary school and we aim at understanding the potential synergies between learning mathematics and learning programming.

The tools that we choose to bring to mathematics students do influence the learning of mathematics that becomes likely or possible (Guin et al., 2005, Ainley, Pratt, & Hansen, 2006). And in that sense bringing programming into mathematics teaching does support certain types of learning. Bringing programming into the classroom with the purpose of learning mathematics easily leads to a version of the *planning paradox*; the more detailed the teacher articulates the mathematical learning goal, the more difficult it can be for pupils to appropriate programming as a personal instrument (Ainley et al., 2006).

Students as producers: Constructionism and a different mathematics

Serious attempts to use programming in teaching mathematics in primary and lower secondary school started with Seymour Papert. Papert's idea was simple–to create an interactive universe (microworld) that children access through mathematics, which prompts them to think mathematically by embedding nuggets of mathematical knowledge into the microworld that the pupils playfully stumble upon while developing projects.

As a means to obtain this goal, Seymour Papert developed the programming language LOGO, where the child steers a small turtle around the screen with commands such as "forward 10" and "right 90". The turtle can leave a trace allowing the child to create various geometrical figures. Papert's pedagogical strategy, constructionism, suggests that children learn in a particularly efficient way when they are engaged in developing constructs such as beautiful patterns, interactive art, computer games, etc., and in his bestseller, Mindstorms (1980), he describes LOGO as a 'mathematical microworld' that allows children to engage in such projects. The teacher's role in such work is to connect the children's work and intentions to "powerful ideas" from our mathematical heritage (Papert, 2000).

During the 1980s there was great enthusiasm and confidence that LOGO and similar programming languages would radically reform mathematics teaching in primary schools, and the first ICMI study on technology in mathematics education was focussed on how technology influenced mathematics as a topic (Churchhouse & International Commission on Mathematical Instruction, 1986). However, the results in mainstream implementation did not entirely live up to the expectations. There are a number of reasons for the disappointing results; for instance, students easily overlook the nuggets of mathematical knowledge (Noss & Hoyles, 1992, Ainley et al., 2006), making their work in the microworld non-mathematical.

Abstraction and concept formation: APOS theory

The idea that programming could be helpful in mathematics education in the late 1980s also developed in the context of teaching mathematics in high school and college. Here the geometric and artistically framed LOGO program was less popular. On the contrary, teachers often utilized common programming languages such as BASIC, COMAL and PASCAL to support learning. One of the outspoken hopes was to create a process-oriented approach to abstract mathematics, basing abstract constructions in concrete numerical computations. The arguments for this approach were often based in constructivism and radical constructivism, which claims that all abstract learning has a concrete starting point, as well as in the and in the discussions of process-object duality (Sfard, 1991). Ed Dubinsky's work is probably the clearest description of the learning potential of programming (see Breidenbach et al., 1992). His theory is often referred to as APOS theory and it is situated in a radical constructivist framework (Glasersfeld, 1995). APOS is an acronym for action, process, object, and scheme. The theory describes mathematical concept formation as beginning with performing actions on well-understood mathematical objects; these actions can be organized in processes and encapsulated into objects. These objects can be related to one another in schemas. The encapsulation stage is, as famously described by Sfard (1991), crucial and hard. And the schematic aspects of concept formation is similar to Skemp's relational understanding (1971). This rather general learning theory of mathematical concept formation relates to the use of computers because they can significantly empower and enrich the concrete numerical calculations that are – in this conception – the necessary foundation for concept formation.

Process approach to mathematics: Algorithmic thinking

The ability to think in algorithms and procedures is promoted as an important learning goal in mathematics. Algorithmic thinking describes students' ability to work with algorithms understood as systematic descriptions of problem-solving and construction strategies, cause-effect relationships, and events. A recipe is a good example of an algorithm: (1) Add all dry ingredients together. (2) Stir. (3) Add 2/3 cup of the water and stir. (4) If the dough is steady, then stir for 2 minutes. Otherwise, go to step (3) and add more water. Algorithmic thinking is about being able to develop, execute, and make machines to perform such algorithms. Donald Knuth (1985) views algorithms as a crucial phenomenon constituting the intersection between computer science and mathematics. He traces the study of algorithms to the mathematical masterpiece Al Kwarizm from the 9th century (Katz, 1993). Knuth defines algorithms as follows (Knuth, 1985, p. 170):

> I tend to think of algorithms as encompassing the whole range of concepts dealing with well-defined processes, including the structure of data that is being acted upon as well as the structure of the sequence of operations being performed; some other people think of algorithms merely as miscellaneous methods for the solution of particular problems, analogous to individual theorems in mathematics.

Hence algorithms, according to Knuth, consist of both a recipe and the actual objects dealt with by the recipe. Knuth analyzes the difference between mathematical thinking and algorithmic thinking. He finds that a first approximation algorithmic thinking relates to (1) representation, (2) reduction, (3) abstract reasoning, (4) information structures, and (5) algorithms. Mathematical thinking can, according to Knuth, relate to all of these, however other aspects are also present such as (a) formula manipulation, (b) behavior of functions, (c) dealing with infinity, and (d) generalization. Hence algorithmic thinking is strongly related to mathematical thinking but emphasizes specific and slightly different aspects than other types of mathematical thinking.

Before we introduce classroom examples exemplifying these learning potentials, we will introduce the instrumental approach that we use as a general theoretical framework for the use of ICT for mathematics teaching. This framework will be used to analyze the cases and create a connected description of the different learning potentials.

THE INSTRUMENTAL APPROACH

The instrumental approach (Guin, Ruthven, & Trouche, 2005) addresses students' use of technology when learning mathematics from the perspective of appropriating digital tools for solving mathematical tasks. It builds on (Verillon & Rabardel, 1995), and views computational artifacts as mediating between user and goal (Rabardel & Bourmaud, 2003). The approach presupposes a continuation and dialectic between design and use, in the sense that a pupil's goal-directed activity is shaped by his use of a tool (this process is often referred to as *instrumentation*), and simultaneously the goal-directed activity of the pupil reshapes the tool (this process is often referred to as *instrumentalization*) (Rabardel & Bourmaud, 2003, p. 673). In students' work with technology the distinction between *epistemic mediations* and *pragmatic mediations* (Guin et al., 2005; Rabardel & Bourmaud, 2003) operationalize the difference between learning with technology and just using technology to solve tasks. Epistemic mediations relate to goals internal to the user – affecting his or her conception of, overview of, or knowledge about something Rabardel & Bourmaud (2003) use the example of a microscope, and Lagrange (in Guin et al., 2005, ch. 5) refers to experimental uses of computers) and pragmatic mediations related to goals outside of the user – making a change in the world (Rabardel & Bourmaud use the example of a hammer, Lagrange (in Guin et al., 2005, ch. 5) refers to the mathematical technique of "pushing buttons"). Finally, Rabardel & Bourmaud (p. 669) introduce sensitivity to a broader conception of the *orientation* of the mediation. Instrumented mediations can be directed towards (a combination of) the objects of an activity (the solution of a task), other subjects (classmates, the teacher), and oneself (as a reflective or heuristic process). Hence the theoretical framework consists of the concepts: *instrumental genesis*, as consisting of *instrumentation and instrumentalization*, the concepts *epistemic* and *pragmatic mediations*, as well as a sensitivity towards the *orientation* of an instrumented mediation. The orientation of the mediation can be towards oneself, external objects, and other subjects.

EXAMPLES OF LEARNING MATHEMATICS WITH PROGRAMMING

These classroom observations are taken from the project *Children as Learning Designers in a Digital School*. The project is the realization of a research call from the Danish Ministry of Education. The research project is directed toward the area students own production and student involvement (Levinsen et al., 2014) and it explores:

1) How students' digital production impact on learning processes and the qualification of learning results regarding subjects and trans-disciplines; and

2) How ICT involves designs for learning that allow students to act as learning designers of their own learning practice in terms of form, framing, and content on their learning, engagement, and motivation.

The project comprises of a number of interventions in different schools. The examples in this paper come from a mathematics class where children in 5th grade (approximately 11 years old) program games for peer pupils to play and discuss using iPads and the software program Hopscotch. We present two activities that we suggest are related to the three different learning potentials described earlier.

Creating a good game: "It has to be fun"

The first example relates directly to the students' potential as artifacts producers. Oliver is trying to solve a problem–he wants to move his figure using tilt (i.e., by tilting the iPad). He asks the others for help. Instead of suggesting a solution, Ally asks him, "Why aren't you just tapping it?" Oliver answers, "Because it's a game, Ally. It should be fun."

The motivation for Oliver is obviously that the game he creates should be fun. Programming is merely a means for obtaining that goal. Throughout the course of the intervention Oliver gets really far in the process of making games. He is very independent and on his own he examines other games in order to, e.g., make points.

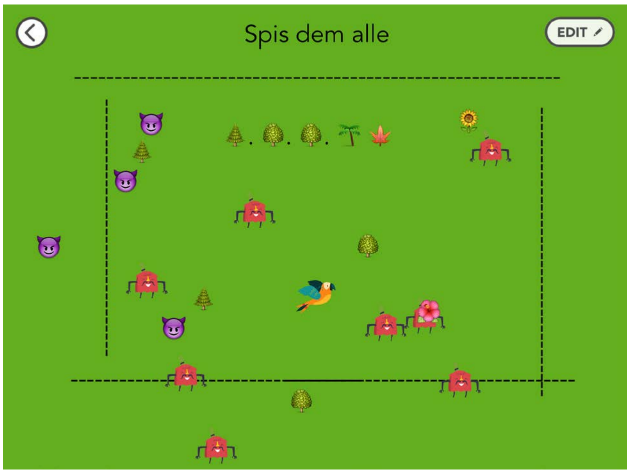

Figure 1: Oliver's first game, "Eat them all". The player controls the parrot by tilting the iPad. The goal is to eat the toasts and avoid the purple devils

For the same reason – wanting to develop good games – more pupils want to make countdowns, scoring systems, control with arrows, etc. They know the game genre well and what is needed to make a good game. These elements can only be done using variables. Despite the lack of algebra knowledge (algebra is considered "above their level" in the school), half the class voluntarily and with a high level of focus attends as the teacher demonstrates how to use algebraic concepts (variable and coordinate systems) to make an arrow control. In order to move one object (e.g., the avatar) by touching another object (e.g., an arrow) the pupils need to make a move-variable. Despite the emergence of this rapid algebra course, the pupils are not working with a task defined by the teacher. The teacher has merely defined a frame, "make a game", and the pupils themselves start defining tasks within it.

From an instrumental perspective the pupils' interest in understanding the mathematical concepts that the teacher are oriented towards can be viewed as a pragmatic end of creating a good game. Such an end is indirectly oriented towards peer students as players of their games. Obtaining the pragmatic goal of creating a game does require students to obtain epistemic goals – in this case about variables and the coordinate system – as sub-goals along the way. But understanding and acknowledging that there are mathematical sub-goals might not be so easy. In this case, mathematical sub-goals are strongly supported by the teacher's choice to create a "what kind of math do I need in order to make my game" crash course, deliberately focusing the pupils' attention on the mathematical aspects of creating arrow control and scoring systems.

Thinking in algorithms

The second example we initially see as relating to algorithmic thinking, but also to using programming as a way to support later abstraction and reification. The activity is introductory (just after the teacher has introduced the course structure and learning objectives). In plenary, the pupils and the teacher program a small cardboard figure that the teacher has set up on the whiteboard. They decide to call him 'Puff'. The teacher challenges the pupils by asking how to make Puff do various things and the following dialogue happened (translated from field notes):

Teacher:	Puff can only speak mathematics. How can I make him go right?
Zack:	Go right.
Teacher:	He does not know how far he should go.
Marc:	Go 2 centimeters to the right.
Teacher:	Yes, but unfortunately he does not know centimeter on the screen.
Austin:	Displace two units to the right.
Teacher:	Yes, units he understands. But he does not know what right is.
Ann:	You must move to a coordinate.
Oliver:	If he should go to the left, then: Go -3.
Ann:	Could you get him to go to a coordinate?
Teacher:	Yes, he would go there–but he would then fly around.

The teacher demonstrates her point by moving the cardboard figure from one point to another instead of sliding between points. She then shows how moving with a positive number makes Puff go right and negative number, as suggested by Oliver, will make him move left. After some discussion the teacher raises another issue:

Teacher:	They [the sprites in Hopscotch] are ego–they see the world from their own noses. How do you think he can go downwards?
Girl:	I am just guessing...can he rotate degrees?
Teacher:	Yes he can.
Zack:	Rotate 90° clockwise.
Teacher:	Now, you have to try programming each other. Give each other a rule and a signal. Use rotation and units. Make a square by controlling the other orally.

Pupils work together in pairs. They try to control each other. Zack and his teammate come over to the teacher and are frustrated. Zack says that he does not know which way to turn when she just says "turn 90° degrees". His teammate complains that he "just lies down on the floor" instead of moving around. The teacher talks with them about being precise and setting an x- and y-axis on the floor.

This example shows how pupils struggle with translating programming the figure on the whiteboard, which has two dimensions, to programming each other in three dimensions. Zack understood that the language should be precise, but he also teases on purpose. Several pupils have this kind of negotiation with mathematical concepts (turning, coordinate system, etc.), but some are also getting away with just saying "turn 90 degrees right/clockwise" without their partners correcting them. Those who are being controlled sometimes find that if they follow the instructions they end up walking into things, especially as the units are not precisely specified. Most use one step as a unit, some are using one foot as a unit.

By having pupils translate the programming activity to a classroom situation the teacher promotes reflection on the relationship between spatiality and algorithms. Another consequence of having pupils mediate programs by playing roles is that they get an understanding of what precision means. After this introduction the pupils described programming as a mathematical language that you 'speak'. From an instrumental perspective, the pupils here aim at affecting other subjects directly through programming and it has the effect that they negotiate what a good algorithm is and what it means to be precise in such instructions. It is a classical point that learning to program can benefit from attempting both to act as the creator of algorithms and as the performer (this is described as "playing turtle" by Papert, 1980). But it is interesting that the pupils' negotiation of the instructions is resolved by the teacher through introducing mathematical concepts (the 2-dimensional coordinate system). The teacher consistently introduces the solutions to pupils' problems in mathematical terms; this seems like a strong didactical strategy that supports the pupils talking and thinking about mathematics when they work.

THE CHALLENGE OF MAINTAINING AN EPISTEMIC FOCUS

In this section, we will discuss whether the mathematics learning potentials that have previously been suggested in the literature about programming and mathematics education can be viewed as genuine mathematics learning potentials in the sense that they involve epistemic mediations towards mathematical concepts. It is obvious from the cases that the pupils need help with mathematical concepts when they try to appropriate a programming language to develop their games. The two examples show how such situations can facilitate the engagement with classical mathematical concepts such as numbers, the coordinate system, and orientation/angles. In both cases the pupils interact with the teacher, each other, and games developed by others in order to handle the challenges. But one can discuss whether the overall pragmatic purpose of improving their skills with Hopscotch and potentially making a better game support or hinder the pupils' epistemic focus on mathematical concepts. The analysis shows that it is – in these specific cases – not reasonable to disregard this as only a pragmatic mediation with little educational value. But this could very well have been the case if the teacher had not been so careful in attracting the pupils' attention to explicit and relevant mathematical ideas. However, the pupils also bring in mathematical ideas (for instance, about angles) without being prompted by the teacher. Hence it would be meaningful to investigate further how the classroom norms and shared ideas about mathematics (the sociomathematical norms discussed by Cobb, Stephan, McClain, & Gravemeijer, 2001) affect the mathematical value of introducing programming.

By using the instrumental approach it is apparent that pupils' epistemic relation to mathematics is necessary for programming to be successful in mathematics education. We see several ways that this epistemic relation can be strengthened or hindered. The teacher did acknowledge and talk about the different goal-levels of an activity; this allowed her to talk directly about mathematical goals, even though these where sub-goals of the larger goal of creating a good game. Constantly focusing attention on mathematical concepts as problem solvers and conflict settlers were also actively applied by the teacher, especially when the pupils programmed each other. When the pupils are either negotiating or in cognitive conflict, this teacher turns to mathematical concepts and principles as part of the way forward for the pupils. In that sense our analysis suggest that the potentials for learning mathematics through programming, as previously described in the literature, depends largely on the teacher's approach and didactical principles.

Reasoning with dynamically linked multiple representations of functions

Guido Pinkernell

University of Education Heidelberg, Heidelberg, Germany

In video-taped interviews, teacher-students were asked to describe and explain effects of a parameter a on the standard representations of $f(x)=x^2+a$ in a computer based dynamic learning environment. An analysis of one particular interesting yet typical misconception leads to differentiating between surface perception and structural insight. Theoretical considerations based on Duval and Davydov lead to postulating that for a full understanding of the relation between a and $f(x)=x^2+a$, a learner needs to identify to structural analogies between the representations of f. A qualitative analysis of further interviews results in a category model of student responses that can be used for diagnostic purposes.

Keywords: Multiple representations, functions, abstraction, ICT, qualitative analysis.

INTRODUCTION

A typical task connected with the use of mathematical software in classroom is to explore the relations between the standard representations of functions. For example, pupils could be asked to explore the effects of a parameter a in $f(x) = x^2 + a$ on the shape and position of the graph of f by means of a dynamically linked multiple representation learning environment, where the value of a is controlled by a slider (Figure 1).

Usually, it seems sufficient to observe that changing the value of a causes the parabola to move upwards while a gives the distance. But is it really as simple as that? Just describe what seems, literally, obvious?

Duval (2002) argues that for showing a full understanding of the concept of function, a learner needs to be able to change within and between various representations of a function, for example, equation, table and graph. This means that properties of one representation are explained by properties of another. If a learner is not able to perform such a change then, following Duval's rationale, he does not understand to the full extent, even if his observations within one representation appear to be perfectly valid.

This article begins with a case study that illustrates Duval's concept of understanding functions. A student describes the effects of the parameter a on the graph of $f(x) = x^2 + a$ (Figure 1). She then realises that one of her observations contradicts what she has learned about how graphs and equations connect, but she is not able to resolve this contradiction. She knows a lot, yet she does not quite understand.

So it appears that learning about functions based on visual perception only is not sufficient. For developing a sound understanding a learner needs to turn his attention from the visual properties of the different representations to structural analogies between them. These analogies do not equate to perceivable similarities between the representations. For identifying structural analogies one needs to "see through" the specific appearance of each representation. In this sense, the identification of structural analogies is a form of abstraction. Hence this article then turns to the concept of learning by scientific abstraction by

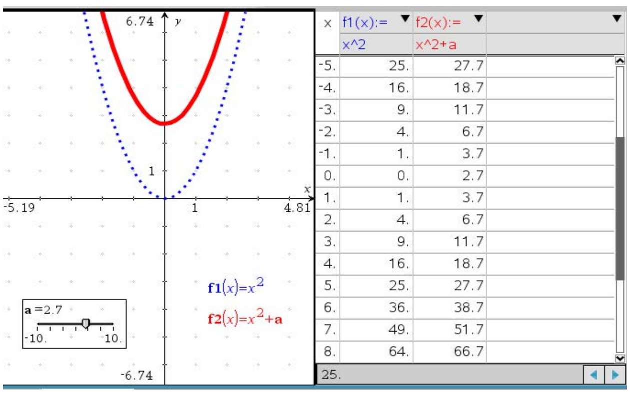

Figure 1: Dynamic multiple representation environment for exploring the effects of a on the representations of $f(x) = x^2 + a$

Davydov (1972). It serves as a suitable theoretical basis for justifying the postulation that learners need to refer to a structural level.

When theoretical considerations lead to expect that learners behave in a specific way then we must be certain that they are able to do so. The last part of this article reports on a qualitative analysis of further interviews with teacher-students where three categories of understanding could be identified, among them references to structural analogies between representations as required by theory.

A CASE STUDY

In videotaped interviews, teacher-students of the University of Education Heidelberg were given the task as shown in Figure 1. They first were asked to describe the changes within graph, table and term when the slider is operated. Then they were asked to explain why they thought their descriptions were correct. One student described the effects of the slider as both a translation and a change of shape:

1 Student: [moves slider to the right] well the parabola moves upwards along the y-axis ... the um how is it called the width [moves both palms repeatedly towards each other as if clapping hands]
2 Interviewer: yesyes, ok
3 Student: changes ... anyway when one moves it to the right ... towards the positive ... [moves slider to the far right such that the parabola nearly vanishes from the screen] ... and when one moves it downwards to the negative [moves slider to the left such that the parabola's vertex nearly touches the lower screen edge] and here the parabola becomes wider but still opens upwards
4 Interviewer: can you explain why the parabola moves up or down when one changes the slider value [points at the slider with a pen]
5 Student: [looks a the slider, murmurs] hm what is a ... what ... is a [leans back, talks louder] a is ... a was something ... a is ... the y-direction
6 Interviewer: ah
7 Student: when I ... upwards ... well then it is not a normal parabola any more then it is, like, somehow narrower

When asking the student to explain her observations (line 4) the interviewer, who is the author of this text, ignores that she describes the effects of a as a translation as well as a change of shape of the curve (lines 1 and 3). The student answers by referring to knowledge about the effects of a she probably had acquired at school (line 5). But, again, she immediately points out that the curve looks shrunken (line 7). This seems to be a problem for her as it conflicts with what she has learned about parameters and graphs (meanwhile the value of a has been set to 1):

8 Student: this is simply a normal parabola that has been moved upwards by one, but the width changes too.
9 Interviewer: why do you say 'but'?
10 Student: the parabola does not move upward only but it becomes narrower too, and then there should be something in front of the [x] squared
11 Interviewer: ah, why?
12 Student: because that's how I learned it

That the parabola has been reduced in size is, with respect to the algebraic structure of x^2+a, wrong. The student is aware hereof since she expects a factor in front of x^2 (line 10) which could explain that the curve's shape seems changed. Yet, considering her descriptions of the effects on the graph only, she proves to be a careful observer. The parabola does appear to be shrunken (Figure 2).

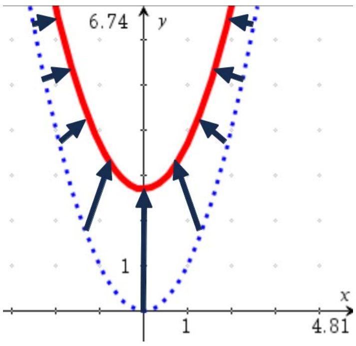

Figure 2: Moved upwards only or shrunken too?

The student realises that her description contradicts what she knows about the effects of a parameter change on the function graph. To resolve this contradiction she needs to explain the effects of a on the graph by means of the specific algebraic properties of the equation, i. e. she needs to perform a coherent representation change. This is achieved by considering the additive structure of the expression x^2+a:

Every single value of $f(x)=x^2$ is increased by a, so each single point $(x|x^2+a)$ of the parabola has been moved upwards from its original position $(x|x^2)$ by a, which affirms that the effect of a can only be interpreted as a vertical translation. So a valid interpretation needs to be based on an analysis of the term structure. Hence algebra plays a decisive role for describing and explaining relations between parameters and functional representations. When a learner describes the effects of a parameter change without giving a sufficient explanation on the base of the algebraic representation it is not clear whether his descriptions are based on his visual impressions only or whether they are based on a structural insight into the situation. This is particularly problematic when these descriptions fulfil the expectations of the teacher: If a learner only mentions a vertical translation by a, does he just reproduce what he sees, or does his description reflect an understanding of the `mechanism´ of how a affects each representation of x^2+a? One risks confusing a correct verbal description with an understanding of the situation, pupils as well as teachers.

Referring to possible restraints of the tool and its use – e.g., lack of visual aids or failing to adjust the window – misses the point this article is trying to make. The fact that misinterpretations can appear indicate a fundamental difference between a concept and its representations. A learning environment with a "perfect" design that avoids misinterpretations does not guarantee that a learner understands how the different representations interact. While giving all the correct answers, he might only reproduce what he sees on the screen, thus confusing the concept with its representations. Each learning environment needs to activate the learner's reflection (Yerushalmy 2005), which means – as it is argued here – that he turns from describing perceptually accessible properties of each representation towards analysing analogies between the three representational forms on a structural level.

UNDERSTANDING MULTIPLE REPRESENTATIONS BY ABSTRACTION

Does the student from the case study understand the effects of a on the representations of x^2+a? She gives a careful description of what she sees on the screen. And she knows, too, how the effects of a parameter on a function graph can be read from a given equation. But she cannot resolve the conflict between her observations and her knowledge. In this sense, she shows a lack of understanding.

So what does she – or a learner in general – need to achieve so that he or she shows a full understanding of the relation between parameters and the representations of function? Giving a description of his observations only is not sufficient as we have argued, even if the description is correct. He needs to give reasons for why his observations are valid, i.e., why they are consistent with the whole of the multiple representation environment. Reasoning by referring to well-known rules might be acceptable, but in the case of the student more was needed to clarify the conflict between what she saw and what she knew. It would be helpful to explain the mechanism of how a and representation of x^2+a connect. This means to refrain from reproducing visual information but to analyse analogies between the representations on a structural level. Focussing on structures instead of surface leads to a cognitive activity that is central for the learning of mathematical concepts: abstracting.

In the context of learning with a dynamic multiple representation environment abstracting means extracting the essential information from representations by conceiving structural analogies between representational forms while eliminating irrelevant surface properties. By referring to the concept of scientific abstraction by Davydov (1972) and others we will show that conceiving structural analogies is achieved by identifying invariants in the dynamic multiple representation environment while the structure of the algebraic representation is decisive.

Mathematical concept formation as the result of abstraction

Mitchelmore and White (2007) identify two different approaches to abstraction among theories of mathematical learning, which they call empirical and theoretical.

Empirical abstraction refers to a cognitive representation of knowledge that results from identifying common properties in a set of examples. "Abstracting is an activity by which we become aware of similarities [...] among our experiences. [...] An abstraction is some kind of lasting change, the result of abstracting, which enables us to recognise new experiences as having the similarities of an already formed class" (Skemp 1986). However, empirical abstraction that is limited to a perceptual analysis of real or cognitive objects can hardly explain the formation of such concepts that meet the scientific requirements of generality and precision. Hence, for the formation of a scientific concept, a theoretical basis is needed which supports argumentation that is independent from perceptual evidence.

Theoretical abstraction: To be valid beyond experience, knowledge needs to be developed within a theoretical system of its own, which comes with specific symbolic representations and rules of argumentation. Following Vygotsky (1934/1986), this symbolic representation form does not need to resemble any physical features of the knowledge that it represents. In fact, perceptually or otherwise empirically accessible properties are unsuitable for forming an abstract concept. "A theoretical idea or concept should bring together things that are dissimilar, different, multifaceted, and not coincident, and should indicate their proportion in the whole [...] Such a concept, in contrast to an empirical one, does not find something identical in every particular object in a class, but traces the interconnection of particular objects within the whole, within the system in its formation" (Davydov 1972/1990, 255).

For continuing our case analysis the concept of theoretical abstraction – or "scientific abstraction" as Davydov puts it (1972/1990) – appears to be suitable: The effects of a on x^2+a can be described as a function $a \rightarrow x^2+a$, which is a function different from f. Its properties can only be derived from changes within the representations of f. The change within the graphical representation of f appears to be a translation and a dilation, here the student is perfectly right. To decide whether this interpretation conforms with the rest of the multiple representation environment, the algebraic expression of $a \rightarrow x^2+a$ needs to be taken into consideration. Its additive structure decides which of the two interpretations of the effect of a on x^2+a is valid. So it is knowledge about symbolic algebra that forms the necessary theoretical basis for understanding relations between the multiple representations of a dynamic learning environment. However, the student is not able to apply her knowledge about algebra to explaining how, or whether at all, her descriptions are valid for the whole of changes within the multiple representations of $f(x) = x^2+a$.

Abstracting as conceiving structural analogies

In a teaching concept of "ascending from the abstract to the concrete" based on Davydov, Giest (2011) states that, with each new learning process, "initial abstractions" are gained from examining a learning material that allows change and variation. From varying the material, invariants become apparent that initiate the necessary reasoning for identifying a constant structure within change. With a dynamic multiple representation environment (e.g., Figure 1) the necessary variation here is twofold. First by operating the slider, thus changing the visible appearance of each representation and second, by switching between the three representation forms. These changes correspond to Duval's (2002) forms of representational changes that characterise a full understanding of the concept of function.

Obviously, the student from the interview meets the first of Duval's requirement at least partially. Within the graphical representation, she gives two pertinent interpretations of the effects of the parameter change on the actual function graph, and from the algebraic representation she can read correct information about the effects of parameters on function graphs in gene. But she does not fulfil the second criterion of Duval. She is not able to make a coherent change between the algebraic and the geometric form of representation here. Or to say it with Giest: She is not able to identify the necessary invariants within the multiple representation environment.

Conceiving structural analogies as identifying invariants

In Figure 1, the invariant in question is not visible, it becomes apparent as changes between and within representational forms. Considering the additive structure of the term of x^2+a, the invariant is characterised by the common operator $+a$. In the equation, the invariant is the summand $+a$ that redefines $f1(x)=x^2$ to $f2(x)=x^2+a$ (Figure 3). In the table, the invariant is the constant difference between the values of $f1$ and $f2$ in all table lines. In the graphical representation, the invariant is the constant vertical distance between the two graphs of $f1$ and $f2$, which is the same at all points. Thus, the invariant has a specific meaning in each representation form, yet, in each form, it can be visualised by an arrow with constant direction and length. Especially the arrows from the geometric representation form show that the effect of a on the graph of x^2+a must be interpreted as a translation only.

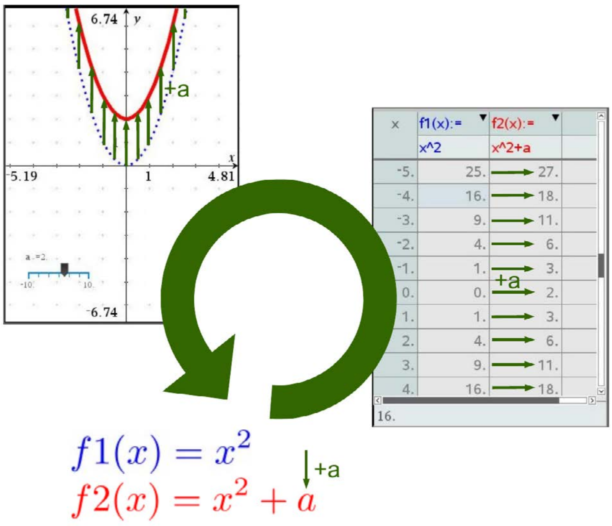

Figure 3: The invariant + *a*, identified in all three representation forms, shows that the effect of *a* on $x^2 + a$ is indeed a translation

We can sum up now: To show understanding of the relation between a parameter *a* and the representations of *f(x)+a* a learner needs to identify the operator *+a* as an invariant within each representation and between all representation forms of *f*.

This seems expecting much from pupils. However, next we report on a study where references to structural analogies in further interviews could in fact be identified.

CATEGORIES OF REASONING: AN INTERVIEW STUDY

Aim and methods

Together with the interview from our case study further interviews were analysed with the aim of categorising students' answers regarding to what extent they showed structural insight into the relations between graph, table and term of *f*. The interviewees were teacher-students of the University of Education Heidelberg from their first to their third year of study, all having selected mathematics as one of their compulsory subjects. The interviews contained questions about various tasks about for exploring the relation between parameters and quadratic functions. The task from Figure 1 was the first. All were accompanied by dynamic multiple representation learning environments, prepared in advance by means of the TI-Inspire CAS software on a laptop. Apart from two questions – the initial one that asked for a description of how the given parameter affected the appearance of graph, table and equation and one that asked the students to explain why they thought their observations were correct – no other questions were fixed in advance.

From the case study and subsequent theoretical considerations above, two a-priori categories were formulated, "reason with reference to a rule" and "reason with structural reference." Roughly, the first comprises all statements where students refer to what they have learned and believe to be generally true, while the second covers all statements that refer to invariants as described above. A refined definition will be presented in the results section. The research questions were as follows:

(A) To what extent can the descriptions and explanations from the interviews be assigned to the two a-priori categories?

(B) How did interviewees exemplify reasons with structural reference?

For the analysis, six interviews were selected which, on first view, promised a sufficiently large range of students' observations and explanations. The categories were developed by means of a qualitative content analysis (QIA, Mayring, 2010). The QIA is a systematic method for text analysis guided by pre-set coding rules. In the variant of the deductive category application these coding rules are derived from the relevant theoretical framework, which then are applied repeatedly by trained coders with the aim of refining the rules by enhancing inter-subjective comprehension. The coders were three teacher-students who did not take part in the interviews selected for coding. As mathematics students they were able to understand the specific terminology of coding rules while, as students, they still relied on a very precise formulation of the rules to agree on common coding.

Results and discussion

Apart from the two a-priori categories two more emerged from the coding process. First a category "proposition" that separated observations prompted by the interviewer's request to describe from explanations prompted by the request to explain, which often were very similar. For this, the well-known Toulmin model of argumentation was introduced to the coders; the model itself was not object of analysis here. Second a category "reason with reference to an example" which became necessary to allow for reasons that explained rules by referring to single values of *x* or *a*, mostly *x=0* or the actual value of *a*. Eventually, the third and most successful coding round in terms of intercoder reliability was based on the following rules:

- Category A "Proposition": All statements or gestures that can be seen as answers to the interviewer's initial prompt "Describe what you see when you operate the slider" and that show characteristics of a general rule. They refer to the effects of changes of the slider on the representations of the given function. If the interviewee modifies his propositions later during interview, these modifications are coded within this category too.

- Category B.1 "Reason with reference to a rule": All statements or gestures that can be considered as reasons for the observations assigned to category A or their modifications and that refer to a rule or sound like one. Such rules often refer to connections between the parameter and the curve's shape or position. The statement does not refer to single parameter values but shows that the interviewee implies a global validity. Such rules do not need to be stated explicitly but the interviewee can also indicate that he knows of such a rule (e.g. "that's how I have learned it"). Even when the interviewee shows understanding at a structural level in some other part of the interview, reasons with reference to rules or knowledge are to be assigned to this category.

- Category B.2 "Reasons with reference to an example": All statements or gestures that can be considered as reasons for the observations assigned to category A or their modifications and that refer a single value of x or to the actual value of the parameter or the actual state of the visible graphical configuration. These statements often refer to connections between the actual value of the parameter or a single value of x and the curve's present shape or position. Even when the interviewee refers to rules or shows understanding at a structural level elsewhere, reasons with reference to rules or knowledge are to be assigned to this category.

- Category B.3 "Reasons with reference to structure": All statements or gestures that can be considered as reasons for the observations assigned to category A or their modifications and that apparently refer to an invariant between different representation forms or within one representation. The invariant here is the value of *a* which takes on a specific appearance in each representation: In the algebraic representation it is the summand *+a*, in the numerical representation it is the difference between the old and new

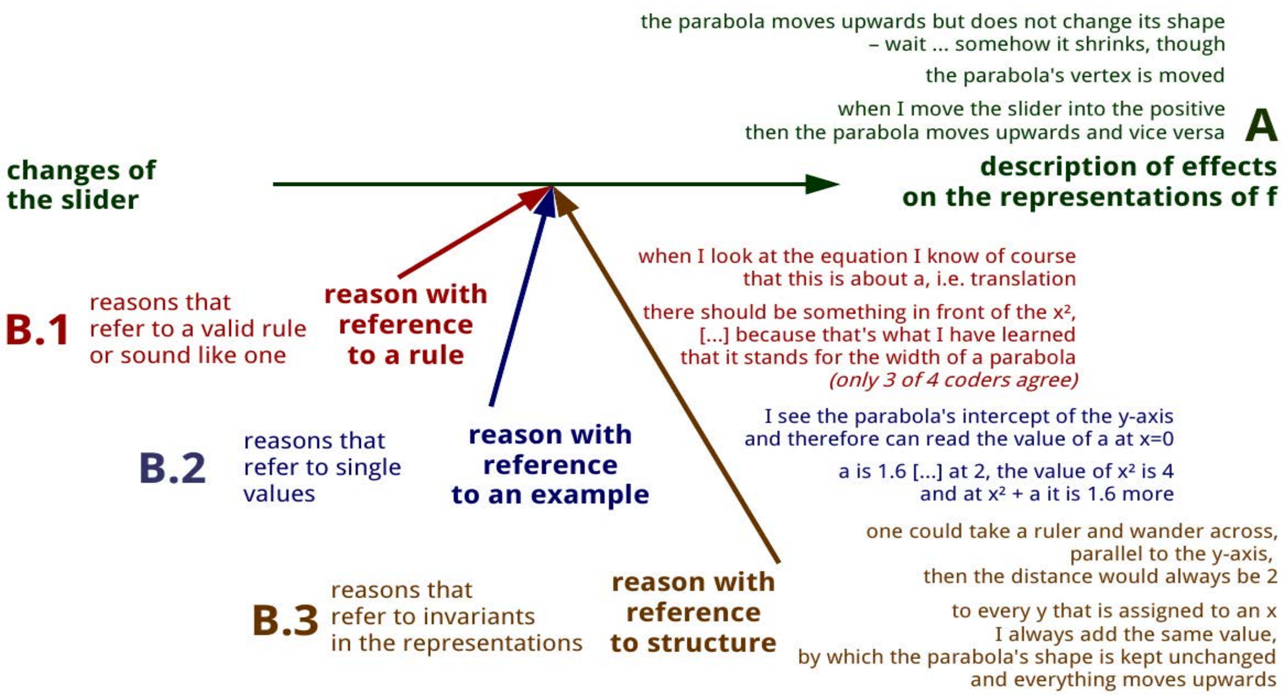

Figure 4: Categories of reasoning while exploring the effects of a parameter *a* on the epresentations of $x^2 + a$ in a computer based learning environment

function value in each table line. In the geometric representation it is the vertical distance between the graphs of both functions at each point. It differs from category B.2 insofar as statements here do not refer to single values of a but to any value of a in general. It differs from category B.1 insofar as a has been globally (i.e., for all values of x) identified within a representation.

The layout of Figure 4 places the four categories at appropriate places within the Toulmin model of argumentation. The proposition (category A) corresponds to Toulmin's "claim" which are descriptions of the effects of slider changes. The three categories of reasoning (B.1, B.2 and B.3) are placed as warrants into the diagram. All categories are illustrated by statements taken from interviews after little linguistic polishing. Generally a statement was considered exemplary when all four coders including the author agreed. One statement for category B.1 is an exception which, to the author, still appears to be a significant example for this category.

For answering research question (A), both a-priori categories were suitable for categorizing students' answers when accompanied by the two more categories as defined by the coding rules above. As for question (B), the two statements cited here indicate a range of possible structural references from evoking dynamic images – here a ruler that moves vertically across the coordinate plane while measuring a constant distance between the two graphs – and a more static view on how the different representational forms connect – here pointing out that, for all x, a is added to the corresponding $f(x)$, which explains the congruence preserving effect of a. The fact that structural references were in fact observable shows that such references can be expected from students. However, these statements also show that references to structural analogies between representations do not need to be as formal as indicated above. The "moving ruler" argument is a convincing example.

The category system from Figure 4 covers responses from the case $a \to x^2 + a$ only, where the invariant is easily identified as the constant vertical distance between the two curves or the constant difference between the two function values, each illustrated by an arrow with constant length (Figure 3). With parameters in other places of the algebraic expression this is different: For example, with $b \to b \cdot x^2$ or $c \to (x + c)^2$ other (mis) interpretations of the effects of the parameter can be expected. However, while coding rules need to be adjusted to these cases, the need for a structural reference still holds on theoretical grounds.

Prospects and consequences

Presently, standardised interviews are being developed for diagnostic purposes based on these results. Apart from diagnostic use, these results may be significant for classroom teaching too. Nearly all students and, in recent interviews, pupils reported that they had little, if any, experience with computers in school. Many were not able to explain the movements on screen which, to them, were totally new. These results plead for an extended use of dynamic software in mathematics teaching. In a dynamic environment, insufficient conceptions about function representations become apparent and can be dealt with openly. Last, these results show that, for an exploratory learning with computer based dynamic multiple representations too, a sound basic knowledge in algebra is necessary. Knowledge about term structure turns out to be essential as it plays a decisive role when validating the explorations.

Looking for help on the Internet: An exploratory study of mathematical help-seeking practices among Mexican engineering students

Danelly Esparza Puga[1] and Mario Sánchez Aguilar[2]

1 Autonomous University of Ciudad Juárez, Juárez, Mexico, danelly.esparza@uacj.mx

2 National Polytechnic Institute, Ciudad de Mexico, Mexico

We report an exploratory study focused on identifying some of the Internet resources used by Mexican engineering students when they need help for their mathematics studies. The study consisted of an initial phase in which a questionnaire was designed and piloted, and a second phase in which such questionnaire was used to conduct individual and group interviews. The results show that looking for mathematical help on the Internet is a widespread practice among students and it is even preferred over traditional sources of help such as the library. Among the most widely used resources are YouTube and Facebook. These and other sites are used to find different ways to solve a problem, to clarify doubts and reinforce knowledge, to get ready-made results, to compare results, and when they skip class and need to catch up.

Keywords: Mathematical help-seeking, Internet resources, social networks.

INTRODUCTION

The phenomenon of help-seeking has captured the interest of sociologists and social psychologists for decades. Generally speaking, these studies have focused on identifying and explaining what demographic, sociocultural, and psychological factors encourage people to seek the help of others. These studies have been conducted mainly in medical, work-related, welfare and social security contexts (see, for example, Cornally & McCarthy, 2011). Early conceptualizations of the concept of help-seeking favoured a perception of it as an undesirable activity, that is, some researchers began to interpret help-seeking as an indicator of lack of independence, which can have high costs for individuals' self-esteem and sense of competitiveness (e.g., Shapiro, 1978). The reconceptualization of the concept of help-seeking provided by Nelson-Le Gall (1985) contributed to assign a positive meaning to the concept in the field of educational research; this in the sense that seeking help can be seen as a useful skill or competence for students to address problems that otherwise would be difficult to address. Help-seeking can be seen as a useful skill for students' self-learning.

Looking for help (or help-seeking) refers to the process of trying to find support from the people and resources around us, when we have questions or need help related to our mathematics lessons. Looking for help is a basic process when studying mathematics, however, the studies addressing help-seeking practices in mathematics instruction are still scarce. Some of these studies have focused on identifying affective elements that motivate students to seek help or avoid it (Ryan & Pintrich, 1999), while other studies have characterized seeking behaviours displayed by mathematics students (Kempler & Linnenbrink, 2006), there are also studies investigating mathematics teachers' knowledge of students' help seeking behaviors when they solve mathematical word problems (Marais, Van der Westhuizen, & Tillema, 2013). A common feature of these studies is that the only considered sources of help are people —teachers, classmates— but technological resources are not considered as potential sources of mathematical help.

Contemporary students' help-seeking practices, however, are changing due to the pervasiveness of the Internet and mobile electronic devices; for instance, there are studies showing that mathematics students from different regions of the world use open online forums to find mathematical help (Puustinen, Volckaert-Legrier, Coquin, & Bernicot, 2009; van de Sande, 2011).

Both studies, by analysing students' exchanges and posts, focus on characterizing the help seeking behaviours that mathematics students manifest when they look for help in open online discussion forums. There is a need for more studies showing what other technological tools mathematics students use nowadays as sources of help and how they use them.

In this paper, we report an exploratory study focused on identifying the Internet sites and web-based tools that some Mexican engineering students use as a source of help for their mathematics lessons. In particular we explore three aspects of their Internet-based help-seeking practices:

1) What sites or tools do they consult when they need help in mathematics and how often do they use them?

2) What are the reasons that lead them to use those sites?

3) What are the reasons why students trust in the information provided by such websites?

The motivation for this study comes from trying to understand how Internet resources are affecting the study processes of contemporary mathematics students: how and why today's students use the Internet to support their mathematical studies? Our study is relevant to the area of research focused on students' learning of mathematics with resources and technology as it helps to expand our understanding about how students independently use the Internet (web-based tools, social networks) as a source of help for their mathematical studies.

CONCEPTUAL FRAMEWORK

As we mentioned before, help-seeking in mathematics education is usually conceptualized as the ability of a student to rely on people —teachers, classmates, relatives— to get help that could be useful to overcome the difficulties that arise when learning mathematics. Karabenick and Puustinen (2013) confirm this when they point out how educational research on help-seeking has focused primarily on interactions in the classroom where students ask for help to the teacher or their classmates. These authors raise the need to expand this area of research in order to understand how new technologies are affecting students' help-seeking practices.

Following the line of thought of Karabenick and Puustinen (2013), in this work we adopted a wider definition of help-seeking in mathematics that includes non-human elements as possible sources of help; thus, in this study, mathematical help-seeking is defined as the ability to use the people and resources around us (including technological resources such as the Internet and mobile devices) as sources of help to overcome the difficulties and doubts that arise during our mathematics learning process.

CONTEXT

The study was conducted at the Institute of Engineering and Technology of the Autonomous University of Ciudad Juarez (UACJ) of Mexico. The Institute is a public institution of higher education that is located in the city of Ciudad Juarez, on Mexico's northern border, south of the city of El Paso, Texas, in the U.S. The Institute has an approximated population of 4,500 students from this area and with socioeconomic backgrounds ranging from medium to low.

One reason for selecting this institution for developing our study was our interest in exploring the Internet-based help-seeking practices among tertiary students. An additional reason for selecting the UACJ was that the first author of this paper works as a teacher at the institution, so this gave us access to both the students and the university facilities to conduct the study.

STUDY POPULATION

Undergraduate students who met two conditions were selected for the study: first, they were taking at least one course in mathematics at the time of the study; and second, they wanted to participate in the study voluntarily. The study involved a total of 21 engineering students of both sexes, distributed into two phases: an initial-exploratory phase and the second phase of the study. More details on the structure of these phases are found in the section "procedure".

All the participants in the study were students from different engineering specialties at the UACJ. We selected students from different engineering specialties because all of them were taking several mathematics courses (calculus, differential equations, linear algebra) as part of their engineering education. At the time of the study their ages varied between 19 and 38 years.

In the initial-exploratory phase four students from three different careers participated: industrial engineering, digital systems engineering, and electrical engineering. At the time they participated in the study, two of the students were enrolled in their first semester, one of them was in the third semester, and the last one was studying the forth semester (engineering studies at the UACJ last eight semesters).

The second phase of the study involved the participation of 17 students from five different engineering specialties: civil, electrical, biomedical, industrial and mechatronics. For this stage we only selected students from intermediate and advanced semesters (from fourth to eighth semester).

PROCEDURE

As mentioned above, the study was divided into two phases. The study began with an initial-exploratory phase in which a questionnaire of seven open-ended questions was used to guide semi-structured interviews; these interviews were conducted between November the 19th and November the 26th, 2012. The aim of this phase was twofold: on the one hand we sought to confirm the hypothesis that some university students use the Internet when they need help or have doubts related to their mathematics lessons; on the other hand we wanted to assess how well the designed questionnaire worked to generate empirical data, this is, to assess whether the wording of the questions was understood by the students or whether the questionnaire produced the type of information needed to answer the questions raised. Examples of the questions included in the initial version of the questionnaire used in this phase were: have you ever used a website to look for help for your mathematics lessons?, if yes, how often do you use these sites?, in your opinion, what Internet sites or tools are trustworthy to look for help in mathematics and what makes them reliable?

This initial phase allowed us to refine the guiding questionnaire to conduct interviews during the second phase of the study. The questions that constituted the final version of the questionnaire are:

1) Have you ever used a website to find help for your mathematics lessons?

2) If yes, what are the websites that you have used for your mathematics lessons?

3) How often do you use these sites?

4) How do you use these sites for your mathematics studies?

5) Mention the benefits of using Internet sites as a source of help for your mathematical studies at the university

6) Mention the drawbacks of using Internet sites as a source of help for your mathematical studies at the university

7) In your opinion, what Internet site or tool is more reliable and what makes it reliable?

This final version of the questionnaire was used during the second phase of the study to interview 17 engineering students from the UACJ. Five of them were interviewed individually, while the remaining 12 were interviewed through two focus groups of six members each. The second phase of the study was developed on three different days: February the 13th, March the 12th, and June the 26th, 2013. The answers given by these 17 students are the main empirical data on which the results of our study are based. All the interviews, both from the initial-exploratory phase and the second phase, were audio recorded for later analysis and transcription.

To analyse the empirical data consisting of individual and group interviews, it was necessary to repeatedly listen to the audio recordings in order to locate the answers to each of the survey questions, and thus try to make a categorization of the answers. During this process it was evident that some students' responses had common elements, which effectively allowed us to produce a categorization of the data. These results are shown in the following section.

RESULTS

This part of the report refers only to the interviews conducted with the 17 students who participated in the second phase of the study, and is divided into four sections: in the first section, the frequency with which students use Internet sites as a source of mathematical help is presented. In the second section we show the most popular sites among the engineering students who participated in the study. Then the students' perceptions of the benefits and limitations of using websites as a source of mathematical help will be described, and finally the reasons given by the students to trust (or mistrust) an Internet site or tool as a source of help are presented.

Frequency of use of websites
All the 17 respondents reported using at least one website as a source of help for their mathematics lessons. Most students are frequent users since 12 out of 17 respondents reported using these sites on a daily basis, while the remaining five students declared that they use these resources during the weekend.

Popular Internet sites and their functionality
Figure 1 shows the websites and tools most frequently mentioned as a source of mathematical help by the engineering students who participated in the study.

The website most mentioned by the students was YouTube. 12 out of the 17 respondents agree that this is the site they turn to when they need to revise and fully understand the topics covered in class.

Facebook is the second most mentioned site, 11 out of 17 students declared to have used it for their mathematics lessons. They claim that Facebook is a tool through which they can contact their classmates or the teacher to clarify questions about the homework or even logistic concerns (like finding out in which room a lesson will be taught). For example, the student number 2 from the focus group number 1 mentioned the following (all the presented excerpts were translated from Spanish to English):

> *Student 2, focus group 1*:
> [...] I use Facebook with my classmates when I have doubts about what was explained in class, because sometimes when I come home I do not remember what I saw.

The next most mentioned site is Google with six mentions. This is the place where some students start their searches of the topics they want to investigate. Most users do specialised searches in Google Books and Google Scholar to delimit the sites or documents where they want to focus their search.

Other websites such as Wikipedia, buenastareas.com, Yahoo! Answers and Slide Share, and Internet tools such as the email, and the online calculator Wolfram Mathematica, were also mentioned because of the different features they offer, like ready-made answers to their mathematical problems:

> *Student 2, focus group 2*:
> [...] I use Wolfram Mathematica to get the results, but sometimes it is not very reliable because omits a few steps [...]

> *Student 4, individual interview*:
> [...] Sometimes you are given a problem and the answers are already uploaded ... I would use Yahoo! Answers when I am struggling and I feel like oh no [...].

In the category "Others" shown in Figure 1 are included tools such as Skype, and websites like Profesores Universia (http://profesores.universia.es), Vitutor (http://www.vitutor.com) among others. These sites

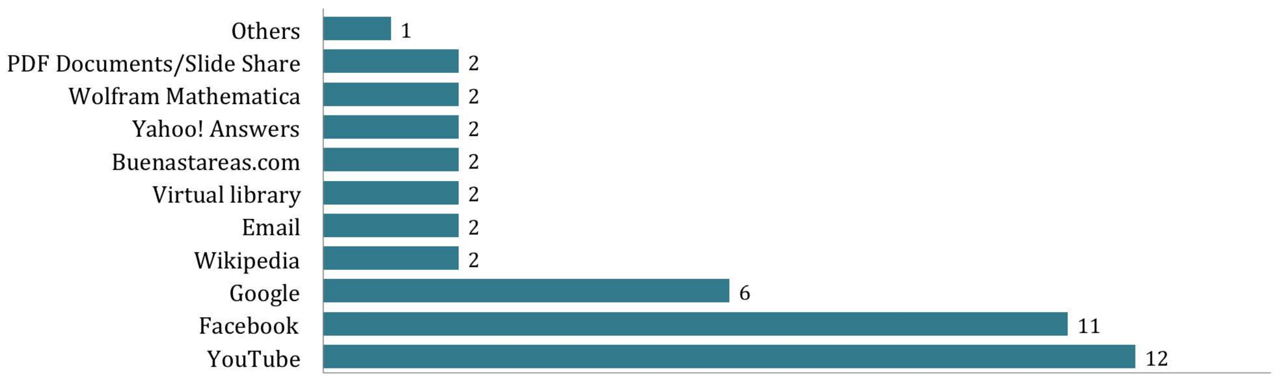

Table 1: Internet sites and tools most mentioned as a source of mathematical help-seeking among the students who participated in this study

are used to find alternate solving methods, comparing results, and finding step-by-step solutions:

> *Student 1, individual interview*:
> [...] There is one called Web Profesores (Teachers Web) which is a site where teachers upload documents or teaching techniques [...] they are written documents [...] once I put a formula that needed on Google and so I got to this page, and there is another one that it is the same... Profesores Universia.

> *Student 5, focus group 2*:
> [...] There is a page called vitutor.com, there are many exercises of many subjects... solved mathematics problems and others to be solved [...] they give you everything step-by-step.

In sum we can say that most of the sites and tools that students turn to are used to: (1) find different ways to solve a mathematical problem, (2) clarify doubts and reinforce knowledge, (3) get ready-made results or mathematical problems solved, (4) compare results, and (5) when they skip a class and need to catch up.

Benefits and limitations as perceived by the students

Students' perceived benefits in using the Internet as a source of mathematical help are diverse. Some students highlight the geographical and temporal unlimited access, making them prefer the Internet over more traditional sources of help:

> *Student 5, individual interview*:
> I think I save... for example, if I go to the library I have to drive... [by using the Internet] I save time and money.

Some students perceive the Internet as a source of help to clarify doubts that is infallible, as stated by this student:

> *Student 3, focus group 2*:
> The benefit that I find is that anything that I look for, I will find it; I get thousands of pages and I will always find something, I will never be in doubt.

Furthermore, we identified four limitations that the interviewed students expressed, these are: (1) restricted access to the sources due to copyright and/or language, (2) lack of reliability of the sources, (3) the Internet can function as a distractor, and (4) there is too much information on the web. To illustrate these limitations, next we present a few excerpts from the interviews:

> *Student 6, focus group 2*:
> The problem is that unless you know what you are looking for, you get very vague answers, there is ambiguous information and copyrights are regulated on the Internet, if you want to read a book you can only see part of it [...] the useful material is restricted.

> *Student 5, focus group 2*:
> It happened to me once while I was studying for an exam, there was a topic that I knew nothing about [...] I found a method that had nothing to do, it was not what I needed [...] at times you put something in and you get like thousand things that are not what you are looking for.

Reasons to trust the information contained on a website

Several students who participated in this study based the reliability of the Internet sources that they consult on the authority provided by the academic degree of the author or the prestige of the institution that produces the resource:

> *Student 3, focus group 1*:
> YouTube seems reliable to me because university teachers upload the videos.

> *Student 5, individual interview*:
> SlideShare... I think is more reliable because there the doctors send [slides presentations].

> *Student 1, individual interview*:
> [...] Profesores Universia because it is supported by several Latin American universities.

> *Student 3, focus group 1*:
> For example in YouTube, well there the videos are from university teachers and themselves make the videos to clarify doubts, for me it is very reliable because they are university teachers and I think they even receive an economic benefit by making the videos [...]

DISCUSSION

In this exploratory study we investigated the Internet-based help-seeking practices among some Mexican engineering students. As other studies indicate (e.g. van de Sande, 2011), we found that the search for mathematical help on the Internet is widespread (12 out of 17 respondents reported using these sites for this purposes on a daily basis). According to the participants in our study, the most commonly used sites are: (1) YouTube, where students can find video recorded lessons to review and deepen the mathematical content covered in class; and (2) Facebook, where they can contact their peers or their teacher to clarify conceptual and logistic doubts related to their mathematical lessons. However, students also report using sites like Yahoo! Answers where they can find ready-made answers to their mathematical tasks.

The students who participated in the study look for mathematical help on the Internet to find different ways to solve a mathematical problem, to clarify doubts and reinforce knowledge, to get ready-made results or mathematical problems solved step-by-step, to compare the results that they obtain, and when they skip class and need to catch up. However, when it comes to assessing the reliability of the information they get from these sites, students seem not to pay attention to the intrinsic mathematical properties of the information obtained (Lithner, 2003), but rather base their assessment on features not related to mathematics, such as the academic prestige of the person or institution that publishes information.

The exploratory nature of this study allows us to see only the surface of a widespread practice that is affecting the way that contemporary students are studying mathematics. Next we outline future avenues of research that could be deepened in order to better understand this phenomenon.

Future avenues of research

One limitation of our study is that it is based on self-report measures of technology use, which may be less accurate than the observations of actual behaviours (Junco, 2014). A future avenue of research could focus on using more direct methods of observation as proposed by Junco (2014) in which recording software is used to document and characterize help-seeking behaviours manifested by mathematics students in different kinds of devices such as computers, tablets and mobile phones.

Another limitation of our study is that it does not deepen into how each site or web tool are used as a source of mathematical help. It is necessary to produce detailed characterizations of how students use tools like Facebook and YouTube to find mathematical help. Also, one could delve into the selection and exclusion criteria applied by students when selecting a particular piece of mathematical information from the sea of information offered by the Internet.

Another relevant line of research would be to include the perspective of mathematics teachers about these practices of mathematical help-seeking: what do they think about these student's practices? Do they consider it a desirable practice? Do they integrate these sources of help into the mathematical instruction that they provide to their students?

We believe that mathematical help-seeking on the Internet is an emergent area of research that is not only fertile but also relevant to study because it is a widespread practice that affects the way in which contemporary students approach school mathematics.

Guided Inquiry learning of fractions – a representational approach

Stefan Schumacher and Jürgen Roth

University of Koblenz-Landau, Institute for Mathematics, Mainz, Germany, Schumacher@uni-landau.de, Roth@uni-landau.de

We present a theoretical model of a representational approach to inquiry based learning (IBL) in this paper. In IBL-environments, students investigate a mathematical domain by using multiple representations such as dynamic simulations and hands-on material guided by specially designed textbooks. In the empirical part, we describe a study focussing on self-generated representations by students with the aim of representing procedures and results.

Keywords: Self-generated representations, protocols, guided inquiry learning, fractions.

CONCEPTUAL FRAMEWORK

In order to introduce the representational approach to inquiry based learning (IBL) in mathematics we define the concept of representational competence as two aspects that are two sides of the same coin. One side is the ability to manipulate and interpret prescribed external representations (representational input) and the other side is the ability to generate own external representations (representational output) (e.g., Izsák, 2011; Schnotz, Baadte, Müller, & Rasch, 2010; Cox, 1999). To build the link between IBL and representational competence, we need to define IBL:

> Inquiry or scientific discovery learning environments are environments in which a domain is not directly offered to learners but in which learners have to induce the domain by experiments or examples. (de Jong, 2005, p. 215)

To specify this definition of IBL to inquiry in mathematics, we need to clarify what makes the work of a mathematician.

> Mathematics proper might be regarded as the science of significant structure. Thus mathematics studies the representation of one structure by another, and much of the actual work of mathematics is to determine exactly what structure is preserved in that representation. (Kaput, 1987, p. 23)

Combining the essence of these two quotes it becomes clear that in IBL-environments in mathematics the goal for students should be to investigate a domain by analysing structures of given representations through examples or experiments with, e.g., hands-on usable material or dynamic representations. This represents the first side of representational competence, the processing of representational input.

In IBL-environments the processing of the representational input in the cognitive system of each participating students is mediated by (1) social interaction within the group the students are working in, (2) interaction of the group with the learning environment or (3) personal interaction of an individual with the learning environment. After the processing in the individual cognitive system of each student, the students are supposed to generate representational output, which is also mediated by social or personal interaction. Our approach is in line with Tytler, Prain, Hubber and Waldrip (2013, p. 3) who see the need for the development of and research on IBL-environments in science learning *"with a strong explicit emphasis on student-generated representational work"*. One major goal of generating representations during IBL is to represent results and solution steps externally. When it comes to student-generated representational work with the aim of presenting results and solution steps, we have to introduce the term "protocol". A protocol can be defined as a record, notation or description of essential stages phases and products of a learning process (e.g., an IBL-process) by using external representations such as texts, other symbols or diagrams (Dörfler, 2000, p. 111f).

The aim of those protocols is to help the students to reflect on the IBL-process. By presenting results in form of protocols, these protocols become part of the learning environment and can therefore be part of the (social or personal) interaction with the learning environment in later stages of the inquiry-process. Furthermore, students can revise their protocols repeatedly during the inquiry process. What we described so far is our theoretical model of the representational approach to IBL (see Figure 1). We have derived this model from classic input-output oriented information-processing models. In our model, the information-processing system is the cognitive system of the participating student. For the presented research, we consider the cognitive system (see Figure 1) and therefore mental processes as a "black box". To get deeper knowledge on IBL from a representational point of view, we might have to open this "black box" in further research. For example the "integrated model of text and picture comprehension" of Schnotz (e.g., Schnotz et al., 2010) or other theories of cognitive processing in multimedia-learning could be used to open this black box.

In this study, we focus on the individual student's ability to generate protocols. We want to investigate

- how the individual's ability to generate protocols (in the case of fractions) develops over time,
- in which way this development can be supported and
- how it is related to the individual's content knowledge (in this case knowledge on fractions).

See the chapter "Research Design and Questions" for a detailed list of the investigated research questions. To investigate the research-questions we conducted a quasi-experimental intervention study with two IBL-conditions and one control condition. The focus of this article is to present the quantitative data from three measurement occasions (pre-, post-, follow-up test). We do not focus on the qualitative analysis of the interaction in the IBL-conditions, even though we videotaped some of the groups during IBL. Nevertheless we want to introduce the IBL-environment we used in the study to make the research more clear.

THE IBL-ENVIRONMENT

In the IBL-environment of the presented study, the students discovered fractions by analysing artworks of Max Bill who is one of the most famous representatives of the so-called "concrete art". Max Bills "progression in five squares" (see the left side of Figure 2) is one of the artworks we used. In this artwork, Max Bill arranged five equal squares in a column and split them progressively into smaller, but in each square equal sized rectangles. Because of the described struc-

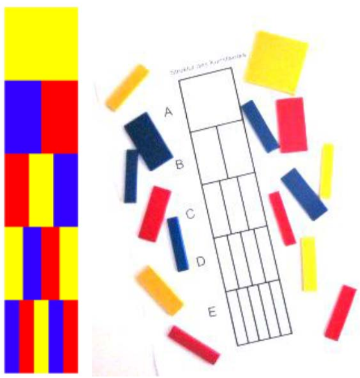

Figure 2: Max Bill "progressi-on in five squares" (left) and an equivalent fraction puzzle (right)

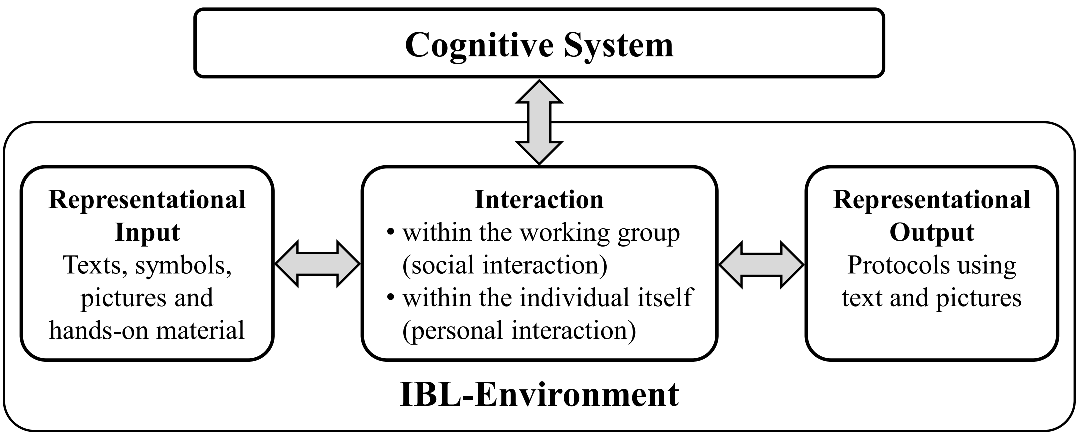

Figure 1: Theoretical model of the representational approach to IBL

Figure 3: Students during an IBL-process

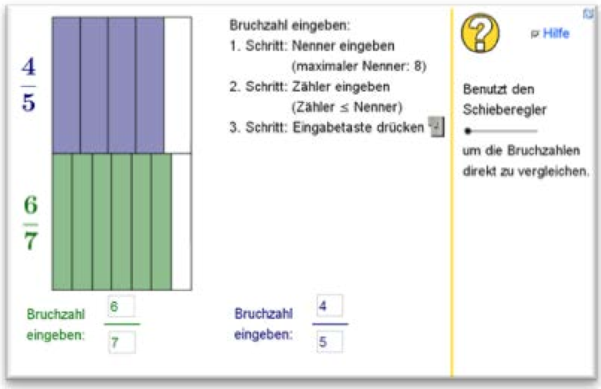

Figure 4: Screenshot of a dynamic visualization to compare fractions

ture, the artwork is suitable for students to explore the underlying structures of the "part-whole-concept of fractions".

For every artwork presented in the IBL-environment hands-on material based on this artwork (see the right side of Figure 2) was available for the students. It consists of the artworks outline structure on a laminated template and puzzle pieces of each coloured sub-area of the artwork. One can interpret each puzzle piece as a fraction of the whole artwork (or in the case of Figure 2 as a fraction of one of the five squares). Therefore, we named those hands-on materials "fraction puzzles". In Figure 3, you can see a student using the fraction-puzzles to reason on an argument on the comparison of unit fractions, the working group discovered in their IBL-process. The students' argument was that one third has to be "bigger" than one fourth, since in the case of the third the whole (the square) gets split into three parts, while in the case of the fourth the whole gets split into four parts. After writing down this argument in form of a protocol, the student in the upper right took a one half puzzle piece and two one fourth pieces (see Figure 3) and said that now the whole also is split into three parts as well. A discussion started after that and some students decided to revise their so far produced protocol. They added that the parts the whole is split into have to be of equal seize.

In addition to the fraction puzzles, students also had the opportunity to use dynamic visualizations (constructed using GeoGebra), again with a structure based on the artworks. Students can use these dynamic visualizations to test hypothesis they put up while dealing with hands-on material by further examples. Using the dynamic representation presented in Figure 4 students can for example test hypothesis on different comparison strategies for fractions.

Since guided IBL can be considered more successful than unguided IBL, we chose to implement a "triple support scheme" (De Jong, 2005; Reid Zhan & Chen, 2003) in the textbooks of our IBL-environment. We implemented *interpretative support* to help the students to interpret the prescribed representations. Whenever we present a task in the textbook that we anticipated as probably hard to solve for at least some of the students, a question mark icon indicates that there is some help provided in a special textbook. In this textbook, we present additional questions, hints or at the most solution steps but never the solution itself. We carried out *experimental support* to guide students while setting up experiments. This for example could be hints how to use the fraction-puzzles or the dynamic visualizations. In the presented study, we focus on *reflective support* with the aim of supporting students to generate protocols. We consider generating protocols as reflection, since students need to reflect on their learning process to be able to generate protocols. Prompts seem to be a promising approach to support the generation of protocols (Rau, Aleven, & Rummel, 2009; Berthold, Eysink, & Renkl, 2009; Berthold, Nückles, & Renkl, 2004). They are defined as "requests that require the learners to process the to-be-learned contents in a specific way" (Berthold, Eysink, & Renkl, 2009). An example for a prompt we used is the following: "Represent the result of the task you just solved and reason why your result is correct using a sketch and a text." In our learning environment, we provide requests like this next to a framed space in the textbook in which the students can represent their results bearing in mind the prompt. When the framed space next to the prompt is empty, we consider

First Unit	– (Unit) fractions in the meaning of the part-whole concept – Comparing Fractions using meaningful semantic strategies on the basis of pictorial representations
Second Unit	– Repetition: Unit fractions in the meaning of the part-whole concept – Equivalence of fractions using graphical representations – Problematization of adding fractions on a semantic level
Third Unit	– Adding fractions on a semantic level through pictorial representations – Fractions with a value greater than one using the part-whole concept – Application of the reached results on a realistic problem situation

Table 1: Content of the learning unit

this as *low instructional level*. In contrast to that, we consider to some extent pre-filled framed spaces as *higher instructional level*. In pre-filled framed spaces, we provide for example the beginning of a sentence or a first rough outline of a sketch, which the students have to accomplish in order to represent their results.

RESEARCH DESIGN AND QUESTIONS

To investigate the students' ability to generate protocols in more detail we conducted a quasi-experimental study with two experimental IBL-conditions comparing two different instruction levels of reflective support through prompts to a control-group. The control-group was taught in a teacher-centred setting. The content of these teacher-centred lessons was the same as in the IBL-environment and in all three conditions students learned in three 90-minute lessons (see Table 1).

We kept learning-time and content consistent over all three conditions. Experimental-Group 1 (EG1) learned with textbooks using prompts on a higher instructional level. Experimental-Group 2 (EG2) learned with textbooks providing prompts on a low instructional level as described earlier.

In this research, eight sixth grade classes from two different German grammar schools took part. We randomly choose one class from each school as the control-group (CG). The other three classes of each school learned in the IBL-environment. The students in the IBL-environment learned together in groups of three to four students. We randomly assigned the students of each class to these working-groups and then each working-group randomly to one of the experimental conditions, by either providing them with textbooks containing prompts on higher (EG1) or low instructional level (EG2). By this distribution a total of $N = 81$ students were assigned to EG1, a total of $N = 68$ students were assigned to EG2 and a total of $N = 50$ students were assigned to CG, which means a total of $N = 199$ students took part in the study (including later dropouts).

We carried out the study in a pre-, post-, follow-up-test design and collected data on two variables at each of the three measurement-occasions. First data on the students' knowledge on fractions was collected and in a second step the students' ability to generate protocols was measured. For the measurement on fraction-knowledge a paper and pencil test was developed. This test has a special focus on the part-whole concept and operations amongst fractions (based on this concept) that were part of the intervention. The items in the test all focus on some kind of switch between representations. A typical task is to find the right pictorial representation for a given fraction in a multiple-choice-item.

For measuring the ability to generate protocols, we developed a new instrument based on so-called "video items". The underlying idea behind video items is to present a short video to the students during the test situation. This video shows a complete problem-solving process simulating IBL. In the case of the presented study, we used videos demonstrating a problem solving process on fractions, using hands-on mate-

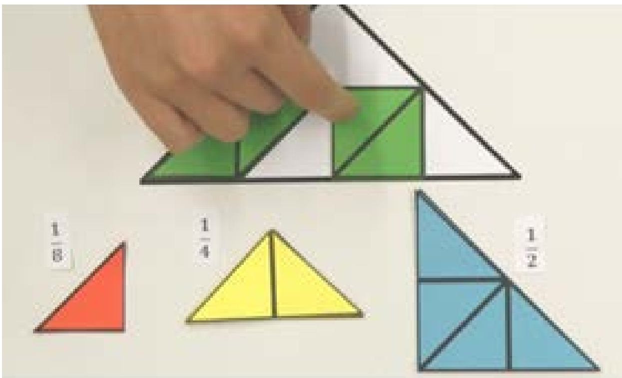

Figure 5: Screenshot of a video item

rials like the fraction puzzles described earlier. For a screenshot of one the videos, see Figure 5. By using videos, we want to simulate an IBL-process, which is in line with our theoretical model of the representational approach to IBL.

The task for students in the test situation is to generate a protocol of the video-content using pen and paper after watching the video.

Raters can evaluate these protocols using categories like the correctness and completeness of the *represented contents* and of the *represented relations between the contents*. In Engl and colleagues (2014), we describe the concept of using video items to measure the ability to generate protocols in detail. See Figure 6 for an example of a protocol based on a video-item.

To close this chapter we list the detailed research questions that contribute to the overall research-question we want to answer with this design:

Research question 1:
Do students in an IBL-setting achieve at least the same learning success as students in a teacher-centred setting?

Research question 2:
In which way does the ability to generate protocols develop over time under the three different conditions and is it possible to identify differences between the groups?

Research question 3:
Is there a correlation between the ability to generate protocols and the knowledge on fractions?

In the following, we present and discuss the results in detail. As said we put a special focus on the ability to generate protocols.

RESULTS

To investigate research question 1 we conducted a repeated measures ANOVA on the fractions-test scores, comparing the three conditions. The main-effect shows a highly significant increase in fraction knowledge over time for the three groups ($F(2,336) = 443{,}793$; $p < .01$). However no significant difference on the interaction between time and group could be detected ($F(4,336) = .986$; $p = .415$). This result shows that not only the teacher-centered setting can be considered successful. It indicates that the used support strategies for the IBL-environment lead to satisfactory learning-outcomes. With a focus on the treatment condition (reflective support through prompts), we can conclude that according to knowledge acquisition it makes no difference whether students are prompted on a high or low instructional-level in the case of the presented IBL-environment. This leads to the conclusion, that other design-principles (experimental and interpretative support) have more impact on knowledge acquisition than the different treatment conditions. What it does not mean is that students should not be prompted to generate protocols at all. We can say that independent of the instructional level

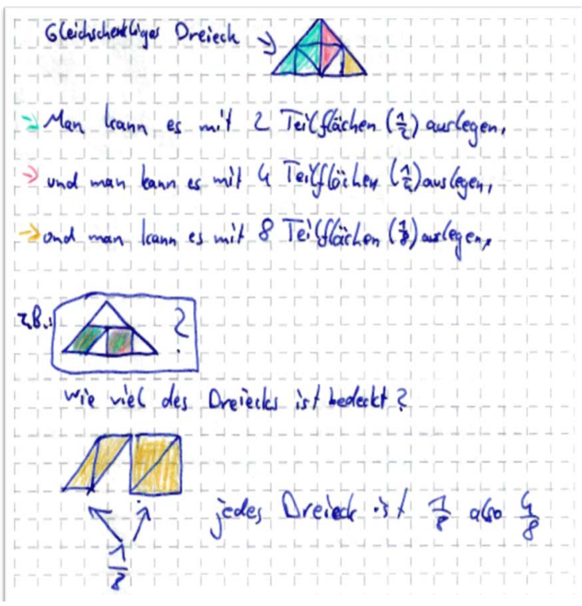

Figure 6: Student generated protocol on the basis of a video-item

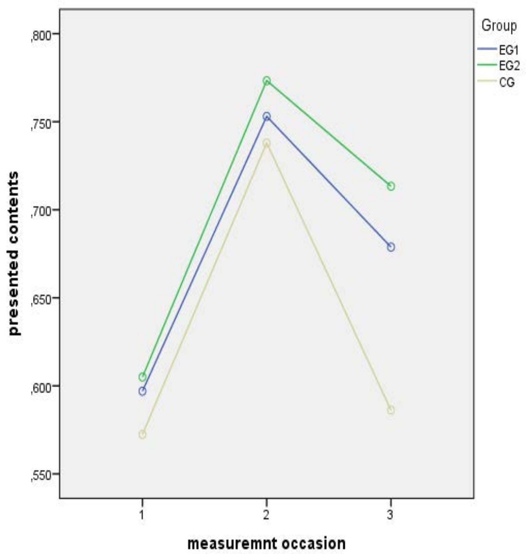

Figure 7: Relative values of presented contents in the protocols

of prompts, students learn successfully in the IBL-environment with the implemented support.

Let us turn to the results relating the ability to generate protocols now. According to the main-effect, the repeated measures ANOVA reveals a highly significant increase in the numbers of correctly presented contents over time ($F(2,306) = 37{,}282; p < .01$). Looking at the interaction between group and time the repeated measures ANOVA does not reveal significant differences between the groups. ($F(4,304) = 1{,}142; p = .337$). However, a Tuckey-HSD Post-Hoc-Test detects a significant difference between EG2 and CG ($p < 0.05$).[1] This result becomes clearer when looking at the difference between EG2 and CG at the third measurement occasion in Figure 7. The interpretation of this result is that EG2 shows a more sustainable ability to generate protocols than the CG. This is interesting because we provided EG2 with prompts on a low instructional level. EG1 also seems to show a more sustainable ability to generate protocols in comparison to CG, even though we cannot detect a significant difference.

What we can conclude from the significant main effect of the ANOVA on the generated protocols is that students develop the ability to represent results by learning on the topic, whether it is in an IBL-environment or a teacher-centered setting. However, students learning in the IBL-environment with prompts on a lower instructional level show a more sustainable ability to represent results.

Regarding research question 3, we detected low correlations between content knowledge and the ability to generate protocols at each measurement occasion (see Table 2). There are high achieving students regarding to fraction knowledge who fail to generate protocols and the other way around. This leads to the conclusion that content knowledge and the ability to generate protocols are two different constructs. We will discuss this interesting result amongst the other results in the closing section of this article.

Pre-Test	$r(180) = .217$	$p < .01$
Post-Test	$r(187) = .210$	$p < .01$
Follow-Up-Test	$r(167) = .224$	$p < .01$

Table 2: Pearson Correlations

1 Since the Tuckey-HSD Post-Hoc-Test uses pairwise testing, we can apply it without the ANOVA showing significant results (Hsu, 1996, pp. 175f.).

CONCLUSIONS AND PRACTICAL IMPLICATIONS

As shown in the results section students improve their ability to generate protocols significantly over time. However, the ability to generate protocols is more sustainable for students who learned in the IBL condition. As for the students of EG2, who were guided to generate protocols by prompts on low instructional level (request to represent results next to empty framed spaces), the described effect was significant. Therefore, when it comes to reflective support, we recommend a low instructional level of prompts. Here we provided the prompts next to empty framed spaces. This means students are open to generate their own creative protocols, considering the hints how to generate the protocol given in the prompts. The benefit of the lower instructional level is that right or wrong, the students generate these protocols truly on their own and therefore represent their way of thinking. Therefore, the teacher can use them to get more detailed information on the students´ thinking process. This would not be possible with pre-filled framed spaces, like in the first research-condition. When interpreting protocols we have to take into account that the quality of a generated protocol is not to be mixed up with high content knowledge. The low correlations between these two constructs clearly indicate this. To find out more about why the correlations are low, it might be interesting to open the black box and try to gain insight into students' mental models and the way they use them to generate protocols.

Another open research question is, whether students we consider "good representers" due to the results of the video items, really use their skills in IBL-settings and if not, how we have to design prompts to make them use their skills. Concerning this, it might also be interesting which factors influence the use of such skills. Motivation might have a huge impact, since our experience from watching students in IBL-environments indicates that the motivation to generate protocols is generally very low.

Game approach with the use of technology: A possible way to enhance mathematical thinking

Carlotta Soldano, Ferdinando Arzarello and Ornella Robutti

University of Torino, Torino, Italy, carlotta.soldano@gmail.com, ferdinando.arzarello@unito.it, ornella.robutti@unito.it

The purpose of this paper is to draw attention to the strategic thinking that students develop facing mathematical games. We hypothesise that prompting a strategic way of thinking within a didactical intervention, called the 'game-approach', could improve students' proving processes and support them in the production of proofs. More precisely, we are designing tasks based on two players' games in a Multi-touch Dynamic Geometric Environment, in which the discovery of the winning strategy coincides with the discovery of a geometric property. We aim to contribute to the debate on the possibility of cognitive and epistemic unity and to deepen the studies based on dragging practises and their cognitive counterpart.

Keywords: Games-approach, logic of inquiry, tablet.

INTRODUCTION AND THEORETICAL FRAMEWORK

Proving has always been one of the most difficult tasks in teaching and learning mathematics: its formal and rigorous features collide with the fallibility and guessing aspects of the processes that produce it. There are not many teachers in Italian schools who think it is necessary that students experience an exploration and an argumentation phase in order to grasp what a proof is. Teachers' convictions are encouraged by traditional textbooks, where students find the usual definition-statement-proof model. The conditions under which students can make conjectures and validate them are left in the shadow. Furthermore, teachers forget that the formalistic aspects are not the main concern in proving processes (see the discussion of "formal" in Arzarello, 2007).

Some scholars have pointed out this aspect of proofs both from an epistemological (Thurstone, 1994; Tymochcko, 1998) and a didactical (Hanna & de Villers, 2012) standpoint. For example, in the book "Proof and Refutations" (1984) the philosopher Imre Lakatos expressed a different view of mathematical statements. As it is well known, based on a detailed discussion of Euler's errors in his search for a topological classification of polyhedra, Lakatos pointed out a dialectic process in this search. He showed that definitions are not carved in stone, but often have to be patched up in the light of later insights, in particular flawed proofs. This gives mathematics a somewhat experimental flavour. Balacheff agrees with Lakatos' approach, and in the introduction to the French editions of the book, he writes:

> Les mathématiques sont aussi prises en compte, non en tant que text de savoir, mais en tant que savoir construit socialment et donc l'acquisition par l'individu doit etre contrôlée comme sens et pas seulement comme langage. (Lakatos, 1984, p. XVIII)[1]

Following Balacheff's point of view, we are studying a fresh way of introducing pupils into mathematics' rules of thinking in order to produce proofs in elementary geometry. The paper aims to present some reflection of a PhD work in progress research. The hypothesis we are checking consists of investigating if and how the introduction of some multi-touch Dynamic Geometric Environment for Tablets offers important facilities to work in this direction. Here we are referring in particular to applications or software that allow users to work on the same screen with more than one finger at the same time. This peculiarity gives the possibility of designing teaching/learning situations, where students are asked to build up and investigate geometric objects in a new and shared way. The aim of such multi-touch activities is to put students into a geometric game situation, and making them ask why it is... / it is not... /may be... / cannot be... / so; and try to answer the question. We hypothesise that questioning develops a specific type of rational behaviour, which can help students understand and produce proofs.

In the literature our idea finds a foundation in the epistemological research of Jaakko Hintikka (1998, 1999). His aim is to replace the classical and static logic by a dynamic and dialectical model: the *Logic of Inquiry*, based on the analysis of the way people develop their strategic thinking in games. According to him, two types of rules characterize any goal directed activity: *definitory rules* and *strategic rules*. For instance, in chess the definitory rules tell you which moves are possible, while the strategic rules tell you which moves is advisable to make in a given situation.

We can apply this idea to the teaching of deductive logic. It is clear that the rules of inference are definitory rules, not strategic ones. At each stage of a deductive argument, there are normally several propositions that can be used as premises of valid deductive inferences. The so-called rules of inference will tell you which of these alternative applications of the rules of inference are admissible. They do not say anything as to which of these rule applications one ought to make or which ones are better than others. For that purpose you need strategic rules.

Students should learn and keep in mind both these rules during the construction of arguments. However, teachers generally explain to students the rules of inference and the way to use them correctly (definitory rules), not which rules are more advisable to use or how to select new arguments (strategic rules). Therefore, students learn how to avoid making mistakes, but not how to discover proofs or to find out new truths by means of deductive inferences.

> In concentrating their teaching on the so-called rules of inference, logic instructors are merely training their students in how to maintain their logical virtue, not how to reason well. (Hintikka, 1999, p. 3).

Clearly, it is not easy to teach strategic rules. If you are engaged in a game, like chess, it is more natural and taken for granted the use of strategic thinking, than when you are doing mathematics. For this reason, we decided to design games (of mathematical kind), whose solution is the discovering of a geometric property. We hypothesize that the result of this choice could lead students to use strategic thinking within the mathematical one.

In literature the idea of using games for educational purposes has come back in fashion thank to the widespread diffusion of mobile devices and virtual games. "A game can provide a structure for the learning that takes place in the environment" (Devlin, 2011, p. 32). We believe that, in order to bring these innovations into the classroom, *epistemic games* (Shaffer & Gee, 2005) need to be designed. The authors define these games as follows:

> Epistemic games are about knowledge, but they are about knowledge in action- about making knowledge, applying knowledge, and sharing knowledge. (Shaffer & Gee, 2005, p. 16).

Games based on geometric property have to be played in an environment that allows students to come back to what has been done or seen, produce interpretations and possibly explanations, anticipate facts and situations, produce forecasts and hypothetical discourses. In other terms, an environment that allow students to answer such questions, as "How is it?", "What is best for me to do?", "How will it be?", "How could it be?", namely they apply strategic rules. DGEs are a powerful tool to support students in the formulation of such questions and, therefore, in the application of strategic ways of thinking within mathematics. Indeed they allow the design of dynamic game situations, where, in order to win, students have to discover/use suitable mathematical properties, which allow them to develop suitable strategic moves. Discussing their strategies and why they were suitable for winning, the teacher can coach them towards the formulation and the proof of the mathematical properties that were behind the game, according to the Logic of Inquiry approach.

A further necessary condition for developing the Logic of Inquiry in the classroom, is to let students be used to questioning by themselves during mathematics activities. Hintikka (1999) formulated the structure of the interrogative model in the form of a game between an idealized *inquirer* and a source of answers called *nature* or *oracle*. The inquirer starts from a given theoretical premise T and his/her aim is to establish a certain given conclusion C. At each stage of the game, instead of making a deductive move, the inquirer may address a question to the answerer (oracle, nature, or whatever the source of new information may be). If nature responds, the answer becomes an additional premise. Hintikka calls such a move an *interrogative move*. After that, the process starts again until all the information added to the premise T lead the inquirer to the conclusion C.

The following example (Hintikka, 1999, p. 31) is illuminating about the interrogative model and its importance in reasoning. It shows that we are able to rewrite the solution of any Sherlock Holmes' story in an interrogative form. The episode we analyse is "the curious incident of the dog in the night-time", extracted from the story called "Silver Blaze". The background is this: the famous racing-horse Silver Blaze has been stolen from the stables in the middle of the night, and in the morning its trainer, the stable master, finds it dead out in the heath. All sorts of suspects crop up, but everybody is very much in the dark as to what really happened during the night.

Watson: "Is there any point to which you would wish to draw my attention?"

Sherlock Holmes: "To the curious incident of the dog in the night-time."

Inspector: "The dog did nothing in the night-time."

Sherlock Holmes: "That was the curious incident."

Even Watson can see that Holmes is in effect asking three questions: "Was there a watchdog in the stables when the horse disappeared?", "Did the dog bark when the horse was stolen?", "Who is it that a trained watchdog does not bark at in the middle of the night?". The following deductive argument is the exact transposition of the three questions of Holmes' inquiry: "There was a watchdog in the stables." "The dog did not bark when the horse was stolen." "A trained watchdog does not bark only at its owner." "Hence, the thief was the owner."

Each question is the source of a new *abduction* [2] and it is also an abduction that marks the transition from an inquiring to a deductive approach. Hintikka's analysis shows that this way of thinking does feature the epistemological basis of mathematics altogether and not only of game theory. In particular, it shows an *epistemic unity* between the argumentation phase, represented by the process of questioning, and the proof, represented by the reorganization of the answers in a deductive chain. In the literature, it has already been studied the cognitive unity between argumentation and proof (Boero, Douek, Morselli, & Pedemonte, 2010). Therefore, the result of epistemic unity can deepen these previous studies. In the interrogative model, we find both natural representations of non-logical reasoning (argumentations), and representations of formal logic. Hintikka observes a similarity between the two types of reasoning, founded on the role of presuppositions in the interrogative inquiry. In fact, before the inquirer is in a position to ask a convening question, i.e. "Who did it?" he or she must establish its presupposition "Someone did it". From the point of view of the transition from one proposition to another, an interrogative step looks rather similar to a deductive step: the latter takes the inquirer from one or more premises to a conclusion, while the former takes the inquirer from the presupposition of a question to its answer.

THE GAME-APPROACH

We divide what we call the game-approach into two phases: the game-task design and the so called Devil's Advocate reflection.

The game-task design consists of the transformation of the geometric properties in a *non-cooperative game,* in which each student has a different aim to reach, that contrasts with that of the other player. The task contains the rules of the game, the players' aims and some questions to answer. During the game, there is a silent inquiring activity in the students' mind. Thank to a Tablet and the schoolmate's feedback the inquiring process develops throughout the game, producing interrogative and deductive moves deeply intertwined: deductions are needed for establishing presuppositions for interrogative moves and interrogative moves are needed to add possible new hypothesis to the process of inquiry. In order to create a significant and relevant mathematical experience, we support students in the construction and development of strategies with questions like "Can you write someone else a way for winning?" which indirectly guides their attention to switch from the particular to the general. John Mason summarized these two-way processes as follows:

> …'to see the general through the particular and the particular in the general' and 'to be aware of

> what is invariant in the midst of change' is how human beings cope with the sense-impressions which form their experience, often implicitly. The aim of scientific thought is to do this explicitly. (Mason, 2005, p. 8)

Finally, we ask students: "How do you know that the method always works?". We hypothesize that, with this question, students can gradually discover the geometric property on which the game is designed, so avoiding a possible gap between it and the mathematics' theory. Students play the game on a shared Tablet and answer the questions working in pairs. Generally, this activity requires a one-hour lesson. After that, we withdraw students' worksheets and prepare a PowerPoint presentation in which we introduce the character called "The Devil's Advocate". This is the second phase, the Devil's Advocate reflection. In this phase, the Devil's Advocate (the teacher or the researcher) makes the Logic of Inquiry more explicit to students. In fact, he questions students to make them think theoretically on what they have found and she insinuates doubts on their deductions and sentences.

THE ANALYSES OF AN EXAMPLE

The episode described below is part of a teaching experiment developed in a tenth grade science class at a private high school. During the activity, the classroom was composed by eight students, working in pairs: they have to read the task, play the game on the tablet and answer some questions on a worksheet. They use GC/htlm5 [3] a newest version of Geometric Constructor (one of the free dynamic geometry software used in Japan since 1989) compatible both with iPad and Android tablets. During this first phase, the role of the teacher is to observe students and to help them if they are in trouble, whereas the role of the researcher is to videotape a single group. The work in pairs activity is followed by the teacher's systematisation of the mathematical content at the blackboard (at that moment the Devil's Advocate reflection has not been designed yet). In the second phase, the teacher asks students what they have discovered during the game in order to engage them as much as possible in the process. The systematisation generally takes place at the beginning of the subsequent lesson for matter of time (each class lasted 50 minutes).

The teaching experiment deals with some themes related to a classical topic included in the National Curriculum 2012 (Indicazioni Nazionali): the circle. The teacher commits almost twelve lessons to the project, developing six themes: the reciprocal position between two circles, the reciprocal position between line and circle, the chords theorem, the angles at the centre and at the circumference, the circumcentre and incentre of triangles, the inscribed and circumscribed quadrilaterals.

The example we will show, describes a non-cooperative game situation involving two players Z and Y. The final aim of the activity is discovering the geometric property that describes the reciprocal positions between two circles. Here is the task given to students: "Play the chase with your schoolmate. Z's aim is changing the length of segment AB by dragging its endpoint in order to make the two circle intersect; Y's aim is changing the length of segment CD by dragging its endpoint in order to avoid the intersection. When does Z win? When does Y win? Move the centre of the circles to examine the possible cases."

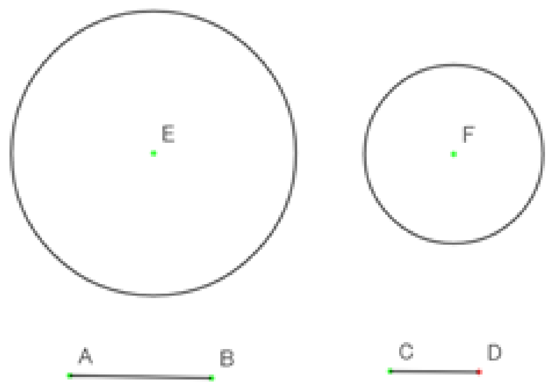

Figure 1: The picture shows what students see on their Tablet

1 Student Y: Have I to run away? *(Reducing radius of circle E more and more)*
2 Student Z: I think you could also move... *(Enlarging more and more the radius of circle F)*
3 Student Y: Yes, but if you are enlarging it, what could I do?
4 Student Z: I think you could also move... you can try to move this one *(pointing the centre E)*
5 Student Y: Wait, wait, wait!
6 Student Z: I think you can try to move this one
7 Student Y: Yes but if I run away...

2a 2b 2c

Figure 2: 2a) First strategy "Running away"; 2b) Second strategy "A circle inside the other"; 2c) Third strategy "One centre"

8 Student Z: I will make it bigger [the circumference F]!
I stay here so I always catch you!

9 Student Y: If I put myself [circumference F] inside *(pointing the area of circumference E)*, you can make yourself [circumference E] bigger and catch me, but I can... if I tighten...

10 Student Z: No! In this way it should be... it should be... Points should coincide *(pointing the two centre E and F)* because I catch you however!

During the game, students switch between two modalities:

- the *played game* in which students play against each other or collaborate and their only aim is to win;

- the *reflected game* in which students take distance from the game to analyse and make judgments about what has happened. Their aim is collaborate to discover the strategy to win.

In the example, line 5 marks the switch from the played game to the reflected game. When students enter into the second modality, they start analysing the different types of situations that could arise during the game. First, they examine the case in which player Y tries to escape by moving the centre of the circle (line 6–8). In this case, player Z always catches him by making his radius larger. Then they experiment with a second strategy: putting the centre of circle Y inside the circle Z. This second solution leads player Z to win over player Y as well. Finally, student Z suggests to student Y a different situation in which the centres of the circles coincide (line 6).

It is important to notice that during the reflected game, students exchange their roles (line 5), since they not only think about their movement, but at the opponent's movement as well, and they identify themselves with the geometric object: each student is the circle that he/she moves on the screen. While students try to discover the strategy to win, they explore unconsciously the reciprocal position between two circles and they implicitly discover the link between it (the reciprocal position between the circles) and the position of centres or the length of the radiuses. Even if the mathematical theory remains implicit in students' actions, words and visualisation during the whole game, students build strong concept images (Tall & Vinner, 1981), which help them in the construction of mathematical concepts.

As in the case of mouse dragging practises (Arzarello, Olivero, Paola, & Robutti, 2002), we aim to analyse the modality of dragging in order to notice if there is a correspondence with the cognitive level. In particular, in mouse dragging practises, there are two main cognitive typologies (Saada-Robert, 1989; Arzarello, 2007):

- the *ascending processes*, from drawings to theory, in order to explore freely a situation, looking for regularities, invariants, etc.

- the *descending processes* from theory to drawings, in order to validate or refute conjectures, to check properties, etc.

In designing the tasks, we started from the two main cognitive typologies which characterize mouse dragging practises and tried to readapt them in order to describe that of games practices. Insofar, we began transferring the results on mono-touch to multi-touch dynamic geometry software: the aim is to observe what remains invariant and what changes in the students' approaches and processes. In particular, in the played game we distinguish between *ascending processes* when students enter into the game, explore the situation freely, look for strategies and *descending processes* when students play with a strategy in act. In the reflected game, instead, we recognize *ascending* *processes* when students explicitly use the strategy and *descending processes* when they try to check it. We are interested in observing whether or not students share the ascending and descending processes.

In line 1 students are in the played game descending processes, they are playing with a strategy in act: Y tries to escape reducing the radius more and more and Z makes his radius larger following Y's movement. The students realise that with this implicit strategy Z always win. Y is going to give up, when Z suggests her the first explicit strategy (line 6): "moving the centre of the circle to escape". Students are now in the reflected game ascending processes, they play with the explicit strategy and they immediately understand that student Y always loses. Line 8 shows the moment in which students are in the reflected game descending processes, because they check the strategy and decide to abandon it. Students come back to the reflected game ascending process and explicit another strategy: "make a circle inside the other". They immediately pass on the descending process and understand that Z continue to win. They abandon the strategy and make explicit a third one: "make the centres coincide". They are one more time in the ascending process.

Under the first two strategies, there is the implicit mathematical property: "if the distance between centres is less than the sum of their radius and major of their difference, circles intersect at two different points". Since for every Y's movement, there are infinite Z's movements such that the distance between centres is minor then the sum of the radiuses and major then their difference, students are lead to the conclusion that Z always wins. Students do not know the mathematical property that leads them to this conclusion, they only experiment the property in an empirical way, through the game.

CONCLUSION AND POSSIBILITY FOR FURTHER RESEARCH

The analysis of the protocols reveals that the game approach makes students explicit their strategic rules of thinking, but it is not enough to give them insights on the impact of the use of strategic rules of thinking on the mathematical reasoning. In particular, we observed that students do not mention the mathematical property on which the game is based. For this reason we have designed two didactical interventions, which are fundamental in order to both make the mathematics rise from the game and overwhelm the possible cognitive discontinuity between the inquiry phase and the deductive phase:

1) The introduction of specific questions, such as "Can you write someone else a way for winning?" and "How do you know that the method always works?"

2) The introduction of the Devil's Advocate reflection.

The first one helps students thinking the reasons why one wins and detect the geometric property, while the second one helps students in the deductive transpositions of their arguments. Both these interventions make the Logic of Inquiry more explicit to students.

Another issue we are addressing now aims at deepening the technological possibilities offered by DGEs in order to make the game more challenging and engaging. For instance, we are designing more complex games, where players must overcome some intermediate steps in order to win. Such steps correspond to parallel steps in a possible proof of the mathematical properties upon which the game is built. For example we are introducing the opportunity for a player to choose from time to time between two alternative possible constructions in the environment. Only one of them will facilitate her/him: exploiting which is the right one to choose corresponds to a mathematical property, which can facilitate the successive proving phase.

ENDNOTES

1. "Mathematics is also taken into account, not as a text to know, but as knowledge socially constructed and therefore the acquisition by the individual must be controlled as sense and not as just as language."

2. The following example (Peirce, 1960, p. 372) clarify what an abduction is. Suppose I know that a certain bag is plenty of white beans. Consider the sentences: a) these beans are white; b) the beans of that bag are white; c) these beans are from that bag. A deduction is a concatenation of the form: b and c, hence a; an abduction is: a and b, hence c. An induction is: a and c, hence b. For more details, see Magnani and colleagues (2001) and Arzarello and colleagues (2000).

3. The inventor of GC/htlm5 is Yasuyuki Ijjma from Aichi University of Education (Japan). To visit the software go to http://iijima.auemath.aichi-edu.ac.jp/ftp/yiijima/gc_html5e/gc.htm.

Online platforms for practising mathematics in German and English speaking countries – a systematic comparison

Martin Stein

Westfälische Wilhelms-Universität, Münster, Germany

During the last years, a multitude of web-based computer assisted systems for learning mathematics were developed. Eva-CBTM (Evaluation of Computer Based Platforms for Training in Mathematics) makes a complete survey of all such platforms (German or English as language). To do so, an evaluation scheme has been developed which assesses the help system, system structure and other features. A significant number of learning platforms will be compared using this assessment system.

Keywords: Software evaluation, learning program, fractions, Khan academy, IXL, Tenmarks.

THE EVA-CBTM-PROJECT

Eva-CBTM is a project for the Evaluation of Computer Based programs for learning and Teaching Mathematics. The aim of Eva-CBTM is to develop a complete system for such an evaluation which has its focus on mathematics didactics, and to apply this system to all relevant international platforms (German and English as language). The evaluation is carried out under the perspective of a formal analysis of the fulfilment of didactical criteria, and the perspective of pupils working with these systems will not be studied in this paper.

Due to the limited space in this paper, the *main focus* will lie here on the description of the *evaluation system*, whereas the results cannot be given in full. For the interested reader, (Stein, 2012) contains detailed results and descriptions of all platforms which were evaluated.

ASPECTS OF EVALUATING SOFTWARE IN EVA-CBTM

The main components of the evaluation system

An analysis of existing criteria catalogues for the evaluation of (mathematical) learning software (for instance, Grosser, 2000 (in German); Handal, Handal, & Herrington, 2006 (in English)) unveils that these are often written from a media-pedagogical perspective or test the user-friendliness of such systems. Such catalogues can be used to evaluate individual programs (and then possibly to compare them). Since they cover a broad range of different types of websites – "drills, tutorials, games, simulations, hypermedia based materials and tools and open-ended learning environments" (Handal & Herrington, 2003, p. 278), they are not specialised enough for analysing and comparing) programs which focus on practise in mathematics only.

School children working with such programs need *feedback* about their work (Handal, Handal, & Herrington, 2006, p. 8), and they normally also need *help,* resp., *assistance* (ibid, p. 13). Every practising software therefore needs an *assessment system* and an *assistance/help system.* Both of these components operate closely together in many cases, such as when the evaluation system notices a mistake and triggers the help section, but it still makes sense to describe the two systems separately.

Additionally, the systems require a *pool of tasks* that must be *structured* in some way. The follow-up-task should be provided by the system, according to whether or not the user was successful in the previous task. With this, we have a *system structure* and a *follow-up system for task selection* as further characteristics of a CBTM-System that are in need of evaluation (ibid, p.

11). Systems can also differ significantly in the question of how many decisions they take autonomously, and how many they leave to the user. This is measured by the *degree of freedom*.

Finally, the *completeness* by which the covered topics are handled has to be evaluated. This aspect is measured in *thematic completeness*. It is given as a percentage that is based on how completely the subject under consideration is covered. Using this percentage value on the point score already given to a system yields the overall evaluation score of the system.

A process model for the interplay between user activities and system activities

Doing mathematics, solving problems, calculating formulas... always follows certain steps: it is a *process*. This work process runs along a time axis that begins with the presentation of the task and ends when the solution is submitted. In *teaching*, we can describe three stages: pre-active, interactive, and post-active (Kysilka et al., 2002, p. 60). Looking at *learning platforms*, we prefer the wording pre-active, formative, and summative, as used in literature about evaluation (see, for instance, Schulmeister, 2002) since the learning software evaluates / assesses the outcomes of the pupils' work.

Explanations

Assistance without request.

Communication between the assessment system and the assistance system.

Assistance provided by the system at the user's request.

User activity, the user's actions are communicated to the assessment system.

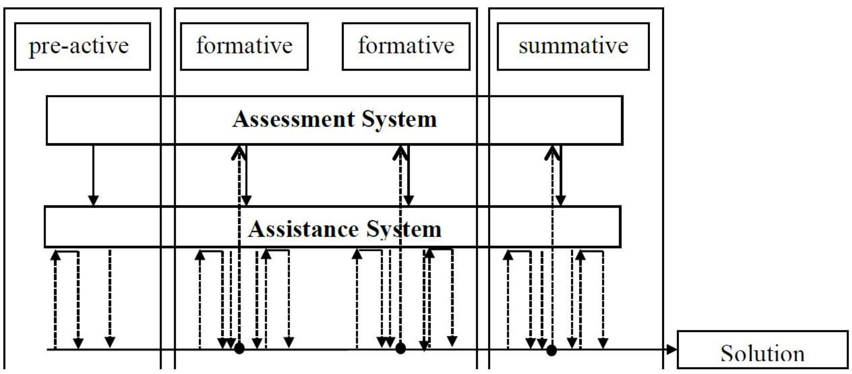

Figure 1

Pre-active: Before the start of the work process – it is clear that user input cannot be evaluated before the user starts to solve the task. However, assistance can be available at this point.

Formative: During the work process – the evaluation of user activities takes place based on the user's inputs. This temporal process is a basic part of any attempt to solve a task. Whether or not the system „notices" this work, is another matter. For that to happen, the system needs to enable the user to enter the consecutive steps of his/her work. Only then we can talk of formative assessment / assistance.

Summative: At the end of the work process – this is the standard kind of evaluation that every teaching and practice system has.

This model is applied at two levels:

- *Micro level*: Each task requires several solution steps. If the system has been programmed to work in this way, it can pick up on the individual steps that the user takes and react appropriately.
- *Macro level*: CBTM systems do not provide tasks in isolation from each other. Instead, they provide sets resp. sequences of tasks. The sequence of work on these tasks can be described and analysed with the same model.

THE EVA-CBTM EVALUATION SYSTEM

Assessment

According to the process model, assessment can take place pre-actively, formatively or summative. Apart from that we have to differentiate between assessments that have a procedural component that touches on questions of heuristic strategy and assessments that solely focus on the current content or input. Three levels are defined for both assessment strategies of which six types of assessment follow, as shown in the Table 1.

Assistance

Literature on e-learning acknowledges demand for feedback and assistance, but lacks any detailed information which could cover the richness of types of assistance by an appropriate evaluation system: Schwier and Misanchuk (1993) demand a gradual increase on the "types, amount, and layers of stimuli and feedback presented" (p. 20). Bescherer and colleagues (2012, p. 152) say, "When students work on their exercises at home, however, lecturers and tutors generally are not available to help out. In such cases, computer-based approaches, where hints and feedback are provided on demand by using software, can be a real asset to learning. However, such feedback needs to be more differentiated than merely pointing out 'right', 'wrong', or 'reread chapter X.' "

One perspective on the topic of assistance in work processes and solution-finding processes offered by literature on mathematics education (see, e.g., Zech, 2002) leads to a catalogue of terms, listed and briefly explained here:

Strategic Assistance: Solution strategies are described, a specific strategy is recommended; *Content-based assistance*: Users are provided with assistance by the task currently in front of them; *Motivating assistance:* The help has an encouraging character („Keep it up", „That was again very good", etc.); *Responsive assistance*: Typical feedback. This contains the basic information as to whether the solution step was correct or incorrect or if the solution method will take you to your goal; *Diagnostic assistance*: The assistance contains information about the cause of the mistake.

Solution-generating assistance: The assistance leads to the solution.

These types can be used

- *Situation specific*: The assistance is focused on the task currently in front of the user, using the concrete numbers of this specific task. For example, there would be two separate, pre-calculated solution methods to the equations $2x+3=7$ and $3x+4=9$.
- *Generalised*: The assistance is general in nature. So, for the solution to the equations $2x+3=7$ and $3x+4=9$, one piece of assistance is given for each task, perhaps for the equation $5x+8=17$.
- *Global topical*: The assistance includes several types of task. For example, the assistance for expansion, finding the common denominator and addition of fractions is all contained within a single explanation.

This system of 18 possible combinations is so nuanced in the case of motivation that a classification of learning systems would not be reliable. For example, it can be argued that the mention of addition

You have added on the right side. Think about it!

Strategic	Content based
simple normative Checks whether the user has found the correct solution method.	**simple normative** Checks if the solution method corresponds to a predefined target. If not, it is regarded as incorrect. If $\frac{1}{2}$ *is expected,* $\frac{2}{4}$ is considered as wrong.
complex normative Choosing an alternative correct solution method is accepted or is reacted to flexibly. E.g., „This method is also possible, but we will continue our calculations as follows..."	**complex normative** Equivalent solution methods are recognised, and are both designated correct or incorrect. $\frac{1}{2}$ and $\frac{2}{4}$ are both recognized as wrong or both as right.
diagnostic The reason behind an incorrect solution method is recognized. „You have carried out the steps in a wrong order."	**diagnostic** The cause of a mistake is communicated. In case of $\frac{2}{3}+\frac{1}{2}=\frac{3}{5}$ the system says, for instance: „You have made the mistake ‚Numerator plus numerator and denominator plus denominator'."

Table 1

… is *strategic assistance* (choose the correct *operation* as a solution strategy), or if it should be seen as *content-based assistance* (it is about the *addition*).

Such a discussion is in any case superfluous – the fact that even in the theoretical analysis uncertainty is creeping in shows that these four categories are much too finely structured to be the basis of an evaluation schema. Using them would lead to unreliable coding.

As such, some items of the classification system can be dropped and in the end the following items remain in the list:

> Motivating Assistance | Feedback on the assessment | Strategic, solution-generating, situation-specific | Strategic, solution-generating, generalised | Strategic, solution-generating, global topical | Content-based, solution-generating, situation-specific | Content-based, solution-generating, generalised | Content-based, solution-generating, global topic

Special *types* of help – for instance, the use of multiple representations or interactive features – are not measured individually in this system. They are scored as content-based, solution generating and can be situation specific or generalized.

The use of *tools* like computer algebra systems or dynamic geometry software can help students learning mathematics and can play an important role in the assistance section of a CBTM-system. However, this was not made an issue of this study: Eva-CBTM analyzed the *fraction arithmetic part of those systems*, and here those tools do not play an important role. If the same study shall be executed for the algebra or geometry section of such systems, the assistance part of the Eva-CBTM evaluation system has to be extended to cover such features.

System structure and choice of exercise

Before we can discuss system structure and exercise choice in a system, some remarks about the framework of exercises are necessary.

Looking at the set of exercises, it becomes immediately clear that the minimal structure is that of a *sequence*. Every system of exercises gives exercises in a certain order – the *exercise series*. Exercise series of this type can be assembled „*ad hoc*", or they can be put together *according to internal evaluation systems*. This is often done according to *difficulty*, although there are other conceivable systems.

Every exercise is provided with certain labels and pointers. A *label* is a piece of information assigned to the task. A *pointer* directs the user to another exercise or sequence. There can be multiple pointers, such as if different follow-up exercises should be chosen based on information about the mistakes made by the user. A *backwards pointer* defines a relationship with a previous exercise or exercise series, which can be defined by labels that determine which previous exercises should be chosen based on certain events.

The interaction between the information about the exercises contained in the labels, the follow-up structure defined by the pointers and the information about previous exercises defined by the backwards pointers leads potentially to an extraordinarily complicated structure of exercises through which the system has to navigate. For practical use, the following *selection structures* can be designated.

Architecture of exercise sequences and the overall system

Ad-hoc arrangement: The program moves from one exercise to the next in such a way that no system is noticeable.

Internal arrangement through evaluation of exercises: Every exercise in a sequence receives a label through which it is evaluated. This is often „difficulty" or „complexity".

External arrangement through evaluation: For every sequence of exercises, preceding and following sequences are defined by an evaluation – e.g., by the level of difficulty. Preceding sequences for the addition of two three-figure numbers are for example the addition of two two-figure numbers or one two-figure number and one three-figure number. *External arrangement by content-based analysis*: Sequences of exercises are connected to others by follow-up relationships. This can be based on different types of exercise analysis: e.g., it is possible to define sequences by the basic skills necessary to solve them. In the case of solving the equation $3x + 4 = 17$ those are addition, division, subtraction, etc. It is also possible to determine which follow-up sequences make the best sense.

The system of choosing exercises

The system of choosing exercises touches on the architecture of the system. More complex systems make decisions dependent on the successes or failures of the learner. They navigate within the defined architecture.

Depending on the starting point in the process model, there are different evaluation possibilities on the Pre-activity, the Formative and the Summative stage. Due to the space restriction we cannot describe this here and have to refer to (Stein, 2012).

Degree of freedom

The above classification only captures the method and the complexity with which a system selects exercises or exercise sequences. CBTM-systems, however, can also be very different in the degree of freedom that they allow the users in their work. The fine grain evaluation system of Eva-CBTM cannot be discussed here; it is described fully in (Stein, 2012).

Thematic completeness

The question of how completely a given system covers its chosen area plays an important role in its evaluation. The evaluation begins with a pedagogical analysis of the topic under observation, based on existing pedagogical and methodological knowledge. Every topic recorded in the evaluation is given an appropriate marker. If in the course of the evaluation a particular system introduces a new aspect, the table is expanded to include this aspect. At the end, the percentage of possible practical topics that each system covers is calculated.

ALLOCATION OF POINT SCORES IN THE EVA-CBTM-SYSTEM

The combination of the different aspects of the evaluation (assistance, assessment, and so on) with the three stages of the process model, each being divided in different categories, leads to a multidimensional matrix. Each cell of this matrix describes one possible feature of the training system. In most cases for each cell a score of 1 point is allocated, if applicable (the few exceptions cannot be discussed here), and 120 allocations have to be placed.

The allocation of one point for each feature is a personal view of the author, other allocations are possible. If, e.g., *assistance* (besides a feedback right / wrong) seems not a desirable feature of a system, for this part of the matrix 0 points would be given. And if the formative part of the matrix is not seen as useful, the same will be done with all cells of the matrix belonging to the formative stage. In the result section, we give a brief summary of the outcome under the heading *Alternative scoring*.

Because the available contents can differ depending on the region for which they were principally designed, this evaluation is carried out in a thematic area that all systems contain, i.e. *calculations with fractions*.

Each of the observed systems is evaluated by three independent evaluators – the evaluation was part of their master thesis (Frankewitsch, Menke, & Wietholt 2012 / available from this author) written under supervision of this author. After a training phase in which examples from different systems were scored by the evaluators and this author, the evaluation was carried out independently by the three evaluators, the scores were compared in a joint meeting of the three evaluators. When the evaluators failed to come to a unanimous evaluation of an item, the reasons for the different ratings of the point under discussion were then discussed by them further, and the final decision was protocolled, together with the reasons for it (see Frankewitsch et al., 2012, pp. 112 ff.). The independent evaluation lead to nearly unanimous results, with a minimum of 2 (4 platforms), a maximum of 6 disagreements (1 Platform), the median is 4 disagreements (out of 120 scores) only.

The scores for assessment, assistance, and so on, are multiplied with 10, which leads to the following values:

> Assessment Strength: AS-value | Assistance (Help) Strength: HS-value | System Structure: SyS-value | Choice of Exercise System: CES-value | Degree of freedom: DF-value | Thematic Completeness: TC-value

The thematic completeness is evaluated as has been described before. The percentage is divided by 100 to yield a decimal number between 0 and 1 which is called TC. The result of the multiplication of TC with the AS-value is the weighted AS-value W-AS, and so on.

CONSIDERATIONS FOR CHOOSING WHICH ONLINE PLATFORMS FOR LEARNING AND PRACTISING MATHEMATICS TO EVALUATE

In the face of the over 60 mathematics-platforms to be found in the internet, often with very different objectives, a definition of the platforms to be evaluated is necessary. The following conditions must be met to be included on the list:

The software can be used completely without a tutor, it serves principally to practise mathematical skills, the mathematical topics of grades 5 to 10 are covered as completely as possible, and the software can be used by interested school children or their parents without involving an external institution (such as the school).

The following list gives an overview of the finally selected platforms.

German language platforms

Abfrager: abfrager.de
Bettermarks: Bettermarks.de
Mathegym: *mathegym.de*
Realmath: realmath.de
Scolaris: scolaris.de
Skilltime: Lernen.skilltime.de

English language platforms

AAA Math: aaamath.com
ALEKS: aleks.com
Aplia: aplia.com
Bettermarks: bettermarks.de
BrainPop: brainpop.com
Ixl: ixl.com
Khan Academy: khanacademy.org
Mangahigh: mangahigh.com
Mathletics: mathletics.eu
MathsOnline: mathsonline.com.au
TenMarks: tenmarks.com

RESULTS

10 points per item

Due to limitation of space, we give the results for those platforms only which yield a score over Q3(=120), and add the result for the weakest platform, to show the spread. (Table 2)

Alternative scoring

If we do not consider the formative stage, and find assistance beyond saying “right” or “wrong” not desirable, the results are as follows in Table 3.

DISCUSSION

The evaluation system developed in this paper leads to a ranking order in which bettermarks is leader far ahead all other systems. An important reason for this is the construction of bettermarks as a system with a strong emphasis on the formative stage. This decision leads to a system in which not only the end result of a computation is assessed, but the intermediate steps as well. In consequence, the evaluation of the assessment system AS-score) and the assistance system (HS-score) of bettermarks leads to far higher scores than that of the other systems – but even if the formative stage is not rated as in the alternative scoring, the leading position of bettermarks remains untouched.

	TC	W-AS	W-HS	W-SyS	W-CES	W-DF	Total
Scolaris	0,22	2	9	2	0	1	14
Mangahigh	0,58	15	58	17	29	1	120
Khan Academy	0,44	15	52	13	17	26	124
IXL	0,69	21	55	21	28	3	128
Tenmarks	0,67	13	87	13	13	1	128
Mathegym	0,62	31	62	12	12	25	142
Bettermarks	0,65	65	164	26	65	46	367

Table 2

Scolaris	Mangahigh	Khan	IXL	Tenmarks	Mathegym	Bettermarks
14	99	89	93	61	102	223

Table 3

Other important aspects under which many of the systems are very weak, and which must be improved to yield higher scores, are *deficits in the assistance system* (IXL: no pre-active help, no formative help, HS-value = 80 (of 410), W-HS=55), and the *assessment system* (Mangahigh: simple normative only, AS-value=25, W-AS=15).

ACKNOWLEDGEMENT

EVA-CBTM was carried out with support from *Bettermarks*, Berlin. The author wants to thank the bettermarks team for many fruitful discussion, and Th. Frankewitsch, V. Menke and M. Wietholt for doing the evaluations with great accuracy.

A learning trajectory of the accumulation function in multiple-linked representational environment

Osama Swidan

University of Haifa, Faculty of Education, Haifa, Israel, osamasw@gmail.com

Our study was designed to identify a learning trajectory for the accumulation function as it learned with multiple representational technology based artifact. Thirteen pairs of 17-year-old students were asked to explain the connections between multiple-linked representations and to conjecture about the mathematical relationship embedded in the artifact. The study was guided by the semiotic mediation theory and the theory of knowledge objectification. We include two rounds of analysis: one to detect mathematical elements involved in learning the accumulation function, another to identify the progression process of learning the accumulation function. The data analysis identified four phases in the processes of objectification along which we suggest a trajectory for learning the accumulation function concept.

Keywords: Accumulation function, multiple-linked representation, semiotic mediation, objectification, learning path.

INTRODUCTION

Constructing a learning trajectory for students is one of the most daunting and urgent issues facing mathematics education today (Steffe, 2004). The main issue concerns the promotion of students' development of new mathematical concepts, especially concepts the development of which is challenging. The accumulation concept, which central to the idea of integration, is one of such concept. Learning the integral concept based on the accumulation function may create opportunity for the student to make the connection between the derivative and the integral which is essential for meaningful learning of calculus (Thompson et al., 2013). Simon (1995) offered the Learning trajectory as a way to explicate an important aspect of pedagogical thinking involved in teaching mathematical understanding. According to Simon, learning trajectory consists of three components: (a) the students' learning goal, (b) a hypothesis about the process of the students' learning of mathematical concept, and (c) tasks to be used to promote the students' learning (Simon, 1995).

Studies regards the learning of the accumulation function concept (Thompson, Byerley, & Hatfield, 2013), have examined the role of graphic and numeric artefacts in learning the accumulation function. In these studies, technology was used mostly in attempts to relate a function with its accumulation function in a simulated-physical situation such that of time graphs involving velocity and position (e.g., Noble, Nemirovsky, Wright, & Tierney, 2001). The present study examines the learning of the integral concepts analytically by high school students as they learn it with dynamic, interactive, and multiple-representation artifacts.

Multiple-representational artifacts enable the development of learning environments that present in separate linked windows the accumulation and its rate of change functions. In an attempt to identify a learning trajectory which help students conceptualizing the accumulation function, our study was designed to explore the objectification processes of the accumulation function when it learn by multiple-linked representations and interactive artifact. To do so, we explore the ways in which high school students learn the accumulation function with multiple-linked representation artifact.

THEORTICAL FRAMEWORK

The study was carried out using the theoretical framework of semiotic mediation (Bartolini Bussi

& Mariotti, 2008) and the theory of knowledge objectification (Radford, 2003). The semiotic mediation theory considers learning as an alignment between the personal meanings arising from the use of a certain artifact for the accomplishment of a task and the mathematical meanings that are deposited in the artifact. Personal meanings are to refer "to a state in which a learner believes/feels/thinks (tacitly or explicitly) that he has grasped the cultural meaning of an object (whether he has or has not)," and a mathematical meanings are to refer, "to the extent that its usage is congruent with its usage by the mathematical community" (Berger, 2005, p. 83). In the context of using artifacts, the semiotic mediation theory describes the relations between personal meanings and mathematical meanings as a double semiotic relationship. On one hand, concentrating on the use of the artifact for accomplishing a task, recognizing the construction of knowledge within the solution of the task. On the other hand, analysing the use of the artifact, distinguishing between the personal meanings arising from the use of the artifact in accomplishing the task and meanings that an expert recognizes as mathematical when observing the students' use of the artifact in order to complete the task. Radford (2003) suggests a semiotic tool to analyse the dynamically evolving relationship between personal and mathematical meanings. The basic components of the semiotic tool are the students' progressive attention and awareness of the mathematical object. Varieties of semiotic means of objectification that have a representational function attract the students' attention to mathematical objects. Furthermore, the properties of the artifact can help students attend to the mathematical objects related to the activity under consideration. Paying attention to the necessary aspects of the mathematical phenomenon and using various semiotic means of objectification, students become aware of the attributes of mathematical objects within that phenomenon. Being aware, students attain objectification of the mathematical objects, which then become apparent to them through various devices and signs.

Given the cultural knowledge deposited in any designed artifact, we consider the linked graphs, the table of values, and the control tools that are the focus of the present study as culturally determined signs that convey knowledge regard the accumulation function. The accumulation function is represented symbolically as $\sum_{i=1}^{n} f(x_i) \cdot \Delta x_i$. The mathematical structure of the accumulation function involve variety of mathematical elements. Such as Δx, product $f(x)\Delta x$, and sum of products $\sum f(x)\Delta x$. These elements are deposited in the artifact used in this study.

The students' learning goal is to come up with conjectures about the mathematical relationship of the accumulation function. We hypothesize the students should become aware of the mathematical elements of the accumulation function as they interact with the artifact. Our aim is to explore the ways in which students become aware of the idea of accumulation as it is represented in the artifact. We propose to answer the following research question:

How and what are the mathematical elements used by the students in the process of becoming aware of the mathematical meanings of the accumulation function when it is learned with multiple-linked representational artifact?

SEMIOTIC POTENTIAL OF THE ARTIFACT

The interactive integral and accumulation artifacts at the heart of our study are part of the calculus unlimited (CUL) artifact. As a multi-representational artifact, CUL contains different types of tools that we grouped into four categories.

I) *Graphing tools*: Two vertically aligned Cartesian systems, coordinated vertically. The trajectory in the upper Cartesian system signifies a function. The function is defined symbolically by the free input of a single variable expression. The trajectory in the bottom system presents the values of Riemann sums $\sum_{i=1}^{n} f(x_i) \cdot \Delta x_i$.

II) *Numeric tools:* The associated table of values contains three columns. The left column presents the upper boundary values, the middle column presents the delta x values and the right column shows the accumulated values.

3) *Accumulation tools*: Because our study focused on the computation of rectangles, the rectangles that appear on request in the upper Cartesian system (the function system) represent the product of $f(x_i + \Delta x_i)\Delta x_i$. Rectangles are color-coded to reflect the product sign (positive or negative) (Figure 1).

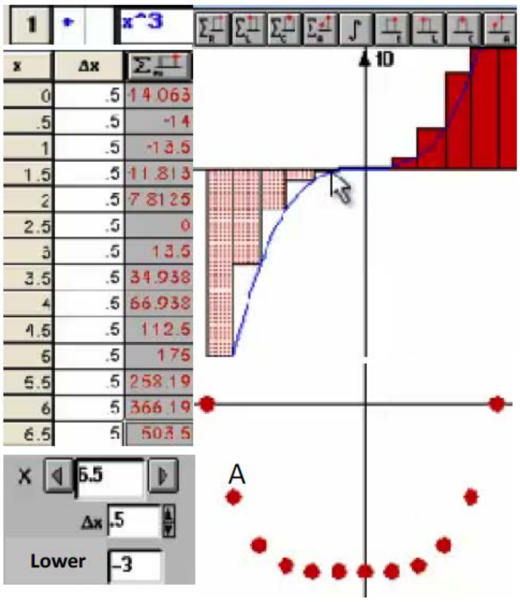

Figure 1: CUL interface

IV) *Boundaries tool:* After the function *f* and the method of accumulation are specified, three parameters determine the value of the accumulation at a given point: the lower and upper boundaries of a bounded region and the width of each interval into which the region should be divided. The design of CUL attempts to direct the attention of the user to these parameters and emphasizes especially the control over the upper boundary value, with its immediate visual feedback of a value of accumulation points. Students control the bounded area by using arrows to move a marker in intervals of Δx to the left or to the right of the lower boundary (Δx is an absolute measure of the interval, thus always achieving a positive value both right and left of the lower boundary). The upper boundary value is represented in the accumulation function graph by a marked coloured point and in the table of values.

STUDY DESIGN

The present study explores approximately 12 hours of learning by 13 pairs of 17-year-old students from two different schools in Israel. The students volunteered to participate in five after-school meetings. At the time the meetings took place, the students had already learned the concepts of function and derivative. The Author introduced them briefly to the interface and illustrated how to use it. He explained, for example, how to input the symbolic expression, how to change the controlling parameters. In particular, the students were told about the technical functionality of the artifact.

To promote the processes of objectification of the accumulation function, we asked the students to explain and explore the possible connection between two given function graphs and the table of values. They were given the instructions in Figure 2.

The learning took place in the computer lab at school. Students were video-recorded and the corresponding computer screens were captured.

Data Analysis. The data analysed through two levels: (a) the macro level: identifies the mathematical elements involved in objectifying the accumulation function. Mathematical elements were defined as segments of discourse in which the students sought to discover the mathematical relationship inherent the accumulation function, for example, delta x, product, sum of product, and the positions of the accumulation function graph. (b) at the meso level, we analyzed the data in two stages: (a) we distinguished personal meanings that are accepted mathematically from those that are not. Statements that in the context of the accumulation function are mathematically wrong were defined as personal meanings that are not accepted mathematically. By contrast, statements that are mathematically correct in the context of the accumulation function were defined as personal meanings that are accepted mathematically. For example, statements like "the y-value of the initial point in the accumulation function is equal to the height of the rectangle," which refers to the objectification product

The task is to explore and explain possible connections between graphs in the upper and the lower Cartesian systems and the linked table of values. You should be able to input function expressions and obtain a pair of graphs such as f(x) = x^2, x^2-9, x^3, (x+3)(x-1)(x+4). While working on the task you may use the CUL artifact to generate graphs by means of symbolic expression, and change the value of X by pressing the ◄ ► arrows in the upper part of the value box, as needed. As default values you can ask to specify 0.5 in Δx box, -3 in the lower box, and -3 in the X box.

Figure 2

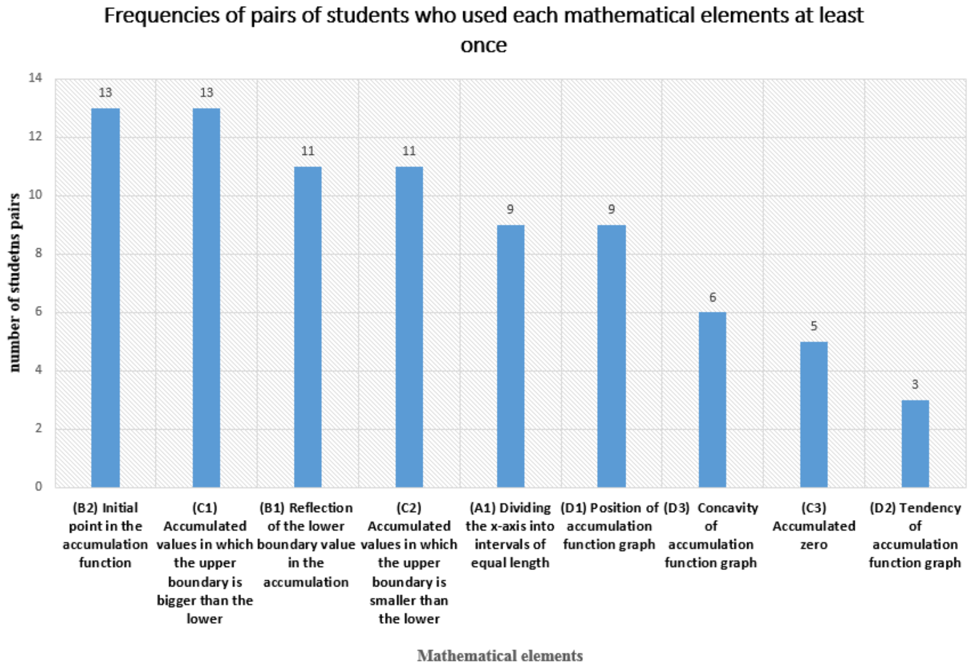

Figure 3: Frequencies of pairs of students who used each elements at least once

were defined as personal meanings that are not accepted mathematically. For each value of delta *x* other than 1, the initial point in the accumulation function is equal to the product of the rectangle dimensions, but not equal to the height of the rectangle. For this reason, we defined this statement as a personal meaning that is not accepted mathematically. Statements like "the y-value of the initial point in the accumulation function is the same as the first rectangle area" were defined as personal meanings that are accepted mathematically. (b) we applied the strategy of evolution over time to each pair of students, to analyze the evolution of personal meanings into mathematical ones over time.

FINDINGS

The detected elements were grouped into four categories: (a) objectifying delta x as splitting the x-axis into equal-length segments, (b) objectifying the product, (c) objectifying the sum of product, and (d) objectifying the properties of the accumulation function graph. Categories (b), (c), and (d) were divided into subcategories based on the mathematical element that is under consideration. In the graph below, we summarized the frequencies of pairs of students who used each element at least once in the learning process.

We found that all the students tried to objectify the product $f(x)\Delta x$, which are represented by the initial value point in the accumulation function graph (point A, Figure 1). Furthermore, all of them tried to objectify the sum of product in a domain in which the upper boundary values are bigger than the lower boundary values (B2, C1). The majority of students (11 pairs) considered the reflection of the lower boundary value in the accumulation function graph (B1). Eleven pairs of students also tried to identify the accumulation function in a domain in which the upper boundary values are smaller than the lower boundary values (C2). Nine pairs tried implicitly to identify delta x as dividing the x-axis into segments of equal length (A1). Nine pairs also considered the position of the accumulation function graph relative to the x-axis (D1). Six pairs tried to objectify the concavity of the accumulation function graph (D3). Five pairs considered the accumulated zero (C3), and three pairs considered the tendency of the accumulation function graph (D2)

Paths followed to learn the accumulation function

In Table 1 we present a distinction between personal meanings that are accepted mathematically and those that are not. The number of episodes associated with each category is also shown in Table 1. For example, in row B2 the number 41 indicates that 41 of all the episodes are associated with the mathematical element 'product' represented by the "Initial value point in the accumulation function." Eighteen of these were considered to be accepted mathematically and 23 were not.

We counted a total of 211 episodes containing mathematical elements. Five percent (10/211) of the episodes were devoted to identifying delta x as dividing the x-axis into intervals of equal length. Thirteen percent (27/211) were devoted to identifying the reflection of the lower boundary value in the accumulation function graph. All of these but one were coded as meanings accepted mathematically. These findings may indicate that the objectification of these two mathematical elements was not challenging for the students. It is possibly that the design of the artifact helped students objectify these mathematical elements. Twenty one percent of the episodes (41/211) were devoted to the objectification of the initial value point. Twenty-three of these were coded as personal meanings that are not accepted mathematically. This finding may indicate that objectification of the product was challenging for the students.

Twenty seven percent of the episodes (57/211) were devoted to objectification of the accumulated values when the upper boundary value is bigger than the lower one. Forty-four episodes of these were coded as personal meanings that are accepted mathematically. In contrast, among the 31 episodes that were devoted to objectification of the accumulated values when the upper boundary value is smaller than the lower one, only four were coded as personal meanings that are accepted mathematically. This finding indicates that the students were better able to objectify the sum of product when the upper boundary is bigger than the lower boundary than the other way around.

Seventeen percent of the episodes (35/211) were devoted to objectification of the properties of the accumulation function. Only three episodes of these were coded as personal meanings that are not accepted mathematically. Twenty-two episodes were devoted to objectifying the position of the accumulation function graph. Two of these were coded as personal meanings that are not accepted mathematically. Four episodes were devoted to the tendency of the accumulation function, and all of them were coded as accepted mathematically. Nine episodes were devoted to the concavity of the accumulation function graph and coded as accepted mathematically. This finding indicates that the students who noticed the last two elements also became aware of their mathematical meaning.

Below we present evolutionary path in the learning process, which we identified through the data analysis. A learning path refers to the organization of learning activities in a proper order composed of knowledge elements, designed task, and artifact such that students can effectively study a subject area.

The chart in Figure 4 show the order in which students were engaged with various mathematical elements, showing also the time elapsed. The data are color-coded. The mathematical elements appear in the left column. The numbers at the bottom represent the time in minutes. We divided each minute into four squares, each one representing 15 seconds. The colours distinguish between personal and mathematical meanings. The grey colour represents personal

Elements	*AcceptedΔ*	Not accepted	*Total*

Table 1: Frequency of mathematical elements distinguishing personal meanings that are and are not accepted mathematically

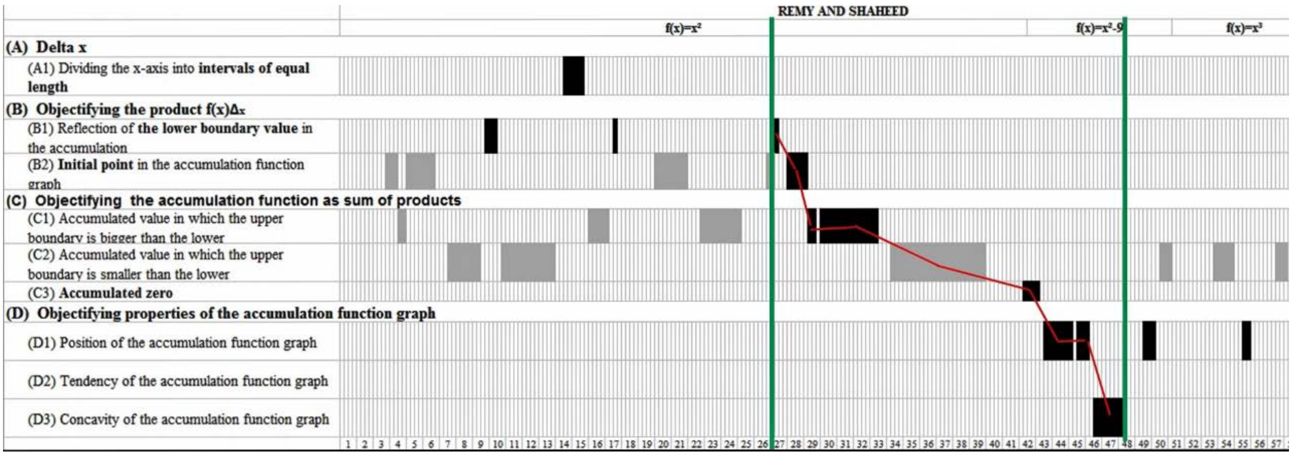

Figure 4: Learning path for Remy and Shaheed

meanings that are not accepted mathematically; the black colour represents personal meanings that are accepted mathematically.

Analysis of the charts suggests a possible path for learning the accumulation function graphically. The chart (Figure 4) illustrate the suggested path, which consists of four phases: (a) objectifying delta x, (b) objectifying the product, (c) objectifying the sum of product, and (d) objectifying the properties of the accumulation function graph. Despite the differences between the charts, the similarity between them is apparent in the trend line.

The students initially identified delta x and ascribed mathematical meaning to it as a divider of the x-axis into intervals of equal length. It seems that objectifying delta x and becoming aware of its role was an important aspect of objectifying the product $f(x)\Delta x$. Students who initially tried to objectify mathematical elements other than delta x returned to objectify delta x after several unsuccessful attempts at identifying the other elements (Figure 3). Objectifying the reflection of the lower boundary value in the accumulation function occurred before the objectification of the initial accumulated point in the accumulation function graph. This finding may point to the principal role played by the lower boundary in students becoming aware of the accumulation function. Although our analysis shows that becoming aware of the product was a complex process (row B2, Table 1), eventually most students were able to objectify the product and ascribe mathematical meaning to it. However, analysis of the chart shows that these students undertook several attempts before becoming aware of the mathematical meaning of the product (Figure 4). This finding indicates that students were able to overcome the complexity of objectifying the product.

Objectifying the sum of the products usually occurred after the students have objectified the product $f(x)\Delta x$. Students who tried to objectify the sum of the products before becoming aware of the product $f(x)\Delta x$ were not able to do so (grey segments in row C1 in Figure 3). Analysis of the chart reveals that only three episodes out of 13 that were coded as not accepted mathematically in category C1 (accumulated value in which the upper boundary is bigger than the lower, Table 1) occurred after the students objectified the product $f(x)\Delta x$. This finding indicates that objectifying the product $f(x)\Delta x$ made possible the objectification of the sum of the products $\sum f(x)\Delta x$.

DISCUSSION

The learning trajectory suggested in this study is comprised of four phases of objectification: (a) delta x, (b) product, (c) sum of product, and (d) accumulation function graph properties. Since delta x is central element of the mathematical structure of the accumulation function, becoming aware to it meanings is an essential part in understanding the accumulation function. The linked dynamic representation play a central role in objectifying delta x. Our decision to determine that delta x is a fix-equal value was inspired by pedagogical rather than mathematical considerations. This decision found useful in drew the students attention which afford them to become aware of the mathematical meanings of delta x.

Objectifying the product was challenging for the students. This finding is consistent with those of Sealey's (2014) study, claiming that difficulties in understanding the product are not necessarily related to performing calculations but rather to how the product is formed. Our findings indicate that the complexity of becoming aware of the product was not related to performing the calculation but to the semiotic structure of the multi-representations. Although, the complexity that accompany the objectification of the product, eventually the students were able to overcome this complexity. The properties of the function graph and controlling the upper boundary afford the students to objectify the product. Varying the upper boundary parameter in a discrete manner and its reflection on the multi-representations drew the students' attention to the connection between the emerging rectangles and the accumulation function graph. The semiotic potential of the artifact encourages the emergence of personal meanings and that the control tools promote evolution toward the accepted mathematical meaning. Concerning objectifying the sum of product, the students have partially become aware of the sum of product. On one hand, objectifying the sum of product in which the upper boundary is bigger than the lower was less challenging for them (Table 1). On the other hand, despite our attempt to provide students with a wide variety of graphs to help them objectify the meaning of the accumulation function for each value of x, they were not able to objectify the accumulation graph in which the upper boundary is smaller than the lower boundary value. This finding is not completely consistent with Sealey's findings that "None of the students spent much time explicitly discussing the concepts represented in the summation layer" (p. 240).

In spite of, the properties of the accumulation function graph is not mentioned implicitly in the mathematical structure. However, becoming aware to the properties of the accumulation function graph is epistemologically important since the transition from local to global observation means an evolution of the meanings because of theoretical reasons. Hence, we believe that this phase should be included in the learning path for objectifying the accumulation function.

ACKNOWLEDGEMENT

This study is a part of Ph.D. dissertation under supervision of prof. Michal Yerushalmy.

Student perceptions on learning with online resources in a flipped mathematics classroom

Evangelia Triantafyllou and Olga Timcenko

Aalborg University Copenhagen, Department of Media Technology, Copenhagen, Denmark, evt@create.aau.dk

This article discusses student perceptions of if and how online resources contribute to mathematics learning and motivation. It includes results from an online survey we conducted at the Media Technology department of Aalborg University, Copenhagen, Denmark. For this study, students were given links to various online resources (screencasts, online readings and quizzes, and lecture notes) for out-of-class preparation in a flipped classroom in mathematics. The survey results show support for student perceptions that online resources enhance learning, by providing visual and in depth explanations, and they can motivate students. However, students stated that they miss just-in-time explanations when learning with online resources and they questioned the quality and validity of some of them.

Keywords: Student perceptions, screencasts, Khan Academy, flipped classroom, mathematics education.

INTRODUCTION AND CONTEXT

One of the recent developments in teaching is the flipped (or inversed) classroom approach (Bergmann & Sams, 2012). In a flipped classroom the traditional lecture and homework sessions are inverted. Students are provided with online material in order to gain necessary knowledge before class, while class time is devoted to clarifications and application of this knowledge. The course content, which is provided for self-study, may be delivered in the form of screencasts and/or pre-class reading and exercises, while class time is mainly used for group work activities. The hypothesis is that there could be deep and creative discussions when the teacher and students physically meet. This teaching and learning approach endeavours to make students owners of their learning trajectories, and relies heavily on current technology.

Various researchers and instructional designers have sought to investigate the advances in flipped learning environments (Bishop & Verleger, 2013). According to such studies, students were very positive about their experience and instructional video components in flipped classrooms (Love, Hodge, Grandgenett, & Swift, 2014) and suggested that flipped classroom approach (1) provided them with an engaging learning experience, (2) was effective in helping them learn the content, and (3) increased self-efficacy in their ability to learn independently (Enfield, 2013).

While the aforementioned approaches report on benefits of the flipped classroom, there are also critics to this approach (Kellinger, 2012; Nielsen, 2012). Concerns include among others: criticism about the accessibility to online instructional resources, the growing move towards no homework, lack of accountability for students to complete the out-of-class instruction, poor quality video production, and inability to monitor comprehension and provide just-in-time information when needed.

Taking into consideration the reported strengths and weaknesses, we introduced this instructional model to a statistics course for Media Technology students (Triantafyllou & Timcenko, 2014). The results of this study revealed appealing qualities but also drawbacks of flipped mathematics classrooms. One of our biggest concerns was the resources, which students would get as a preparation for the class. In that study, the students got links to online mathematics courses, lecture slides from a mathematics course they had attended, and screencasts of problem solutions. The screencasts were produced by us using a smart pen. With regard to the screencasts, the results showed that students found them helpful, they appreciated the fact that they could skip or re-watch parts of the solution, and they felt they were supported when studying challenging concepts. Nevertheless, less than half of them watched most of them and they mentioned as a weakness the fact that they cannot ask questions for clarification during a recorded lesson. Moreover, our personal experience was that creating quality screen casts is time consuming and hard.

Therefore, we decided to conduct a survey study in order to further investigate student perceptions and preferences on online resources and especially screencasts as part of a flipped mathematics classroom. The study was carried out during a mathematics workshop, which was implemented using the flipped classroom model. The workshop was offered to fifth semester Media Technology students as an introduction to their computers graphics rendering and computers graphics programming courses. In the following sections, we discuss previous studies on student perceptions on online resources and describe our methodological approach. Afterwards, we present and analyse the results of this survey study. We conclude this paper with a discussion and an outline of future work.

BACKGROUND

Various researchers have sought to investigate student perceptions and learning with online resources, both in traditional and flipped classrooms (McGarr, 2009). In the case of traditional classrooms, online resources are given to students for revision or preparation for assessments. Regarding student use of such resources, Biehler et al. introduced interactive modules containing domain knowledge, exercises, diagnostic tests and illustrations within blended bridging courses in mathematics and found that slightly more than 50% of the students used the diagnostic tests (Biehler, Fischer, Hochmuth, & Wassong, 2012). Kay and Kletskin introduced problem-based screencasts covering key areas in mathematics. The screencasts were created as self-study tools, and used by higher education students to acquire pre-calculus skills (Kay & Kletskin, 2012). The results indicated that a majority of students used the screencasts frequently.

As far as student perceptions of online resources are concerned, Biehler et al. found that students considered them helpful, while Kay and Kletskin reported that students viewed online resources as easy to use, effective learning tools, rated them as useful or very useful, and reported significant knowledge gains in pre-calculus concepts.

Factors that determine student perceptions of online resources have been also investigated. In the study by Biehler et al., the results showed that the use of such resources was highly depended on the learning type of the student. Yoon and Sneddon conducted a study on student perceptions of the effective use of lecture recordings (screencasts) in undergraduate mathematics courses and they identified a set of factors that determine student perceptions of live and recorded lectures as competing or complementary. Personal learning styles, study habits, esteem for the lecturer and the possibility of interaction in the lecture can namely make students prefer live lectures rather than lecture recordings (Yoon, Oates, & Sneddon, 2014).

Nevertheless, there are researchers, who challenge the learning that unfolds in online environments (Parslow, 2012; Schwartz, 2013). Such critics claim, for instance, that some online resources have no pedagogical underpinnings, don't allow learners to build knowledge hierarchically, and don't offer meaningful or personalized feedback.

Our past research revealed that Media Technology students encounter challenges in their mathematics learning, because they lack motivation and basic skills in mathematics (Triantafyllou & Timcenko, 2013). In our previous study these students perceived screencasts to be helpful and supporting for out-of-classroom learning, but we wanted to investigate further if and why these students choose to learn using such resources.

METHODOLOGY

In order to explore student perceptions and preferences on online resources, we conducted an online survey study at the Media Technology Department of Aalborg University Copenhagen. We surveyed fifth semester students, who had just finished a mathematics workshop, which served as an introduction to two semester courses: computer graphics rendering and computer graphics programming. This workshop aimed at recapitulating prerequisite mathematics knowledge for these courses (i.e. linear algebra, geometry and trigonometry).

The mathematics workshop followed a flipped classroom model of instruction. To facilitate this, we created a list of various online resources to provide students with instruction outside of the classroom (before the lectures). We gave students a detailed reading guide that provided information on the topics covered by each resource and a studying sequence. The online resources included: (1) Selected Khan Academy screencasts and related practice problems (www.khanacademy.org/), (2) Selected sections of the www.mathisfun.com webpage, that contains both explanations, visualizations and quizzes, (3) Selected readings from the www.betterexplained.com webpage, which aims at presenting mathematics in an intuitive way, using text and visualizations, (4) scanned lecture notes from their past mathematics course covering the relevant subjects. We chose different sources, in order to provide support in solving exercises, brief and simple introduction to the related concepts and real-life examples and intuitive explanations. Students had to take an online quiz out of classroom before attending the workshop. The quiz contained questions similar to past mathematics exams. Therefore, the students were aware with this kind of questions. We used the quiz in order to observe student understanding, recurrent misconceptions and common mistakes, since the vast majority of students had passed these exams in the past. The information exchange between the teacher and the students (i.e., resources for out of classroom learning, assignments, news forum) and the quizzes were facilitated by the Moodle VLE.

The online survey used a Likert scale in order to collect student responses on use of the assigned or other online resources, and on perceptions of learning when using them. Items in the survey were measured using 5-point rating scales, with the range of answers from "strongly disagree" to "strongly agree." Moreover, there were items, which gave students the opportunity to provide information in an open-ended manner.

The survey was sent to the 100 students subscribed to the mathematics workshop. Since the survey was optional, it was not possible to ensure all students completed it. Forty six students responded to the survey, yielding a response rate of 46%. The response rate is relatively high, but it should be noted that it was not a simple random sample. For example, there could be bias towards more diligent students (who may be potentially more likely to give positive feedback), or only the students who actually used the online resources. The results of our past study and the large sample size help to some extent to mitigate the influence of this bias.

RESULTS AND ANALYSIS

From the analysis of the survey results, we excluded two responses, because they were incomplete. Therefore we had a sample size of forty four responses (N=44, 61% male and 39% female). Nearly all survey respondents (91%) said that they had used some online resources in mathematics either for the mathematics workshop or in the past (Figure 1). The distribution of usage for the different resources is shown in Figure 2 (students were allowed to select more than one option). One third of the respondents having used some online

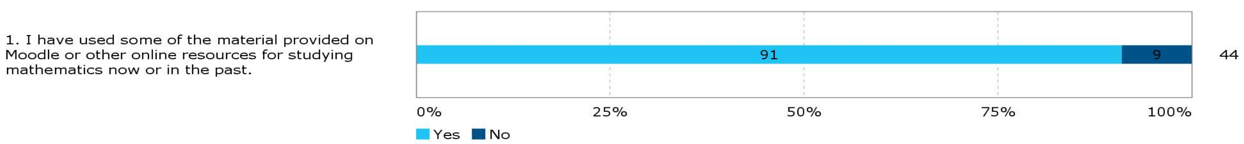

Figure 1: Proportion of students surveyed who have used online resources for mathematics

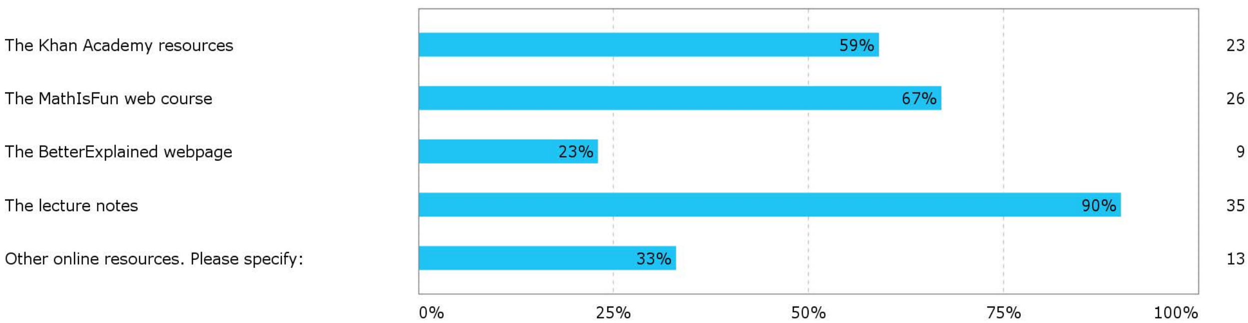

Figure 2: Distribution of answers to the question "Which material have you used?"

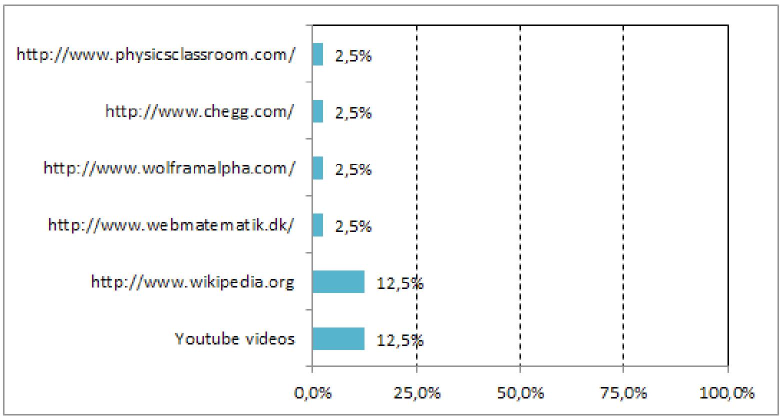

Figure 3: Distribution of other online resources among survey responses

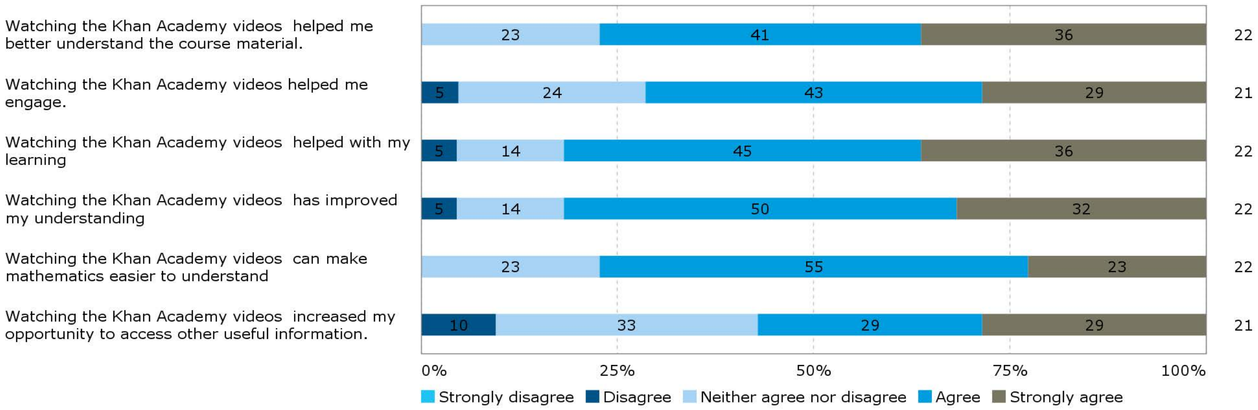

Figure 4: Percentage agreement and disagreement of students with statements on watching Khan Academy videos (screencasts)

resources, made also use of resources we did not suggest. These resources are shown in Figure 3.

Students who used online resources were invited to respond to a series of statements on watching Khan Academy screencasts and reading online resources. We made this separation, because watching a problem solution triggers different thinking from reading a text or even a written solution to a problem. In the following analysis, we combine "Strongly agree" and "Agree" answers to summarize those people who agreed with the statements and "Strongly disagree" and "Disagree" answers to summarize people who disagreed with the statements.

Figure 4 summarizes the results for the statements on Khan Academy screencasts. A significant majority of students who used these screencasts found that watching them has helped with their learning and has improved their understanding (82% and 81% respectively). The statements on screencast contribution on understanding the course material and making mathematics easier received also high agreement scores (78% and 77% respectively). Less strong agreement (72%) was seen with the second statement, which relates to their use for increasing engagement and even less (58%) with the statement about screencasts increasing opportunities to access other useful information.

Figure 5 summarizes the results for the statements on other online resources. The vast majority of students who used some kind of online resources found that reading online resources has helped with understanding the course material and has improved their understanding (90% and 86% respectively). The statements on screencast contribution on improved learning and on increasing opportunities to access other useful information received also high agreement scores (82% and 79% respectively). Less strong agreement (76%) was seen with the fifth statement, which relates reading online resources to making mathematics easier to understand and even less (58%) with the statement on online resources helping students engage.

In addition to agreeing or not with these statements, we asked students to define the strong and weak points of these resources. We included these two open-ended

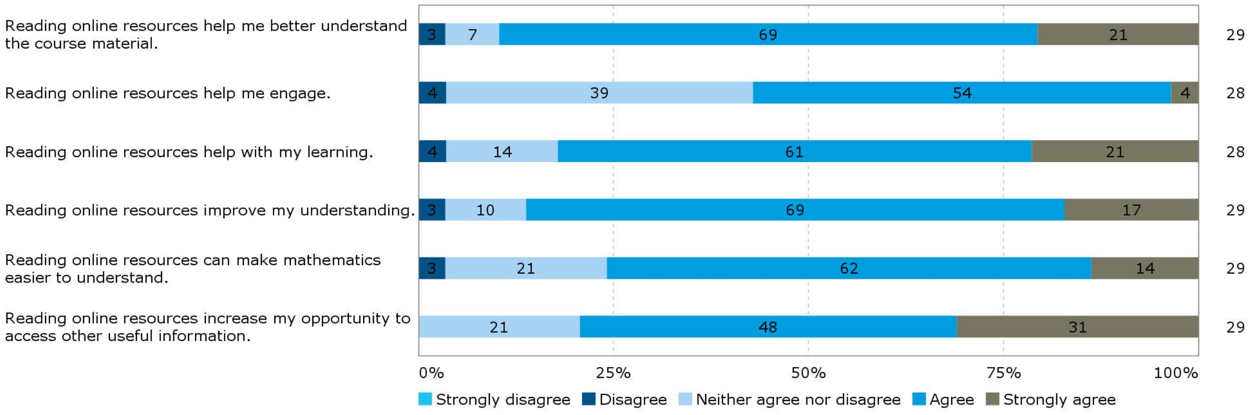

Figure 5: Percentage agreement and disagreement of students with statements on reading online resources

Strong points	Frequency	Weak points	Frequency
The narrator is good at explaining	27.3%	None	13.6%
You can pause/rewind	18.2%	They are long	13.6%
Visual explanations	18.2%	I don't know	13.6%
They come along with quizzes	18.2%	No one to ask questions	9.1%
They helped me focus	13.6%	Complicated language	9.1%
Clear structure	9.1%	They are boring	4.6%
Good tempo/pace of explanation	9.1%	Too abstract	4.6%
Easy to understand	4.6%	Sometimes confusing	4.6%
Step by step explanations	4.6%	Knowledge does not "stick" in memory if you just watch and don't practice yourself	4.6%
They are fun	4.6%		
Easily accessible	4.6%	You don't know which video to watch, in case you experience knowledge gaps	4.6%

Table 1: Student perceptions on strong and weak points of Khan Academy screencasts

Strong points	Frequency	Weak points	Frequency
Different explanations for the same topic	31.0%	No one to ask questions	20.7%
Easily accessible	17.2%	Debatable quality / validity	20.7%
Visual explanations, animations	17.2%	Possibly time consuming to find what needed	13.8%
Can be fun	6.9%	Overwhelming amount of information	10.34%
Explanations on specific topics	6.9%	Sometimes confusing	6.9%
A fast way to find information	6.9%	Notation and categorization may differ	6.9%
Easy to understand	6.9%	Possibly inaccessible due to technical problems	3.5%
Reproducibility	3.4%	No one to check your understanding	3.5%
You can get help from others	3.4%	Our brain gets used to search for knowledge, not to memorize it	3.5%
They are fun	4.6%		
Some come along with quizzes	4.6%		

Table 2: Student perceptions on strong and weak points of reading online resources

questions, because we wanted to give students the opportunity to provide further information on their perceptions in an open-ended manner. The strong and weak points of Khan Academy screencasts as pointed out by the students are shown in Table 1, while the strong and weak points of reading online resources are shown in Table 2. For building these tables, we have grouped answers with the same meaning but different wording.

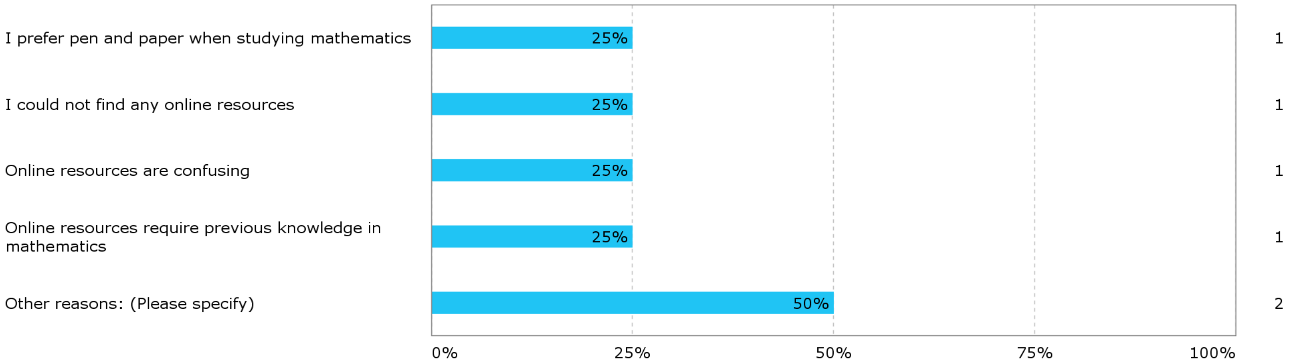

Figure 6: Distribution of answers to the question "Why have you never used online resources?"

Respondents who said that they did not use any online resource for mathematics were asked the reasons for it. Fifty percent of the students mentioned other reasons, namely "I was never introduced to anything good" and "(they are) too complex, no explanations, (I) can't even solve the very first exercise". The other statements were equally favored by students (Figure 6). Students were also asked which tools they use for studying mathematics. Books and notes were mentioned by 50% of the students, pen and paper by 25%, Matlab by 25% and study groups by 25%.

DISCUSSION AND CONCLUSION

In this online study, we surveyed Media Technology students on their perceptions on online resources in mathematics. The survey consisted of both close- and open-ended questions in order to better sketch student perceptions. We observed a general consistency between close- and open-ended questions. Regarding Khan Academy screencasts, students found them to provide good and detailed explanations, although some mentioned that they look messy or confusing sometimes. Students perceived them also as being engaging and helping creating focus. The least supported statement on screencasts is the one on screencasts creating links to other useful information. This can be explained by the mission of the Khan Academy website to be a closed environment, where students should find all the information and support they would need (screencasts, practice problems, feedback from teachers/peers, etc.). What students missed in screencasts was mostly the ability for just-in-time explanations, being shorter and using less complicated language. However, the last one can be attributed to the fact, that Media Technology students lack basic skills and thus also terminology in mathematics. Another fact worth mentioning is that 13.6% of the students stated that screencasts have no weak points. We would like here to acknowledge the fact that questionnaire data can be biased since survey respondents tend to answer questions in a manner that will be viewed favorably by others (King & Bruner, 2000). Therefore, we plan on incorporating more reliable methods for collecting data on resource usage, such as analyzing log data from Moodle.

Reading online resources were perceived by students to help answering specific questions and understanding the course material. They are perceived also as a means to find links to other useful information and to find different explanations on the same topic. Animations and visualizations are other aspects that students valued with regard to online resources. Nevertheless, 20.7% of the students mentioned the lack of just-in-time explanations and the matter of the quality and validity of such resources. There were also students (13.8%) stating that it could be time consuming to browse the internet for specific information.

As to the reasons for students not to choose online resources, the survey results show some indication that there are students who still prefer books and pen and paper for studying mathematics. However, the number of students who completed the survey and did not use online resources is very small (N=4), therefore we cannot draw any statistically significant conclusions based on these answers.

The survey results indicate that online resources were seen by students completing the online survey as valuable and useful as an aid to learning. We conducted this study in the context of a flipped classroom, where students were asked to prepare themselves before the lectures, by using this aid. Since working with mathematics by themselves is perceived by students the most important learning (Sikko & Pepin, 2013), we believe that the decision of which tools should support this individual learning is a crucial one. Our survey has indicated that watching screencasts is perceived more engaging than reading online resources, while reading online can help to find explanations that make sense to the individual. However, students still perceive face-to-face instruction as paramount, since the problems of the inability to follow comprehension and the lack of just-in-time explanations are still to be solved.

Although the results revealed that students perceive online resources as contributing to their learning and understanding, it is difficult to draw firm conclusions in terms of improvements to student learning as at this stage it has not been possible to measure this quantitatively. In the literature, there are few studies on the flipped classroom that examined student performance throughout a semester. In such cases, mainly pre- and posttest methods have been employed for student assessment. While the results from such studies are encouraging, there is not sufficient evidence for generalization beyond specific contexts (Bishop & Verleger, 2013). Thus, a further quantitative study will be designed for student assessment throughout a whole semester.

Discrete or continuous? – A model for a technology-supported discrete approach to calculus

Hans-Georg Weigand

University of Würzburg, Würzburg, Germany, weigand@dmuw.de

In recent decades, the approach to calculus in mathematics classrooms has changed: a quite formal approach—closely linked to the teaching of calculus at university and based on the sequence concept—has been transformed to an intuitive access to the concepts of limit and derivative. The importance of sequences has so far decreased that they are sometimes no longer even taught in the calculus course. In recent years, this concept has been criticized for not developing adequate perceptions of the basic concepts of calculus and not sufficiently preparing the students for scientific courses at university. In this paper, we will present an alternative discrete step-by-step approach to the basic concepts of calculus. It shows the theoretical basis of the on-going project "ABC – A discrete Approach to the Basics of Calculus" (see Weigand, 2014).

Keywords: Calculus, discrete mathematics, limit, derivative, digital technologies.

During recent decades, teaching the concept of derivative in mathematics classrooms has changed. In the seventies and eighties of the last century, especially in continental European countries such as France, Italy, Germany, and the Eastern European countries, the limit concept was based—in close relationship to college or university mathematics—on extensive work with sequences. A formal definition of the limit of a sequence and the proving of certain theorems concerning the convergence of sequences were the basis for the definition of the derivative of real-valued functions. In the late eighties and nineties—based on the calculus courses of Emile Artin (1957) and Serge Lang (1964/1973)—the model of an *intuitive limit concept* was introduced in mathematics education, which was adopted as a concept for high schools (Blum 1975) and has since then been widely accepted in schools and is the dominant concept today (Törner et al., 2014).

Within the frame of the intuitive limit concept, no formal definition of a limit occurs. The access to the derivative starts with the discussion of real-valued continuous functions, using an intuitive limit concept such as "... coming closer and closer ..." and calculating the derivative of polynomial functions by algebraic transformations without any formal definition of the limit. Using sequences is not necessary in this concept, at least as long as one does not consider more complex functions, for example trigonometric and exponential functions. The idea of the original concept of a simplified limit concept in the 1980s has been to consider sequences "later," but in reality, for example in many new curricula such as in Germany, sequences are no longer part of calculus in mathematics lessons.

It becomes clear that this has been a turning point regarding the concept of calculus in mathematics lessons. The changes in the access to the derivative concept changed the contents and the structure of the entire calculus curriculum. A concept-oriented approach to calculus was substituted by an application-oriented approach. There is a danger that learners stay on an intuitive and technical level and that basic ideas or conceptions for a content-oriented or integrated understanding of the mathematical concepts are not given.

In the following, we ask for the *understanding* of the basic concepts of calculus, concerning:

— the present situation and (empirical) results if we look at the knowledge of students and freshmen at the university;

- the theoretical basis or the basic knowledge to be able to understand the mathematical concepts of limit and derivative;
- a constructive strategy to develop these basic concepts in the classroom.

This article gives a theoretical framework for a new or an alternative access to the basic concepts of calculus. It uses digital technologies as a calculation and drawing tool to present sequences or discrete functions and to compare the properties of different functions or sequences. It has to be seen as a basis for a follow-up empirical investigation.

CONCERNING THE UNDERSTANDING OF THE BASIC CONCEPTS OF CALCULUS

The understanding of the *concept of limit* has quite often been the subject of theoretical reflections and empirical investigations (Keene et al., 2014). It is well known that many students have problems with the formal definitions of the concepts of limit and derivative. They are either not able to use the definition properly in a given context, or they are able to solve problems on a formal level, but lack an advanced understanding of the concepts (e.g., Tall & Vinner, 1981). The main results of the investigations concerning the learning, teaching, and understanding of the limit concept in the last decades are:

a) Conceptual *understanding* of the formal limit concept is challenging for high school students as well as for some college and university students and requires explanations and visualizations using different representations (beyond the symbolic representation).

b) The understanding of the *process of the construction or calculation of limits* in the sense of *step-by-step processes on numerical and graphical levels* is essential for the understanding of the limit concept beyond a formal definition. This can be supported by computer visualizations.

To understand the *concept of derivative*, it is necessary—besides understanding limit processes—to have adequate conceptions of the *rate of change* and to understand—in relation to limit processes—the transformation from the *average* rate of change to the *local* rate of change (see Rasmussen et al., 2014).

There are numerous propositions concerning the use of digital technologies and their dynamic possibilities of visualizing the approximation processes on a numerical and graphical level (e.g., Kidron & Zehavi, 2002; Martinovic & Karadag, 2012). All those suggestions have in common that they work with real-valued continuous functions and visualize—with programs such as Geogebra[1]—the limit processes dynamically with a sequence of secants converging to the tangent in a point of the graph of the function and/or the numerical process of convergence in the frame of a table (in a spreadsheet). The necessary transition from the continuous perspective to the discrete stepwise process—the discretization process—concerning the limit process, which includes selecting either a sequence of points on the graph or a sequence of numerical values converging to a selected value of the function or to a point on the graph, has to be made by the learners on their own.

The detailed (re-)construction of the limit process and the possibility of step-by-step thinking in the frame of this process has always been the strongest argument for working with sequences and their limits before starting to work with the limit of real-valued functions and their limit processes, for example the first derivative.

SEQUENCES AND DIGITAL TECHNOLOGIES

As a consequence of the increasing role of digital technologies in mathematics and mathematics education, discrete mathematics, and hence sequences, have gained importance. This was emphasized by the NCTM *Standards for School Mathematics* (1989), which included discrete mathematics as a separate standard for grades 9 to 12: “Sequences and series ... should receive more attention, with a greater emphasis on their descriptions in terms of recurrence relations.”[2] Sequences are prototypes of discrete objects in mathematics.

In the *Principles and Standards for School Mathematics* (NCTM 2000), however, discrete mathematics is no longer a separate standard but is now distributed across the standards and spans the years from kindergarten through twelfth grade. *Iteration and Recursion*

1 www.geogebra.org

2 http://standards.nctm.org/Previous/CurrEvStds/9-12s12.htm

are explicitly emphasized as one of the three important areas of discrete mathematics.

Even though sequences are not explicitly defined or introduced as a separate concept in the mathematics curriculum, they are used quite often implicitly or in an intuitive way: Many real-life problems allow mathematical representations with sequences, for example growth processes or problems involving goods and their cost, or approximation algorithms such as the Heron-method for calculating irrational numbers or the Newton-method for calculating zeroes of functions are based on iteration sequences.

Nowadays, computers or digital technologies make it possible to generate sequences, to create symbolic, numerical, and graphical representations, and to switch between different representations—by just pressing of a button. In the following, digital technologies are a tool allowing a discrete access to the concept of limit and derivative as a preliminary stage working with these concepts on a continuous level.

A STEP-BY-STEP CONCEPT FOR A DISCRETE APPROACH TO CALCULUS

We will now present a concept of a discrete access to calculus, which develops the concept of the average rate of change based on a discussion of various sequences by looking at discrete functions. The advantage of this concept is not presented in the beginning, the concept of rate of change is instead developed by using discrete examples. By gradually changing the step size of the discrete actions at hand, limit processes are prepared by comprehensible step-by-step actions and are thus easier to understand. Here, the computer is used both as a tool for the representation and visualization of sequences and functions, and as well as a tool for creating recursively defined sequences in particular, which allows the user to switch between symbolic, numerical, and graphical representations (see Weigand, 2014).

Level 1: Sequences and growth processes

Sequences can be explained or defined on a formal level via an explicit mapping $a_n: \mathbb{N} \to \mathbb{R}$, or they can be defined recursively. This is widely used for the representation of growth processes, for example *linear* growth by , *exponential* growth by $a_{n+1} = A \cdot a_n$, and *limited* growth by $a_{n+1} = a_n + P \cdot (B - a_n)$, $n \in \mathbb{N}$, while all other variables are being real numbers. These sequences can easily be visualized using a spreadsheet or a computer algebra system such as Geogebra. The main goal of this first level is to become acquainted with the recursive kind of definition of sequences, to see the relationship between local aspects, between successive elements, and global aspects of the whole sequence, and to see the dependence of elements of the sequence on the initial value and the parameters. In (Thies & Weigand, 2003) and (Weigand, 2004) it is shown that high school students (grade 11) can solve problems in the frame of growth processes while working experimentally with digital representations of recursively defined sequences.

Level 2: Difference sequences

The aim of this second level is the introduction of the concept of difference sequences $(\Delta a_n)_{\mathbb{N}}$, $\Delta a_n := a_{n+1} - a_n$, of a given sequence $(a_n)_{\mathbb{N}}$. The concept may be introduced in connection with real-life problems, for example the average air temperature in one year during the last 100 years, which may be presented in a table and a graph. The given relations in examples like this are not based on algebraic formulas. This would encourage students to not immediately working on a formal level and foster the understanding of the relationship between the sequence and the difference sequence by operating s step-by-step.

Level 3: The concept Z-functions and their difference functions

3.1 Quadratic Z-functions

Starting with sequences or functions defined on the domain $\mathbb{N}$, we gradually extend the concept of sequence to functions defined on $\mathbb{Z}$, $f: \mathbb{Z} \to \mathbb{R}$, and advance to more subdivided discrete domains. We call functions $f: \mathbb{Z} \to \mathbb{R}$ "Z-functions." These functions f with $y = f(z)$ are "extended sequences," defined on integers $z \in \mathbb{Z}$,

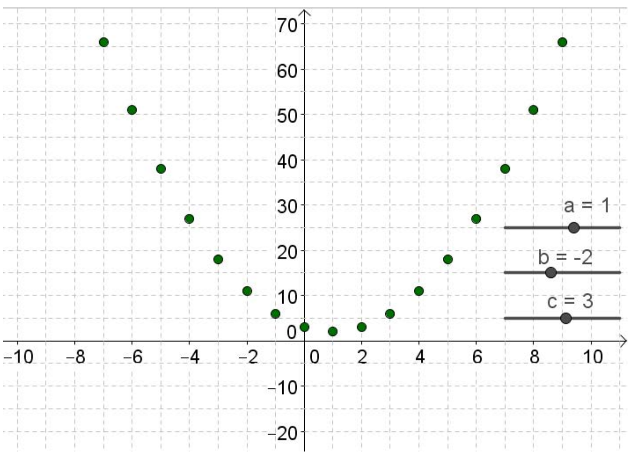

Figure 1: $f(z) = z^2 - 2z + 3$

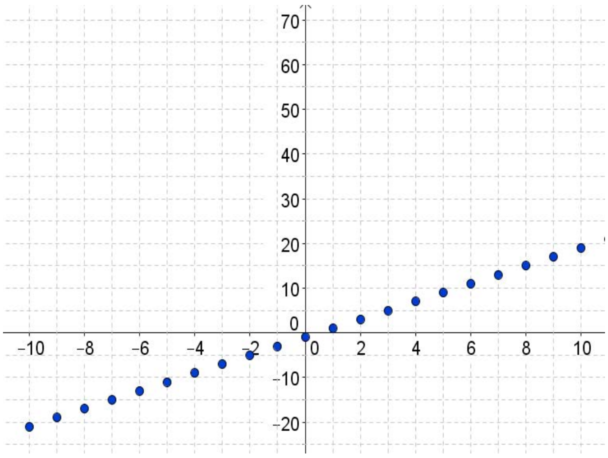

Figure 2: $D_f(z) = f(z + 1) - f(z)$

for example $f(z) = z^2 - 2z + 3$. We will now look at these Z-functions in relation to their difference-Z-functions D_f: $D_f(z) = f(z + 1) - f(z)$.

The values of D_f can be interpreted as the slope of a right-angled triangle with two legs of lengths $|f(z + 1) - f(z)|$ and $|\Delta z| = 1$. $D_f(z)$ is the *rate of change* of the graph between the points $(z, f(z))$ and $(z + 1, f(z + 1))$. Digital technologies are used to visualize the dependence of D_f on the used parameters of f: $f(x) = az^2 + bz + c$ graphically and to give reasons for the behavior of D_f.

3.2 Polynomial Z-functions

The concept of Z-functions can be extended to polynomial functions of a higher degree, as the respective difference functions can be obtained algebraically in an equally simple manner. For the family of Z-functions

$$f(z) = az^3 + bz^2 + c\,z + d,$$

for example, we get the (family of) difference-Z-functions D_f with

$$D_f(z) = 3az^2 + (3a + 2b)z + a + b + c.$$

We can see in particular that D_f is a quadratic function, which is also apparent in the graph.

As an example we look at the Z-function $f(z) = 0.1z^3 - z + 1$, with the corresponding difference-Z-function $D_f = 0.3z^2 + 0.3z - 0.9$ and their respective graphs.

The calculations can easily be extended to difference functions of higher order Z-functions, especially by using a CAS.

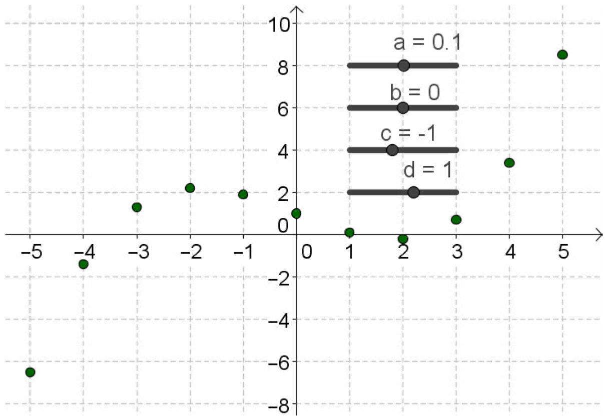

Figure 3: Z-function $f(z) = 0.1z^3 - z + 1$

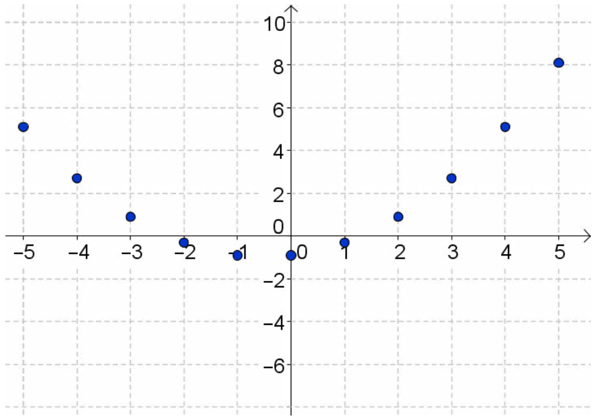

Figure 4: $D_f(z) = f(z + 1) - f(z)$

The advantage of working with these discrete functions is the possibility of obtaining the *rate of change of discrete polynomial functions* only through algebraic transformations and the possibility of *step-by-step argumentations* concerning the properties of the function, especially concerning the rate of change and the difference function.

3.3 Exponential Z-functions

Using the graphical representation of the Z-function $E(z) = a^z$, $a \in \mathbb{R}^+$, $z \in \mathbb{Z}$, and its difference-Z-function, we obtain the graphs shown in Figures 5 and 6.

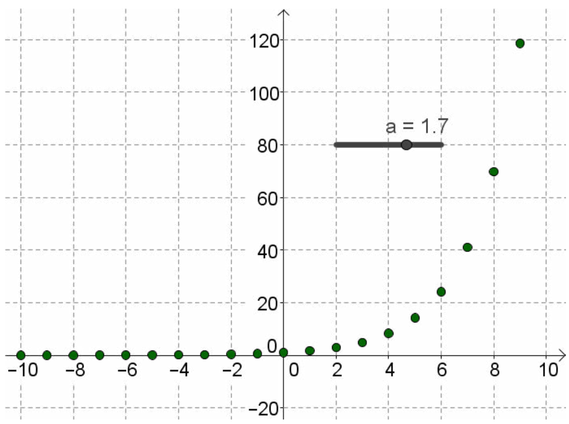

Figure 5: The Z-function $E(z) = 1.7^z$

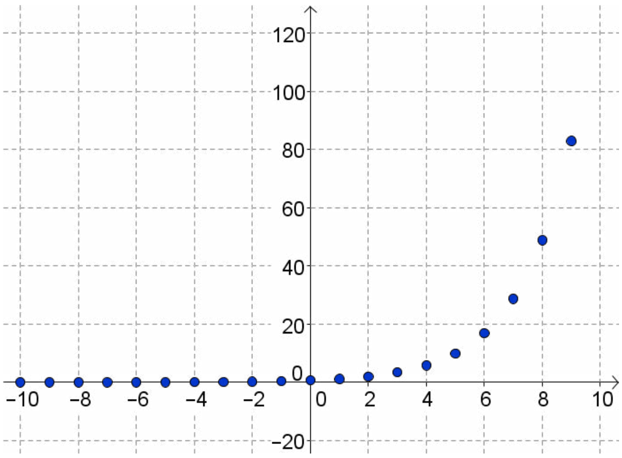

Figure 6: Difference sequence

It is striking how similar the "shapes" of the graphs of the Z-function and difference-Z-function are. A calculation on the formal level gives the following result:

$$D_e(z) = E(z+1) - E(z) = a^{z+1} - a^z = a^z(a-1) = E(z) \odot (a-1).$$

The value $D_e(z_0)$ is obtained by the difference sequence for a given value z_0 by multiplying the value $E(z_0)$ by the factor $(a - 1)$. Geometrically, the graph of the Z-function is the result of an orthogonal affinity of the difference-Z-function with the z-axis as the axis of affinity. For $a = 2$, the two graphs match exactly! There is therefore a value for which the difference-Z-function equals the Z-function!

Level 4: The function of the difference quotients

The difference function D_f with $D_f(z) = f(z + 1) - f(z)$ of a Z-function f can be interpreted as the slope of the Z-function f concerning the points $(z, f(z))$ and $(z + 1, f(z + 1))$ of the graph of f.

The next step of an expansion of the Z-function is considering a domain with non-integer values, but

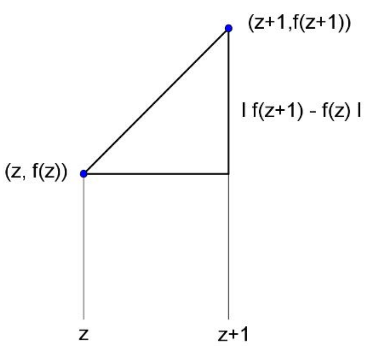

Figure 7

we will still remain within discrete domains. The idea of the difference function as well as the calculation of the slope can be used as long as the domain consists of discrete values.

In a first step the domain $\mathbb{Z}$ of the Z-function f is expanded by considering the values $z_{10} = \frac{z}{10}, z \in \mathbb{Z}$. This means $z_{10} \in \mathbb{Z}_{10} = \{..., -\frac{2}{10}, -\frac{1}{10}, 0, \frac{1}{10}, \frac{2}{10}, ...\}$ and we obtain the Z_{10}-function $f_{10}: \mathbb{Z}_{10} \to \mathbb{R}$. To get the rate of change of successive values, we restrict the calculation to an interval of the length , and get the *difference-quotient-Z_{10}-function*

$$D_{f10}(z_{10}) = \frac{f(z_{10} + \frac{1}{10}) - f(z_{10})}{\frac{1}{10}},$$
$$z_{10} \in \mathbb{Z}_{10} = \{..., -\frac{2}{10}, -\frac{1}{10}, 0, \frac{1}{10}, \frac{2}{10}, ...\}.$$

For example, the difference-quotient-Z_{10}-function belonging to the cubic Z_{10}-function $f(z_{10}) = 0.1z_{10}^3 - z_{10} + 1$ is

$$D_{f^*}(z_{10}) = \frac{f(z_{10} + \frac{1}{10}) - f(z_{10})}{\frac{1}{10}} = 0.3z_{10}^2 + 0.03z_{10} - 0.999$$

This can be generalized to an interval of the length $\frac{1}{n}, n \in \mathbb{N}$, and the difference-quotient-Z_n-function (see Weigand, 2014).

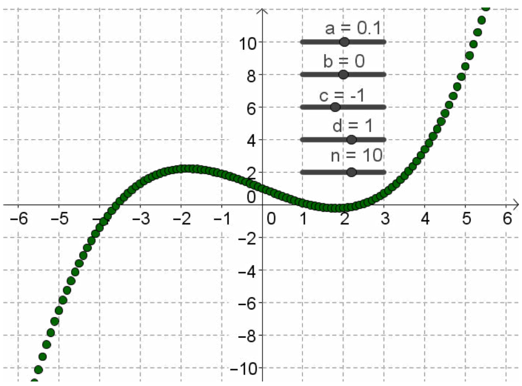

Figure 8: The Z_{10}-function $f(z_{10}) = 0.1z_{10}^3 - z_{10} + 1$

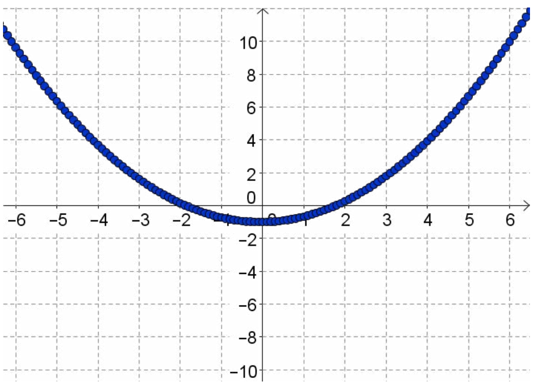

Figure 9: The difference-quotient-Z_{10}-function of f

It emphasizes the *global view of a function* and its (discrete) *difference-quotient-function*, and from the beginning—while working with Z-functions—it draws the attention to the relation between *function* and *difference-Z-function*. Thus, it prepares the understanding of the relation between a function and its derivative function.

Level 5: The local rate of change

The preceding steps to the access to the derivative emphasized the *global view* of the function and the difference-quotient-Z_n-function. The next step will be the concentration on the local view of a function while seeing the relation to the local rate of change of a function.

We continue with any real function f, choose a fixed value $z_0 \in \mathbb{Z}_n$, or even a generalized value $x_0 \in D \subseteq \mathbb{R}$, and consider the sequence of the difference quotient for a real-valued function f with respect to the value of x_0 for $n = \{1, 2, 3, ...\}$:

$$n \to D_n(x_0) = \frac{f(x_0 + \frac{1}{n}) - f(x_0)}{\frac{1}{n}}.$$

Thereby, we obtain a—special—sequence of difference quotients for the function f at the point $(x_0, f(x_0))$. For $f(x) = ax^2 + bx + c$ we get:

$$D_n(x_0) = 2ax_0 + b + \frac{a}{n}.$$

Now, the sequence $D_n(x_0)$ can also be interpreted—considering the graph of f—as the sequence of the slope of the secants through the point $(x_0, f(x_0))$.

Seeing the construction of the derivative of a function f in a special point of the graph of f as a sequence of slopes of secants, the discrete-Z_n-functions with growing n provide a basis for the calculation of the *local rate of change*.

CONCLUSION

The way presented here can be seen as a preliminary stage of the—nowadays already traditional—intuitive limit concept approach with continuous functions. The advantage of the discrete way described here is that working with continuous functions–subsequently after the discrete approach and the working with sequences or Z-functions–and the development of the concept of derivative can be based on a content-oriented level of understanding of the limit concept. To develop this level–beyond an intuitive level of understanding–is the main reason while explicitly working with sequences or discrete functions. Applying this idea of discrete actions or calculations, the concept of derivative of continuous functions is developed on mathematical aspects and properties of the limit or the approximation process and not only on intuitive perspectives.

It is expected that the proposed strategy prepares the concept of *local derivative* of a function at one point and gives a chance of a better understanding of this approximation process because of the possibility of the stepwise construction of this process. But it is also expected that the parallel presentation of sequences (or discrete functions) and their difference sequences (or functions) allow also a well-founded understanding of the concept of a *(global) derivative* function. The aim of the proposed concept is the better understanding of the concept of derivative. It is part of the project *"ABC – A discrete Approach to the Basics of Calculus" (see Weigand 2014)*. It is partially—concerning the first levels—empirically evaluated, theoretically extended to a global concept regarding the access to the derivative, and now needs to be evaluated in an authentic classroom setting. It does not—and cannot—avoid the "cognitive conflict" (Tall, 1992) or the necessity of a conceptual change from the discrete thinking used in working with sequences, difference sequences, and rates of change or difference quotient sequences to working with limits and derivatives of real functions. But it successively develops and explains the approximation processes for an understanding of the derivative concept between the intuitive level, nowadays widely used in classrooms, and the formal mathematical level at university. It emphasizes the processes of understanding the concepts; it is a "procept" (Gray & Tall, 1994; Tall, 2013) for an access to the derivative.

The next step in the frame of this project is the construction and development of classroom, learning or teaching units and the empirical evaluation of the results. This will be done in the near future.

Using slider tools to explore and validate

Mats Brunström and Maria Fahlgren

Karlstad University, Department of Mathematics and Computer Science, Karlstad, Sweden, mats.brunstrom@kau.se

Technologies in mathematics education provide different tools. Researchers have elaborated on students' use of some of these tools. For instance, students' use of dragging tools (Arzarello, Olivero, Paola, & Robutti, 2002) and measuring tools (Olivero & Robutti, 2007) have been categorized into different modalities. However, research on different ways of using slider tools seems to be sparse. The aim of this study is to identify and categorize different uses of slider tools when students investigate how different values of parameters influence the graphical representation of functions.

Keywords: Slider tools, parameters.

THEORETICAL FRAMEWORK

The theoretical framework combines two different aspects. The first aspect concerns students' use of dragging tools. In the context of dynamic geometry software, Arzarello and colleagues (2002) introduced a hierarchy of different uses of dragging, i.e. dragging modalities. Mainly, two different purposes with dragging were noticed: *drag to explore* and *drag to validate* (Olivero & Robutti, 2007). These two different ways to use dragging have been subdivided into different dragging modalities (Arzarello et al., 2002).

The second aspect concerns the concept of parameters and the associated tool, known as the slider tool or slider bar. The slider tool has been highlighted as a means to examine the visual effect on a graph while changing the value of a parameter (Drijvers, 2003; Zbiek, Heid, Blume, & Dick, 2007). However, Zbiek and colleagues (2007) raised the concern that the slider tool, besides the symbolic and graphical representation, could be regarded as a third representation which might obscure the connection between the parameter value and its visual effect.

METHODOLOGY

In this study, six upper secondary students worked in pairs with tasks designed for a dynamic software environment, in this case *GeoGebra*. The mathematical topic under consideration was the sine function, $y = A \sin (Bx + C) + D$. The students were supposed to investigate how different values of the parameters influence the graph.

To collect data, both video and screen recordings were used. The students worked in pairs in front of *one* computer. The position of the camera was at an angle behind the students to capture how they pointed at the screen when explaining their positions. The screen recordings made it possible to see in detail how students used the software. Both the recordings and transcripts were used to identify the different ways in which students used the slider tool.

RESULTS

The study students used slider tools to *explore* mathematical situations and make conjectures. Further, when they had formulated a conjecture they used the slider tool to *validate* the conjecture. These results correspond to earlier research concerning different dragging and measuring modalities (Arzarello et al., 2002; Olivero & Robutti, 2007). Thus, we suggest that the different uses of slider tools could be categorized into *Exploring* and *Validating*.

Furthermore, we could discern different 'slider modalities' within each category (exploring and validating). We identified the following three exploring modalities: *wandering sliding, exploring systematically,* and *maintain a property. Wandering sliding* could be compared to *wandering dragging* (Arzarello et al., 2002) and *wandering measuring* (Olivero & Robutti, 2007). *Exploring systematically* is reminiscent of *guided dragging* and *guided measuring* since the students examined particular cases in an intentional way.

In the second category, i.e., validating, we identified three different modalities: *checking local hypothesis, slide to validate*, and *validating systematically*. While students use the first modality to check hypotheses about special cases, they use the other two modalities to check more general conjectures. These two modalities could both be compared to *validation measuring* (Olivero & Robutti, 2007).

Feedback from dynamic software supports creative mathematical reasoning

Jan Olsson

Umeå University, Applied Educational science, Umeå mathematical educational research center (UMERC), Umeå, Sweden, jan.olsson@umu.se

Previous studies have shown that students learn mathematics better when they are engaged in creative reasoning, but that students in regular teaching mainly undertake imitative reasoning. It is therefore important to develop and examine didactical designs that support creative reasoning. These studies examine a didactic design where students work in pairs solving a complex task supported by dynamic software. The studies show that dynamic software supports creative reasoning by providing timely feedback closely connected to the students' activities.

Keywords: Dynamic software, mathematical reasoning, problem solving.

Even though studies has shown that creative reasoning is more efficient for learning than imitative reasoning (Jonsson, Lithner, Norqvist, & Liljekvist, 2014) there is a wide range of research reporting that regular teaching is guiding students into imitative strategies (Hiebert & Grouws, 2007; Lithner, 2008). Lithner (2000) found imitative strategies are a main obstacle when students are solving tasks for which they don´t know a solving method in advance. Imitative strategies are associated to imitative reasoning, IR, i.e., students are trying to recall remembered procedures and facts that are usable to solve the task. Creative mathematical reasoning, CMR, is characterized by creating new (for the student) solving methods supported by argumentation anchored in intrinsic mathematic components (Lithner, 2008).

The didactical situation of the study was designed to invite students to engage in CMR. Pairs of students were solving a task to which they didn´t know a solving method in advance and there were no hints like, e.g. predicting outcome. They had access to dynamic software, GeoGebra. Features of dynamic software like multiple synchronized representations (e.g., algebraic and graphic), immediate response, no explicit indications of right or wrong answer for specific tasks, have been suggested to support students´ reasoning (Barwise & Etchemendy, 1998). The instructions of the tasks meant an intellectual challenge (Schoenfeld, 1985) and the students were responsible to create a solution method (Brousseau, 1997). Students working in pair have been found engaging in discussions and mutual explanations during problem solving (Mullins, Rummel, & Spada, 2011). Data were collected through screen- and video recordings. The main object of analysis was students´ reasoning associated to their use of dynamic software. Lithner´s framework of imitative and creative reasoning (2008) was used to categorize students´ reasoning. The use of feedback was analyzed through Shute´s theories of formative feedback theories (2008).

The study shows that GeoGebra supports CMR by providing neutral immediate feedback. The feedback becomes the object for students' evaluation and argumentation, the latter is an important component of CMR. Furthermore, students who predicted the outcome before submitting the algebraic formula used the given feedback to elaborate on their problem solving and engaged in CMR. Students that did not predict the outcomes solely used the feedback to state if they were right or wrong and by that merely engaged in IR.

The poster presentation will be made up of illustration and descriptions of the didactical design, examples of tasks used, method, CMR an IR-reasoning, and the results of the study.

Learning trajectory for conceptualizing the fundamental theorem of calculus using dynamic and multiple linked representations tools

Osama Swidan

University of Haifa, Faculty of Education, Haifa, Israel, osamasw@gmail.com

This study was designed to evaluate and elaborate a hypothetical trajectory for learning the fundamental theorem of calculus (FTC) by high school students using dynamic and multiple linked representations tools. The study focuses on 13 pairs of 17-year-old students. Data analysis identified the learning foci involved in conceptualizing the FTC, based on which I suggest a trajectory for learning the FTC.

Keywords: Learning trajectory, Fundamental theorem of calculus, technological tools.

INTRODUCTION

How to promote students' development of new mathematical topics, especially topics whose development is unsure, is one of the significant problems facing mathematics education. One of these topics is the fundamental theorem of calculus (FTC). Many students miss out on the conceptual learning of the FTC (Thompson & Silverman, 2008; Bressoud, 2011). I suggest a hypothetical learning trajectory (HLT) for conceptualizing the FTC using multiple linked representations and dynamic tools that can help students construct an understanding of mathematical concepts. The proposed learning trajectory can make the mathematical learning process more profitable (Steffe, 2004). My aim is to evaluate and elaborate the HLT for learning FTC by high school students learning with a dynamic and multiple linked representations tool.

THE HYPOTHETICAL LEARNING TRAJECTORY

I construct the HLT for FTC based on the functional approach for learning calculus notions. In this approach, the derivative is considered to be a rate of change function and integration is considered to be an accumulation function. At the first level of the HLT, students are asked to conceptualize the Riemann accumulation function as a sum of products. Next, they are asked to conceptualize the accumulation function as a convergence of Riemann accumulation functions. At the third level, they are asked to conceptualize the accumulation function as a rate of change function. Finally, they are asked to conceptualize the evaluation part of the FTC.

THEORETICAL FRAMEWORK

Simon (1995) offered the HLT as a way to explicate an important aspect of pedagogical thinking involved in teaching mathematical understanding. In particular, he described how mathematics educators can conceive the design and use of mathematical tasks to promote mathematical conceptual learning. An HLT consists of three components: (a) the students' learning goal, (b) a hypothesis about the process of the students' learning of mathematical concept, and (c) tasks to be used to promote the students' learning (Simon, 1995). The HLT perspective provides no framework for thinking about the learning process. Therefore, I used the mechanism of reflection on activity-effect relationships to explain the relationship between conceptual learning and mathematical tasks (Simon & Tzur, 2004). This mechanism provides a description of how the learner's goal-directed activity can lead to the generation of new and more sophisticated conceptions for the learner.

METHOD

The present study explores approximately 55 hours of learning by 13 pairs of 17-year-old students. The students volunteered to participate in four after-school meetings. To study the progression processes of the

FTC, we asked students to explain and explore the possible connection between two given function graphs and the table of values. We designed the tasks to be learned by the students based on the mathematical structure of the FTC. The data for the present paper were collected from all the students who participate in the study. All the pairs of students in each session were video-recorded as they engaged in solving the task assigned to them.

PRIMARY FINDINGS

The data analyses suggest that the HLT constructed based on the mathematical structure of the FTC helps students conceptualize the FTC. Based on the data analysis process, I detected the learning foci used by the students to find the possible connections between the graphs, and the mathematical relationships involved in the FTC. These foci can be used to elaborate the HLT for conceptualizing the FTC. In this poster, I present the elaborated learning trajectory for FTC and discuss the role of the learning focus in conceptualizing the components of the FTC. I also present the ways that students used to connect between the differentiation and integration.

INTRODUCTION

The 'theory working group' (under various names) has been a feature of CERME since CERME4. An early and constant focus has been 'networking theories', exploring ways of using different theories in mathematics education research (MER) into learning and teaching mathematics. The CERME9 'Call for papers' included:

— The need to go beyond a specific theory when researching a phenomena

— Benefits and/or strategies and/or difficulties in connecting theories

— Conditions for a productive dialogue between theorists

— Difficulties and strategies when gathering results from different frameworks

— Linking theoretical and methodological approaches

— The epistemological dimension in theories

— Steps towards (local/global) theoretical convergence in MER

In our 12 hours together at CERME9 we discussed 19 research papers and two posters; our task in these five pages is to introduce you to the ones (almost all of them) which have been accepted for these Proceedings. We arrange the papers into five groups in the next section. These groups are not 'strongly defined' but are, we believe, useful for communication. The closing section examines issues arising from the papers as a whole and future possibilities. For reasons of space, we refer to the papers by the surname(s) of the author(s) alone.

SUMMARY OF THE PAPERS AND POSTERS

The two papers, by Chevallard, Bosch & Kim and by Dudley-Smith, are grouped in relation to the question 'What is a theory?' Yves Chevallard is the founder of the Anthropological Theory of the Didactic (ATD) and Chevallard and colleagues address the above question directly via the ATD:

> ATD conduces to focus the research effort on examining the implicit, unassuming or even wanting parts of technologies and theories. It then appears that a theory is made up of two main components, that we may call its "emerged part" and "immersed part" … a theory is thus a hypothetical reality that assumes the form of a (necessarily fuzzy) set of explicit and implicit statements about the object of the theory. A theory is

> in truth the current state of a dialectic process of theorisation ...

Dudley-Smith does not directly address the above question but uses 'Social Activity Method' to interpret (deform/recontextualise) theories in order to explore theoretical networking. It is difficult to summarize this paper, but the following words of the author express a key idea:

> well-formed research activities are incommensurable – they are emergent and not graspable as such, even by themselves. The term "continuity" between theories can refer only to those metonymic chains of signifiers that are of interest *to the recontextualising regard of the theory in question*– hence also the possibility of discontinuity.

The papers by Castela, by Zaragoza and by Roos and Palmér are grouped under the heading 'theories in mathematics education'. Castela considers theoretical diversity and networking theories from the points of view of the ATD and of Bourdieu's theory of social fields. The processes of developing theoretical knowledge is shaped through praxeologies that take place in a community. Further to this "A field is characterised by a game that is played only by its agents, according to specific rules". Using these two approaches, Castela argues that networking will result from researchers from different paradigms working together on the same objects. Zaragoza presents a structuralist definition of a theory as a net of 'theory-elements' connected via a 'specialisation'. A *theory-element* is determined by: the portions of reality it conceptualizes; the *laws* which apply; and potential and actual models. Specialisation concerns the models and laws related to theory-elements. Zaragoza applies these ideas to networking theories and the ATD. Roos andPalmér explore the use of Wenger's 'communities of practice' construct in ten published mathematics education studies. The paper documents differences over these ten papers with regard to: foci on pre-existing or designed communities of practice; foregrounding/backgrounding individuals/groups; constructs (e.g., practice, identity, ...) used. Roos and Palmér conclude, "if a researcher says that (s)he has been using Wenger's social theory of learning, we can be quite sure that we do *not* know exactly what that use of Wenger's theory might imply".

The papers by Holm, by Monaghan and by Şay and Akkoç and the poster by Shvarts and Zagorianakos are grouped under the heading 'connecting theories'. Holm reports on an attempt to use both the SOLO taxonomy and the ATD in order to better understand the advantages of peer collaborative learning exercises for group investigation. The analysis shows that these two frameworks evaluate different dimensions of students' behaviour and relating SOLO-levels to characteristics of ATD praxeology was not possible but the two theories are complementary in terms of understanding student activity. Monaghan focuses on tool use in mathematics and how different theories in mathematics education view tool use. Tool use is important in activity theory (AT) but the consideration of tool use in AT studies varies with the unit of analysis. AT places human agency at the centre of activity and, in contrast to actor network theory (ANT), undervalues non-human agency. Monaghan attempts to 'synthesise' AT and ANT with regard to tool use. Şay and Akkoç examine teachers' social and social-mathematical norms and their instrumental orchestrations in technology-enhanced learning environments in a study designed to investigate how orchestration types and norms affect each other. They found teacher-centred orchestrations in classes where the dominant norm was 'teacher as the mathematical authority' and student-centred orchestrations in classes where the endorsed social norms put students into the centre. Shvarts and Zagorianakos explore the complementarity of activity theory and phenomenology through a detailed analysis of perceptual action by an eye-tracking methodology. While activity theory predicts the development of the perception of visual models through involvement into cultural practice, the data showed that it is the child who makes sense from the presented practice, at the levels of her operative intentionality and the intentionality of act.

The papers by Florensa, Bosch and Gascón and by Kidron are grouped under the heading 'epistemological aspects of theories'. Florensa and colleagues argues that didactics involves both the problem of the development of knowledge and the problem of the diffusion, the use and the transposition of knowledge. Using the ATD, the paper considers means to analyse learning and teaching practices within real institutional environments. The construct 'reference epistemological model' is used to explore extant and new praxeologies through the elaboration of alternative mathematical organisations that could be close to or very distant from the institutional contents that are taught and learned. Kidron considers "mathematical objects not as absolute objects, but as entities which arise from the practices of given institutions" and this "leads us to analyze the role of both, the epistemological dimension and the socio cultural dimension, in theories". The paper provides "an example of networking that demonstrates how the social dimension might influence the epistemological analysis".

The remaining papers (and one poster) have been grouped under the heading 'issues in mathematics education related to theories'. The papers by Bingolbali and Bingolbali and by Godino, Batanero, Cañadas and Contreras focus on teacher-learners. Bingolbali and Bingolbali argue that student-centred teaching (SCT) consists of two components: mixed teaching methods and principals. They state six principles of SCT: valuing students' prior knowledge into consideration; handling students' difficulties with appropriate methods; developing students' skills; providing effective feedback; creating communicative classrooms; integrating assessment into instruction. Godino and colleagues argue that the inquiry-transmission polarity of instructional models is a simplification of a complex reality. The paper outlines semiotic, epistemological and cognitive assumptions of the onto-semiotic approach to mathematical knowledge and instruction which recognizes a key role to both inquiry and transmission models. The paper by Kent and Foster also challenges a polarity in mathematics education, conceptual versus procedural understanding in mathematics. The paper asks if it would be appropriate to describe a learner in possession of an algorithm for responding satisfactorily to such prompts as displaying conceptual understanding. They relate this question to Searle's 'Chinese Room' thought experiment and draw on Habermas' theory of communicative action to develop implications for addressing the problem of interpreting learners' mathematical understandings.

The papers by Ertas and Aslan-Tutak and by Perez focus on the teacher. Ertas and Aslan-Tutak report on tests of mathematics content knowledge (MCK) and mathematics pedagogical content knowledge (MPCK) given to senior student mathematics teachers and senior mathematics students. The performance of the student teachers was significantly higher than that of the mathematics students in the test on MCK. The paper discusses the reasons behind this unexpected finding and notes the challenges to measure MPCK. Perez presents the notion of adaptive conceptual frameworks employed to conduct design-based research with the aim of developing ICT supported mathematics instruction. The paper employs three frameworks: one used when the researcher engages with the teachers; one used to understand outcomes and to plan the next design cycle; one for organizing and supporting the teachers' professional development. Perez uses ideas from 'networking theories' to consider interactions between the frameworks.

The papers by Koichu and the poster by Seidou focus on the learner. Koichu focuses on problem solving and introduces a 'confluence framework' which "consolidates ideas taken from several frameworks", mainly John Mason's theory of shifts of attention. The central premise of the framework is that a key solution idea to a problem can be constructed by a solver as a result of shifts of attention that come from individual effort, interaction with peer problem solvers or interaction with a source of knowledge about the solution. Seidou's framework is Brandom's 'inferentialism' which prioritises inference over reference or representation. The paper reports on students' language 'moves' (how claims are put forward) while reasoning in a geometric sorting activity, "The open-ended aspect of this task creates favorable conditions for a fruitful game of giving and asking for reasons".

The papers by Siller, Bruder, Hascher, Linnemann, Steinfeld and Sattlberger and by Lindenskov, Tonnesen, Weng and *Østergaard* focus on policy. Siller and colleagues report on a project that developed a competency grid to assess the quality of Austrian end of school examination questions. The competency grid has three dimensions (operating, modelling and reasoning) and four levels related to students' mathematical actions: "activity theory forms the background for the didactic interpretation of such initially pragmatic levels". Lindenskov and colleagues report on efforts to develop early "interventions for marginal student groups". The work was inspired by critical theories in mathematics education and practical intervention approaches from various countries. The paper investigates possible contextual influences on networking theories. The paper presents a 'program logic model' for early interventions.

ISSUES ARISING FROM THE PAPERS AND FUTURE POSSIBILITIES

To highlight the productivity and limitations of the work done in the TWG, we propose to consider the questions that have been raised by the papers, their reviews during the discussions, and also issues that have been disregarded or overlooked.

The issue of networking theories was omnipresent in previous 'theory' TWGs since 2005. It has been approached, here, in a different (maybe more mature?) way. The efforts have focused on some basic epistemological and methodological reflections (the nature of theorising, for example) rather than on the description and study of networking strategies. Some new questions have also been opened to a broader debate, with a view to developing research topics in the years to come. One such issue can be called "the question of questions": it relates to the way in which teachers' and students' difficulties can be made sense of by different theories and how the research problems thus arrived at depend on the approach taken. In this context, the issue of mathematics education as a discipline seems especially relevant: what is the place of the didactics of mathematics as a discipline in the arts and sciences realm? How is it related to the didactics of other disciplines and to the other sciences? Can it lead the development of teaching and of teacher education?

Another "big" question that deserves to be addressed is the relationship between local and global theorizations. Many proposed "theories" in (mathematics) education seem to be content with trying to account for a deliberately limited number of didactic phenomena: in this respect, they can be termed "local" constructs for which we have to make clear the didactic dimensions they take into account as well as those they (necessarily or not) overlook. This is especially important since what is called a "theory" or a "theoretical approach" in a given research vein may vary in its degree of development, from limited models to more extensive theoretical constructions. For this reason, it is essential to be constantly aware that theories are living entities in continuous development, and that most "global" theories started with a local or limited scope. The main aim, purpose or ambition adopted by a given theorisation process may result, in this context, as a crucial variable to be taken into account, an issue closely related to the notional and methodological tools elaborated to control and ensure the solidity and productivity of the intended theoretical construction.

The balance between group and individual advancement in the development of research areas is also an interesting topic to approach, in terms for instance of the cultures and craft methodologies elaborated within communities, which are often not easy to disseminate through the traditional channels of science communication (papers, surveys, doctoral dissertations, conference proceedings, etc.). Finally, and related to these last issues, the contrast between findings across different approaches is a question that has never been directly addressed, especially when these findings appear to be, if not contradictory, at least not directly compatible. More generally, a more straightforward, frank, and even antagonistic approach to the problem of theoretical diversity could prove fruitful.

Research papers

Principles of student centred teaching and implications for mathematics teaching

Erhan Bingolbali and Ferhan Bingolbali

Gaziantep University, Gaziantep, Turkey, erhanbingolbali@yahoo.co.uk

This paper aims to present principles of student-centred teaching (SCT) and provide some implications for mathematics teaching. We have determined six main principles of SCT: i) Taking students' prior knowledge into consideration. ii) Handling students' difficulties with appropriate methods. iii) Developing students' skills (e.g., reasoning). iv) Providing effective feedback. v) Creating communicative classroom environment. vi) Integrating assessment into instruction. We first present the rationale of the study and note the ambiguity regarding student-centred related terms. We then propose that STC approach consists of two main components: mixed teaching methods and principals. The paper ends with discussion and implications of SCT approach for mathematics learning and teaching.

Keywords: Student centred teaching, mathematics, mixed teaching methods.

INTRODUCTION

The emphasis on individual learning has paved the way for the emergence of new terminology regarding the learning and teaching both in education as a whole and mathematics education in particular in the last three decades. One such term is that of student-centred teaching. Intuitively although it might appear to be a straightforward term, it seems that not only the term is not well defined but also what is attributed to the term is not clear. As teacher educators, our experience with pre-service and in-service teachers has also revealed that the term student-centred teaching often is attributed to only constructivist approach (e.g., discovery learning) and students' physical activeness in the classroom, whilst cognitive activeness was regarded as secondary if not disregarded at all. The vagueness regarding the meaning of the term has been the rationale for the emergence of this study. With this in mind, this paper attempts to examine the term SCT and aims to propose some principles in order to contribute to its conceptualisation especially for the practitioners working in the field.

Considering that the term SCT is wide-ranging, any attempt to determine its principles requires an examination of multiple theories. To this end, an eclectic literature (e.g., behaviourist, cognitivist, constructivist, sociocultural perspectives on learning and teaching) has been examined. Six main principles have been determined to characterize the SCT. These principals develop from both the relevant literature as detailed below and our interpretation of what the teachers and candidates might need to know for conducting a SCT approach. Although we do not claim that they are sole principles of SCT, we argue that they provide an overall aspect of what the SCT might include. The determined principles are as follows:

1) Taking students' prior knowledge into consideration
2) Handling students' difficulties with appropriate methods
3) Developing students' process skills
4) Providing effective feedback
5) Creating communicative classroom environment
6) Integrating assessment into instruction

In what follows, we first explain why we chose to examine the term SCT and present our stance on it. We then explain each principle in light of the relevant literature and relate them to SCT. We conclude the paper with discussions of the principals.

THE TERMINOLOGY

Dissatisfaction with teacher-centred approach (often known as traditional teaching) and behaviour-oriented perspective in learning and teaching has directed educators to pay more attention to students and their cognitive needs. This shift in attention has resulted in generating new terms and concepts to capture the new phenomenon. Student-oriented terms that have been commonly used amongst educators are the result of such undertaking. As a result of such endeavours, the terms such as student-centred learning, student-centred pedagogy, child-centred learning, student-centred education, learner-centred learning and student-centred teaching come into use. Common to all these terms is the students and their individual learning.

A close examination of these terms reveals several problematic issues though. First, it appears that student-centred terms have sometimes been reduced to ideas popular to Piaget's constructivist developmental theory and hence "discovery learning". Second, the terms have mainly been associated with students' physical activeness rather than cognitive ones. Third, sometimes a passive role is attributed to the teachers since the students are construed be more active. Fourth, the terms have been loosely used and it is not exactly clear what meaning is actually attributed to them. Lastly, it seems that since the terms have mainly been used by the practitioners for practical reasons and have hence been not the foci of the systematic research, it has been difficult to provide a research-informed operationalization of them for the teaching activities.

Given that the terms are commonly being utilized in the field, we as the researchers cannot be incognizant of their uses and need to make contribution into their clarification. In this study, we particularly prefer to use the term SCT for two reasons. First, we think that the term student-centred learning or similar ones have some shortcomings. This is because all learning, passive or active, is student-centred in nature. Besides, whilst examining different approaches to learning and teaching (e.g., behaviourism, constructivism), although the quality of learning may show variation, what mainly differs is indeed the teaching or the teaching methods. That is why we prefer to use SCT, not student-centred learning. Second, as the teachers are responsible for the teaching, they need to know how to conduct student-centred teaching and hence we take the teachers as the main addressee. In what follows, we present our position on SCT.

OUR STANCE ON STUDENT-CENTRED TEACHING

We use the term student-centred in the sense that students and their learning needs should be prioritised in the learning and teaching activity. For instance, if a teacher takes students' difficulty with a concept into account and teaches accordingly, this suggests that students' needs are prioritised and the teaching has a student-centred feature. Determination of students' needs, however, is not a simple endeavour. This, of course, depends on the teacher competency regarding the subject matter they teach. Moreover, the needs of students can show variability. The nature of concepts and the student competency are just only two factors that can cause the variability. For example, in teaching group concept in abstract algebra, to us, what the students need is the definition in the first place as it is very difficult for them to discover the group concept through such approach as problem-based learning. The concept's nature hence determines what the students' needs are and that affect the teaching. On the other hand, if a teacher values conceptual/meaningful understanding, arousing the need for learning and developing reasoning skills etc., then teaching, for instance, "triangle inequality fact" via problem-based learning method and hence providing the students with opportunity to discover or at least attempt to discover the fact can be more fruitful. Given that all these aspects (e.g., reasoning) are important for the learning, this type of teaching is also considered to have a student-centred feature.

One problematic issue that may arise with "discovering" the inequality fact is that: what happens if a student or students cannot "discover" the fact even though the guidance is provided? If one is concerned with students' needs, it is then possibly acceptable that sharing the formula of "$|a-b| < c < a+b$" with students is more reasonable. That is to say, teachers should (sometimes have to) provide the formula or the fact for the benefit of the students. In teaching, teachers hence may sometimes use a mixed instructional approach (e.g., both traditional and constructivist ones) depending on the concepts and students' needs. This is, to us, what makes the teaching student-centred. In fact, Godino and colleagues (2015) also note that there is a need for mixture of construction/inquiry and trans-

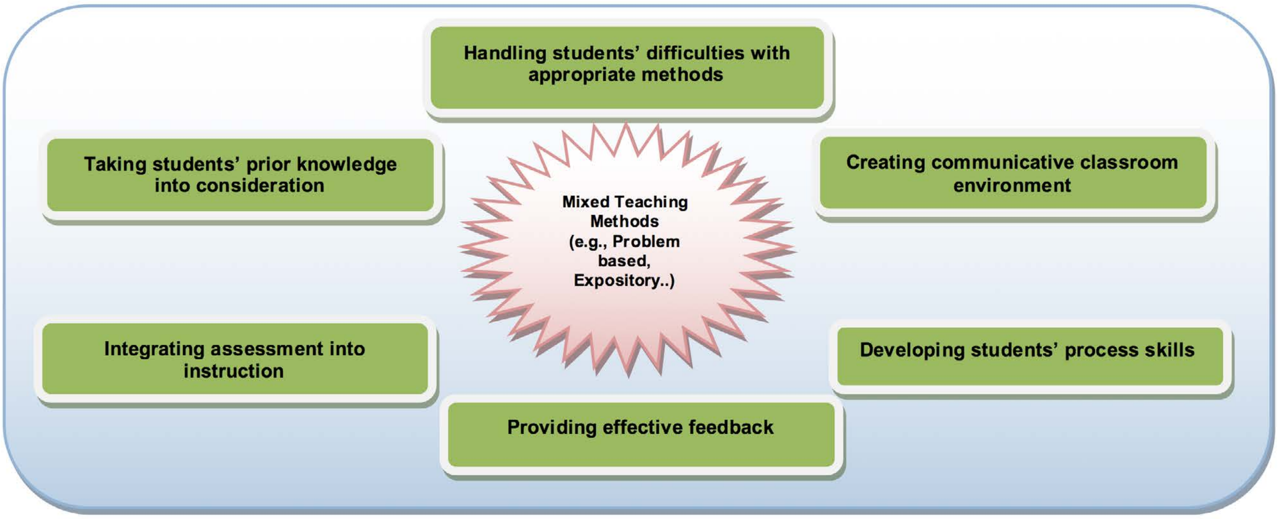

Figure 1: SCT, teaching approach and its principals

mission of knowledge that might optimize learning. They are also critical of basing the instruction solely on "Inquiry-Based Learning" (IBL) or "Problem-Based Learning" (PBL) methods and note that these methods might be more suitable for only gifted students and that these methods generally disregard heterogeneity of the students and the variety of knowledge to be learnt.

In this paper, even though SCT is often associated with constructivist approach in education, we argue that this view is problematic and student-centred teaching needs reconceptualization. We also think that having a practical method (we name it as mixed teaching method) as we presented above is not sufficient to conduct the SCT either, and that is why we propose its principals as well (see, Figure 1). In practice, there is a need for both principals and the mixed teaching method.

As can be inferred from Figure 1, our position is that SCT approach consists of two main components: *mixed teaching methods* and *principals*. In teaching, a teacher might employ mixed methods, that is, the teacher may use both problem-based and expository teaching methods in the same lesson. Yet, to conduct the mixed methods effectively and to take students' needs at the centre, a teacher also needs some principals. The principals guide the methods and enable their implementations. We now turn our attention to principals, their underpinnings and where they stem from.

Taking students' prior knowledge into consideration

Prior knowledge is essential for any learning and teaching activities. Learning theories (e.g., cognitivism, cognitive and social constructivism), particularly the ones shaping the current learning and teaching experiences in many classrooms, emphasise the role of prior knowledge in the learning processes. For instance, as a cognitive learning theorist, David Ausubel put forward the following view on the role of prior knowledge in learning:

> If I had to reduce all of educational psychology to just one principle, I would say this: The most important single factor influencing learning is what the learner already knows. Ascertain this and teach him accordingly. (Ausubel, 1968, p. 18).

Ausubel's comments can be construed as a radical reaction to behaviourists' view of learning. Prior knowledge draws explicit attention in Piaget's works as well. To Glasersfeld (1995, p. 18), one of the two basic principles (radical) constructivism is that "knowledge is not passively received but built up by the cognizing subject". In Piaget's constructivist theory of knowing, since knowledge is actively constructed, not passively received, then the prior knowledge becomes indispensable in the learning process. For instance, in explaining the notion of assimilation, Piaget (1976, p. 17, cited in von Glasersfeld, 1995, p. 18) notes the importance of prior knowledge:

> ...no behaviour, even if it is new to the individual, constitutes an absolute beginning. It is always grafted onto previous schemes and therefore

amounts to assimilating new elements to already constructed structures (innate, as reflexes are, or previously acquired).

Prior knowledge is not only essential to assimilation but also fundamental to the other two components (accommodation and equilibrium) of Piaget's theory. From a Piagetian perspective, it is thus vital that the teacher takes the prior knowledge into account in teaching. This stance of course requires an examination of students' readiness for the teaching. For instance, in teaching the area of parallelogram, it is important to determine what the students know about the area and the concept itself. The previous experience that the individual brings to learning settings has hence important effects on what he/she is going to learn. We thus take this as a principle of SCT as it is concerned with students' needs. We think that any teaching method with students' needs in mind should begin with determining learners' current knowledge level, types of experience they have and needs analysis.

Handling students' difficulties with appropriate methods

The issues of how students learn and why some have difficulties in learning have always drawn the attention of researchers. Many learning theories (e.g., APOS, Cottrill et al., 1996) have been put forward for the former. For the latter, it is known that students' learning difficulties, misconceptions and errors are the reality of classrooms. Nesher (1987, p. 33) appears to even value the existence errors and notes that "the student's "expertise" is in making errors; that this is his contribution to the process of learning". If students are experts of making errors, then any instructional consideration has to take them into account and teachers need to have an expert approach of handling them. Students' difficulties in learning are also important in the sense that they have been the cause for the emergence of many innovations, including new learning theories, teaching materials and new approaches to teaching etc.

Difficulties generally manifest themselves as errors in the classroom settings. It is critical for teachers to be able to notice the underlying conceptions that cause the errors to emerge. Diagnosing the errors and the causes are hence crucial. Following that, it is essential to have a plan of how to handle the difficulty. This plan might include selecting the appropriate materials and method of handling. For instance, the relevant literature proposes many different ways of handling the difficulties. Such handling methods as cognitive conflict, giving correction, ignoring are just some examples of teachers' dealing with errors (e.g., Santagata, 2004). Deciding which method to use might depend on the nature of the errors and the teacher's competency. Students' learning difficulties are hence one of the most influential factors that influence the learning and teaching. To us, SCT must take this issue into account and acts accordingly. We think that the teaching concerned with students' difficulties has the characteristic of SCT and has a better chance of getting over students' difficulties.

Developing students' process skills

Traditional teaching has mainly been concerned with the knowledge (e.g., fraction, function, derivative) and its transmission to the students. However, the aim of schooling is not only to transmit the knowledge or teach concepts. One of the essential goals of schooling is to teach students to think (Padilla, 1990) in general and to reason, justify and make connections in particular. As Padilla (1990) notes "all school subjects should share in accomplishing this overall goal."

In addition to teaching concepts, equipping students with basic skills has also become a goal for many curricula. For instance, in science education these skills are named as basic process skills and six such skills are targeted: i.) observation; ii.) communication, iii.) classification; iv.) measurement; v.) inference; vi.) prediction. In mathematics education, NCTM (2000) names the skills as process standards and notes that mathematics instruction should aim to develop such skills as i.) problem solving, ii.) reasoning and proof, iii.) communication, iv.) connections, and v.) representation. In addition to conceptual understanding, procedural fluency and productive disposition, Adding It Up (NRC, 2001) document also propose strategic competence and adaptive reasoning as a part of mathematical proficiency. All these suggest that skills have become an essential goal of the curricula in that the teaching should be concerned not only with concept teaching but also with skills acquisition.

The development of these skills may have many advantages. First, they enable students to think, justify and make connections. Second, skills can help students have conceptual understanding and therefore meaningful learning (Ausubel, 1968; Skemp, 1978). Without the skills, concepts in mind may stay disconnected and compartmentalised. Third, the skills may help the students be better problem solvers and hence apply their concepts to real life settings. With all these advantages in mind, we think that the teaching concerned with students' intellectual development must also aim to develop students' process skills. We therefore take the teaching process skills as a main principle of SCT and argue that conceptual and meaningful learning is more plausible through teaching them.

Providing effective feedback

Students' learning is complete with interesting experiences from showing an exemplary performance to making errors, having fundamental misconceptions and not having a sense of direction of what to do under some particular circumstances. An examination of what the students know, where they show good or poor performance and what to do next is sometimes needed for instructional decisions. All these are somehow related to effective feedback and its conduction.

Feedback is regarded as "one of the most powerful influences on learning and achievement" (Hattie & Timperley, 2007, p. 81). Feedback is defined as "information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding" (ibid, p. 81). Winner and Butler's (1994) conceptualisation of the feedback is also helpful.

> "feedback is information with which a learner can confirm, add to, overwrite, tune, or restructure information in memory, whether that information is domain knowledge, meta-cognitive knowledge, beliefs about self and tasks, or cognitive tactics and strategies" (p. 5740, cited in Hattie & Timperley, 2007).

As the quotation suggests, feedback can be provided by different agents and in many distinctive forms. A conceptualisation of feedback in the sense of Winner and Butler requires a careful examination of what task to choose, what kind of discourse to create and what method to use to handle students' learning outcomes on the part of the teacher. The teaching concerned with student needs is hence expected to pay attention to the quality of the feedback that the students get and acts accordingly. We therefore argue that one of the basic characteristics of the SCT lies at the quality of feedback provided to the learners.

Creating communicative classroom environment

As students participate in the learning activity as groups and since teaching students in groups is an indispensable reality of the schooling, the teaching cannot solely be reduced to the teaching of an individual and that it needs to address the classroom as a whole. In such situations, the issue of how the teaching, which takes students at the centre, can be conducted also needs to be examined and discussed. To us, a communicative classroom environment can be like an open society so that students can freely express their answers, make arguments and explanations. That is to say, a democratic classroom environment is needed so that students express their opinions. In this connection, Yackel and Cobb's (1996) notions of social and socio-mathematical norms can be employed as a guide for creating such a classroom environment. In such classrooms, different solution methods, reasoning, justification can be encouraged for all students. In such an environment, it is then more possible for students to obtain different perspectives and develop a critical habit of mind. We therefore take communicative classroom environment as a principle of SCT to guide the teacher concerned with student-centred teaching. It should be noted that the application of this principle in the classroom helps the teacher gain insight into the other principles as well. For instance, a communicative classroom environment may pave the way for the expression of free speech and that might help to diagnose the learners' difficulties. The teacher can hence employ this principle to have an overall picture of the instruction with regard to other principles as well.

Integrating assessment into instruction

Traditionally, assessment follows the instruction. This type of assessment is termed as summative and is concerned with cumulative evaluations. It is currently proposed that assessment needs to be built up into and integral to the instruction. This type of assessment is termed as formative one and is concerned with regular control of students' conceptions and understanding (Van De Walle et al., 2010). This type of assessment shapes spontaneous decisions regarding the instruction and the findings reveal that effective formative assessment can increase students' speed of learning by giving the effective feedback (Wiliam, 2007).

As far as SCT is concerned, it is proposed that assessment and instruction need be intertwined.

Assessment should not be something to be done at the end of instruction. Assessment concerned with students' development, difficulties and learning has to be in time and based on students' needs. In this regard, rather than evaluating students through one method (e.g., test) students' performances need to be assessed through different methods. Assessment also should not only be concerned with concept mastery but also with process skills proficiency. As a result, we think that SCT needs to be student-centred in terms of assessment as well. Moreover, as the Assessment Principle in Principles and Standards stresses: "(1) assessment should enhance students' learning, and (2) assessment is a valuable tool for making instructional decisions" (Van de Walle et al., 2010, p. 76). When the assessment is carried out in this respect, we think that it can contribute to the development of the SCT instruction.

DISCUSSION AND CONCLUSIONS

We have attended to the ambiguity of the term SCT and noted that what is attributed to the term is often not clear. We have also stated that SCT has been mainly associated with constructivist approach and argued that reducing it to this approach is misleading. A functional SCT approach does prioritise the students and their needs rather than a particular instructional approach per se. In the light of the relevant literature, alongside the mixed teaching methods, we have provided six principles that might contribute to conceptualisation of SCT. We are aware that the proposed SCT principles are generic in nature. This is particularly due to both the nature of the term and the teaching itself. Although this is the case, we hold the belief that for the practitioners it is important to have a general perspective of SCT as well. This is because; having a broad perspective can help the teacher put a particular learning objective into practice. Therefore, although the proposed principles are generic; they might help the teacher have a broad perspective on SCT and to put it into practice.

Most of current educational reforms suggest student-centred teaching and the chief addressees are teachers and teacher candidates. Although they are expected to conduct SCT, they generally do not have a guideline of how to do that. We believe that these principles as a totality might act as a guide for teachers and candidates to practice SCT. For instance, the principles can be used to design and implement lesson plans. We also think that these principles can be used to develop or assess in-service and pre-service teachers' competencies and knowledge bases. For instance, a teaching programme addressing methods of handling students' difficulties may contribute to the development of teachers' pedagogical content knowledge base. In addition, the SCT principles can be employed as theoretical framework to analyse the classroom discourse and determine whether the teaching is SCT or not. For example, it can be utilized to determine the extent to which the teaching values the process skills. Similarly, the framework can enable one to see how students' difficulties are handled and to show which the types of feedback are provided in the classroom.

As mentioned above, we are aware that these principles are generic and that is why they cannot be specific to any discipline. The nature of disciplines and their concepts will shape how each principle is put into practice. For instance, whilst handling a difficulty or error, one needs to know the nature of the concept and teach accordingly. More specifically, let's take division of two fractions as an example. If the concept is to be taught in an SCT manner, in the light of SCT principles, the teacher first has to take learners' prior knowledge of fraction and division into account. Knowing students' difficulty with division of fractions can help the teacher make necessary preparation, which would improve the instruction. These all suggest that the nature of concept in a discipline itself can affect how SCT is perceived and conducted.

Process skills can play an important role in making SCT approach specific to a particular discipline or carries its distinctive characteristics. Reasoning, justification or representation of the concepts, for example, can differ from one discipline to another. For instance, the function can be represented in many forms (e.g., numeric, graphical, algebraic, verbal). When the teacher teaches this function with its multiple representations alongside with their interconnections to enrich students' understanding, this would suggest that the teaching has a student-centred feature.

Finally, as this work is still in progress, we suggest that further research needs to be carried out to see how functional the proposed principals are and examine them in the real classroom settings. There is also a need for making each principal more explicit. Further research is also needed to examine practitioners' conceptions (e.g., values, beliefs) of SCT and how these conceptions play role in its implementation.

Considering theoretical diversity and networking activities in mathematics education from a sociological point of view

Corine Castela

Normandie Université, LDAR, Caen, France
Université de Rouen, LDAR, Mont-Saint-Aignan, France, corine.castela@univ-rouen.fr

The paper focuses on the social dimensions of the issues addressed in this working group, social being considered at different levels: interactions, culture, and institutions. It addresses the following questions: what is a theoretical framework? Why are theories so numerous in mathematics education? Is it necessary to reduce this multiplicity? Why or why not? The reflection is based on the anthropological theory of the didactic (ATD) and on Bourdieu's theory of social fields. Assuming that the latter is not necessarily well-known in the mathematics education community, and that it offers an interesting potential to enrich the debate within the networking semiosphere, I devote a substantial part of my text to give an idea about the way Bourdieu applies his theory to science.

Keywords: Praxeology, paradigm, institutional determination, symbolic capital.

INTRODUCTION

Addressing the topic of theoretical diversity in mathematics education from a social point of view is not something new in the European research community. The central preoccupation in this WG has been, since CERME4, the barrier to effective communication created by the multiplicity of theories, be it communication within the field or with external partners from policy makers to educative professionals. Radford (2008, p. 318) suggests considering the networking practices as located in a *semiosphere*, that is, "an uneven multi-cultural space of meaning-making processes and understandings generated by individuals as they come to know and interact with each other". It is quite representative of the interaction dimension in networking activities. Among the social aspects this paper considers, some have been more erratically present in the discussions. For instance, the WG11 leaders' introduction at CERME4 (Artigue et al., 2006, p. 1240) refers to a theoretical "more intrinsic diversity linked to the diversity of educational cultures and to the diversity of the institutional characteristics of the development of the field in mathematics education in different countries or global areas." This issue of theoretical multiplicity linked to cultural diversity has not recently been discussed in CERME. Yet the influence of cultural contexts on the research in mathematics education has been discussed in the second plenary talk of CERME9. This confirms the need to address such topic in this WG. My position is that our reflection about theoretical diversity is obstructed by some beliefs that should be deconstructed and that, in order to do so, we need theoretical tools from inside and outside the mathematics education field. In this paper, my objective is to present some tools, borrowed from ATD and from Bourdieu's field theory, which I find helpful to go forward. I briefly show how I use them to consider the social dimension of theoretical multiplicity and to discuss the unifying-theories injunction, thus developing a rational discourse (*logos*) with social concerns about the issues addressed. The adjective "sociological" in the heading must be understood in this etymological meaning, this paper does not avail itself of the sociology scientific field.

Before going any further, I emphasise that, in my opinion, a valuable discussion about connecting theories relies on the participants having minimum knowledge about the theories at stake in the papers. Aside for some well-known theories, I believe it is the author's responsibility to provide the readers with a first understanding of the invoked theories. I try to do so regarding Bourdieu's field theory, assuming that ATD is familiar enough in our research community. Hence, the second part of this text encompasses large quotes intending to provide the readers with a direct, though limited, access to the key elements of Bourdieu's analysis of science which I draw on later. Other theories appear as examples in the discussion for which I can only provide references.

THEORY, RESEARCH PRAXEOLOGY, RESEARCH PARADIGM?

In this part, I recall and connect, especially for the newcomers to theory networking like myself until recently, crucial models elaborated by the first participants in this group to address the issue of what is actually a theoretical framework. This gives me the opportunity to address the issue of what is a theory in the ATD and to discuss some points of Chevallard, Bosch and Kim's contribution to this TWG (2015). Then I propose to encompass into the theory modelling the contribution of well-identified research communities, thus considering the social dimension of networking theories.

What will we consider as networking theories in this 2015 session?

An eight-year-long joint work in CERME as well as in research projects like Remath has largely evidenced that what is at stake cannot be reduced to networking of theories considered as "organized networks of concepts (including ideas, notions, distinctions, terms, etc.) and claims about some extensive domain…" (Niss, 2007, p. 1308). Other research aspects are involved in the interconnection activities. Two directions have been proposed to model this complexity. Radford (2008) describes the concept of theory using the triplet (P, M, Q) where P is a system of basic principles, including implicit views and explicit statements, M a methodology, and Q a set of paradigmatic research questions. Hence, connecting two theories means connecting two triplets. Artigue, Bosch and Gascón (2011) use the notion of praxeology to model research theories and practices. Introduced by Chevallard as a general model for all human activities (see Bosch & Gascón, 2014, for an introduction to ATD), a punctual praxeology is a quadruplet $[T/\tau/\theta/\Theta]$ with only one type of tasks T and one associated technique τ, θ being the technology of τ, i.e. a rational discourse accounting for this technique. "The fourth component is called the "theory" and its main function is to provide a basis and support of the technological discourse" (ibid, pp. 67–68). Moreover, ATD considers more complex levels of praxeological organisations gathering punctual praxeologies which have a common technology (*local* praxeology) or a common theory (*regional* praxeology). A regional research praxeology is described through a set of research questions considered relevant when others are not, correlated techniques, their technologies and a theory. Artigue, Bosch and Gascón (2011) consider that this is the proper level to address networking issues.

What is a theory in this model? In the case of well-developed research praxeologies, the theory may fit with Niss' definition. However, not all such theories operate as identifier of their associated praxeology, because some are not recognised as "a Theory" in the research field. For instance, let us consider the so-called "double approach" (of the teachers' practices) developed by Robert and Rogalski (2002). A regional "double approach" praxeology obviously exists in mathematics education. Its theory, in both ATD and Niss' meaning, is well developed, coordinating elements from several identified theories like Theory of Conceptual Fields and Activity Theory with some more isolated concepts or results from didactics and cognitive ergonomy. Yet, there is no "Double Approach Theory", the praxeology access to social existence in the research field relies on other means, like the publication of a collective book gathering different studies (Vandebrouck, 2008) and its English translation (2013).

Now, let me emphasise that, within ATD, most praxeologies' theories are not this developed (see Chevallard et al., 2015, to go further on this issue); they may not fit with Niss' definition. One strength of this modelling of research activities is that it may be used to account for the research praxeological dynamics as Artigue and colleagues (2011, p. 2382) do: "Research praxeologies can appear as different kinds of amalgams, more or less organized depending on the maturity of the field". They highlight the part played by the technological discourse in such a stage of praxeology, when the theory of the amalgam is underdeveloped and unable to organise through a coherent whole the first results produced by the research practices. I will focus on the social dimension of the development process: the emerging praxeological organisation would not strengthen and access a certain form of social existence in the research field without the setting up of a group of researchers with common concerns, collaborating towards the development of the praxeology.

In the case of the double approach, such a group was first created around A. Robert and J. Rogalski within the Parisian laboratory Didirem, especially through the completion of several PhD theses. In 2015, the double approach community still exists; it is disseminated far beyond its original laboratory. This idea that there is no research praxeology recognised in the mathematics education field (or in some subfield) without an associated community of researchers is not accounted for by the praxeological model. Thus, I propose an extended model, called a research paradigm [1], composed of a praxeology and a correlated social organisation, working as an institution.

Connecting the three models

The praxeological model and Radford's model appear as efficient tools to account for the fact that connecting theories is not only connecting conceptual structures. They share several aspects: Q is the set of T, M the set of $[\tau/\theta]$, the explicit part of P belongs to Θ, such as does a fourth component, the set of key concepts K, added to Radford's triplet in (Bikner-Ahsbahs & Prediger, 2014). Yet each model highlights an aspect the other one overlooks. With regard to methodology, the praxeological twofold description $[\tau/\theta]$ provides an appropriate tool to consider what is happening in the case of methodological exchanges between theories (with Radford's meaning of the term), an issue addressed by (Radford, 2008, p. 322). The technique may or may not change, but certainly a new technological discourse will be produced to justify that the imported technique is consistent with the importing theory and its principles. Regarding principles, there is no place in a praxeology for the implicit part of P. This claim needs some discussion. Chevallard and colleagues (2015) argue that "a theory is made up of two main components, that we may call its "emerged part" and "immersed part. [...] In ATD, a theory is thus a hypothetical reality that assumes the form of a (necessarily fuzzy) set of explicit and implicit statements about the object of the theory." This recognises the need to encompass an implicit dimension in the human activity modelling. Yet, I dispute the idea that implicit views may be considered as parts of the praxeological *logos* component. According to the etymological meaning of this Greek term, the *lógos* is an explicit discourse. In my opinion, the praxeological model must carry this meaning where the $[\theta/\Theta]$ block refers to explicit, socially legitimised knowledge, to the *savoir* in French. However, referring to ATD and its institutional dimension, I assume that the way a praxeology lives in a given institution is determined by a set of constraints, among which culturally shared incorporated norms, many of them being implicit. Studying this implicit praxeology environment is a condition to furthering the process of developing the praxeology, as highlighted by Chevallard and colleagues (2015). As for research, the paradigm model I propose provides a tool to take into account both emerged and immersed parts: within a given paradigm, researchers' actions are regulated by the reference to the research praxeology and through the influence of the associated social organisation.

In summary, the research paradigm model presents three strong points: incorporating the different aspects of the (P, M, Q, K) and $[T/\tau/\theta/\Theta]$ models; including in the modelling project the contribution of the research community that in some cases or times plays a decisive role in the scientific identification of the research praxeology; and considering social interactions between communities within the networking issue.

LOOKING AT MATHEMATICS EDUCATION RESEARCH FROM OUTSIDE

I now present tools that I use in the last part of the paper to interpret the paradigm multiplicity in mathematics education and the injunction to unify theories.

Institutional determinations

An ATD important contribution has been to introduce the notion of ecology in mathematics education in order to fight the pedagogical voluntarisms. The mathematical and didactic praxeologies are subjected to a complex system of conditions "that cannot be reduced to those immediately identifiable in the classroom" (Bosch & Gascón, 2014, p. 72). They are constrained by a whole scale of institutional determinations among which ATD considers at the highest generic levels the influence of Civilisation and Society (ibid, p. 73). This is only one example of the crucial part given to institutions by ATD, it aims to show that this theory always immerses the addressed questions in the whole anthropological reality, with a special focus on the social organisations and the way they determine human activities. In what follows, I apply this approach to mathematics education research.

Bourdieu's field theory applied to science

A field is a structured social space, relatively autonomous from the wider social space and strongly differentiated from other fields. According to Bourdieu, science is a field. The field theory focuses on the 'closed field' dimension of these spaces, providing analysis of what is going on inside; this is the interesting contribution for our group since ATD provides adequate tools to consider external influences.

A field is characterised by a game that is played only by its agents, according to specific rules. The agents are individuals and structured groups, in science they are isolated scientists, teams or laboratories. The conformity of agents' actions to the game rules is partly controlled by objective visible means, but the key point of the theory, through the concept of *habitus*, is the inculcation of the field social rules into the agents' subjectivity. This individual system of dispositions, partly embodied as unconscious schemes, constitutes an individual's right of entry into the field.

The field game is twofold. Firstly, it is productive of something that is the field legitimised goal in the social space. The rules, and therefore the individual dispositions, are fitted to achieve the goal that every agent considers desirable. In the case of science, the goal is epistemic: accepting tacitly the existence of an objective reality endowed with some meaning and logic, scientists have the common project to understand the world and produce true statements about it. Bourdieu further adds a social dimension to the Bachelardian conception of the scientific fact construction:

> In fact, the process of knowledge validation as *legitimation* [...] concerns the relationship between the subject and the object, but also the relationship between subjects regarding the object [...]. The fact is won, constructed, observed, in and through [...] the process of verification, collective production of truth, in and through negotiation, transaction, and also homologation, ratification by the explicit expressed consensus – *homologein*. (Bourdieu, 2001/2004, pp. 72–73).

Despite this social nature, scientific homologation produces objective statements about the world thanks to specific rules of the scientific critical scrutiny, "the reference to the real, [being] constituted as the arbiter of research" (ibid, p. 69). Bourdieu also emphasises that constructed facts are all the more objective as the field is autonomous and international.

Secondly, the game is a competition between the agents, resulting in an unequal distribution of some specific form of capital, source of advantage in the game, source of power on the other agents. Thus, a field, including the scientific one, appears as:

> a structured field of forces, and also a field of struggles to conserve or to transform this field of forces. [...] It is the agents, [...] defined by the volume and structure of the specific capital they possess, that determine the structure of the field [...This one] defined by the unequal distribution of capital, bears on all the agents within it, restricting more or less the space of possible that is open to them, depending on how well placed they are within the field... (ibid, pp. 33–34)

The capital includes several species, for instance, in science, laboratory equipment, funding, and journal edition. I focus on the symbolic capital, especially on its scientific modality:

> Scientific capital is a particular kind of symbolic capital, a capital based on knowledge and recognition. (ibid, p. 34)

> A scientist's symbolic weight tends to vary with the distinctive value of his contributions and the *originality* that the competitor-peers recognize in his distinctive contribution. The notion of *visibility* [...] evokes the differential value of this capital which, concentrated in a known and recognized name, distinguishes its bearer from the undifferentiated background into which the mass of anonymous researchers merges and blurs. (ibid, pp. 55–56)

This theory of science as a field challenges an idyllic vision of the scientific community, disinterested and consensual. However, through the hypothesis of embodied dispositions, it avoids considering the scientists' participation to the capital conquest in terms of personal ambition or cynicism.

In summary, I will focus on the fact that scientific strategies are considered twofold.

> They have a pure – purely scientific- function and a social function within the field, that is to say, in relation to other agents engaged in the field. (ibid, p. 54)

> Every scientific choice is also a strategic strategy of investment oriented towards maximization of the specific, inseparably social and scientific profit offered by the field. (ibid, p. 59)

One can see a true correspondence between the triplets (institution, subjects, *assujettissements*-subjugation) of ATD (Chevallard, 1992) and (field, agents, *habitus*) of the field theory. In what follows, I consider mathematics education research as an institution immersed in and determined by a complex system of other institutions, and as a field of forces, subfield of the scientific global field.

EXTERNAL DETERMINATIONS OF THE "THEORIES ISSUE"

Research in didactics as externally determined in its questions and answers

I now consider the fact that the realm of reality of mathematics education research studies is determined by various economic, political, cultural institutions of different sizes. No one may dispute the vast distance that separates the following two objects of study: on the one hand, the passing down of arithmetic techniques in the Aymara villages of northern Chile, whose culture developed specific calculation praxeologies, and on the other hand, the use of software in the French education system to promote the learning of algebra. Is looking for universal regularities the epistemic priority of mathematics education research when, unlike physics for instance, the studied reality is so diverse? Assuming that such common phenomena exist (the didactical contract is often cited as such), which part of the two aforementioned complex realities are they able to account for? Moreover, given that the research intends to act upon the mathematics education reality, a more crucial question would be: to what extent can these regularities support engineering projects? In this paper, I will consider that adapted tools must be designed to address the problems raised by the diverse educational institutions around the world, in order to understand the dysfunctions and to produce solutions that are acceptable to these institutions and their subjects. The research questions as well as the produced answers are determined by local characteristics. The paradigm multiplicity therefore appears as a result of the epistemology of a science intending to act upon the studied reality. To take only one example, the ethnomathematics paradigm has been developed in South America as well as in Africa, as a response to a massive failure in mathematics education within educative systems that are still based on the colonial vision and present "mathematics [...] as an exclusive creation by the white race" (Gerdes, 2009, p. 31, my translation). Ethnomathematics follows as a paradigm from the need to "multiculturalise the curricula of mathematics to improve the quality of education and increase the social and cultural-self-confidence of all students". (ibid, p. 21)

Research in didactics as externally determined in its workings

Obviously, research depends on national and inter-national political and economic institutions which provide the material and the human resources. From this derives the existence of mathematics education research sub-institutions we partly find in the ICMI structure. But other institutions influence the research activities through less evident ways and means, such as cultures with more or less extended spheres of influence, up to civilisation. In spite of their scientific specific *habitus*, researchers with common culture also build upon this culture to address the research issues. That is one among other sources of some tacit principles of a paradigm. In other words, the paradigm multiplicity also results from the cultural multiplicity of the agents within the mathematics education research field. The researchers' cultural specificity may echo the educative local reality they study, hence resulting in a form of coherence and perhaps of efficiency. At the same time however, several paradigms may coexist in the same society, in the same country, investigating the same education system with different philosophical, ideological positions. As an example, let me consider ATD and the double approach that are strongly differentiated by their conception of the human being: ATD highlights the multi-institutional building of the framework within which the individual develops and acts (Chevallard, 1992, p. 91), the double approach focuses on the individual variations (Vandebrouck, 2008, p. 20). This second viewpoint is more present in the Western education research paradigms than the first one. I hypothesise that this is deeply correlated with the societies' characteristics and that it is not mere coincidence that ATD emerged in France.

Another example of external determination is the project of reducing theoretical diversity itself. This project is epistemologically founded within Bourdieu's theory since, as seen above, communication between researchers at the most international possible level is crucial in the construction of the scientific facts. However, it also comes from the requirements of political institutions, the Babel Tower aspect of research in mathematics education affecting its credibility. The proposed solution is unifying theories. Policy makers refer to the exact sciences model, and so does, rather surprisingly, mathematics education research itself, still (over)determined by its *alma mater*, mathematics. This reference neglects the diversity of educative reality. It forgets the exact sciences very long lifetime conducive to the unifying process, and that with the colonial expansion many local paradigms have simply been ignored, the occidental ones being imposed to the defeated countries. So the present homogenous theoretical landscape results as much from domination as from unification.

At this point, I have argued that the paradigm diversity is in some sense epistemologically legitimate in mathematics education and results from some social determinations of research. I have also noted that the unifying injunction might be considered as introduced into the field from outside for questionable reasons.

MATHEMATICS EDUCATION RESEARCH AS A POWER GAME

In this part, I build upon Bourdieu's statement that every scientific strategy has a social function within the field, i.e. has something to do with the distribution of power among the agents. In such a framework, the production of independent theories as well as the call for their integration in new entities are taken as contributing to the contestation and conquest of positions. For a researcher, being recognised as the creator of an identified theory clearly increases his scientific capital, much more than a less visible participation to the collective development of an existing paradigm would. This "visibility factor" fosters the paradigm multiplication, especially at the theory level; it should certainly be controlled when individual positions are at stake. However, let me now consider an emergent research community: in this case, developing a specific paradigm is an asset to free from the domination by older communities, generally tending to impose their own paradigms as ready tools which are adapted even for new problems. I will mention here the socioepistemology (Cantoral, 2013), deliberately developed by a group of Mexican researchers with the dual intent of creating tools adapted for the educative reality in South America and putting an end to what was considered as an extension of colonisation through the exclusivity of Western paradigms in didactics research.

I have already put forward that the need to unify paradigms could be epistemologically challenged by virtue of the diversity of the didactic reality depending on the societies and countries involved. Now, I question it as an obstacle to an autonomous organisation of didactical research in countries where the latter is just emerging. To finish, I reverse this point of view: if developing a paradigm is empowering for a community in the field, the call for reducing the paradigm multiplicity has something to do with relative positions of the research institutions incorporated to the paradigm. It is an aspect of the social game in the field, certainly determined by other levels of power struggles outside the scientific field as well.

CONCLUDING REMARKS

In this paper, my intent was not to contest the importance of interactions between mathematics education researchers. I recognise the crucial part of the broadest possible communication in the construction of scientific facts and the major difficulty deriving from the paradigm multiplicity in the field. My aim was to bring to light some aspects of the multidimensional complexity of this well-documented phenomenon, so far almost unexplored in this TWG. Multiplicity is an epistemological adaptation to the diversity of educational realities and a social result of symbolic power struggle within a recent research field, somehow less submitted to colonial and capitalistic rules to determine the power repartition than have been (and perhaps are) the oldest basic sciences. Hence, if reducing the number of paradigms appears as a direct solution, which favours communication thanks to a common conceptual language, this shortcut may be epistemologically inadequate for mathematics education research. Moreover, from the social point of view, it should be considered as the current hidden form of the exercise of power conquest in the field.

Unifying theories in order to produce a common discourse is not the appropriate way to scientificity for mathematics education research in its present state: that is the opinion I have tried to convey through this text. Building on the Remath project experience among others (Artigue & Mariotti, 2014), I suggest that collaborating which brings together researchers who refer to different paradigms might be more relevant; theory networking will result from working together on the same objects. The challenge is to develop scientific research collaboration praxeologies.

ENDNOTE

1. Using the term paradigm may be provisory. It refers to Kuhn's notion of scientific paradigm (1962). Yet, in the postscript to the second edition (1970), Kuhn writes that: "Paradigms are something shared by the members of such groups [scientific communities]" (p. 178). It seems that he does not include communities within the paradigm model.

What is a theory according to the anthropological theory of the didactic?

Yves Chevallard[1], Marianna Bosch[2] and Sineae Kim[1]

1 Aix-Marseille University, Marseille, France, y.chevallard@free.fr

2 Ramon Llull University, IQS School of Management, Barcelona, Spain

The question tackled here centres on the notion—or, more precisely, the many notions—of theory often used in discussing scientific matters. The analysis that we attempt develops within the framework of the anthropological theory of the didactic (ATD). It purports to show that current usage refers mostly to the "emerged parts" of so-called theories and largely ignores their "immersed parts", which are the correlate of their intrinsic implicitness and historical incompleteness. This leads to favour open theorization over entrenched theory.

Keywords: Theorization, praxeology, knowledge, human activity, institutions.

INTRODUCING THE NOTION OF THEORY

In this study we examine the meaning and scope of a key concept of ATD which, paradoxically, since the inception of this theory, seems to have been consistently overlooked: that of *theory*. A word akin to English "theory" exists in many European languages [1]. According to John Ayto's *Dictionary of Words Origins* (1990), the history of *theory* goes as follows:

> **theory** [16] The etymological notion underlying *theory* is of 'looking'; only secondarily did it develop via 'contemplation' to 'mental conception.' It comes via late Latin *theōria* from Greek *theōríā* 'contemplation, speculation, theory.' This was a derivative of *theōrós* 'spectator,' which was formed from the base *thea-* (source also of *theā́sthai* 'watch, look at,'·from which English gets *theatre*). Also derived from *theōrós* was *theōreīn* 'look at,' which formed the basis of *theṓrēma* 'speculation, intuition, theory,' acquired by English via late Latin *theōrēma* as *theorem* [16]. From the same source comes *theoretical* [17]. (p. 527)

A paper by a classical scholar, Ian Rutherford, gives more information on the uses of the word *theoria* in Ancient Greece:

> The Greek word *theoria* means "watching," and has two special senses in Greek culture: first, a religious delegation sent by a Greek city, to consult an oracle or take part in a festival at a sanctuary outside its territory, and second, philosophical contemplation. *Theoria* in the first sense is attested from the sixth century bce until the Roman Empire, but the sources are particularly rich in the Hellenistic period. Sacred delegates were called *theoroi*, were often led by a so-called *architheoros*, and if they went by sea, the vehicle was a *theoris*-ship. (Abstract)

The first of these two senses has almost disappeared from modern usage. The second sense opened the way for our common uses of *theory*. In the following, we concentrate on "modern" meanings of this word, which dictionaries usually condense into a small number of categories, as does for example the English *Wiktionary*. The entry dedicated to *theory* in this dictionary begins classically with the etymology of the word, then passes on to the uses of it that it does retain:

> **theory** (*countable and uncountable*, *plural* theories)
>
> 1) (obsolete) Mental conception; reflection, consideration. [16th-18th c.]
>
> 2) (sciences) A coherent statement or set of ideas that explains observed facts or phenomena, or which sets out the laws and principles of something known or observed; a hypothesis confirmed by observation, experiment etc. [from 17th c.]

3) (uncountable) The underlying principles or methods of a given technical skill, art etc., as opposed to its practice. [from 17th c.]

4) (mathematics) A field of study attempting to exhaustively describe a particular class of constructs. [from 18th c.] *Knot theory classifies the mappings of a circle into 3-space.*

5) A hypothesis or conjecture. [from 18th c.]

6) (countable, logic) A set of axioms together with all statements derivable from them. *Equivalently*, a formal language plus a set of axioms (from which can then be derived theorems). *A theory is consistent if it has a model.*

In what follows we shall draw upon such semantic summaries in order to suggest that the notion of theory developed in ATD can account for the diversity of usages that exist today.

SOME BASICS OF ATD

In ATD, the basic "entities" are *persons x* and *institutions I*. These notions are close to their ordinary counterparts, although they are more general: in ATD, a newborn infant is a person; and, to take just one easy example, a class, with its students and teachers, is an institution. An institution *I* comprises different *positions p*— in the case of a class, that of student and of teacher. To every person *x* or institutional position *p* is assigned a "praxeological equipment", which is the system of "capacities" that, under appropriate conditions, enables the person *x* or any person *x'* occupying position *p* to act and think through one's actions.

Any praxeological equipment, be it *personal* or *positional*, is made up of, among other things, "notions". Most persons and institutional positions thus have a certain notion of theory—if only through the overused phrase "in theory". The present study could then be said to be partly about the notion of theory in ATD (taken as an institution). However that may be, it is essential to detach oneself from the seemingly undisputed belief that there would exist a unique, shared *notion* of theory of which the meaning would simply vary according to the context of use. In ATD, every person, every institutional position is supposed to be endowed with a peculiar notion of theory, that notion being shaped by the *constraints* to which the person or position is currently subjected. This phenomenon is at the origin of the processes of institutional transposition, of which didactic transposition is but a particular case (Chevallard, 1992). In order to make headway, we shall now delineate the "anthropological" notion of theory—which, at the start, is only one such notion amongst others.

THE NOTION OF PRAXEOLOGY IN ATD

ATD posits a theory of human activity that hinges on an essential and founding notion: that of *praxeology* (Chevallard, 2006, 2015; see also Bosch & Gascón, 2014). The word *praxeology* has been around for (at least) two centuries in the sense recorded by most dictionaries, in which it is held to refer to the "study of human action and conduct", to the "study of practical or efficient activity", or to the "science of efficient action". The use made here of the word pertains properly to ATD and departs decisively from this old-established, though infrequent, use. A key tenet of ATD is that when a person x acts purposely and knowingly, her doings can be analysed into a (finite) sequence of *tasks* t_1, t_2, ..., t_n. Contrary to the common meaning of the term (which has a ring of unpleasantness about it), *task* is taken here in a very general sense, irrespective of its volume or pettiness: *to open this door* and *to smile to this neighbour* are tasks; *to scratch this person's back*, *to write this sonnet*, *to save this polar bear*, *to prove this theorem*, and *to play this guitar chord* are tasks as well. Any task t is regarded as a "specimen" of a *type* of tasks T. In order to execute the task t of type T, a person x draws on a determined *technique*, denoted τ_T, that is to say a (more or less precise) way of accomplishing (at least some) tasks t of type T. No technique τ can cope with the totality of tasks of a given type T—its range of success is usually called the *scope* of τ. If, for example, it is clear that elementary techniques for factoring numbers all have a limited scope, it is true also, for obvious reasons, that *any* technique whatsoever eventually reaches its limits.

Let us take another example, that of a technique for finding the quotient of number a by number b (with $a, b \in \mathbb{N}^*$), which we make explicit on a specimen. Considering that $12 = 2 \times 2 \times 3$, in order to arrive at the quotient of 417 by 12, we first determine the quotient of 417 by 2, which is the quotient of 416 by 2, i.e. 208. We then calculate the quotient of 208 by 2, which is simply 104; and finally we determine the quotient of 104 by 3, which is the same as the quotient of 102 by 3, or 34. The quotient of 417 divided by 12 is "therefore" 34. (Indeed, $417 = 34 \times 12 + 9$.) The inverted commas that surround *therefore* hint at the fact that many people—including mathematics teachers—will highly doubt the validity of this technique, on the grounds that it leads one to carelessly get rid of successive remainders. This paves the way for another key notion that ATD hinges on: the notion of *technology*. This word is used in ATD with its etymological value: as the suffix *-logy* indicates, a technology is a "discourse" on a given technique τ. This discourse is supposed, at least in the best-case scenario, both to *justify* the technique τ as a valid way of performing tasks t of type T and to throw light on the logic and workings of that technique, making it at least partially intelligible to the user. As concerns the technique of division shown above, it seems difficult to hit upon a full-fledged technology that would justify it, let alone *explain* it—if the technique is duly valid, *why* is it so? For lack of space, we shall leave these two mathematical tasks—justify and explain the aforementioned technique—to the perplexed reader.

A key point must be stressed. Owing to the presence of the suffix *-logy*, the word *technology* carries with it the idea of a *rational* discourse (about some *tekhne*—a Greek word meaning "a system or method of making or doing", that is, a technique or system of techniques). In the universe of ATD, there is no such thing as *universal* rationality. Every person x, every institution I, and every position p has its own rationality, afforded by the technologies present in its "praxeological equipment." Of course, persons and institutions strive to indulge their "rationality" or even to impose it upon others. The interplay between competing rationalities is a major aspect of what it is the mission of didactics to explore.

We have now arrived at a crossroads. It appears that no technological justification is self-sufficient: it relies on elements of knowledge of a higher level of generality, which, whenever they do not go unnoticed—they often do—, sound more abstract, more ethereal, oftentimes abstruse, as if they expressed the point of view of a far removed, pure spectator—a *theoros*. In ATD, such items of knowledge, sometimes dubbed "principles" (or "postulates", etc.), compose the *theory* that goes with the triple formed by the *type of tasks* T, *technique* τ, and *technology*. This theoretical component is denoted by the letter Θ ("big theta") while the technology is denoted by (small) θ. We thus arrive at a quadruple traditionally denoted by $[T / \tau / \theta / \Theta]$. It is this quadruple that we call *a* praxeology; it is called a *punctual* praxeology because it is organised around the type of tasks T, considered as a "point".

It should be clear that, by its very definition, ATD's notion of theory already subsumes case 3 of the English *Wiktionary*'s definition of *theory*: "The underlying principles or methods of a given technical skill, art etc., as opposed to its practice. [from 17th c.]." Let us take a step forward. A central tenet of ATD is that all "knowledge" can be modelled in terms of praxeologies. The "praxeological equipment" of a person x or institutional position p is defined to be the more or less integrated system of *all* the praxeologies that the person x or a person x' in position p can draw upon to do what this person is led to do. A praxeology can be denoted by the letter $\wp$ (called "Weierstrass p"). It can be construed as the union of two parts or "blocks": the *praxis* part $\Pi = [T / \tau]$, also called the *practico-technical* block, and the *logos* part $\Lambda = [\theta / \Theta]$ or *technologico-theoretical* block. One can write: $\wp = \Pi \oplus \Lambda = [T / \tau] \oplus [\theta / \Theta] = [T / \tau / \theta / \Theta]$. The operation $\oplus$ is sometimes called the *amalgamation* of the *praxis* and *logos* parts. The amalgamation of Π and Λ should be interpreted as a *dialectic* process of "sublation" [2] through which the *praxis* and *logos* parts are at the same time negated as isolated parts but preserved as partial elements in a synthesis, which is the praxeology $\wp$. Let us for a moment relabel "knowledge part" the *logos* part and "know-how part" the *praxis* part of a praxeology $\wp$. The dialectic sublation of "knowledge" and "know-how" that $\wp$ is supposed to achieve is hardly ever actualized. More often than not, the *praxis* and the *logos* observable in a person's or institutional position's praxeological equipment do not fit well together. The *praxis* block may be poorly developed while the *logos* part seems to be ahead of the game—a state of things often expressed by saying something like "he knows the theory, but can't apply it." Or the *praxis* part seems to be going smoothly but the *logos* part is so poor that it fails to substantially explain or justify the featured technique, which is consequently turned into a mere "recipe." The failure to arrive at a "well-balanced" praxeology is the rule, not the exception—a key phenomenon that we will now dwell upon.

INCOMPLETENESS AND IMPLICITNESS IN PRAXEOLOGIES

When it comes to discussing praxeological matters, people are prone to using metonymies or, more precisely, synecdoches [3]. This synecdochic bent generally selects as a derived name some (supposedly) "noble" part or feature of the thing to name. The widely shared propensity to metonymize shows up in particular in the use of the word *knowledge*—which is the "lofty" part of a praxeology—to name the *whole* praxeology. It is even more manifest in the generalized use of *theory* as including not only what ATD calls *technology*, but also the *praxis* part and, therefore, the whole praxeological matter. In common parlance, *theory* refers usually, though somewhat fuzzily, to a complex of praxeologies sharing a common "theory" (in a sense acknowledged by the naming institutions). Such a "body of knowledge" can be denoted by the formula $[T_{ij} / \tau_{ij} / \theta_i / \Theta]$ with $i = 1, ..., n$ and $j = 1, ..., m_i$, where the theory Θ "governs" all the technologies θ_i, each technology θ_i "governing" in turn the techniques τ_{ij}. Such a praxeology goes by the name of *global* praxeology. It is this generic analysis that ATD offers when one comes to speak of, for instance, "group theory" or "number theory" or "chaos theory" or "knot theory," etc. It is to be observed that, in doing so, the praxeological complex to which one refers is defined "in intension" rather than "in extension." It allows one to identify conceptually the *possible* content of the praxeological complex, while its real "extension" remains somewhat unspecified. Of course, it is risky to be so unmethodical when it comes to describing praxeological organisations. Naming a part to mean the whole leads to forget or neglect other parts. Therefore, the resulting praxeologies cannot be efficient tools for action—just as a car stripped down to the engine is of little avail to travel (even if, again metonymically, "motor" can be used to refer to the whole car).

This is however one aspect only of the problem of incompleteness in praxeologies. Any praxeology whatsoever can be said to be incomplete, be it technically, technologically or theoretically. And it is the fate of all praxeologies to continually go through a process which can further the development of any of their constituent parts: the technique can be further "technicized", the technology "technologized", and the theory "theorized". Consider the following easy example relating to the century-old "rule of three", that of the so-called "unitary method", which L. C. Pascoe in his *Arithmetic* (1971) introduces as "helpful to those who initially have difficulties with the ideas of ratios" (p. 64). Traditional arithmetical techniques were essentially *oral*: to do mathematics, one had to *say* something, in order to arrive at the sought-for result. For instance, if it is known that 132 tickets cost £165, how much will be paid for 183 tickets? The right "saying" goes somewhat as follows [4]: "If 132 tickets cost £165, then 1 ticket costs 132 times *less*, or £$\frac{165}{132}$; and 183 tickets cost 183 times *more*, or £$\frac{165}{132} \times 183$, that is £228.75." Here the type of tasks T is clearly delineated; and so is the propounded technique τ_0. As is often the case with arithmetic, the technology θ of τ is essentially embodied in the "technical discourse" above, that both activates τ and explains—makes plain—its logic, thereby justifying it. As always, the "justifying efficacy" of θ depends much on the apparent "naturalness" of the supposedly self-evident reasoning conveyed by the technical discourse recited (if n cost p, then 1 costs p/n, etc.). There exist, of course, other techniques. Some centuries ago, people would have said something like "132 is to 165 as 183 is to price p", writing down the "proportion" 132:165::183:p. Using the (technological) assertion that, in such a proportion, the product of the "means" (i.e. 165 and 183) equals the product of the "extremes" (i.e. 132 and p), they would have arrived at the equation $165 \times 183 = 132 \times p$, which gives $p = \frac{165 \times 183}{132}$. This formula appears to agree with the one found using τ_0, provided one knows the (technological) equality $\frac{a \times c}{b} = \frac{a}{b} \times c$. But this age-old technique τ_{-1} was technologically—not technically—*more demanding*, because the reason why the key technological assertion (about means and extremes) is true remains hidden—which, for most users, turns τ_{-1} into a recipe.

The technique τ_0 can be modified in (at least) two subtly different ways. One consists in introducing an easy technological notion from daily life, that of *unit price*, which leads to a technical variant of τ_0: "If 132 tickets cost £165, then 1 ticket costs 132 times *less*, or £$\frac{165}{132}$, that is £1.25; and m tickets will cost m times *more*, or £$1.25 \times m$." This technical variant τ_{01} is a little bit more complex technically (by contrast, τ_0 skips the calculation of the unit price, though the technological concept of unit price is already implicitly present); but it provides more *technological comfort* to the layman. Another variant results from a decisive *theoretical* change. While people generally understand the expression "number of times" as referring to a *whole* number of times, as was the case in the tickets problem, a major advance in the history of numbers consisted in regarding *fractions* as true numbers, on a par with what came to be called *natural* numbers—fractional numbers being called by contrast *artificial* numbers. A second step forward, not yet taken by so many people, consists in extending the scope of the expression "number of times" to include *fractional* numbers, so that, for instance, 183 is $\frac{183}{132}$ times 132 (i.e. $183 = 132 \times \frac{183}{132}$), from which it follows that the price of 183 tickets is $\frac{183}{132}$ times the price of 132 tickets, or $\frac{183}{132}$ times £165, that is £165 × $\frac{183}{132}$ (which is yet another resolvent). As long as one accepts to think in terms of *fractional* number of *times*, we have a new technique, τ_{02}, much more powerful and comfortable than τ_0 or τ_{01}. Knowing for instance that the price of 2988 tickets is £3735, we can now say that the price of 2012 tickets will be $\frac{2012}{2988}$ times the price of 2988 tickets, i.e. £3735 × $\frac{2012}{2988}$; etc. While the variation leading to τ_{01} only called for a rather easy modification in the technique's technological environment, here the change affects the *theory* itself, which in turn leads to a new technological concept, that of a fractional number of times.

In mathematics as well as the sciences, praxeologies turn out to be no less incomplete than in other fields of human activity. Many aspects of a praxeology's incompleteness are in fact linked to the impression of "naturalness" that so many people feel when they use (or even observe) this praxeology. Of course, the notion of naturalness undergoes institutional variations—let alone personal interpretations. But it is too often assumed that what is natural is, by definition, an unalterable given that does not have to be "justified." This, of course, runs contrary to the scientific tradition, of which it is the ambition to unveil the figments of institutional or personal imagination. Thus the French mathematician Henri Poincaré (1902, p. 74) regarded the principle of mathematical induction as "imposed upon us with such a force that we could not conceive of a contrary proposition." However, almost at the same time, progress in mathematics showed that this supposedly self-existent principle could be derived from the well-ordering principle [4]. The same phenomenon had happened more than two centuries earlier. The leading character was then John Wallis. According to Fauvel, Flood, and Wilson (2013), here is what happened:

> On the evening of 11 July 1663, he lectured in Oxford on Euclid's parallel postulate, and presented a seductive argument purporting to derive it from Euclid's other axioms. As Wallis observed, his argument assumes that similar figures can take different sizes. Wallis found this assumption very plausible, and if it were true then the parallel postulate would be a consequence of the other axioms of Euclid. It does, however, imply a remarkable result: in any geometry in which the parallel postulate does not hold, that similar figures would have to be identical in size as well as in shape, and so scale copies could never be made. (pp. 129–130)

Seventy years later, Girolamo Saccheri was to observe that Wallis "needed only to assume the existence of two triangles, whose angles were equal each to each and sides unequal" (Bonola, 1955, p. 29). Wallis's proof of the parallel postulate [5] opened the way to a major change that we can subsume under a broader historical pattern. By making *explicit* a theoretical property of Euclidean space—"To every figure there exists a similar figure of arbitrary magnitude" (Bonola, 1955, p. 15)—, Wallis reduced the incompleteness (in ATD's sense) of Euclidean geometry as a praxeological field. But he contributed much more to the mathematical sciences: he discovered a *constraint* that, until then, had been taken for granted (and thus ignored) and which turned out to be crucial in the development of geometry, in that it drew a clear demarcation line between Euclidean geometry and the yet to come non-Euclidean geometries.

At this point, we must introduce another key notion of ATD: that of *condition*, stealthily used in the behavioural sciences (through the idea of conditioning or being conditioned) and akin to more widespread notions such as *cause*, *variable*, and *factor*. Didactics is defined in ATD as the science of the conditions of diffusion of knowledge to persons and within institutions. More generally, ATD views any science—including mathematics—as studying a certain kind of conditions with a bearing on human life and its environments. In this respect, given an institutional position p, it is usual (and useful) to distinguish, among the set of conditions considered, those that could be *modified* by the people occupying position p, and those which cannot be altered by these people (though they could be modified by those in some position $p' \neq p$). Any science seeks to accrue knowledge and know-how in order to make the most of prevailing conditions and, in the case of constraints, to create new positions for which these constraints become modifiable conditions. Now, before doing so, it is necessary to *identify* such conditions and constraints, and this is precisely what happens in the Wallis episode, where the Euclidean constraint of invariance by similarity is brought out as a key theoretical property. At the same time, revealing some constraint usually brings forth alternative conditions that had gone unnoticed until then—non-Euclideanism, in the case at hand—and which become new objects of study. It must be stressed here that a science does not know in advance the complete set of conditions and constraints it has to cope with: constructing this set is, by nature, a never-ending task. All these considerations extend to any field of activity, whose praxeological equipments are the outcomes of facing sui generis conditions and constraints. We have now arrived at a position where it makes sense to revert to the question from which we started.

WHAT IS A THEORY?

It must be emphasized here that the interrelated notions of technique, technology and theory do not refer so much to "things" as to *functions*. A technique is a construct which, under appropriate conditions, performs a determined function—the technical function. The same may be said about technology and theory, which respectively perform the technological and theoretical functions. Up to a point, these last two functions look weakly distinguishable—indeed, any contrastive definition is sure to be plagued with counterexamples. Obviously, there are some general criteria allowing one to discern the technological from the theoretical: the first of them is regarded as more concrete, more specific and straightforward, while the second one is approached as being more abstract, more general, more meditative and far-fetched, as if it were reminiscent of its origins. In addition, as has been already highlighted, in an intellectual tradition that has persisted to this day, the second one is valued more highly than the other is. However, these considerations may impede the recognition of an essential phenomenon: the use which is often made of words like *theory* refers to the *explicit* aspects of an entity which we described as definitely subjected to inexplicitness and incompleteness.

From the point of view of ATD, it appears that the technological and theoretical components of a praxeological organisation—that is to say, its *logos* part—are almost always misidentified, because the usual view of them tends to focus on their "explicit" part, which looks generally pretentious and assumptive. This tendency clearly shows through the case 2 of the definition of *theory* given by the English *Wiktionary*: "(sciences) A coherent statement or set of ideas that explains observed facts or phenomena, or which sets out the laws and principles of something known or observed." This of course is representative of a dominant theory about... theories. Moreover, *theory* is often liberally used to label what boils down to a few guidelines or precepts which, taken together, do *not* function as the theory of any clearly identified object; for a theory should always be a theory *of something*, built around the scientific ambition to study this "something".

The metonymic use of *theory* is no problem in itself: when one says that ATD is a theory of "the didactic", *theory* refers, as is usual in mathematics for example, to the whole of a praxeological field. But it is a symptom of our propensity to give the word free rein with the uneasy consequence that the debate on theory is deprived of its object. By contrast, ATD conduces to focus the research effort on examining the implicit, unassuming or even wanting parts of technologies and theories. It then appears that a theory is made up of two main components, that we may call its "emerged part" and "immersed part". To avoid engaging here in a titanic work, we summarize in two points the constant lesson that praxeological analysis consistently teaches us. Firstly, the immersed part of a theory—in mathematics and, as far as we know, elsewhere—is replete with inexplicit tenets that are necessary to keep the emerged part afloat. Secondly, these tenets have surreptitious, far-reaching consequences, which often go unnoticed and usually unexplained at both the technological and the technical levels. What people do and how they do it owes much to "thoughts" unknown to them—unknown, not unknowable.

In ATD a theory is thus a hypothetical reality that assumes the form of a (necessarily fuzzy) set of explicit and implicit statements about the object of the theory. A theory is in truth the current state of a dialectic process of theorisation of which it offers an instantaneous and partial view that may prove delusive. The study and exploration of a theory is tantamount to furthering the very process of theorisation. One main feature of this process is that it allows for the expansion of too often ad hoc, punctual praxeologies $[T / \tau / \theta / \Theta]$ into deeply-rooted global praxeologies $[T_{ij} / \tau_{ij} / \theta_i / \Theta]$. The process of theorisation, as well as the networking of theorisations, has thus a liberating effect, in which, by the way, the use of well-chosen terms and symbolic notations helps achieve mental hygiene and theoretical clarity in bringing about what Bachelard once called the asceticism of abstract thought.

Discriminatory networks in mathematics education research

Russell Dudley-Smith

University College London, UCL Institute of Education, London, UK, rdudleysmith@ioe.ac.uk

This paper is written in an organisational language developed in the context of mathematics education by Dowling (2009, 2013) – social activity method (SAM) – as a commentary on Radford's (2008, 2014) discussion of theoretical networking. An exemplar is given of SAM's approach of recontextualising, and thus learning from, what it finds of interest elsewhere – here, Chevallard's Anthropological Theory of the Didactic (ATD). The approach puts emphasis on the autonomy and emergent quality of well-formed research activity. SAM is not, however, solipsistic: it is designed to recursively self-organise in relation to what it encounters elsewhere but on the explicit basis of its own principles. By biasing a reading of ATD, SAM's organisational language develops in the form of a discriminatory research network.

Keywords: Anthropological Theory of the Didactic, deformance, discriminatory research networks, recontextualisation, Social Activity Method.

INTRODUCTION

Writing about theoretical networking presents a formidable challenge. This paper looks at the relation between two research programmes in the domain of mathematics education research, Social Activity Method (Dowling, 1998, 2009, 2013 – hereafter SAM) and the Anthropological Theory of the Didactic (hereafter ATD; Bosch & Gascón, 2014) together with one meta-theory of theoretical networking (Radford, 2008, 2014). This already involves three specialised assemblages of principles and tacit knowledges: to introduce all three would exceed the space available. This limitation is addressed by considering the other approaches as an illustration of how, *from SAM's point of view,* theoretical dialogue might be achieved. For this reason, it is the principles of SAM that are given most emphasis: these are then used to *select* principles from the other approaches. This means that the principles of ATD and Radford's meta-theory must, fundamentally, be misread – what I shall refer to as a (I hope, productive) *deformance* (Dowling, 2009) of them.

SAM has in common with some other research in mathematics education an interest in the specificity of social activity in the context in which it is produced and reproduced (see especially Dreyfus & Kidron, 2014, p. 87). Its focus is on the strategies that lead to emergent alliance; ordered relations of action in which people may come to recognise themselves as working together e.g. as *in SAM* or *ATD.* I first introduce the central *Domains of Action Schema* of SAM. This provides principles for further application of the method in forming a regard on both ATD and Radford's work. One part of this schema – the esoteric domain – is then considered in greater detail to allow a discussion of the continuities and discontinuities between SAM and ATD. A new schema is then generated to bias a reading of ATD from the regard of SAM.

The question I address is: what can a strongly institutionalised research programme in mathematics education, SAM, make of another such strongly institutionalised approach, ATD? How does this allow *SAM* to learn and thus deform itself? It needs the greatest emphasis that SAM *makes no assumptions at all about what ATD might or might not learn* because SAM assembles only its own principles. From the point of view elaborated here there can be no literal connection of similars: any metonymic chain between signifiers of two research programmes involves *recontextualising work.* A secondary question is: what light does this shed on the need for meta-theories to conceptualise theoretical networking such as the one proposed by Radford?

For the purpose of clarity and to summarise the position and rationale of the paper: well-formed research activities are incommensurable – they are emergent and not graspable as such, even by themselves. The
